Configure the LPSPI master to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the slave.

See the chip data sheet for the specific input setup time in Master Loopback mode.

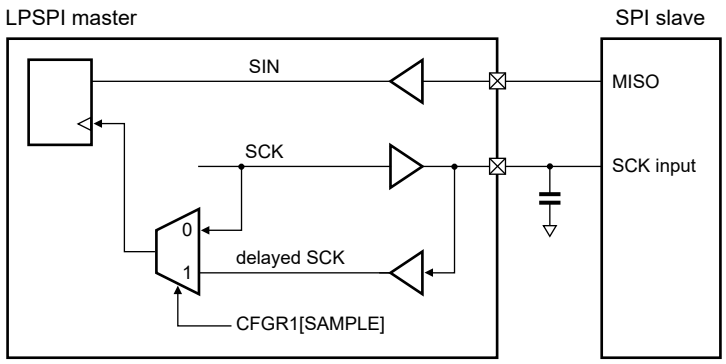

Figure 380. Clock loopback

66.4.2.2 Slave mode

LPSPI Slave mode:

- Uses the same shift register and logic that Master mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

66.4.2.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Slave mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Slave mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 565. Command word in Slave mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Slave mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register.
CONTC	Continuing command	When the continuing command is enabled in Slave mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

66.4.2.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

66.4.2.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

66.4.2.2.4 Clocked interface

LPSPI supports interfacing with external masters that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

66.4.2.3 Low-power modes

Table 566. Low-power modes

Chip mode	LPSPI operation
Run	Normal operation
Deep Sleep	Can continue operating in Deep Sleep mode if LPSPI is using an external or internal clock source that remains operating during Deep Sleep mode
Low-Power-Stop (also called Power Down)	Waits for the current transfer to complete any pending operation, before entering Low-Power-Stop mode

66.4.2.4 Debug mode

Table 567. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug or Halted mode)	Can continue operating in Debug mode, if CR[DBGEN] = 1

66.4.2.5 Clocking

Table 568. LPSPI clocks

Type of clock	Description
Functional	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Master and Slave modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK).
External	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends on the mode (Master or Slave): — In Master mode, the SCK clock is generated internally. — In Slave mode, the SCK clock is supplied externally.
Bus	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information for more.

66.4.2.6 Reset

Table 569. LPSPI resets

Type of reset	Description
Chip	Resets the LPSPI logic and registers to their default states.
Software	• Resets the LPSPI logic and registers to their default states, except for the Control register. • The LPSPI software reset is controlled using CR[RST].
FIFO	• Resets the transmit and command FIFO and the receive FIFO. • CR[RTF] and CR[RRF] are write-only. • After being reset, FIFO is empty.

66.4.2.7 Interrupts and DMA requests

The following table lists Slave mode sources (status flags) that can generate LPSPI interrupts and LPSPI slave transmit and receive DMA requests.

Table 570. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER].	Y	TX	Y
RDF	Receive data flag	Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER].	Y	RX	Y
WCF	Word complete flag	Indicates that the word is complete and the last bit of the word has been sampled.	Y	N	Y
FCF	Frame complete flag	Indicates that the frame is complete and PCS is deasserted.	Y	RX	Y
TCF	Transfer complete flag	Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty.	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Master mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Master mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set.	Y	N	Y
DMF	Data match flag	Indicates that the received data matches the configured data match value.	Y	N	Y
MBF	Module busy flag	Indicates that LPSPI is busy performing an SPI bus transfer.	N	N	N

66.4.2.7.1 End-of-packet DMA transfer

The end-of-packet functionality is designed for serial interfaces where you may not be aware of the size of the transfer in advance and the data is pushed by an external device. Examples include UART receive, I2C Slave mode, and SPI Slave mode. The end-of-packet processing is intended to ensure that data is not stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet is different for each serial interface but the serial peripheral and DMA process it in the same way. For example, UART end of packet is signaled by an idle line condition, I2C end of packet by a stop and/or repeated start condition, and SPI end of packet by PCS negation.

If you configure the serial peripheral to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, then data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.

- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop is complete and no additional data is pulled from the receive FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes following end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of the packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop is complete, including final offsets and optional interrupts, channel linking and scatter/gather. The final destination address can optionally be saved in the system memory or is available in the destination address register.

After the DMA terminates the major loop, no servicing of the receive FIFO occurs until either software or hardware reconfigures the DMA (for example, channel linking or scatter/gather). This delay must be minimized to avoid receiver FIFO overrun. NXP does not recommend automatic DMA end-of-packet processing when there are only a few words transferred between end-of-packet conditions. That is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

66.4.2.8 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 571. Peripheral triggers

Type of trigger	Description	Additional information
Frame output	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts). • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output	The word output trigger: • Asserts at the end of each received word. • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	
Input	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input: • The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected. • When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle.	

66.4.3 External signals

Table 572. External signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Slave mode	I/O

Table continues on the next page...

Table 572. External signals (continued)

Signal	Name	Description	I/O
		• Output in Master mode	
PCS[0]	Peripheral chip select	• Input in Slave mode • Output in Master mode	I/O
PCS[1]/HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0: • Input in either Slave mode or when used as master host request • Output in either Master mode or when used as slave host request	I/O
PCS[2]/DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3]/DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Slave mode • Output in Master mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
SOUT/DATA[0]	Serial data output	Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers)	I/O
SIN/DATA[1]	Serial data input	Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers)	I/O

66.4.4 Initialization

This module does not require initialization.

66.4.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

66.4.5.1 LPSPI register descriptions

LPSPI provides an efficient interface to an SPI bus, either as a master or slave. An SPI bus is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

Register	Offset
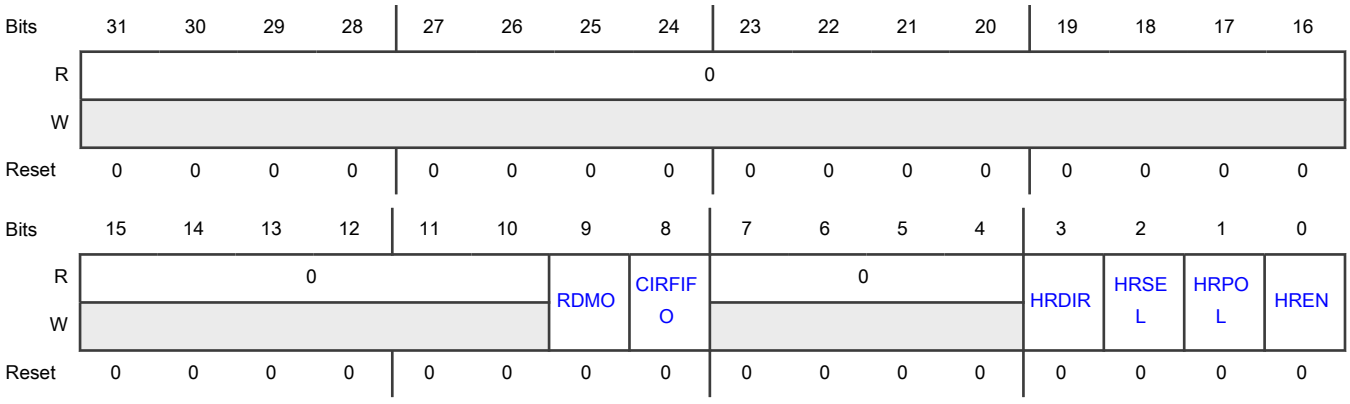
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only Enables receive data match. When enabled, all received data that does not cause SR[DMF] to assert is discarded: • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable Enables circular FIFO. When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. You must configure the HREQ pin only as an output when LPSPI is in Slave mode. The HREQ pin direction must be an input for Master mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable Enables LPSPI, in Master mode, to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Slave mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

66.4.5.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function

Includes fields to configure LPSPI. You must write to this register only when LPSPI is disabled.

In addition to pin and output configurations, this register contains match configuration details; the following table shows match conditions specified in MATCFG.

Table 573. Match conditions for CFGR1[MATCFG]

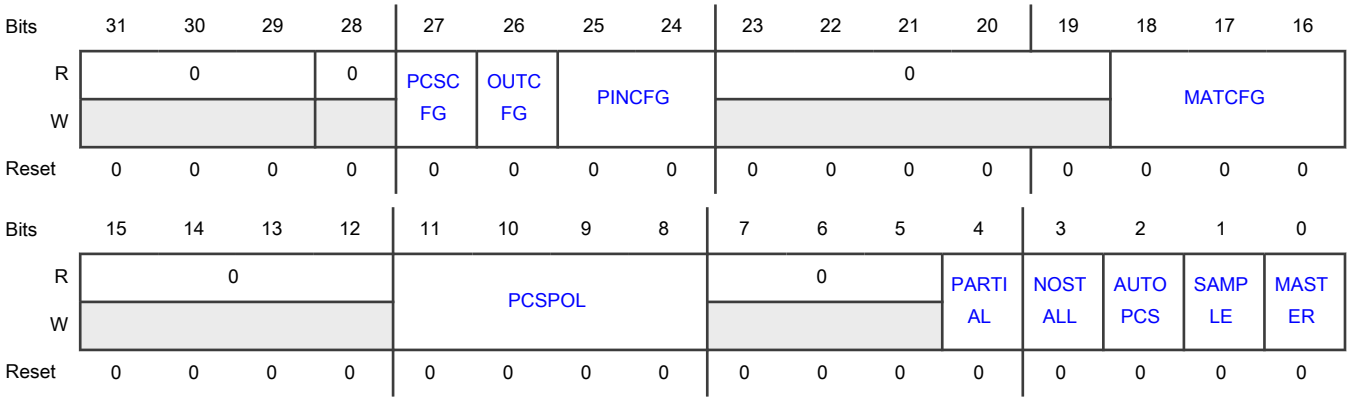
Condition	Description
Match first data word with compare word	Match if first data word equals MATCH0 logically ORed with MATCH1 first_data_word == (MATCH0 || MATCH1)
Match any data word with compare word	Match if any data word equals MATCH0 logically ORed with MATCH1 any_data_word == (MATCH0 || MATCH1)
Sequential match, first data word	Match if first data word equals MATCH0, and second data word equals MATCH1 (first_data_word == MATCH0) && (second_data_word == MATCH1)
Sequential match, any data word	Match if any data word equals MATCH0, and the next data word equals MATCH1

Table continues on the next page...

Table 573. Match conditions for CFGR1[MATCFG] (continued)

Condition	Description
	(any_data_word == MATCH0) && (next_data_word == MATCH1)
Match first data word (masked) with compare word (masked)	Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (first_data_word && MATCH1) == (MATCH0 && MATCH1)
Match any data word (masked) with compare word (masked)	Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (any_data_word && MATCH1) == (MATCH0 && MATCH1)

Diagram



Fields

Field	Function
31-29 —	Reserved
28 —	Reserved
27 PCSCFG	Peripheral Chip Select Configuration Specifies PCS pin configuration. When performing parallel transfers, you must configure this field to enable the desired transfer. 0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Retain last value 1b - 3-stated
25-24 PINCFG	Pin Configuration Specifies the pins used for input and output data during serial transfers. This field is ignored when performing parallel transfers. 00b - SIN is used for input data; SOUT is used for output data 01b - SIN is used for both input and output data; only half-duplex serial transfers are supported 10b - SOUT is used for both input and output data; only half-duplex serial transfers are supported 11b - SOUT is used for input data; SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Specifies the condition that causes SR[DMF] to assert. See the match conditions listed in Table 1 for more information. **NOTE** When writing to this field, either the old value or new value must be in the disabled state (0). You cannot transition from a nonzero value to another nonzero value. 000b - Match is disabled 001b - Reserved 010b - Match first data word with compare word 011b - Match any data word with compare word 100b - Sequential match, first data word 101b - Sequential match, any data word 110b - Match first data word (masked) with compare word (masked) 111b - Match any data word (masked) with compare word (masked)
15-12 —	Reserved
11-8 PCSPOL	Peripheral Chip Select Polarity Specifies the polarity of each PCS pin. Bit *n* in this field (the least-significant bit is bit 0) corresponds to PCS[*n*]. **NOTE** The entire PCSPOL field is not fully supported in every LPSPI module instance. See the LPSPI chip-specific information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - Active low 0001b - Active high
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LPSPI, when in Slave mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. See Partial received word for more information. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LPSPI, when in Master mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Slave mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least four LPSPI functional clock cycles, divided by the prescaler (see TCR[PRESCALE]) selected between each word to ensure correct operation. This field is ignored in Master mode. 0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LPSPI, when in Master mode, samples input data. Writing 1 to this field causes LPSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration, the input data setup time in Master mode is equal to the input data setup time in Slave mode. In Slave mode, this field is ignored. **NOTE** When SAMPLE = 1, both the input and output buffers must be enabled for the SCK pin. 0b - SCK edge 1b - Delayed SCK edge

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 MASTER	Master Mode Specifies the LPSPI operating mode, Master or Slave. This field directly controls the direction of the SCK and PCS pins. 0b - Slave mode 1b - Master mode

66.4.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register when CFGR1[MATCFG] > 0.

Diagram

66.4.5.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields that are used only in Master mode; you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1, do one of the following:

- Write to all four fields in Clock Configuration (CCR) simultaneously and only once in a 32-bit data.
- Modify the values of CCR[SCKPCS] and/or CCR[PCSSCK]; write only these two upper bytes in a 16-bit data or one of them in an 8-bit data.
- Modify CCR1[PCSPCS] and CCR1[SCKSCK] only or CCR1[SCKSET] and CCR1[SCKHLD] only, write respectively to CCR[DBT] or CCR[SCKDIV] in 8-bit data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKPCS								PCSSCK

R	0								0							
W	DBT								SCKDIV							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKPCS	SCK-to-PCS Delay Configures SCK-to-PCS delay. In Master mode, this field helps you configure the delay from the last SCK edge to PCS negation: • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 379 for more information.
23-16 PCSSCK	PCS-to-SCK Delay Configures PCS-to-SCK delay. In Master mode, this field helps you configure the delay from PCS assertion to the first SCK edge: • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 379 for more information.
15-8 DBT	Delay Between Transfers Configures the delay between transfers. Writing to this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 SCKDIV	SCK Divider Updates the contents of CCR1[SCKSET] and CCR1[SCKHLD]. Baud rate = function clock ÷ (2^PRESCALE × (SCKSET + SCKHLD + 2))

66.4.5.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields, which are used only in Master mode. You can change them only when LPSPI is disabled (CR[MEN] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKSCK								PCSPCS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SCKHLD								SCKSET							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay Configures SCK inter-frame delay in Master mode: • This field helps you configure the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For backward compatibility, writing to CCR[DBT] updates this field with the value written.
23-16 PCSPCS	PCS to PCS Delay Configures PCS to PCS delay in Master mode: • This field helps you configure the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is two cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between two transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the selected prescaler. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8 SCKHLD	SCK Hold Configures the hold phase of the SCK pin in Master mode: • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • It is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 379 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup Configures the setup phase of the SCK pin in Master mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • It is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 379 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

66.4.5.1.14 FIFO Control (FCR)

Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Indicates the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

66.4.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Pushes the data into the transmit FIFO, in the same order as written.

When you write to either this register or to Transmit Data (TDR), each write pushes data into the transmit FIFO. You must write to this register only using 32-bit writes, which are tagged and cause the command register to update; after that the entry reaches the top of the FIFO and LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word:

- In Master mode, writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when PCS deasserts.
- In Master mode, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- In Slave mode, the command word must be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the transmit FIFO after writing to this register; wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading this register returns the current state of the register. Reading this register at the same time that it is loaded from the transmit FIFO can return an incorrect register value. It is recommended to:

- Read this register when the transmit FIFO is empty.
- Read this register more than once and then compare the returned values.

Diagram

W	0															
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. You can update this field only when PCS is deasserted. See Figure 379 for more information. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase Indicates whether data is captured or changed on the leading edge of SCK and captured or changed on the following edge of SCK. You can update this field only when PCS is deasserted. See Figure 379 for more information. 0b - Captured 1b - Changed
29-27 PRESCALE	Prescaler Value Specifies the division of the LPSPI functional clock. For all SPI bus transfers, this value is applied to Clock Configuration (CCR). You can update this field only when PCS is deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. This field is updated only when PCS is deasserted. **NOTE** This entire field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2] 11b - Transfer using PCS[3]
23 LSBF	LSB First Indicates whether data is transferred with MSB first or LSB first. 0b - MSB first 1b - LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disable byte swap 1b - Enable byte swap
21 CONT	Continuous Transfer Enables continuous transfer: • In Master mode, this field keeps PCS asserted at the end of the frame size until a command word is received that starts a new frame. • In Slave mode, when this field is enabled, LPSPI only transmits the first FRAMESZ bits, after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Disable 1b - Enable
20 CONTC	Continuing Command Enables the command word to be changed within a continuous transfer in Master mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64 bits, then a continuing command word must be loaded on a 64-bit boundary. In Slave mode, this field modifies the internal RXMSK and TXMSK configuration after the first FRAMESZ bits and until PCS negation: • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1, this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits. This allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19 RXMSK	Receive Data Mask Masks receive data (receive data is not stored in the receive FIFO). 0b - Normal transfer 1b - Mask receive data
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from the transmit FIFO and the output pin is 3-stated). In Master mode, TXMSK initiates a new transfer that cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either RXMSK or TXMSK must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

66.4.5.1.17 Transmit Data (TDR)

Offset

Register	Offset
TDR	64h

Function

Pushes the data into the transmit FIFO, in the same order that the data is written. You can write to this register using 32-, 16-, or 8-bit writes.

When you write to this register or to Transmit Command (TCR), each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R

R																
W	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DATA	Transmit Data Indicates transmit data. Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits) means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

66.4.5.1.18 Receive Status (RSR)

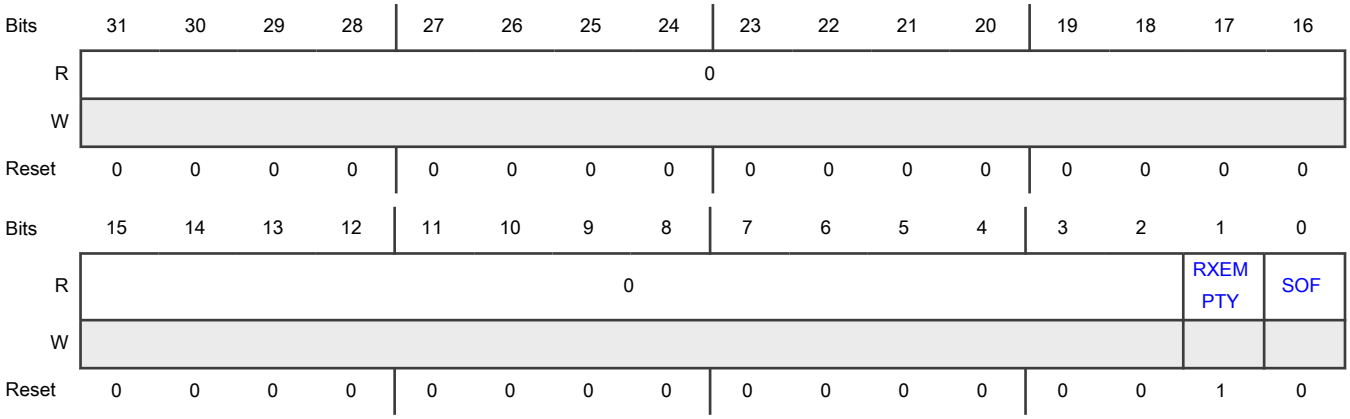
Offset

Register	Offset
RSR	70h

Function

Contains data flow status fields for receive FIFO.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RXEMPTY	RX FIFO Empty Indicates whether the receive FIFO is empty. 0b - Not empty 1b - Empty
0 SOF	Start of Frame Indicates whether this is the first data word received after PCS assertion. 0b - Subsequent data word 1b - First data word

66.4.5.1.19 Receive Data (RDR)

Offset

Register	Offset
RDR	74h

Function
Pulls the first entry from the receive FIFO.

66.5 Low-Power Universal Asynchronous Receiver/Transmitter (LPUART)

66.5.1 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and infrared data association (IrDA)-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

66.5.1.1 Block diagram

Figure 381 shows the transmitter portion of LPUART.

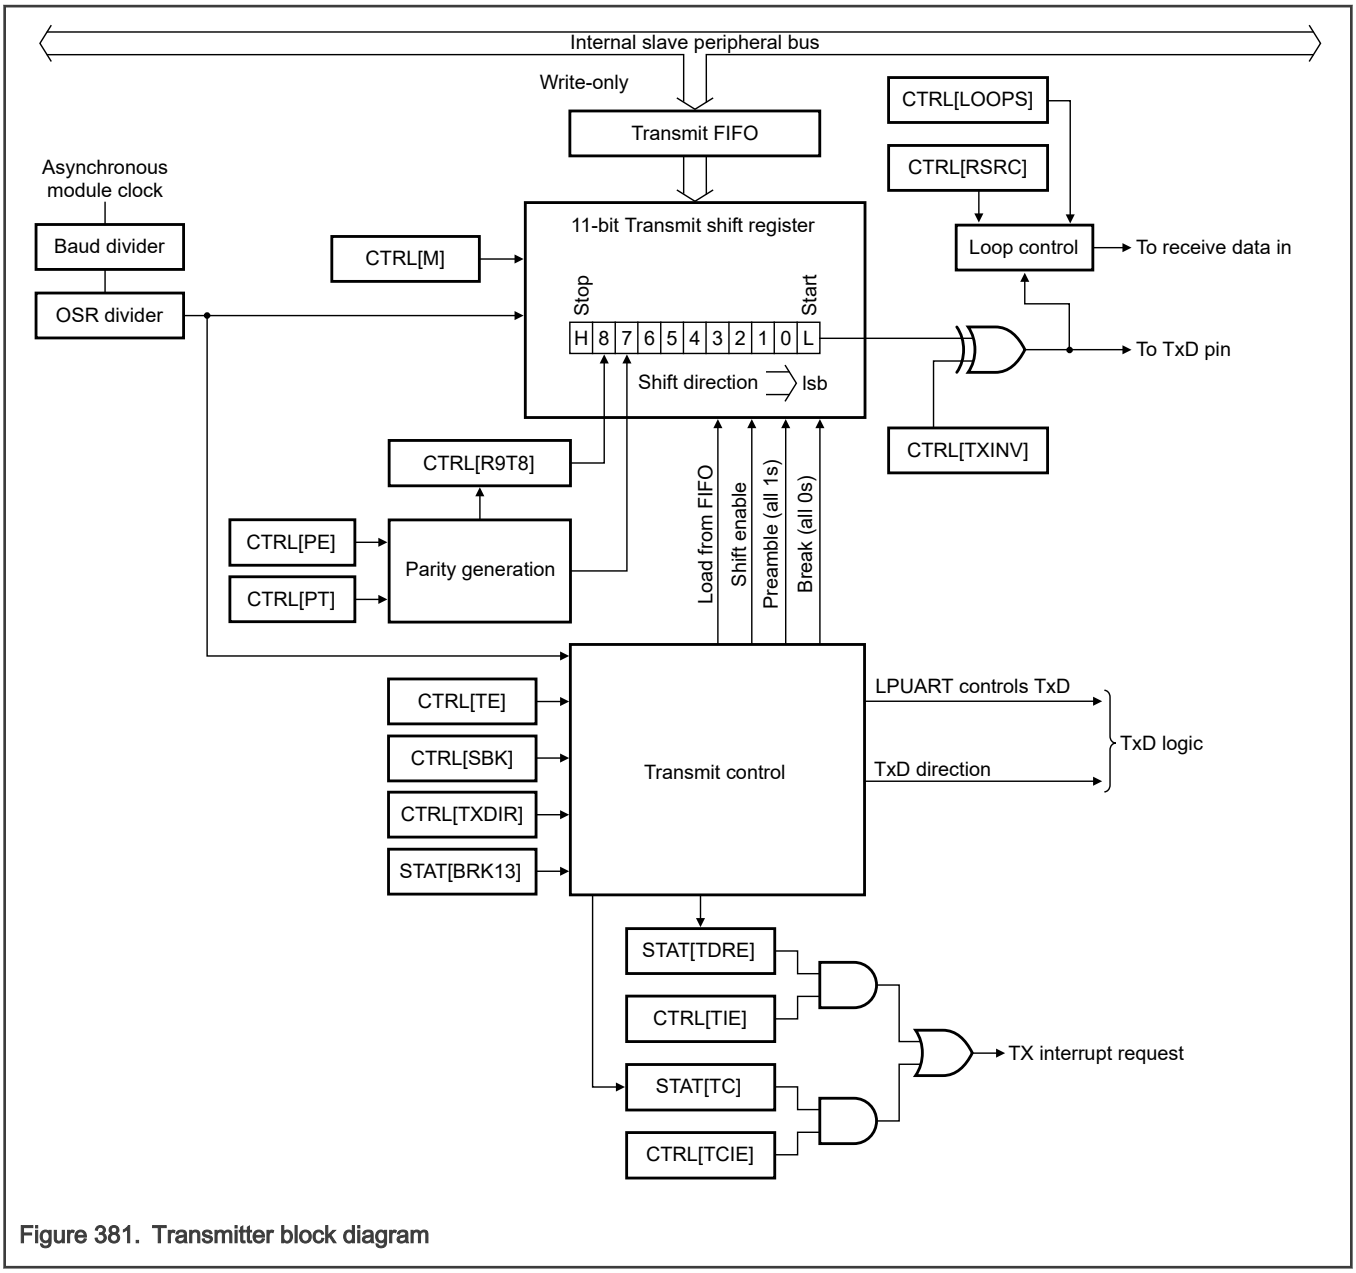

Figure 381. Transmitter block diagram

Figure 382 shows the receiver portion of LPUART.

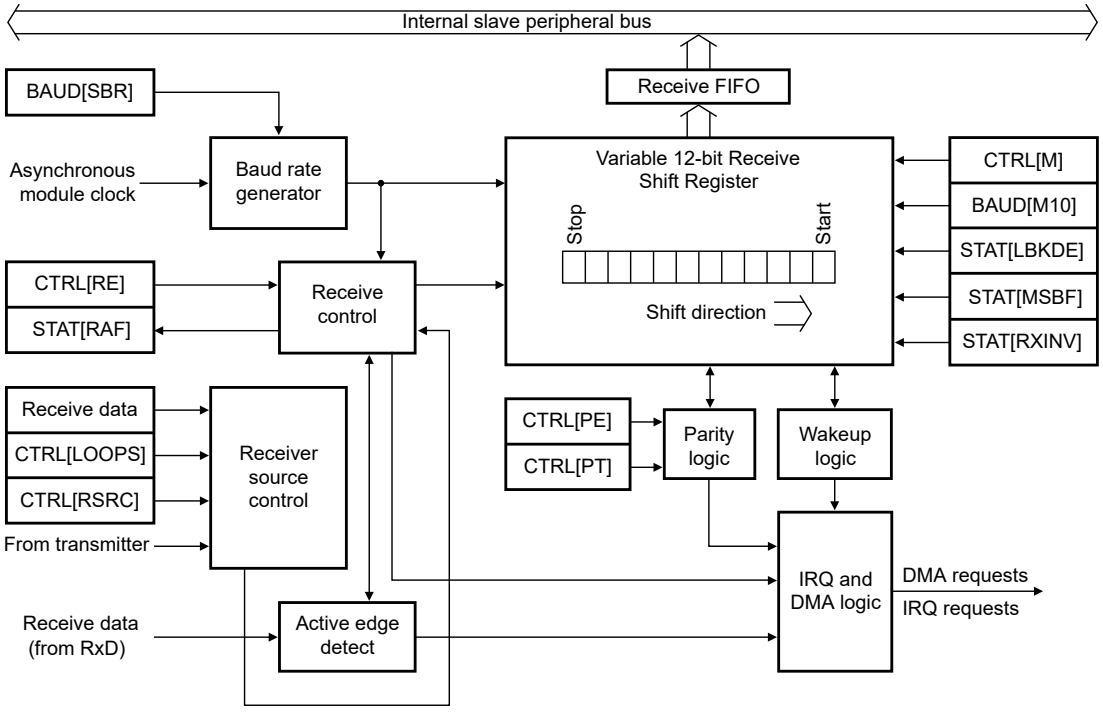

Figure 382. Receiver block diagram

66.5.1.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) from 4× to 32×
- Asynchronous operation of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wake-up methods:
  - Idle line wake-up

  - Address mark wake-up
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

66.5.2 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

66.5.2.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time.

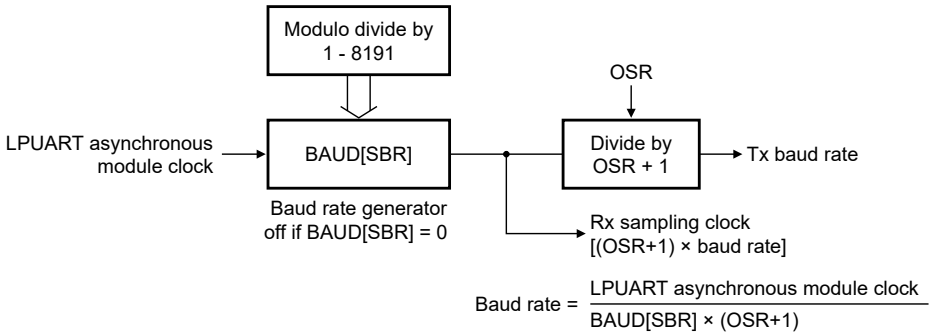

Figure 383. Baud rate generation

Baud rate generation is subject to these sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit (see Data sampling technique) are also closer together, which may impact noise sensitivity.

66.5.2.2 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. A noise error will occur if the three samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the three stop bit samples are a logic zero.

As the receiver samples an incoming frame, it may re-synchronize the oversampling clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

In general, increasing the number of samples per bit will increase the baud rate tolerance and decreasing the number of samples per bit will reduce the baud rate tolerance. Note that since LPUART implements triple voting on consecutive receive data samples, increasing the number of samples per bit will move those samples closer together which would reduce the width of noise that can be filtered by the triple voting logic.

66.5.2.3 Calculating baud rate tolerance

Using the following definitions:

- SAM is the number of sample points per bit (valid range from 8 to 32; equal to (OSR + 1) × (BOTHEDGE + 1)).
- BIT is the number of bits in a character including start, data and stop bits (valid range from 9 to 13).

The ideal baud rate tolerance can be calculated as follows:

- Slow data rate tolerance = ((SAM ÷ 2) - 1) ÷ ((SAM × BIT) - (SAM ÷ 2) + 2)
- Fast data rate tolerance = ((SAM ÷ 2) - 2) ÷ (SAM × BIT)

As an example, if configured for 8-bit data, 1 stop bit (BIT = 10) and with OSR=0x7 and BOTHEDGE = 1 (SAM = 16):

- Slow data rate tolerance = (8 - 1) ÷ (160 - 8 + 2) = 7 ÷ 154 = 4.54%
- Fast data rate tolerance = (8 - 2) ÷ 160 = 6 ÷ 160 = 3.75%

If configured for 9-bit data with 1 stop bit (BIT = 11) with same oversampling configuration, then:

- Slow data rate tolerance = (8 - 1) ÷ (176 - 8 + 2) = 7 ÷ 170 = 4.12%
- Fast data rate tolerance = (8 - 2) ÷ 176 = 6 ÷ 176 = 3.41%

NOTE

Additional factors can contribute to a lower baud rate tolerance than the ideal. These include clock uncertainty or jitter on the LPUART functional clock source, differences in rise and fall times on the transmitter output and synchronization of the external receive pin to the local LPUART functional clock.

66.5.2.4 Transmitter functional description

This section describes the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the Idle state. The transmitter then remains idle until data is available in the transmit FIFO and programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data

bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in transmit FIFO is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

66.5.2.4.1 Break character length

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, write 0 and then write 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

Table 574. Break character length

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
0	0	0	0	0	10
0	0	0	0	1	11
0	0	0	1	0	9
0	0	0	1	1	10
0	1	0	—	0	11

0	—	1	—	0	12
0	—	1	—	1	13
1	0	0	0	0	13
1	0	0	0	1	13
1	0	0	1	0	12

Table continues on the next page...

Table 574. Break character length (continued)

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
1	0	0	1	1	12
1	1	0	—	0	14
1	1	0	—	1	14
1	—	1	—	0	15
1	—	1	—	1	15

66.5.2.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with CTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

66.5.2.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

You can configure HDCR[RTSEXT] to the desired length by delaying the transmitter's RTS_B negation by up to 256-bit clock (baud rate) after the last stop bit.

66.5.2.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

The following figure shows the receiver enable signal asserted. This connection can also connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled when driving. A pullup can pull RXD to a nonfloating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

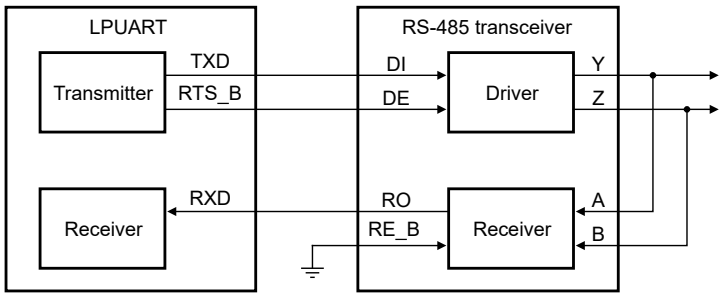

Figure 384. Transceiver driver enable using RTS_B

66.5.2.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data.
- Different variations of the receiver wake-up function.

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, along with N (7, 8, 9, 10) bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full (STAT[RDRF] = 0), the data character is transferred to the receive FIFO, resulting in STAT[RDRF] becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the FIFO by reading Data (DATA). See Interrupts for details about flag clearing.

66.5.2.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes they are synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, noise flag (STAT[NF]) becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the "1->0" (one to zero) transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This synchronization to the start bit is termed as resynchronizarion.

When BAUD[RESYNCDIS] is 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] is 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

Table 575. LPUART resynchronization settings

Resynchronization	BAUD[RESYNCDIS] = 0	BAUD[RESYNCDIS] = 1
For the starting bit falling edge	Yes	Yes
For all falling edges after the start bit	Yes	No

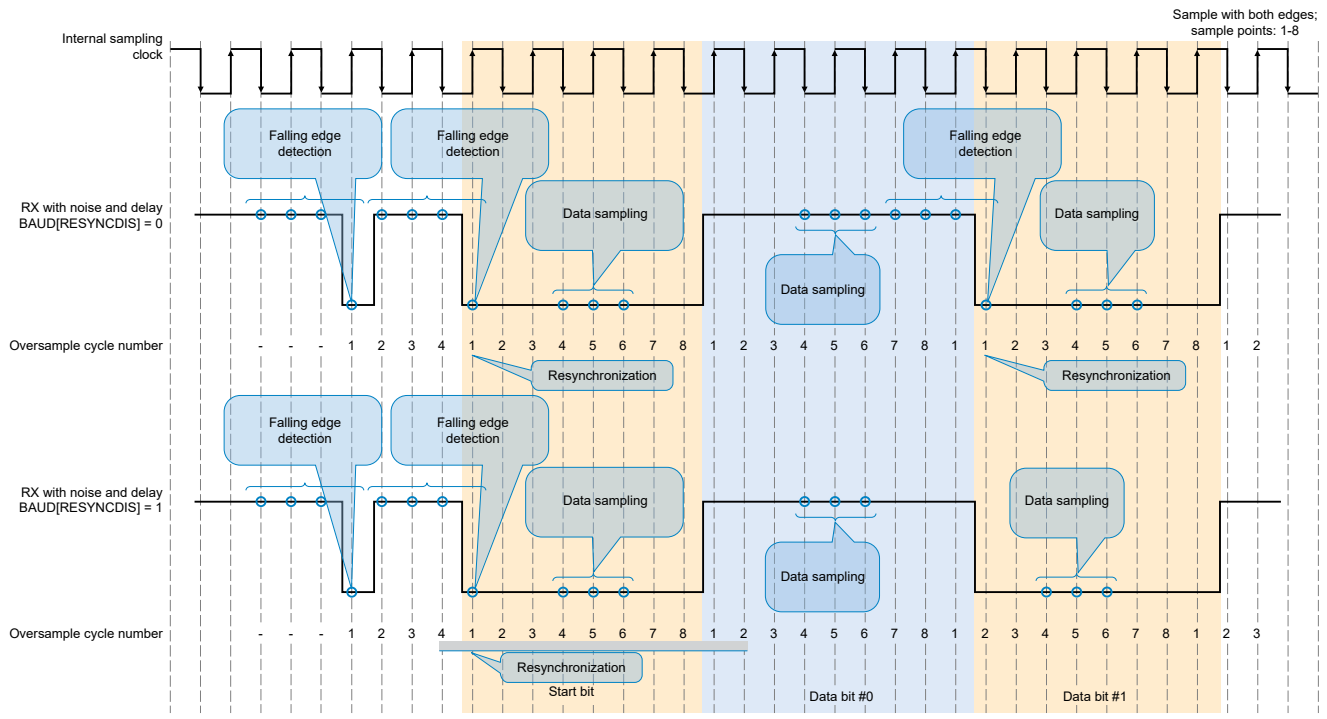

Figure 385. LPUART resynchronization diagram

66.5.2.5.2 Receiver wake-up operation

Receiver wake-up and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wake-up, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 576. Receiver wake-up options

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wake-up
0	0	X	X	Normal operation
1	0	00	00	Receiver wake-up on idle line; STAT[IDLE] = 0
1	0	00	01	Receiver wake-up on idle line; STAT[IDLE] = 1
1	0	00	10	Receiver wake-up on address mark
1	1	11	10	Receiver wake-up on data match
0	1	00	X0	Address mark address match; STAT[IDLE] = 0 for discarded characters
0	1	00	X1	Address mark address match; STAT[IDLE] = 1 for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match on and match off; STAT[IDLE] = 0 for discarded characters
0	1	10	X1	Match on and match off; STAT[IDLE] = 1 for discarded characters

66.5.2.5.2.1 Idle line wake-up

When CTRL[WAKE] is 0, you can configure the receiver for an idle line wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

These are the ways to detect an idle line:

- When CTRL[ILT] is 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] is 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

66.5.2.5.2.2 Address mark wake-up

When CTRL[WAKE] is 1, you can configure the receiver for an address mark wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address mark wake-up.

Address mark wake-up allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address mark bit is received even if the receiver is sleeping during most of this character time.

66.5.2.5.2.3 Data match wake-up

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data match wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] is 1, or that matches MATCH[MA2] when BAUD[MAEN2] is 1.

66.5.2.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or the second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1 if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or the second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

66.5.2.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) and data is transferred to the receive FIFO only on a match.

- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

66.5.2.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

NOTE

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

66.5.2.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] is 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.

66.5.2.6 Additional LPUART functions

66.5.2.6.1 Data modes

You can configure the LPUART transmitter and receiver to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but you must read them before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address mark wake-up so that the ninth data bit can serve as the wake-up bit. The 10-bit Data mode is typically used with parity and address mark wake-up so that the ninth data bit can serve as the wake-up bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

66.5.2.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle line wake-up and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

After the extended idle time is enabled for the receiver, you can configure an idle line condition by using REIR[IDTIME], which specifies the number of bits (baud rate) since the last stop bit that is required for an idle condition to be detected. This replaces the configuration of CTRL[ILT] and CTRL[IDLECFG].

The transmitter can also enable the extended idle time. In this case, any idle character queued through the transmit FIFO forces the transmitter to be idled for the configured number of bit clocks before the idle character is read from the FIFO and the transmitter continues.

After you enable the transmitter extended idle time, the transmitter does not automatically queue an idle character whenever it is enabled.

66.5.2.6.3 Loop mode

Enable Loop mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 0. You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

Loop mode also internally connects the RTS_B output to the CTS_B input and the DTR_B output to the DSR_B input.

66.5.2.6.4 Single-Wire mode

Enable Single-Wire mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 1. Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

Half Duplex Control (HDCR) replaces the implementation of CTRL[LOOPS] and CTRL[RSRC], and you can use this register to configure various options for both Single-Wire and Half-Duplex operations, using independent RXD and TXD pins:

- HDCR[TXSTALL] replaces the CTRL[TXDIR] functionality and prevents the transmitter from becoming busy or asserting the RTS_B transmitter if STAT[RAF] is 1.
- You can select the TXD pin, as the source for the receiver, to configure HDCR[RXSEL] for a single-wire operation. If HDCR[RXSEL] is 1, you must configure the TXD pin for an open-drain operation.
- HDCR[RXMSK] masks the receiver input when the RTS_B transmitter is asserted (this applies even if you have not configured RTS_B as an output).
- HDCR[RXWRMSK] blocks storage of the receive data in the receive FIFO when the RTS_B transmitter is asserted. This setting does not affect the receiver idle functionality.
- HDCR[RTSEXT] delays the negation of the RTS_B transmitter by the configured number of bit clocks (baud rate).

66.5.2.6.5 Timeout counter

LPUART implements four general-purpose timeout counters; counters 0 and 1 are used to monitor the receiver and counters 2 and 3 are used to monitor the transmitter. When enabled, you can configure each counter to monitor one of the following conditions:

- Idle time in number of bits, starting to increment when first enabled and an idle condition is detected. The counter restarts whenever a character is received or transmitted.
- Idle time in number of bits, starting to increment after the next character is received or transmitted. The counter restarts whenever a character is received or transmitted.

- Idle time is more than the timeout interval, in number of bits, but less than the extended idle timeout. The counter restarts whenever a character is received or transmitted. You can use this to detect a gap between characters that is greater than a threshold (timeout) but less than the configured extended idle time. This configuration requires the extended idle feature for the transmitter or receiver to be enabled for a proper operation.
- Number of characters received or transmitted is equal to the configured timeout. The counter asserts at the start of the character that equals the timeout value.

The timeout counters restart counting whenever the counter is disabled and then enabled. These timeout counters are disabled when the corresponding STAT[TSF] field is 1. If the timeout enable is still set after STAT[TSF] becomes 0, the timeout counter restarts as if the counter had been disabled and then enabled. You can measure the idle time in bit times from the end of the last stop bit and until a start bit is validated.

66.5.2.7 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

66.5.2.7.1 Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, and negates when the next valid start bit is detected.

66.5.2.7.2 Input trigger

LPUART supports a peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger instead of the CTS_B pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.
- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free-running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

66.5.2.8 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

66.5.2.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is 1.

66.5.2.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

66.5.2.8.3 Start-bit detection

When STAT[RXINV] is 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

66.5.2.8.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

66.5.2.8.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

66.5.2.8.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

66.5.2.9 MODBUS protocol

66.5.2.9.1 MODBUS frame structure

MODBUS is an application layer messaging protocol, positioned at level 7 of the OSI model. It provides client and server communication between devices connected on different types of buses or networks.

The MODBUS protocol defines a simple protocol data unit (PDU) independent of the underlying communication layers. The mapping of the MODBUS protocol on specific buses or network can introduce some additional fields on the application data unit (ADU).

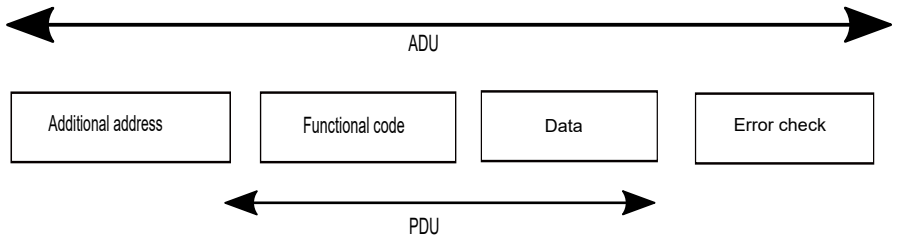

Figure 386. MODBUS frame structure

The function code field informs the server about which action to perform, as requested by the client (only the client can initiate the communication), where the data field contains additional information that the server uses to take the action defined by the function code. MODBUS PDU for serial line communication = 256 - server address (1 byte) - CRC (2 bytes) = 253 bytes.

You can set up a MODBUS controller to communicate on standard MODBUS networks using either of the two transmission modes: ASCII or RTU. RTU mode allows better character density and throughput for the same baud rate as the ASCII format allows 7 bits to represent a character where RTU keeps 8 bits for data representation in each packet.

66.5.2.9.2 MODBUS frame for LPUART

Though the protocol resides in the application layer, it can also be checked at the physical layer using LPUART by considering the frame structure shown in the following figure, following RTU mode of data transmission.

Start	Address	Function	Data	CRC	End
3.5 Char time	8 Bit	8 Bit	N * 8Bit	16 Bit	3.5 Char time

Figure 387. MODBUS frame for LPUART

An entire message frame of MODBUS must contain start character, address, function code, data, and end character. LPUART does not support CRC calculation for TX and RX, instead, each LPUART packet containing frame information is transmitted with its individual parity, and the same is checked in RX. Following the last transmitted character, a similar interval of at least 3.5 character times marks the end of the message and a new message can begin after this interval. The entire message frame must be transmitted as a continuous stream. If a silent interval of more than 1.5 character times occurs before the completion of the frame, the receiving device flushes the incomplete message, and assumes that the next byte is the address field of a new message. The correctness of timeout logic ensures the correctness of the MODBUS frame using LPUART.

Registers such as REIR, TEIR, TOCR, TOSR, TIMEOUT[0 - 3], TCBR, and TDBR are useful for realizing MODBUS using LPUART. The TX IDLE time is configured by using TEIR[IDTIME].

For higher baud rates, MODBUS recommends adopting fixed t1.5 and t3.5 times of 750us ms and 1.75 ms. The receiver idle line wake-up can be used by a MODBUS device to only wake-up on a matching address or broadcast address received after a valid idle time. The receiver end-of-packet DMA transfer can be used to offload the reception of a MODBUS packet onto the DMA controller.

66.5.2.9.3 MODBUS TX and RX programming sequence

The following programming sequences can be useful for sending and receiving MODBUS frames using LPUART.

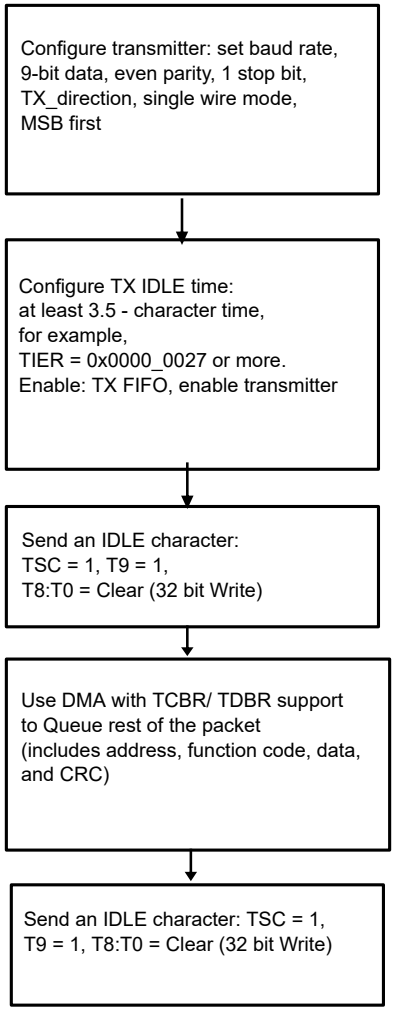

Figure 388. MODBUS TX programming

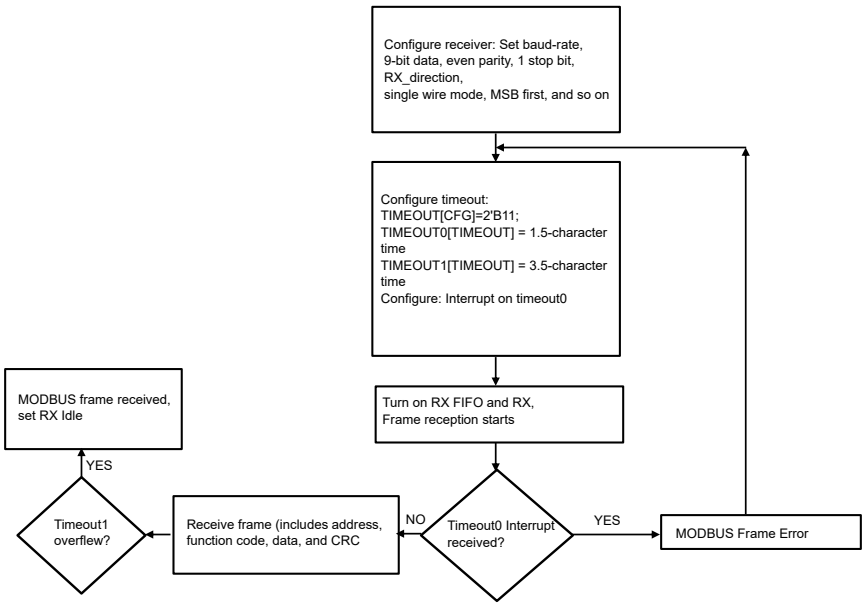

Figure 389. MODBUS RX programming

66.5.2.10 Modes of operation

66.5.2.10.1 Low-Power modes

NOTE

See the chip-specific information for specific low-power modes available on your chip.

66.5.2.10.2 Debug mode

LPUART remains functional in Debug mode.

66.5.2.11 Clocking

Table 577. Types of clocks

Clock	Description
Functional	Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wake-up.
Bus	Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

66.5.2.12 Reset

Table 578. Types of resets

Reset	Description
Chip	Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states.

Table continues on the next page...

Table 578. Types of resets (continued)

Reset	Description
Software	Resets the LPUART logic and registers to their default states, except for Global (GLOBAL). GLOBAL[RST] controls the LPUART software reset.
FIFO	Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty.

66.5.2.13 Interrupts

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. If STAT[TDRE] is 1, it indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] is 1, a hardware interrupt is requested when STAT[TDRE] is 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] is 1, a hardware interrupt is requested when STAT[TC] is 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] field is 0.

When a program detects that STAT[RDRF] is 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has 1 as the value of STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition getting lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (the value of CTRL[RE] being 1).

MODEM Status (MSR) can generate an interrupt from a configured status field, which STAT[MSF] indicates.

Timeout Status (TOSR) can generate an interrupt from a configured status field, which STAT[TSF] indicates.

66.5.2.14 DMA

66.5.2.14.1 DMA burst support

To support efficient DMA transfers to the transmit FIFO, two alias regions are implemented to support incrementing 8-bit, 16-bit, or 32-bit write accesses to the transmit FIFO:

- Transmit Command Burst (TCBR0 - TCBR127) is a 512-byte region that supports pushing 16-bit data into the transmit FIFO.
- Transmit Data Burst (TDBR0 - TDBR255) is a 1024-byte region that supports pushing zero extended 8-bit data into the transmit FIFO.

The aforementioned regions are contiguous, so a DMA transfer can start in Transmit Command Burst (TCBR0 - TCBR127) to initialize the transfer including address mark, idle word, or break character, and then complete the transfer in Transmit Data Burst (TDBR0 - TDBR255) with the data to transmit, without changing the transfer size.

The transmit FIFO block writes overflow the FIFO, but that does not signal an error. Do not perform 32-bit writes to Transmit Data Burst (TDBR0 - TDBR255) unless there are four empty slots in the transmit FIFO, and do not perform 16-bit writes to this register unless there are two empty slots in the transmit FIFO.

66.5.2.14.2 End-of-packet DMA transfers

The end-of-packet functionality is designed for serial interfaces where you may not know the size of the transfer in advance and the data is being pushed by an external device. The end-of-packet processing ensures that data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet is different for each serial interface, but the serial peripheral and DMA process it in the same way. For example, an idle line condition signals the UART end of packet, the Stop and/or Repeated Start condition signals the I2C end of packet, and PCS negation signals the SPI end of packet.

When the serial peripheral is configured to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The field that triggered the end-of-packet condition becomes 0 when the minor loop completes following the end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. You can, optionally, save the final destination address to the system memory. The final destination address is also available in the destination address register.

Because the DMA terminates the major loop, no servicing of the receive FIFO occurs until you or the hardware reconfigures the DMA (for example, channel linking or scatter-gather). You must minimize this delay to avoid receiver FIFO overrun. The automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. This is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

66.5.3 External signals

Table 579. External signals

Signal	Description	I/O
TXD	Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or the transmit direction is configured for receive data.	I/O
RXD	Receive data	I
CTS_B	Clear-to-send	I

Table continues on the next page...

Table 579. External signals (continued)

Signal	Description	I/O
RTS_B	Request-to-send	O
DTR_B	Data terminal ready	O
DSR_B	Data set ready	I
DCD_B	Data carrier detect	I
RIN_B	Ring indicator	I

66.5.4 Initialization

This module does not require initialization.

66.5.5 LPUART register descriptions

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. LPUART does not verify whether programmed values in the registers are correct; you must write valid values to them.

Fields

Field	Function
31-16 —	Reserved
15-8 RXFIFO	Receive FIFO Size Indicates the number of characters in the receive FIFO, which is 2^RXFIFO.
7-0 TXFIFO	Transmit FIFO Size Indicates the number of characters in the transmit FIFO, which is 2^TXFIFO.

66.5.5.4 Global (GLOBAL)

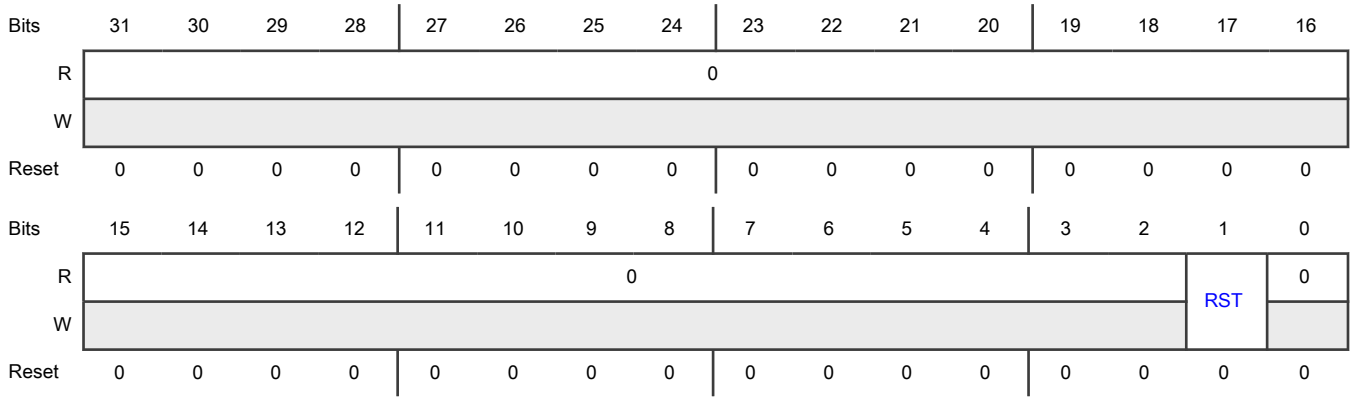
Offset

Register	Offset
GLOBAL	8h

Function

Performs global functions.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RST	Software Reset Specifies whether the module is reset. This field resets all internal logic and registers, except Global (GLOBAL). The reset takes effect immediately and remains asserted until you negate it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 —	Reserved

66.5.5.5 Pin Configuration (PINCFG)

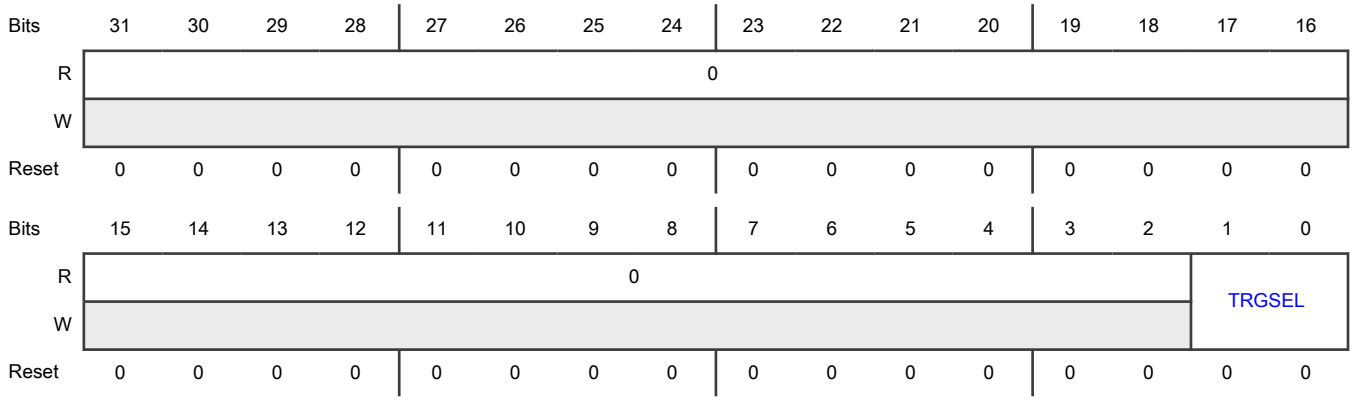
Offset

Register	Offset
PINCFG	Ch

Function

Enables the selection of input pins.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 TRGSEL	Trigger Select Configures the input trigger usage. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Input trigger disabled 01b - Input trigger used instead of the RXD pin input 10b - Input trigger used instead of the CTS_B pin input 11b - Input trigger used to modulate the TXD pin output, which (after TXINV configuration) is internally ANDed with the input trigger

66.5.5.6 Baud Rate (BAUD)

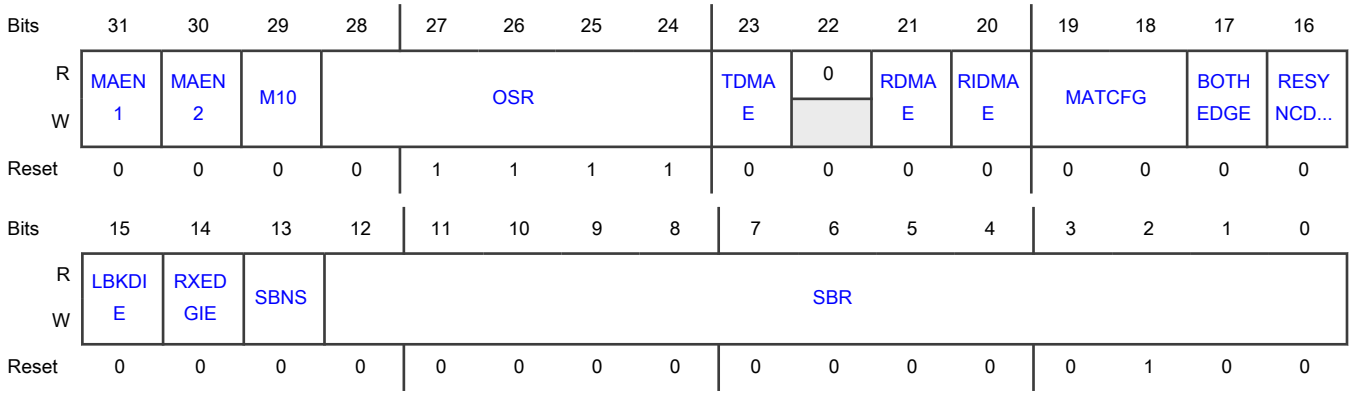
Offset

Register	Offset
BAUD	10h

Function

Configures the baud rate.

Diagram



Fields

Field	Function
31 MAEN1	Match Address Mode Enable 1 Enables automatic address matching or data matching mode for MATCH[MA1]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
30 MAEN2	Match Address Mode Enable 2 Enables automatic address matching or data matching mode for MATCH[MA2]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
29 M10	10-Bit Mode Select Causes the tenth bit to be a part of the serial transmission. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters 1b - Receiver and transmitter use 10-bit data characters
28-24 OSR	Oversampling Ratio Configures the OSR of the receiver. You must change the value of this field only when both the transmitter and receiver are disabled. **NOTE** BAUD[OSR] results in an OSR of BAUD[OSR] + 1, for example, BAUD[OSR] = 0_0101b results in a final division by 6. 0_0000b - Results in an OSR of 16 0_0001b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0010b - Reserved 0_0011b - Results in an OSR of 4 (requires BAUD[BOTHEDGE] to be 1) 0_0100b - Results in an OSR of 5 (requires BAUD[BOTHEDGE] to be 1) 0_0101b - Results in an OSR of 6 (requires BAUD[BOTHEDGE] to be 1) 0_0110b - Results in an OSR of 7 (requires BAUD[BOTHEDGE] to be 1) 0_0111b - Results in an OSR of 8 0_1000b - Results in an OSR of 9 0_1001b - Results in an OSR of 10 0_1010b - Results in an OSR of 11 0_1011b - Results in an OSR of 12 0_1100b - Results in an OSR of 13 0_1101b - Results in an OSR of 14 0_1110b - Results in an OSR of 15 0_1111b - Results in an OSR of 16 1_0000b - Results in an OSR of 17 1_0001b - Results in an OSR of 18 1_0010b - Results in an OSR of 19 1_0011b - Results in an OSR of 20 1_0100b - Results in an OSR of 21 1_0101b - Results in an OSR of 22 1_0110b - Results in an OSR of 23 1_0111b - Results in an OSR of 24 1_1000b - Results in an OSR of 25 1_1001b - Results in an OSR of 26 1_1010b - Results in an OSR of 27 1_1011b - Results in an OSR of 28 1_1100b - Results in an OSR of 29 1_1101b - Results in an OSR of 30 1_1110b - Results in an OSR of 31 1_1111b - Results in an OSR of 32
23 TDMAE	Transmitter DMA Enable Enables STAT[TDRE] to generate a DMA request. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable Enables STAT[RDRF] to generate a DMA request. 0b - Disable 1b - Enable
20 RIDMAE	Receiver Idle DMA Enable Enables STAT[IDLE] to generate a DMA request. If this field is 1, reading Data (DATA) when either DATA[RXEMPT] or DATA[IDLINE] is 1 generates an end-of-packet response until the completion of the DMA minor loop. During an end-of-packet response, reading Data (DATA) returns 0000_33FFh and does not pull data from the receive FIFO. STAT[IDLE] becomes 0 on completion of the minor loop, provided an end-of-packet response is generated and either the receive FIFO is empty or the receiver is active. 0b - Disable 1b - Enable
19-18 MATCFG	Match Configuration Configures the match addressing mode used. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Address match wake-up 01b - Idle match wake-up 10b - Match on and match off 11b - Enables RWU on data match and match on or off for the transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given OSR. This field must be 1 for OSRs between x4 and x7 and is optional for higher OSRs. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver samples input data using the rising edge of the baud rate clock. If this field is 1, the receiver samples input data using the rising and falling edges of the baud rate clock. 0b - Rising edge 1b - Both rising and falling edges
16 RESYNCDIS	Resynchronization Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Disables resynchronization of the received data word when a data one followed by data zero transition is detected. You must change the value of this field only when the receiver is disabled. 0b - Enable 1b - Disable
15 LBKDIE	LIN Break Detect Interrupt Enable Enables STAT[LBKDIF] to generate hardware interrupt requests. If this field is 0, hardware interrupts from STAT[LBKDIF] (uses polling) are disabled. If this field is 1, hardware interrupts are requested when STAT[LBKDIF] is 1. 0b - Disable 1b - Enable
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables STAT[RXEDGIF] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[RXEDGIF] are disabled. If this field is 1, hardware interrupts are requested when STAT[RXEDGIF] is 1. Changing the value of CTRL[LOOPS] or CTRL[RSRC] when this field (RXEDGIE) is 1 can cause STAT[RXEDGIF] to become 1. 0b - Disable 1b - Enable
13 SBNS	Stop Bit Number Select Determines whether data characters include one or two stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - One stop bit 1b - Two stop bits
12-0 SBR	Baud Rate Modulo Divisor Sets the modulo divide rate for the baud rate generator. • If SBR is 0, baud rate generator is disabled. • If SBR is 1–8191, baud rate = baud clock ÷ ((OSR + 1) × SBR). You must update the 13-bit baud rate setting [SBR12:SBR0] only when both the transmitter and receiver are disabled (both CTRL[RE] and CTRL[TE] are 0).

66.5.5.7 Status (STAT)

Offset

Register	Offset
STAT	14h

Function

Provides the module status.

Diagram

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag Indicates whether a LIN break character is detected. This field becomes 1 when the LIN break detect circuitry is enabled and a LIN break character is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag Indicates whether an active edge on the receive pin has occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 whenever the receiver is enabled and an active edge (falling if STAT[RXINV] is 0; rising if STAT[RXINV] is 1) on the RXD pin occurs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not occurred 1b - Occurred When writing 0b - No effect 1b - Clear the flag
29 MSBF	MSB First Specifies the first bit that is transmitted after the start bit. If this field is 0, LSB (bit 0) is the first bit transmitted after the start bit (which means, the first bit received after the start bit is identified as bit 0). If this field is 1, MSB (identified as bit 9, bit 8, bit 7, or bit 6) is the first bit that is transmitted, after the start bit, depending on the settings of CTRL[M], CTRL[PE], and BAUD[M10]. Writing 1 to this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - LSB 1b - MSB
28 RXINV	Receive Data Inversion Specifies whether receive data is inverted. Writing 1 to this field reverses the polarity of the received data input. You must change the value of this field only when the receiver is disabled. **NOTE** Writing 1 to this field inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Inverted 1b - Not inverted
27 RWUID	Receive Wake Up Idle Detect Controls, for CTRL[RWU] on idle character detection, whether the idle character that wakes up the receiver writes 1 to STAT[IDLE]. For address match wake-up, this field controls whether STAT[IDLE] = 1 when the address does not match. You must change the value of this field only when the receiver is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] does not become 1 when an address does not match. If this field is 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] becomes 1 when an address does not match. 0b - STAT[IDLE] does not become 1 1b - STAT[IDLE] becomes 1
26 BRK13	Break Character Generation Length Selects the longer transmitted break character length. The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - 9 to 13 bit times 1b - 12 to 15 bit times
25 LBKDE	LIN Break Detection Enable Enables LIN break detection. If this field is 0, LIN break detect is disabled, and only a normal break character can be detected. If this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] is 0), 12 bit times (if CTRL[M] is 1), or 13 bit times (if BAUD[M10] is 1). This field selects a longer break character detection length. When the field is 1, receive data is not stored in the receive FIFO. **NOTE** This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it ignores all characters except a LIN break. 0b - Disable 1b - Enable
24 RAF	Receiver Active Flag Indicates whether the LPUART receiver is idle or active. This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line. 0b - Idle, waiting for a start bit 1b - Receiver active (RXD pin input not idle)
23 TDRE	Transmit Data Register Empty Flag Indicates whether the transmit FIFO level is greater than, equal to, or less than the watermark.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0 again, write to Data (DATA). This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Greater than watermark 1b - Equal to or less than watermark
22 TC	Transmission Complete Flag Indicates whether the transmitter is active. This field becomes 0 when a transmission is in progress or a preamble or break character is loaded; in other words, when the transmitter is active (sending data, a preamble, or a break). The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted; in other words, when the transmission activity is complete. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active 1b - Transmitter idle
21 RDRF	Receive Data Register Full Flag Indicates whether the receive FIFO level is less than, equal to, or greater than the watermark. This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA). A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received. 0b - Equal to or less than watermark 1b - Greater than watermark
20 IDLE	Idle Line Flag Indicates whether an idle line is detected. This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end

Table continues on the next page...

Table continued from the previous page...

Field	Function
	of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line. For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Idle line detected 1b - Idle line not detected When writing 0b - No effect 1b - Clear the flag
19 OR	Receiver Overrun Flag Indicates whether there is receive overrun. This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received. When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun 1b - Receive overrun (new LPUART data is lost) When writing 0b - No effect 1b - Clear the flag
18 NF	Noise Flag Indicates whether noise is detected in the received character of Data (DATA). The advanced sampling technique used in the receiver takes three samples in each of the received bits. If some of these samples disagree with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No noise detected 1b - Noise detected When writing 0b - No effect 1b - Clear the flag
17 FE	Framing Error Flag Indicates whether a framing error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No framing error detected (this does not guarantee that the framing is correct) 1b - Framing error detected When writing 0b - No effect 1b - Clear the flag
16 PF	Parity Error Flag Indicates whether a parity error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received when parity is enabled (CTRL[PE] is 1) and the parity bit in the received character does not agree with the expected parity value. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No parity error detected 1b - Parity error detected When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 MA1F	Match 1 Flag Indicates whether the received data is equal to MATCH[MA1]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA1 1b - Equal to MA1 When writing 0b - No effect 1b - Clear the flag
14 MA2F	Match 2 Flag Indicates whether the received data is equal to MATCH[MA2]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA2]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA2 1b - Equal to MA2 When writing 0b - No effect 1b - Clear the flag
13-10 —	Reserved
9 TSF	Timeout Status Flag Indicates whether a field in Timeout Status (TOSR) is 1 and configured to generate an interrupt. 0b - Field is 0 1b - Field is 1
8 MSF	MODEM Status Flag Indicates whether a field in MODEM Status (MSR) is 1 and configured to generate an interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Field is 0 1b - Field is 1
7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers. This field has no effect when configured for LSB first and you must change the value of this field only when both the transmitter and receiver are disabled. If this field is 0, address mark in character is MSB. If this field is 1, the address mark is stored in Data (DATA) at MSB (or MSB-1 when the parity bit is enabled). In other words, the address mark in character is the last bit before the stop bit (or parity bit when enabled). 0b - Disable 1b - Enable
0 LBKFE	LIN Break Flag Enable Enables the LIN break flag to assert whenever a LIN break character is detected. Unlike STAT[LBKDE], this does not impact data being stored in the receive data buffer, but does cause STAT[LBKDIF] to become 1 whenever a LIN break is detected. Because a LIN break is longer than a normal character, the LIN break triggers a write to STAT[RDRF] with the data fields as 0 and STAT[FE] as 1. The character following the LIN break has DATA[LINBRK] as 1 to indicate that the previous character was a LIN break. You must change the value of this field only when both the transmitter and receiver are disabled. If this field is 1, the LIN break character is detected at a length of 11-bit times (if CTRL[M] is 0), 12 (if CTRL[M] is 1), or 13 (if BAUD[M10] is 1). 0b - Disable 1b - Enable

66.5.5.8 Control (CTRL)

Offset

Register	Offset
CTRL	18h

Function

Controls various optional features of the LPUART system.

You must write to the fields of this register only when both the transmitter and receiver are disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 R8T9	Receive Bit 8 Transmit Bit 9 Contains R8 and T9 that correspond to different functions. R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA). T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written.
30 R9T8	Receive Bit 9 Transmit Bit 8 Contains R9 and T8 that correspond to different functions. R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA). T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R9 is a read-only field and T8 is a write-only field; the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode Determines the direction of data at the TXD pin, in Single-Wire mode, when LPUART is configured for a single-wire half-duplex operation (CTRL[LOOPS] and CTRL[RSRC] are 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Input 1b - Output
28 TXINV	Transmit Data Inversion Specifies whether transmit data is inverted. Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Not inverted 1b - Inverted
27 ORIE	Overrun Interrupt Enable Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. 0b - Disable 1b - Enable
26 NEIE	Noise Error Interrupt Enable Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled. 0b - Disable 1b - Enable
25 FEIE	Framing Error Interrupt Enable Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled. 0b - Disable 1b - Enable
24 PEIE	Parity Error Interrupt Enable Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled. 0b - Disable 1b - Enable
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] is 1. 0b - Disable 1b - Enable
22	Transmission Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCIE	Enables STAT[TC] to generate interrupt requests if STAT[TC] is 1. 0b - Disable 1b - Enable
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] is 1. 0b - Disable 1b - Enable
20 ILIE	Idle Line Interrupt Enable Enables hardware interrupts. This field enables STAT[IDLE] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[IDLE] are disabled and polling is used, and if this field is 1, hardware interrupts are enabled when STAT[IDLE] is 1. 0b - Disable 1b - Enable
19 TE	Transmitter Enable Enables the LPUART transmitter. Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated. You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] and DATA[R9T9] = 1. 0b - Disable 1b - Enable
18 RE	Receiver Enable Enables the LPUART receiver. After you write 0 to this field, this field remains 1 until the receiver finishes receiving the current character (if any). 0b - Disable 1b - Enable
17 RWU	Receiver Wake-Up Control Specifies whether the LPUART receiver in standby is waiting for a wake-up condition. You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] is 0 or an address match when CTRL[WAKE] is 1 and STAT[RWUID] is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write 1 to this field only when CTRL[WAKE] is 0 (wake-up on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an Idle condition is detected before the IDLE flag is allowed to be reasserted. 0b - Normal receiver operation 1b - LPUART receiver in standby, waiting for a wake-up condition
16 SBK	Send Break Specifies whether queue break character(s) are to be sent. Writing 1 and then 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is 1, and bit times of logic 0 are queued as long as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent. You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - Normal transmitter operation 1b - Queue break character(s) to be sent
15 MA1IE	Match 1 (MA1F) Interrupt Enable Enables the MA1F interrupt. 0b - Disable 1b - Enable
14 MA2IE	Match 2 (MA2F) Interrupt Enable Enables the MA2F interrupt. 0b - Disable 1b - Enable
13 —	Reserved
12 —	Reserved
11 M7	7-Bit Mode Select Specifies the data characters that the receiver and transmitter use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must change the value of this field only after both the transmitter and receiver are disabled. 0b - 8-bit to 10-bit 1b - 7-bit
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before you write 1 to STAT[IDLE]. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
7 LOOPS	Loop Mode Select Selects Loop mode. After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]). 0b - Normal operation: RXD and TXD use separate pins 1b - Loop mode or Single-Wire mode
6 —	Reserved
5 RSRC	Receiver Source Select Determines the source of the receiver shift register input if CTRL[LOOPS] is 1. This field has no effect unless CTRL[LOOPS] is 1. If this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin. Additionally, the CTS_B pin is not used and internally driven by the RTS_B output. If this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input. 0b - Internal Loopback mode 1b - Single-wire mode
4	9-Bit Or 8-Bit Mode Select Specifies the data characters that the receiver and transmitter use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
M	0b - 8-bit 1b - 9-bit
3 WAKE	Receiver Wake-Up Method Select Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character • An idle condition on the receive pin input signal If this field is 0, CTRL[RWU] is configured for idle line wake-up, and if this field is 1, CTRL[RWU] is configured with address mark wake-up. 0b - Idle 1b - Mark
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - After the start bit 1b - After the stop bit
1 PE	Parity Enable Enables hardware parity generation and checking. If parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - Disable 1b - Enable
0 PT	Parity Type Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1): • Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd. • Even parity means that the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity 1b - Odd parity

66.5.5.9 Data (DATA)

Offset

Register	Offset
DATA	1Ch

Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

NOTE

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	NOISY	PARITYE	FRETSC	RXEMPT	IDLINE	LINBRK	R9T9	R8T8	R7T7	R6T6	R5T5	R4T4	R3T3	R2T2	R1T1	R0T0
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise. 0b - Received without noise 1b - Received with noise
14 PARITYE	Parity Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - Received without a parity error 1b - Received with a parity error
13 FRETSC	Frame Error Transmit Special Character Specifies the way the dataword is received. For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0. 0b - Received without a frame error on reads or transmits a normal character on writes 1b - Received with a frame error on reads or transmits an idle or break character on writes
12 RXEMPT	Receive Buffer Empty Indicates whether the receive buffer contains valid data. This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register. 0b - Valid data 1b - Invalid data and empty
11 IDLINE	Idle Line Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. It can be read as “1” on the first character when the receiver is first enabled. The difference between this field and STAT[IDLE] is that, STAT[IDLE] flag does not set on an idle line after the receiver is first enabled, it needs to receive a character before it can become set, whereas this field does not have this limitation and can be set on the first character received if an idle line is detected beforehand. 0b - Not idle 1b - Idle
10 LINBRK	LIN Break Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. If this field is 0, the LIN break detect circuitry is disabled. 0b - Not detected 1b - Detected
9 R9T9	Read receive FIFO bit 9 or write transmit FIFO bit 9
8	Read receive FIFO bit 8 or write transmit FIFO bit 8

Table continues on the next page...

Table continued from the previous page...

Field	Function
R8T8	
7 R7T7	Read receive FIFO bit 7 or write transmit FIFO bit 7
6 R6T6	Read receive FIFO bit 6 or write transmit FIFO bit 6
5 R5T5	Read receive FIFO bit 5 or write transmit FIFO bit 5
4 R4T4	Read receive FIFO bit 4 or write transmit FIFO bit 4
3 R3T3	Read receive FIFO bit 3 or write transmit FIFO bit 3
2 R2T2	Read receive FIFO bit 2 or write transmit FIFO bit 2
1 R1T1	Read receive FIFO bit 1 or write transmit FIFO bit 1
0 R0T0	Read receive FIFO bit 0 or write transmit FIFO bit 0

66.5.5.10 Match Address (MATCH)

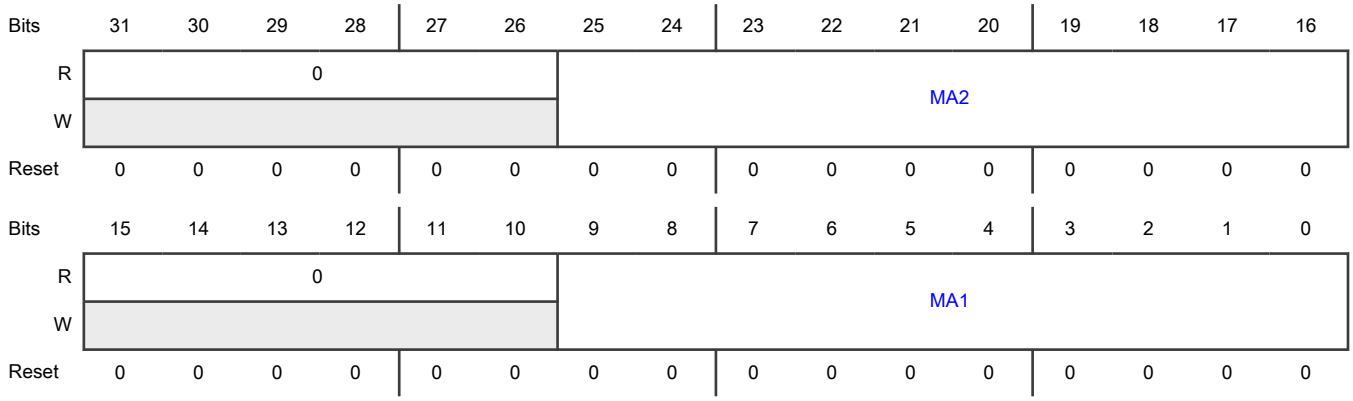
Offset

Register	Offset
MATCH	20h

Function

Provides addresses for address matching during the receiver operation.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] only when the associated Baud Rate (BAUD) field is 0.
15-10 —	Reserved
9-0 MA1	Match Address 1 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] fields only when the associated field in Baud Rate (BAUD) is 0.

66.5.5.11 MODEM IrDA (MODIR)

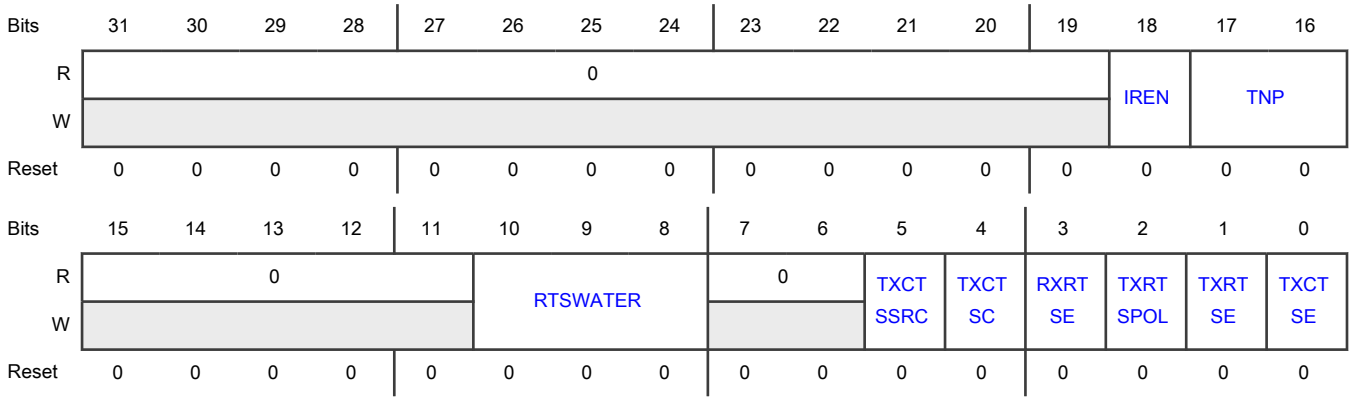
Offset

Register	Offset
MODIR	24h

Function

Controls options for setting the MODEM configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	IR Enable Enables IR modulation and demodulation. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Disable 1b - Enable
17-16 TNP	Transmitter Narrow Pulse Specifies whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled. You must change the value of this field only when both the transmitter and receiver are disabled. The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width. 00b - 1 ÷ OSR 01b - 2 ÷ OSR 10b - 3 ÷ OSR 11b - 4 ÷ OSR
15-11 —	Reserved
10-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the receiver's RTS_B output. The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the

Table continues on the next page...

Table continued from the previous page...

Field	Function
	purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match. You must change the value of this field only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - The CTS_B pin 1b - An internal connection to the receiver address match result
4 TXCTSC	Transmit CTS Configuration Configures whether the CTS state or input is checked or sampled at the start of each character or only when the transmitter is idle. 0b - Sampled at the start of each character 1b - Sampled when the transmitter is idle
3 RXRTSE	Receiver RTS Enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver has no effect on RTS. If this field is 1, RTS is deasserted if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1. RTS is asserted if STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. **NOTE** Do not write 1 to both MODIR[RXRTSE] and MODIR[TXRTSE]. 0b - Disable 1b - Enable
2 TXRTSPOL	Transmitter RTS Polarity Controls the polarity of the transmitter RTS. This field does not affect the polarity of the receiver RTS that remains negated in the active-low state unless MODIR[TXRTSE] is 1. You must change the value of this field only when the transmitter is disabled. 0b - Active low 1b - Active high
1	Transmitter RTS Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXRTSE	Controls the operation of RTS before and after a transmission. You must change the value of this field only when the transmitter is disabled. If this field is 0, the transmitter has no effect on RTS, and if this field is 1, a character is placed into an empty transmit shift register. RTS asserts 1-bit time before the start bit is transmitted and deasserts 1-bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit. 0b - Disable 1b - Enable
0 TXCTSE	Transmitter CTS Enable Enables the operation of the transmitter. You can write 1 to this field irrespective of the states of MODIR[TXRTSE] and MODIR[RXRTSE]. If this field is 1, the transmitter checks the state of the CTS signal each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the TXD signal remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS, when a character is being sent, do not affect its transmission. 0b - Disable 1b - Enable

66.5.5.12 FIFO (FIFO)

Offset

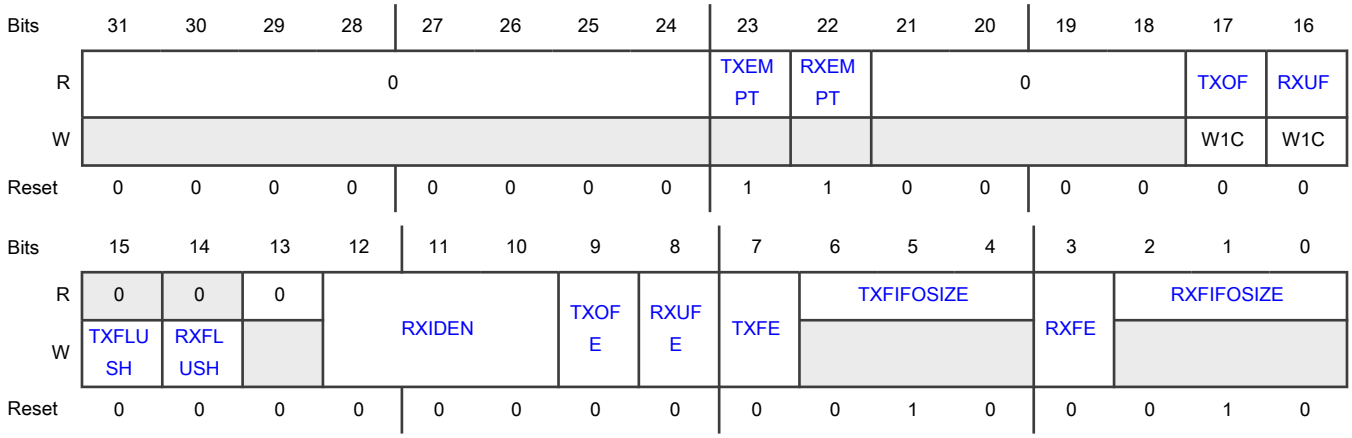
Register	Offset
FIFO	28h

Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO Or Buffer Empty Indicates whether the transmit buffer is empty. This field becomes 1 when there is no data in the transmit FIFO or buffer. The field does not consider data in the transmit shift register. 0b - Not empty 1b - Empty
22 RXEMPT	Receive FIFO Or Buffer Empty Indicates whether the receive buffer is empty. This field becomes 1 when there is no data in the receive FIFO or buffer. The field does not consider data in the receive shift register. 0b - Not empty 1b - Empty
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates whether more data has been written to the transmit FIFO than it can hold. If this field is 0, no transmit FIFO overflow has occurred since the last time the field was cleared, and if this field is 1, at least one transmit FIFO overflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[TXOFE]. However, an interrupt is issued to the host only if FIFO[TXOFE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
16 RXUF	Receiver FIFO Underflow Flag Indicates whether more data has been read from the receive FIFO than was present. If this field is 0, no receive FIFO underflow has occurred since the last time the field was cleared, and if this field is 1, at least one receive FIFO underflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[RXUFE]. However, an interrupt is issued to the host only if FIFO[RXUFE] is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underflow 1b - Underflow When writing 0b - No effect 1b - Clear the flag
15 TXFLUSH	Transmit FIFO Flush Causes all data that is stored in the transmit FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the transmit FIFO or buffer clears out. This does not affect data in the transmit shift register. 0b - No effect 1b - All data flushed out
14 RXFLUSH	Receive FIFO Flush Causes all data that is stored in the receive FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the receive FIFO or buffer clears out.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This does not affect data in the receive shift register. 0b - No effect 1b - All data flushed out
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable Enables STAT[RDRF] to become 1 when the receiver is idle for a number of idle characters and the FIFO is not empty. This feature is not supported when the receiver extended idle time is enabled. 000b - Disable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle 001b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for one character 010b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for two characters 011b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for four characters 100b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for eight characters 101b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 16 characters 110b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 32 characters 111b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 64 characters
9 TXOFE	Transmit FIFO Overflow Interrupt Enable Enables FIFO[TXOF] to generate an interrupt to the host. 0b - Disable 1b - Enable
8 RXUFE	Receive FIFO Underflow Interrupt Enable Enables FIFO[RXUF] to generate an interrupt to the host. 0b - Disable 1b - Enable
7 TXFE	Transmit FIFO Enable Enables the transmit FIFO. If this field is 0, the transmit buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[TXFIFOSIZE]. Both CTRL[TE] and CTRL[RE] must be 0 before you change the value of this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the built-in FIFO structure for the transmit buffer is enabled. FIFO[TXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth Indicates the maximum number of transmit datawords (transmit FIFO buffer depth) that can be stored in the transmit buffer. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256
3 RXFE	Receive FIFO Enable Enables the receive FIFO. If this field is 0, the receive buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[RXFIFOSIZE]. Both CTRL[RE] and CTRL[TE] must be 0 before you change the value of this field. If this field is 1, the built-in FIFO structure for the receive buffer is enabled. FIFO[RXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth Indicates the maximum number of receive datawords (receive FIFO buffer depth) that can be stored in the receive buffer before an overrun occurs. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256

66.5.5.13 Watermark (WATER)

Offset

Register	Offset
WATER	2Ch

Function

Provides the ability to set a programmable threshold for notification, or sets the programmable thresholds to indicate that transmit data can be written or receive data can be read.

You may read this register at any time but must write to it only when CTRL[TE] is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 —	Reserved
27-24 RXCOUNT	Receive Counter Indicates the number of datawords in the receive FIFO or buffer. If a dataword is being received in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate the room left in the receive FIFO or buffer.
23-19 —	Reserved
18-16 RXWATER	Receive Watermark Generates an interrupt or a DMA request if the number of datawords in the receive FIFO or buffer is greater than the value of this field. For proper operation, the value of this field must be less than the size of the receive FIFO or buffer, as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-12 —	Reserved
11-8 TXCOUNT	Transmit Counter Indicates the number of datawords in the transmit FIFO or buffer. If a dataword is being transmitted to the transmit shift register, it is not included in the count. This value may be used in conjunction with the value of FIFO[TXFIFOSIZE] to calculate the room left in the transmit FIFO or buffer.
7-3 —	Reserved
2-0 TXWATER	Transmit Watermark Generates an interrupt or a DMA request when the number of datawords in the transmit FIFO or buffer is equal to or less than the value of this field. For proper operation, the value of this field must be less than the size of the transmit buffer or FIFO, as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

66.5.5.14 Data Read-Only (DATARO)

Offset

Register	Offset
DATARO	30h

Function
Indicates the first entry in the receive FIFO, but does not pull data from the FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Did not change state 1b - Changed state When writing 0b - No effect 1b - Clear the flag

66.5.5.17 Receiver Extended Idle (REIR)

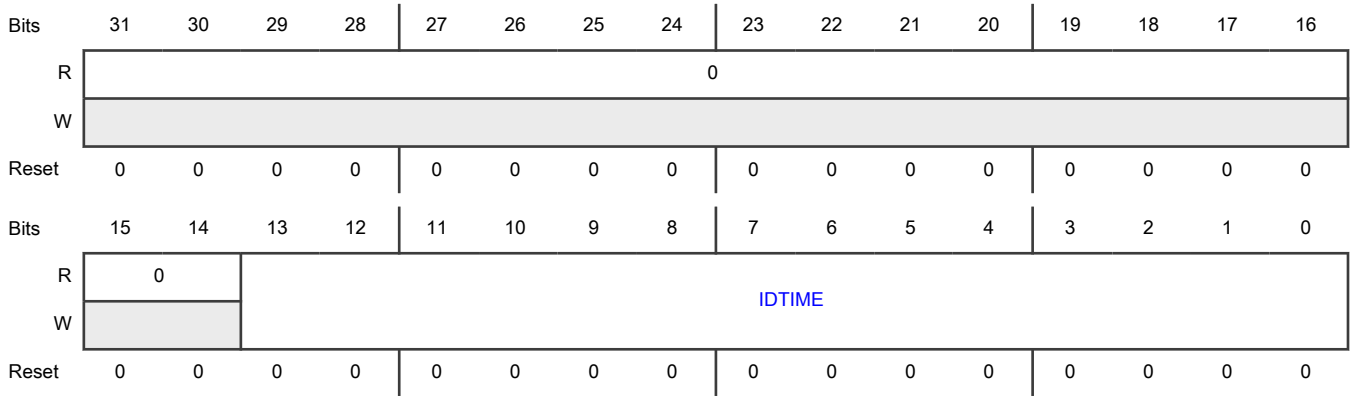
Offset

Register	Offset
REIR	48h

Function

Configures the receiver extended idle functionality. You must not change this value when the receiver is enabled.

Diagram



Fields

Field	Function
31-14 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
13-0 IDTIME	Idle Time Configures the idle length in number of bits (baud rate) since the end of the last stop bit. This affects the behavior of the idle wake-up, STAT[IDLE], DATA[IDLINE], and STAT[RAF]. The minimum supported extended idle time is equal to one idle character. The extended idle feature is disabled when this field is 0.

66.5.5.18 Transmitter Extended Idle (TEIR)

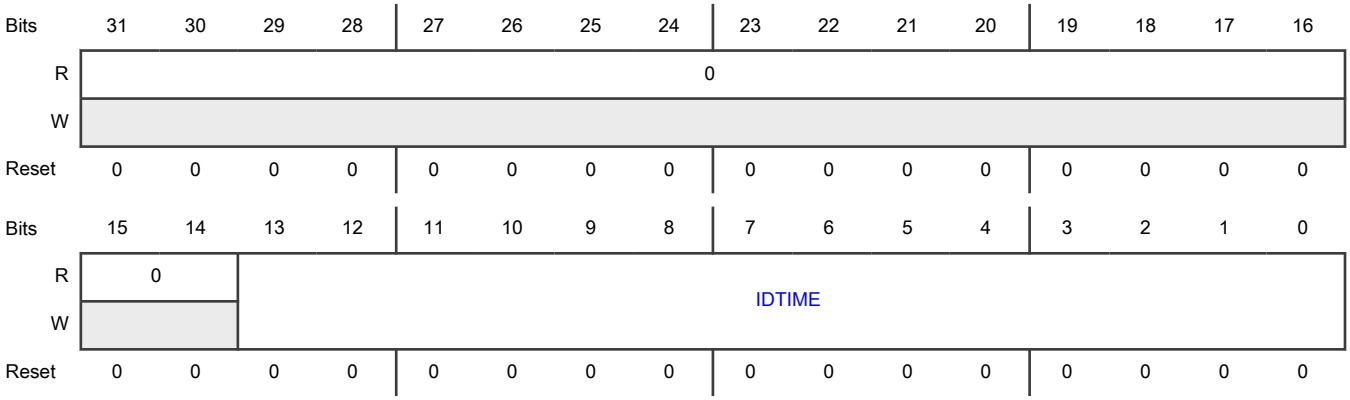
Offset

Register	Offset
TEIR	4Ch

Function

Configures the transmitter extended idle functionality. You must not change this value when the transmitter is enabled.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 IDTIME	Idle Time Configures the transmitter idle time in number of bits (baud rate) whenever an idle character is queued through the transmit FIFO. An idle character is not automatically queued whenever the transmitter is enabled. The minimum supported extended idle time equals one idle character. The extended idle feature is disabled when this field is 0.

66.5.5.19 Half Duplex Control (HDCR)

Offset

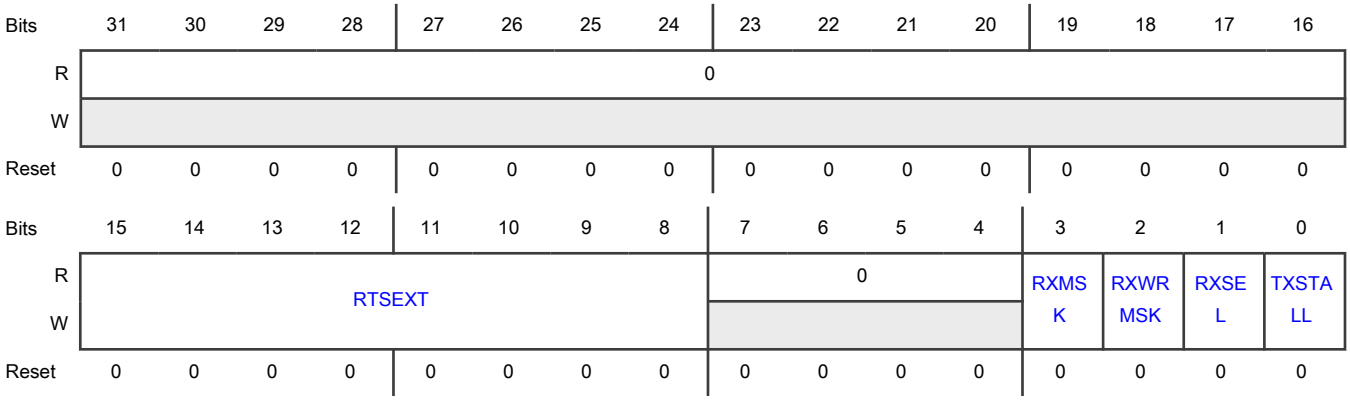
Register	Offset
HDCR	50h

Function

Provides control for half-duplex-related operations.

You can use this register instead of CTRL[LOOPS], CTRL[RSRC], and CTRL[TXDIR] functions, although you can use CTRL[LOOPS] to loop-back the transmitter outputs to the receiver.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 RTSEXT	RTS Extended Specifies RTS extension. The transmit RTS_B remains asserted for (RTSEXT + 1) bit times after the end of the last stop bit. This applies even when the transmitter's RTS_B output is disabled and is only used internally to mask the receiver.
7-4 —	Reserved
3 RXMSK	Receive Mask Specifies whether the transmitter RTS_B masks the receive data pin. When enabled, the transmitter RTS_B masks the receive data pin. 0b - Do not mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Mask
2 RXWRMSK	Receive FIFO Write Mask Specifies whether the transmitter RTS_B masks writes to the receive FIFO. When enabled, the transmitter RTS_B masks receive FIFO writes, but the idle flag is not affected. 0b - Do not mask 1b - Mask
1 RXSEL	Receive Select Specifies the receive data pin. When enabled, the receive data is sourced from the TXD pin. 0b - RXD 1b - TXD
0 TXSTALL	Transmit Stall Specifies whether the transmitter becomes busy when the receiver is active. When enabled, the transmitter does not become busy or asserts transmitter RTS_B when the receiver is active (STAT[RAF] is 1). 0b - No effect 1b - Does not become busy

66.5.5.20 Timeout Control (TOCR)

Offset

Register	Offset
TOCR	58h

Function

Configures the behavior of the timeout logic. Timeouts 0 and 1 are used to monitor the receiver and timeouts 2 and 3 are used to monitor the transmitter.

Fields

Field	Function
31-12 —	Reserved
11-8 TOF	Timeout Flag Indicates whether the corresponding timeout occurred. The timeout counter is disabled when this field is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0000b - Not occurred 0001b - Occurred When writing 0000b - No effect 0001b - Clear the flag
7-4 —	Reserved
3-0 TOZ	Timeout Zero Indicates whether the corresponding timeout counter equals 0.

66.5.5.22 Timeout N (TIMEOUT0 - TIMEOUT3)

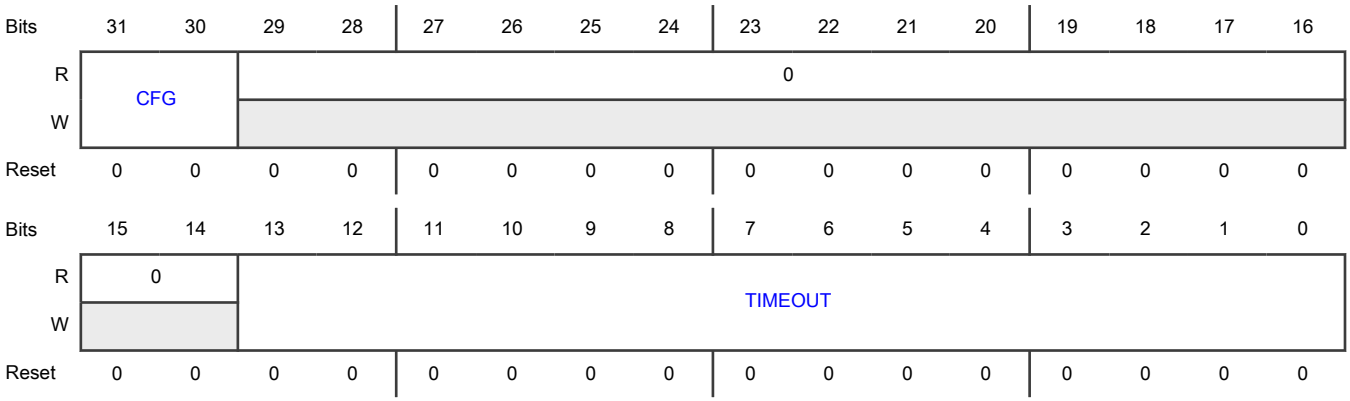
Offset

Register	Offset
TIMEOUT0	60h
TIMEOUT1	64h
TIMEOUT2	68h
TIMEOUT3	6Ch

Function

Configures the corresponding timeout counter and status field. Timeouts 0 and 1 are used to monitor the receiver and timeouts 2 and 3 are used to monitor the transmitter. You must write to this register only when the corresponding timeout is disabled or when the value of the corresponding timeout field is 1.

Diagram



Fields

Field	Function
31-30 CFG	Idle Configuration Configures the behavior of TIMEOUT[TIMEOUT]. 00b - Becomes 1 after timeout characters are received 01b - Becomes 1 when idle for timeout bit clocks 10b - Becomes 1 when idle for timeout bit clocks following the next character 11b - Becomes 1 when idle for at least timeout bit clocks, but a new character is detected before the extended idle timeout is reached
29-14 —	Reserved
13-0 TIMEOUT	Timeout Value Configures the timeout value.

66.5.5.23 Transmit Command Burst (TCBR0 - TCBR127)

Offset

For a = 0 to 127:

Register	Offset
TCBRa	200h + (a × 4h)

Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller, using aligned 8-bit, 16-bit, or 32-bit writes. The size of this register is 512 bytes:

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to TCBR*x*[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[15:8] pushes the data written to DATA[15:8] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to TXBR*x*[31:16] is ignored.

15-0 DATA	Data Enables writing data to Data (DATA).

66.5.5.24 Transmit Data Burst (TDBR0 - TDBR255)

Offset

For a = 0 to 255:

Register	Offset
TDBRa	400h + (a × 4h)

Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The size of this register is 1024 bytes:

- An aligned 32-bit write in this region pushes four DATA byte entries into the transmit FIFO (DATA0 byte first). The register access is extended by three wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two DATA byte entries into the transmit FIFO (DATA0 or DATA2 first). The register access is extended by one wait state.
- An 8-bit write in this region pushes one DATA byte entry into the transmit FIFO.

Byte writes to Data (DATA) use the contents of CTRL[R9T8] for the ninth data bit, CTRL[R8T9] for the tenth data bit, and zero extend DATA[FRETSC].

Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

67.1.1 Module instances

This device has two instances of the SAI module, SAI0 and SAI1.

67.1.2 SAI0/1 TCR2, RCR2, and MCR configuration

Table 581. SAI0/1 configuration

Instance	Register bit	Configuration
SAI0	TCR2[MSEL], RCR2[MSEL]	00 - SAI0 Bus Clock 01 - SAI0 MCLK output 10 - SAI1 MCLK output 11 - Reserved
SAI1	TCR2[MSEL], RCR2[MSEL]	00 - SAI1 Bus Clock 01 - SAI1 MCLK output 10 - SAI0 MCLK output 11 - Reserved
SAI0	MCR[MSEL]	SAI MCR register generates SAI MCLK output. 00 - SYSCON SAI0CLKDIV output 01 - Reserved 10 - SAI1 MCLK output 11 - Reserved
SAI1	MCR[MSEL]	SAI MCR register generates SAI MCLK output. 00 - SYSCON SAI1CLKDIV output 01 - Reserved 10 - SAI0 MCLK output 11 - Reserved

SAI1 bit clock, frame sync, and transmitter/receiver enable are synchronous with SAI0 in multiple SAI synchronous mode.

67.2 Overview

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats such as I^{2}S, AC97, TDM, and Codec/DSP interfaces.

67.2.1 Block diagram

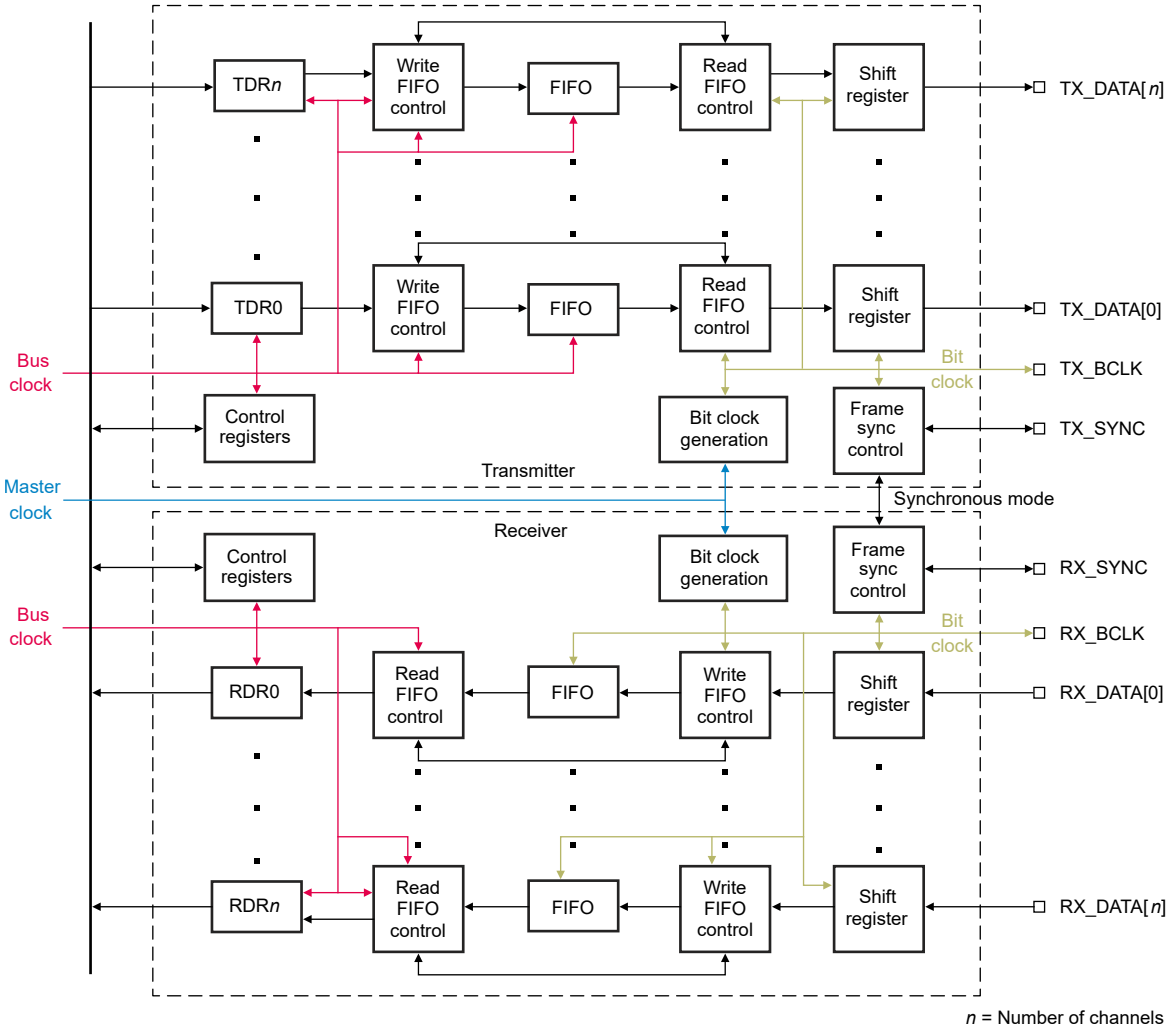

Figure 390. Block diagram

67.2.2 Features

Features can vary among chips and among SAI modules on the same chip. See the chip-specific SAI information at the beginning of this chapter.

- Transmitter with independent bit clock and frame synchronization supporting 2 data lines
- Receiver with independent bit clock and frame synchronization supporting 2 data lines
- Maximum frame size of 32 words per data line
- Word length of 8 to 32 bits

- Word length configured separately for the first word and remaining words in a frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive data line supports:
  - Graceful restart after FIFO error.
  - Automatic restart after FIFO error without software intervention.
  - 8-bit and 16-bit data packing into each 32-bit FIFO word.
  - Multiple-data-line FIFOs combining into single-data-line FIFO.

67.3 Functional description

This section provides a complete functional description of SAI.

67.3.1 Modes of operation

- Run mode
- Stop mode
- Debug mode

67.3.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

67.3.1.2 Stop mode

There are two situations in which you can configure the SAI transmitter or receiver to continue operating in Stop mode:

- The SAI transmitter or receiver uses an externally generated bit clock.
- The SAI transmitter or receiver uses an audio master clock that operates when the chip is in Stop mode.

Write 1 to TCSR[STOPE] to configure the transmitter to run in Stop mode, and write 1 to RCSR[STOPE] to configure the receiver to run in Stop mode.

The SAI transmitter and receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

When the chip enters Stop mode, if TCSR[STOPE] = 0, the transmitter is disabled after completing the current transmit frame. Similarly, when the chip enters Stop mode, if RCSR[STOPE] = 0, the receiver is disabled after completing the current receive frame. Entry into Stop mode is blocked (not acknowledged) when waiting for the transmitter and receiver to be disabled at the end of the current frame.

67.3.1.3 Debug mode

You can configure either or both the SAI transmitter and receiver to continue operating in Debug mode:

- Write 1 to TCSR[DBGE] to configure the transmitter to run in Debug mode.
- Write 1 to RCSR[DBGE] to configure the receiver to run in Debug mode.

When TCSR[DBGE] and RCSR[DBGE] are 0 and the chip enters Debug mode, SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

67.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other. You can configure the SAI transmitter and receiver to operate with a synchronous bit clock and frame sync (see TCR2[SYNC] and RCR2[SYNC]).

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in Synchronous mode only after configuring both the transmitter and receiver.

- Enable the transmitter last and disable the transmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in Synchronous mode only after configuring both the receiver and transmitter.
- Enable the receiver last and disable the receiver first.

When operating in Synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter and receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration register settings must be consistent across both the transmitter and receiver.

67.3.2.1 Multiple SAI Synchronous mode

Some chips support synchronous operation between multiple SAI modules. This mode requires you to configure the source of the bit clock and frame sync for asynchronous operation, and to configure the remaining users of the bit clock and frame sync for synchronous operation.

Synchronous operation between multiple SAI transmitters or receivers also requires you to enable the source of the bit clock and frame sync for any of the synchronous transmitters or receivers to be enabled. NXP recommends that the source of the bit clock and frame sync is the last enabled and the first disabled.

When operating in Synchronous mode, only the bit clock, frame sync, transmitter enable, and receiver enable are shared. Otherwise, the separate SAI modules operate independently, although configuration register settings must be consistent across both the transmitter and receiver.

67.3.3 Frame sync configuration

When enabled, SAI continuously transmits and receives frames of data. Each frame consists of a fixed number of words, with each word consisting of a fixed number of bits. Within each frame, you can mask any word, causing the receiver to ignore that word and the transmitter to 3-state during that word.

The frame sync signal indicates the start of a frame. A valid frame sync requires the detection of a rising edge (if active high) or falling edge (if active low). The transmitter or receiver cannot be busy with a previous frame. SAI ignores a valid frame sync (in Target mode) or does not generate one (in Controller mode) for the first four bit-clock cycles after enabling the transmitter or receiver.

You can configure the transmitter and receiver frame sync independently by using any of the following options:

- Generate externally or internally
- Configure to be active high or active low
- Assert with the first bit in the frame or one bit early
- Assert for a duration between one bit-clock cycle and the first word length
- Configure the frame length from 1 to 32 words
- Configure the word length from 8 to 32 bits, with separate configurations for the length of the first word and that of the remaining words
- Transmit or receive words MSB first or LSB first

You cannot change these configuration options after enabling the SAI transmitter or receiver.

67.3.4 Data FIFO

Each transmit and receive channel includes a 8 × 32-bit FIFO. Use Transmit Data (TDR0 - TDR1) and Receive Data (RDR0 - RDR1) to access FIFO data.

67.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit-wide register via the First Bit Shifted (FBT) configuration field. This field selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required FBT configuration are shown in Figure 391 for LSB-first configurations and Figure 392 for MSB-first configurations.

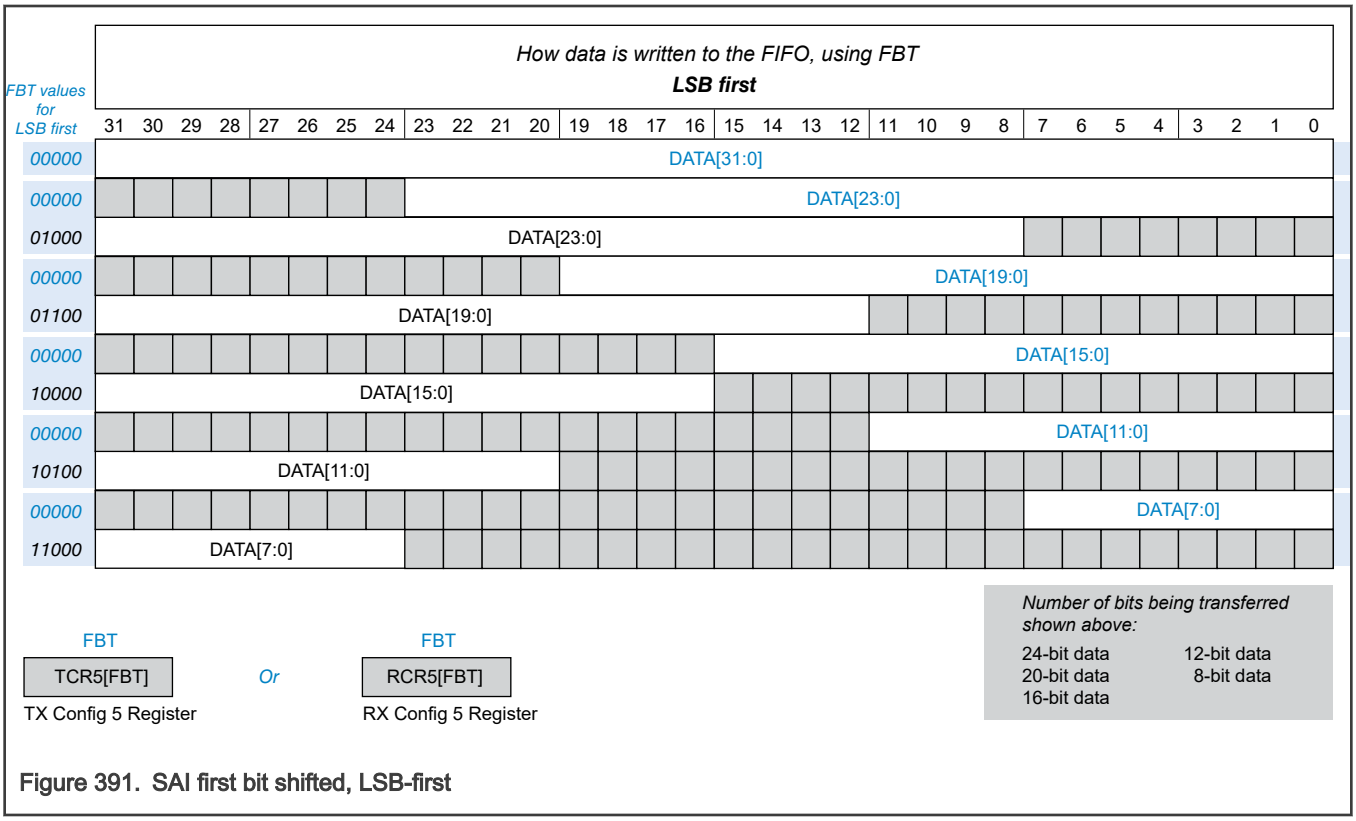

Figure 391. SAI first bit shifted, LSB-first

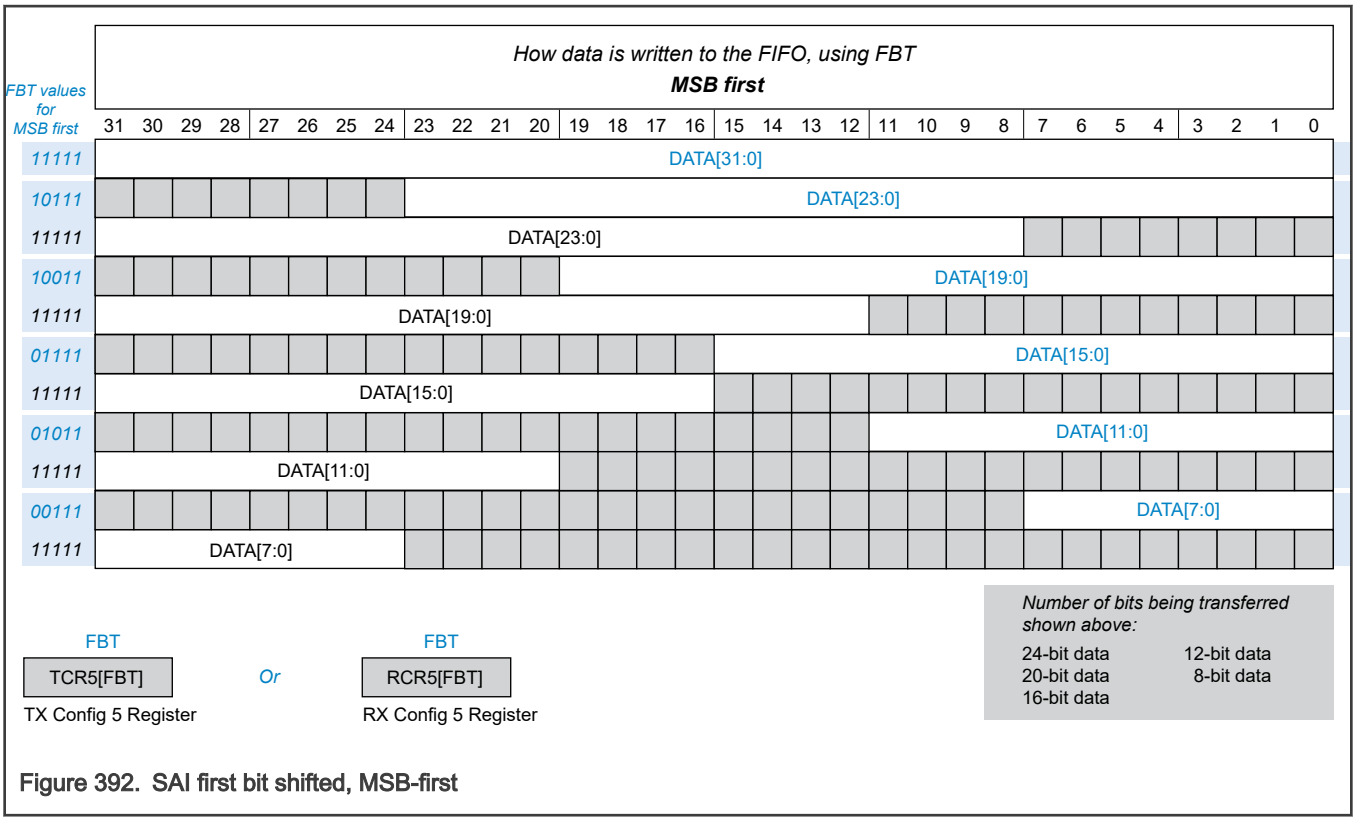

Figure 392. SAI first bit shifted, MSB-first

67.3.4.2 FIFO pointers

When writing to one of the Transmit Data (TDR0 - TDR1) registers, the write FIFO pointer of the corresponding Transmit FIFO register (TFR*n*[WFP]) increments after each valid write. SAI supports 8-bit, 16-bit, and 32-bit writes to TDR*n*, and the FIFO pointer increments after each individual write. Use only 8-bit writes when transmitting up to 8-bit data, and use only 16-bit writes when transmitting up to 16-bit data:

- If the transmit FIFO is full, SAI ignores writes to TDR*n*.
- If the transmit FIFO is empty, write to TDR*n* at least three bit-clock cycles before the start of the next unmasked word. This write avoids a FIFO underrun.
- Before enabling the transmitter, initialize the transmit FIFO with data. The transmitter starts a new frame after enabling the transmitter. If no data is in the FIFO, the transmitter immediately generates an error.

When reading one of the Receive Data (RDR0 - RDR1) registers, the read FIFO pointer of the corresponding Receive FIFO register (RFR*n*[RFP]) increments after each valid read. SAI supports 8-bit, 16-bit, and 32-bit reads from RDR*n*, and the FIFO pointer increments after each individual read. Use only 8-bit reads when receiving up to 8-bit data, and use only 16-bit reads when receiving up to 16-bit data:

- If the receive FIFO is empty, SAI ignores reads to RDR*n*.
- If the receive FIFO is full, read RDR*n* at least three bit-clock cycles before the end of an unmasked word. This read avoids a FIFO overrun.

67.3.4.3 FIFO packing

Using FIFO packing, you can store multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter or receiver. You could emulate this feature by adjusting the number of bits per word and number of words per frame. FIFO packing, however, does not require even multiples of words per frame, and it fully supports word masking.

When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive). In this way, FIFO packing supports scenarios where different words within each frame are stored in different areas of memory.

Using 16-bit FIFO packing for transmitting, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first transmitted word is taken from the 16-bit word at byte offset 0h. (The first bit is selected by TCR5[FBT], and you must configure it within this 16-bit word.) The second transmitted word is taken from the 16-bit word at byte offset 2h. (The first bit is selected by TCR5[FBT][3:0].) After the 16-bit word has been transmitted, the transmitter transmits logic zeroes until the start of the next word.

Using 16-bit FIFO packing for receiving, the receive shift register is stored after every second unmasked received word. If there is an odd number of unmasked-received words in each frame, the receive register is also stored, at the end of each frame. The first received word is stored in the 16-bit word at byte offset 0h. (The first bit is selected by RCR5[FBT], and you must configure it within this 16-bit word.) The second received word is stored in the 16-bit word at byte offset 2h. (The first bit is selected by RCR5[FBT][3:0].) The receiver ignores received data until the start of the next word after the 16-bit word has been received.

8-bit FIFO packing is similar to 16-bit packing, except four words are loaded or stored into each 32-bit FIFO word. The first word is stored in byte offset 0h, the second word in byte offset 1h, and so on. You must configure TCR5[FBT], RCR5[FBT], or both within byte offset 0h.

67.3.4.4 FIFO Combining mode

This mode enables separate FIFOs for multiple data channels to be used as a single FIFO for software accesses, as a single data channel, or both. The enabled data channels must be contiguous and data channel 0 must be enabled when using FIFO Combining mode.

You can combine FIFOs for software access by writing to transmit FIFO registers and reading from receive FIFO registers. Doing so enables a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. After FIFO Combining mode is enabled (TCR4[FCOMB] > 00b), the first software access to a FIFO register accesses the first enabled channel FIFO. The second access to a FIFO register accesses the second enabled channel FIFO. This process continues until software accesses the last enabled channel FIFO and the pointer resets to the first enabled channel FIFO. To reset the pointer manually, you can reset the FIFOs or disable FIFO combining on software accesses.

Combining FIFOs for transmit data channels enables one data channel to use the FIFOs of all enabled channel FIFOs. In this case, the data output is identical on each enabled data channel. The transmit shift registers for all enabled data channels load at the start of each frame. The registers also load upon every *n*th unmasked word, where *n* is the number of enabled data channels. The first word transmitted loads from the first enabled channel FIFO; the second word transmitted loads from the second enabled channel FIFO. This loading continues until the end of the frame.

Combining FIFOs for receive data channels enables one data channel to use the FIFOs of all enabled channel FIFOs. In this case, the received data from channel 0 is stored in each enabled data channel. The receive shift registers for all enabled data channels are stored after every *n*th unmasked word, where *n* is the number of enabled data channels. The first word received is stored in the first enabled channel FIFO; the second word received is stored in the second enabled channel FIFO. This storage continues until the end of the frame.

NOTE

The first word in each frame is always stored in the first enabled data channel. NXP recommends that the number of unmasked words in each frame be evenly divisible by the number of enabled data channels.

Combining FIFOs for data channels loads or stores each channel FIFO at the same time. As a result, FIFO error conditions are only checked every *n*th word, where *n* is the number of enabled data channels. If any enabled data channel meets the warning flag or request flag conditions, SAI asserts the FIFO warning and request flags.

67.3.5 Word mask register

The SAI transmitter and receiver each have a word mask register (Transmit Mask (TMR) and Receive Mask (RMR)) that you can use to mask any word in the frame. The word mask register is double buffered. You can update it before the end of each frame to mask a particular word in the next frame.

TMR causes the transmit data pin to be 3-stated for the length of each selected word; the transmit FIFO is not read for masked words.

RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

67.3.6 Clocking

- Audio controller clock
- Bit clock
- Bus clock

67.3.6.1 Audio controller clock

The audio controller clock generates the bit clock when you configure the receiver or transmitter for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio controller clocks to generate the bit clock.

The SAI peripheral controls the pin direction and postdivider of an audio controller clock. The postdivider can divide down the clock output on the MCLK signal pin without affecting the audio controller clock that the transmitter and receiver use.

The audio controller clock generation and selection is chip-specific. See chip-specific clocking information about how the audio controller clocks are generated.

67.3.6.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that an audio controller clock can generate internally or an external source can supply. SAI can also have synchronous bit clock and frame sync operation between the receiver and transmitter, or between multiple SAI peripherals. The transmitter and receiver configuration affects the bit clock and frame sync in the following ways:

- If you configure both the transmitter and receiver for asynchronous operation, each uses its own bit clock and frame sync.
- If you configure the transmitter for asynchronous operation and the receiver for synchronous operation, both use the transmitter bit clock and frame sync.
- If you configure the receiver for asynchronous operation and the transmitter for synchronous operation, both use the receiver bit clock and frame sync.

Your choice of synchronous or asynchronous operation selects the bit clock and frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled.
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames.

In asynchronous operation, a SAI transmitter or receiver can use a bit clock externally generated by a SAI module instance that is disabled in Stop mode. In this case, disable the transmitter or receiver before entering Stop mode. This issue does not apply when the transmitter or receiver is in synchronous operation because all synchronous SAI modules are enabled and disabled simultaneously.

67.3.6.3 Bus clock

The control and configuration registers use the bus clock to generate synchronous interrupts and DMA requests.

NOTE

Although no minimum bus clock frequency is specified, the frequency must be fast enough (relative to the bit clock frequency) to serve the FIFOs. You must meet this requirement without generating a transmitter FIFO underrun or receiver FIFO overflow condition.

67.3.7 Reset

SAI is asynchronously reset on system reset. SAI has a Software reset and a FIFO reset.

67.3.7.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. The SAI receiver includes a software reset that resets all receiver internal logic, including bit clock generation, status flags, and FIFO pointers.

These software resets do not reset the configuration registers. The software resets remain asserted until you clear them via software.

67.3.7.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the value of the FIFO read pointer. This FIFO reset empties the FIFO contents. Use this reset after TCSR[FEF] becomes 1, and before SAI reinitializes the FIFO and TCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by writing 1 to the appropriate bit in TCR3[CFR]. Use this reset only when the corresponding bit in TCR3[TCE] is 0.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the value of the FIFO write pointer. This FIFO reset empties the FIFO contents. Use this reset after RCSR[FEF] becomes 1 and SAI reads any remaining data from the FIFO, and before RCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by writing 1 to the appropriate bit in RCR3[RCE]. Use this reset only when the corresponding bit in RCR3[RCE] is 0.

67.3.8 Interrupts and DMA requests

In SAI, the transmitter and receiver generate separate interrupts and DMA requests, but use the same status flags. SAI generates asynchronous versions of the transmitter and receiver interrupts to wake the CPU from Stop mode. SAI only generates asynchronous interrupts when the system clock is gated but the corresponding BCLK signal is active.

67.3.8.1 FIFO request flag

SAI sets the transmit FIFO request flag (TCSR[FRF]) when the number of entries in any enabled transmit FIFO is less than or equal to the transmit FIFO watermark configuration (TCR1[TFW]). SAI clears this flag when the number of entries in each enabled transmit FIFO is greater than TCR1[TFW].

SAI sets the receive FIFO request flag (RCSR[FRF]) when the number of entries in any enabled receive FIFO is greater than the receive FIFO watermark configuration (RCR1[RFW]). SAI clears this flag when the number of entries in each enabled receive FIFO is less than or equal to RCR1[RFW].

The FIFO request flag can generate an interrupt when TCSR[FRIE] = 1. It can generate a DMA request when TCSR[FRDE] = 1.

67.3.8.2 FIFO warning flag

SAI sets the transmit FIFO warning flag (TCSR[FWF]) when the number of entries in any of the enabled transmit FIFOs is empty. SAI clears this flag when the number of entries in each enabled transmit FIFO is not empty.

SAI sets the receive FIFO warning flag (RCSR[FWF]) when the number of entries in any of the enabled receive FIFOs is full. SAI clears this flag when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an interrupt when TCSR[FWIE] = 1. The flag can generate a DMA request when TCSR[FWDE] = 1.

67.3.8.3 FIFO error flag

SAI sets the transmit FIFO error flag (TCSR[FEF]) when any enabled transmit FIFOs underrun. After the error flag is set, all enabled transmit channels transmit zero data before SAI clears TCSR[FEF].

When you write 1 to TCR4[FCONT], the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun. It continues only after new data is written to the transmit FIFO. In this case, clear TCSR[FEF] without reinitializing the transmit FIFOs.

SAI sets the receive FIFO error flag (RCSR[FEF]) when any enabled receive FIFO overflows. After the flag is set, all enabled receive channels discard their received data until SAI clears RCSR[FEF] and the next receive frame starts. Empty all enabled receive FIFOs before SAI clears RCSR[FEF].

When you write 1 to RCR4[FCONT], the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow. It continues only after data has been read from the receive FIFO. In this case, clear RCSR[FEF] without emptying the receive FIFOs.

TCSR[FEF] and RSCR[FEF] can only generate an interrupt.

67.3.8.4 Sync error flag

SAI sets a sync error flag (TCSR[SEF] or RCSR[SEF]) when both of these conditions are true:

- The frame sync is generated externally.
- The external frame sync asserts when the transmitter or receiver is busy with the previous frame.

SAI ignores the external frame sync assertion and sets the sync error flag. When this flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

TCSR[SEF] and RCSR[SEF] can only generate an interrupt.

67.3.8.5 Word start flag

SAI sets the word start flag (TCSR[WSF]) at the start of the second bit-clock cycle for the selected word. You can select this word via TCR3[WDFL].

TCSR[WSF] can only generate an interrupt.

67.4 External signals

Name	Function	I/O
TX_BCLK	Transmit bit clock: the bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated.	I/O
TX_DATA[1:0]	Transmit data: the bit clock synchronously generates the transmit data; this signal is 3-stated when not transmitting a word.	O
RX_BCLK	Receive bit clock: the bit clock is an input when externally generated and an output when internally generated.	I/O

Table continues on the next page...

RX_SYNC	Receive frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA[1:0]	Receive data: the bit clock synchronously samples the receive data.	I
MCLK	Audio controller clock: the audio controller clock is an input when externally generated and an output when internally generated.	I/O

67.5 Initialization

To initialize SAI:

1. Enable the clock to SAI.
2. Reset the internal transmitter logic and receiver logic by writing 1 to TCSR[SR] and RCSR[SR], respectively.

67.6 Memory map and register definition

A read or write access to an address from offset 108h and above results in a bus error.

67.6.1 SAI register descriptions

67.6.1.1 SAI memory map

SAI0 base address: 4010_6000h

Fields

Field	Function
31	Transmitter Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TE	Enables the transmitter. When you write 0 to this field, the transmitter remains enabled, and this field remains 1 until the end of the current frame. 0b - Disable 1b - Enable (or transmitter has been disabled and has not yet reached the end of the frame)
30 STOPE	Stop Enable Enables transmitter operation in Stop mode. 0b - Disable 1b - Enable
29 DBGE	Debug Enable Enables transmitter operation in Debug mode, which does not affect the transmit bit clock. If you write 0 to this field, the transmitter operation is disabled after completing the current frame. 0b - Disable 1b - Enable
28 BCE	Bit Clock Enable Enables the transmit bit clock, separately from TCSR[TE]. This field automatically becomes 1 when TCSR[TE] becomes 1. When you write 0 to this field, the transmit bit clock remains enabled, and the field remains 1 until the end of the current frame. 0b - Disable 1b - Enable
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO and sets the FIFO read and write pointers to the same value, which may or may not be zero. **NOTE** The FIFO reset is asserted for one cycle only. Reading this field always returns zero. SAI resets the FIFO pointers when the transmitter is disabled or the FIFO error flag is set. 0b - No effect 1b - FIFO reset
24 SR	Software Reset Resets the internal transmitter logic, including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The software reset remains asserted until software writes 0 to the field. 0b - No effect 1b - Software reset
23-21 —	Reserved
20 WSF	Word Start Flag Indicates whether the start of the configured word has been detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
19 SEF	Sync Error Flag Indicates whether an error in the externally generated frame sync has been detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
18 FEF	FIFO Error Flag Indicates whether an enabled transmit FIFO has underrun. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
17 FWF	FIFO Warning Flag Indicates whether an enabled transmit FIFO is empty. 0b - Not empty 1b - Empty
16 FRF	FIFO Request Flag Indicates whether the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark. 0b - Watermark not reached 1b - Watermark reached
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables word start interrupts. 0b - Disable 1b - Enable
11 SEIE	Sync Error Interrupt Enable Enables sync error interrupts. 0b - Disable 1b - Enable
10 FEIE	FIFO Error Interrupt Enable Enables FIFO error interrupts. 0b - Disable 1b - Enable
9 FWIE	FIFO Warning Interrupt Enable Enables FIFO warning interrupts. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
8 FRIE	FIFO Request Interrupt Enable Enables FIFO request interrupts. 0b - Disable 1b - Enable
7-5 —	Reserved
4-2 —	Reserved
1 FWDE	FIFO Warning DMA Enable Enables the DMA warning. 0b - Disable 1b - Enable
0 FRDE	FIFO Request DMA Enable Enables DMA requests. 0b - Disable 1b - Enable

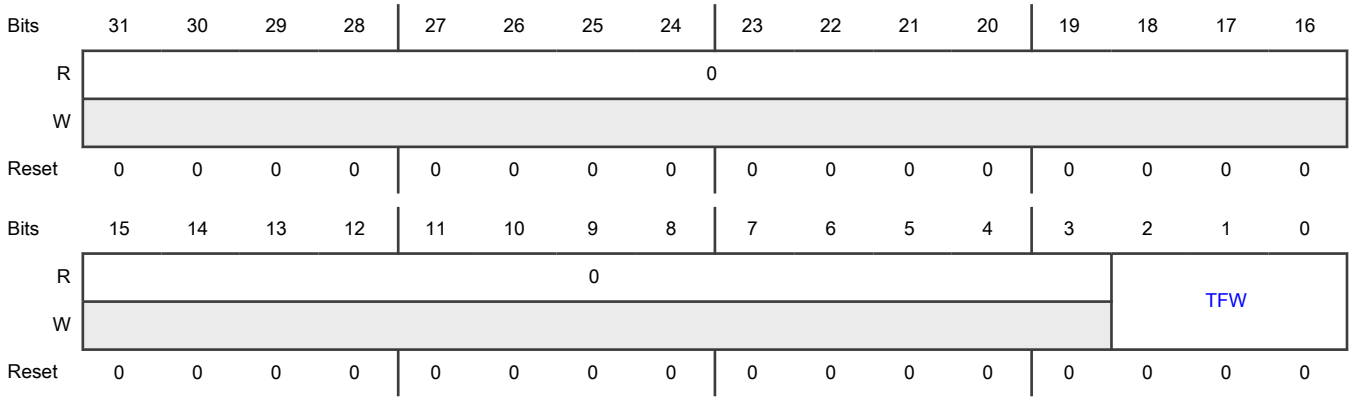
67.6.1.5 Transmit Configuration 1 (TCR1)

Offset

Register	Offset
TCR1	Ch

Function
Configures the watermark level for all enabled transmit channels.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 TFW	Transmit FIFO Watermark Indicates the number of 32-bit FIFO words in the watermark level of the transmit FIFO. 000b - 1 001b - 2 010b-110b - (TFW +1) 111b - 8

67.6.1.6 Transmit Configuration 2 (TCR2)

Offset

Register	Offset
TCR2	10h

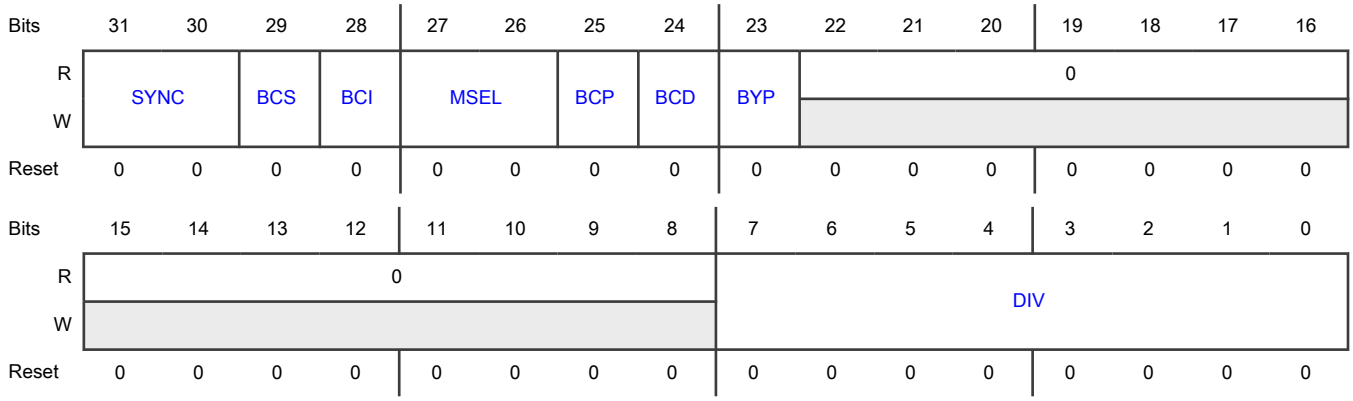
Function

Contains the SYNC mode and clock setting fields.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram



Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures Asynchronous and Synchronous modes of operation. When configured for Synchronous mode, you must configure the receiver or other SAI peripheral for asynchronous operations. 00b - Asynchronous mode 01b - Synchronous with receiver 10b - Synchronous with another SAI transmitter 11b - Synchronous with another SAI receiver
29 BCS	Bit Clock Swap Swaps the bit clock used by the transmitter. When you configure the transmitter in Asynchronous mode and this field is 1, the receiver bit clock (RX_BCLK) clocks the transmitter. This configuration allows the transmitter and receiver to share a bit clock, while the transmitter continues to use the transmit frame sync (TX_SYNC). When you configure the transmitter in Synchronous mode, you must write the same value to the transmitter BCS field and the receiver BCS field. When both are 1, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but both use the receiver frame sync (RX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source 1b - Swap the bit clock source
28 BCI	Bit Clock Input Enables the internal logic to be clocked as if the bit clock is generated externally. When this field is 1 while using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the transmitter is delayed by the pad output delay. (The pad input clocks the transmitter as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Use the Target mode timing from the data sheet for the transmitter when this field is 1. In Synchronous mode, this field allows the transmitter to use the Target mode timing from the data sheet, while the receiver uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral. **NOTE** When BCI = 1, both the input buffer and output buffer must be enabled for the BCLK pad. 0b - Disable 1b - Enable
27-26 MSEL	MCLK Select Selects the audio controller clock option used to generate an internally generated bit clock. This field has no effect when SAI is configured for an externally generated bit clock. **NOTE** Depending on the chip, some controller clock options might not be available. See the chip-specific information for the meaning of each option. **NOTE** Choose the same value for this field and for RCR2[MSEL]. 00b - Bus clock 01b - Controller clock (MCLK) option 1 10b - Controller clock (MCLK) option 2 11b - Controller clock (MCLK) option 3
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on rising edge and sample inputs on falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on falling edge and sample inputs on rising edge. 0b - Active high 1b - Active low
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Generate externally in Target mode 1b - Generate internally in Controller mode
23 BYP	Bit Clock Bypass Bypasses the bit clock divider. When bypassed, the internal bit clock is divide-by-one of the audio controller clock. When not bypassed, the internal bit clock is generated from the bit clock divider.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Choose the same value for this field and for RCR2[BYP]. 0b - Disable 1b - Enable
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Determines the value by which SAI divides down the audio controller clock to generate the bit clock (when configured for an internal bit clock). The division value is (DIV + 1) × 2.

67.6.1.7 Transmit Configuration 3 (TCR3)

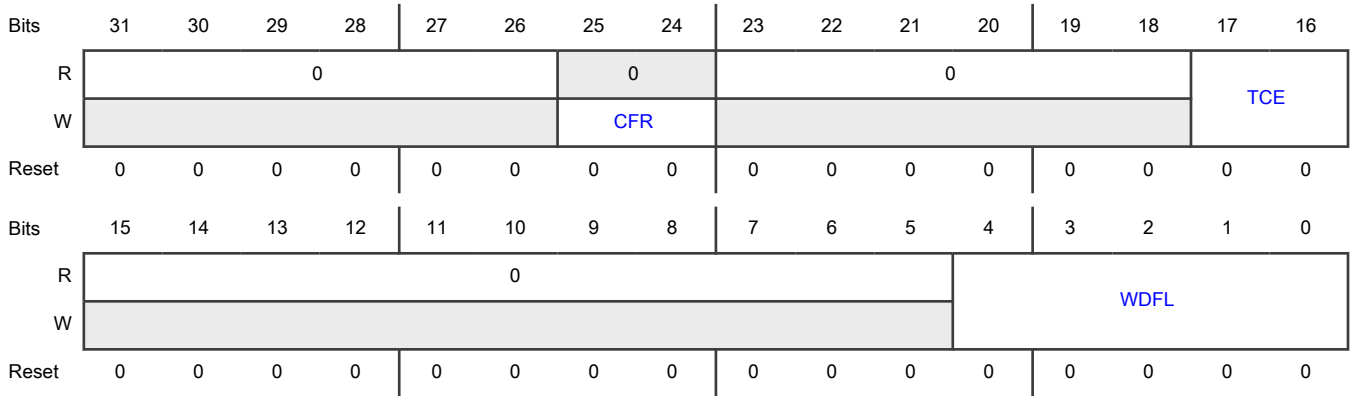
Offset

Register	Offset
TCR3	14h

Function

Contains the transmit channel settings.

Diagram



Fields

Field	Function
31-26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. You must reset FIFO pointers only when a channel is disabled or the FIFO error flag is set. The width of this field = the number of transmit channels (call it *n*). For example, if this field is 2 bits wide, bit position 24 refers to the transmit channel 1 FIFO pointer and bit position 25 refers to the transmit channel 2 FIFO pointer. Writing 1 to bit 24 resets the transmit channel 1 FIFO pointer, and writing 1 to bit 25 enables the transmit channel 2 FIFO pointer. Writing 1 to bit *n* resets the transmit channel *n* FIFO pointer. **NOTE** When there is only one channel, you do not need the individual channel FIFO reset (TCR3[CFR]). For a single channel, use the global FIFO reset (TCSR[FR]). • 0b – No effect • 1b – Reset transmit data channel *n* FIFO
23-18 —	Reserved
17-16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operations. Changing this field takes effect immediately for generating the FIFO request and warning flags. It takes effect at the end of each frame for transmit operations. The width of this field = the number of transmit channels (call it *n*). For example, if this field is two bits wide, bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Writing 1 to bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Writing 1 to bit *n* enables transmit channel *n*. For each transmit data channel: • 0b – Disable • 1b – Enable
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Selects the word that sets the word start flag (TCSR[WSF]). The value must be one less than the word number. For example, writing 0 selects the first word in the frame. When you configure this field with a value greater than TCR4[FRSZ], TCSR[WSF] is never set.

67.6.1.8 Transmit Configuration 4 (TCR4)

Offset

Register	Offset
TCR4	18h

Function

Contains the transmit fields for FIFO Combine mode, FIFO Packing mode, and frame sync settings.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			FCONT	FCOMB		FPACK		0				FRSZ			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			SYWD					0		CHMOD	MF	FSE	ONDEM	FSP	FSD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when SAI must continue transmitting after a FIFO error is detected. When this field is 0 and a FIFO error occurs, SAI continues from the start of the next frame after the FIFO error flag clears. When this field is 1 and a FIFO error occurs, SAI continues from the same word that caused the FIFO error after the FIFO warning flag clears. 0b - Continue from the start of the next frame 1b - Continue from the same word that caused the FIFO error
27-26 FCOMB	FIFO Combine Mode Enables FIFO Combine mode for specified operations. When FIFO Combine mode is enabled for FIFO writes, software writing to any FIFO data register alternates the write among the enabled data channel FIFOs. For example, if two data channels are enabled:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The first write is performed to the first enabled data channel FIFO. • The second write is performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO Combine mode for FIFO writes resets the pointer back to the first enabled data channel. When FIFO Combine mode is enabled for FIFO reads from the transmit shift registers, the transmit data channel output alternates between the enabled data channel FIFOs. For example, if two data channels are enabled: • The first unmasked word is transmitted from the first enabled data channel FIFO. • The second unmasked word is transmitted from the second enabled data channel FIFO. Because the first word of the frame is always transmitted from the first enabled data channel FIFO, NXP recommends that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - Disable 01b - Enable on FIFO reads (from transmit shift registers) 10b - Enable on FIFO writes (by software) 11b - Enable on FIFO reads (from transmit shift registers) and writes (by software)
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 bits or 16 bits, only the first 8 bits or 16 bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer only increments when you write the full 32-bit FIFO word. 00b - Disable FIFO packing 01b - Reserved 10b - Enable 8-bit FIFO packing 11b - Enable 16-bit FIFO packing
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit-clock cycles. The value must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. You cannot configure the sync width to be longer than the first word of the frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-6 —	Reserved
5 CHMOD	Channel Mode Specifies the mode of transmit data pins. In TDM mode, transmit data pins are 3-stated when slots are masked or channels are disabled. In Output mode, transmit data pins are never 3-stated, and they output zero when slots are masked or channels are disabled. 0b - TDM mode 1b - Output mode
4 MF	MSB First Configures what is transmitted first: LSB or MSB. 0b - LSB 1b - MSB
3 FSE	Frame Sync Early Determines when frame sync is asserted. 0b - First bit of the frame 1b - One bit before the first bit of the frame
2 ONDEM	On-Demand Mode Determines when the internal frame sync is generated. When this field is 1, and the frame sync is generated internally, a frame sync is only generated after the FIFO warning flag is cleared. 0b - Generated continuously 1b - Generated after the FIFO warning flag is cleared
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Active high 1b - Active low
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Generated externally in Target mode 1b - Generated internally in Controller mode

67.6.1.9 Transmit Configuration 5 (TCR5)

Offset

Register	Offset
TCR5	1Ch

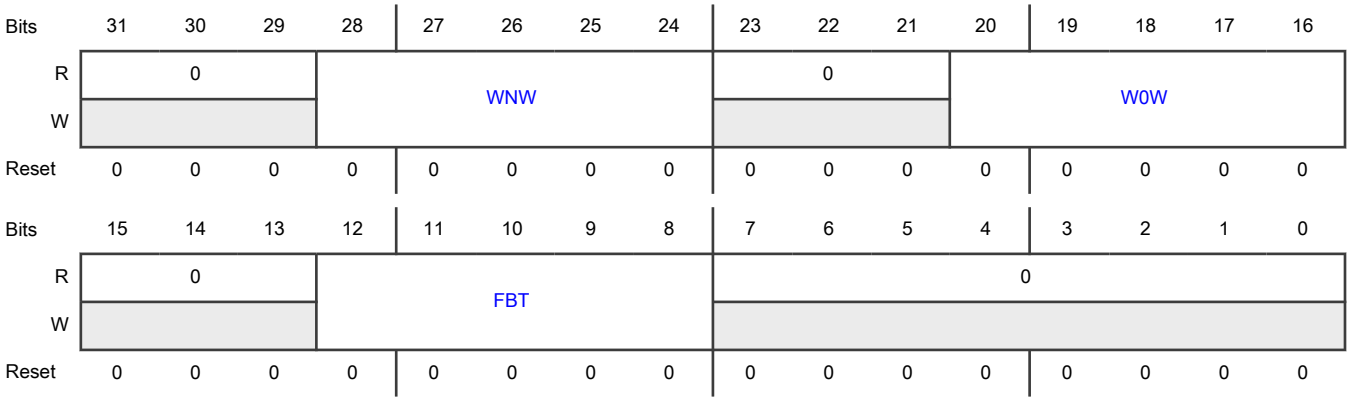
Function

Contains transmit word width and bit index settings.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, except for the first one in the frame. The value written must be one less than the number of bits per word. SAI does not support word widths of less than 8 bits. SAI does not support bit settings 0–6 (0b–0_0110b). 0_0111b - 8 0_1000b - 9 0_1001b-1_1110b - (WNW value + 1) 1_1111b - 32
23-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-16 W0W	Word 0 Width Configures the number of bits in the first word of each frame. The value written must be one less than the number of bits in the first word. SAI does not support word widths of less than 8 bits when there is only one word per frame. SAI does not support bit settings 0–6 (0b–0_0110b). 0_0111b - 8 0_1000b - 9 0_1001b-1_1110b - (W0W value + 1) 1_1111b - 32
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB-first, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB-first, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB-first. The value written must be less than or equal to 31-word width when configured for LSB-first. See Data alignment for details. 0_0000b - 0 0_0001b-1_1110b - FBT 1_1111b - 31
7-0 —	Reserved

67.6.1.10 Transmit Data (TDR0 - TDR1)

Offset

Register	Offset
TDR0	20h
TDR1	24h

Function

Contains transmit data.

When the transmit FIFO is not full, writes to this register push the data written into the transmit data FIFO. When the transmit FIFO is full, SAI ignores writes to this register.

Diagram

Fields

Field	Function
31 WCP	Write Channel Pointer Indicates whether this data channel is the next FIFO to be written when FIFO Combine mode is enabled for write operations. 0b - No effect 1b - Next FIFO to be written
30-20 —	Reserved
19-16 WFP	Write FIFO Pointer Indicates the FIFO write pointer for the transmit data channel.
15-4 —	Reserved
3-0 RFP	Read FIFO Pointer Indicates the FIFO read pointer for the transmit data channel.

67.6.1.12 Transmit Mask (TMR)

Offset

Register	Offset
TMR	60h

Function

Contains the mask for the transmit word. This register is double-buffered and updates:

- When TCSR[TE] first becomes 1.
- At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

Diagram

Fields

Field	Function
31 RE	Receiver Enable Enables the receiver. When you write 0 to this field, the receiver remains enabled and the field remains 1 until the end of the current frame. 0b - Disable 1b - Enable (or receiver disabled and not yet reached end of frame)
30 STOPE	Stop Enable Enables receiver operation in Stop mode. 0b - Disable 1b - Enable
29 DBGE	Debug Enable Enables receiver operation in Debug mode, which does not affect the receive bit clock. 0b - Disable after completing the current frame 1b - Enable
28 BCE	Bit Clock Enable Enables the receive bit clock, separately from RCSR[RE]. This field becomes 1 automatically when RCSR[RE] becomes 1. When you write 0 to this field, the receive bit clock remains enabled, and this field remains 1 until the end of the current frame. 0b - Disable 1b - Enable
27-26 —	Reserved
25 FR	FIFO Reset Empties the FIFO, and sets the FIFO read and write pointers to the same value, which can be zero. Reading this field always returns zero. **NOTE** The FIFO reset is asserted for one cycle only. You must reset FIFO pointers only when the receiver is disabled or the FIFO error flag is 1. 0b - No effect 1b - Reset
24 SR	Software Reset Resets the internal receiver logic including the FIFO pointers. Software-visible registers are not affected, except for the status registers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The software reset remains asserted until you clear it. 0b - No effect 1b - Software reset
23-21 —	Reserved
20 WSF	Word Start Flag Indicates whether SAI has detected the start of the configured word. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
19 SEF	Sync Error Flag Indicates whether SAI has detected an error in the externally generated frame sync. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
18 FEF	FIFO Error Flag Indicates whether an enabled receive FIFO has overflowed. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Receive overflow detected When writing 0b - No effect 1b - Clear the flag
17 FWF	FIFO Warning Flag Indicates whether an enabled receive FIFO is full. 0b - Not full 1b - Full
16 FRF	FIFO Request Flag Indicates whether the number of words in an enabled receive channel FIFO is greater than the receive FIFO watermark. 0b - Watermark not reached 1b - Watermark reached
15-13 —	Reserved
12 WSIE	Word Start Interrupt Enable Enables word start interrupts. 0b - Disable 1b - Enable
11 SEIE	Sync Error Interrupt Enable Enables sync error interrupts. 0b - Disable 1b - Enable
10 FEIE	FIFO Error Interrupt Enable Enables FIFO error interrupts. 0b - Disable 1b - Enable
9 FWIE	FIFO Warning Interrupt Enable Enables FIFO warning interrupts. 0b - Disable

Table continues on the next page...

1 FWDE	FIFO Warning DMA Enable Enables DMA warnings. 0b - Disable 1b - Enable
0 FRDE	FIFO Request DMA Enable Enables DMA requests. 0b - Disable 1b - Enable

67.6.1.14 Receive Configuration 1 (RCR1)

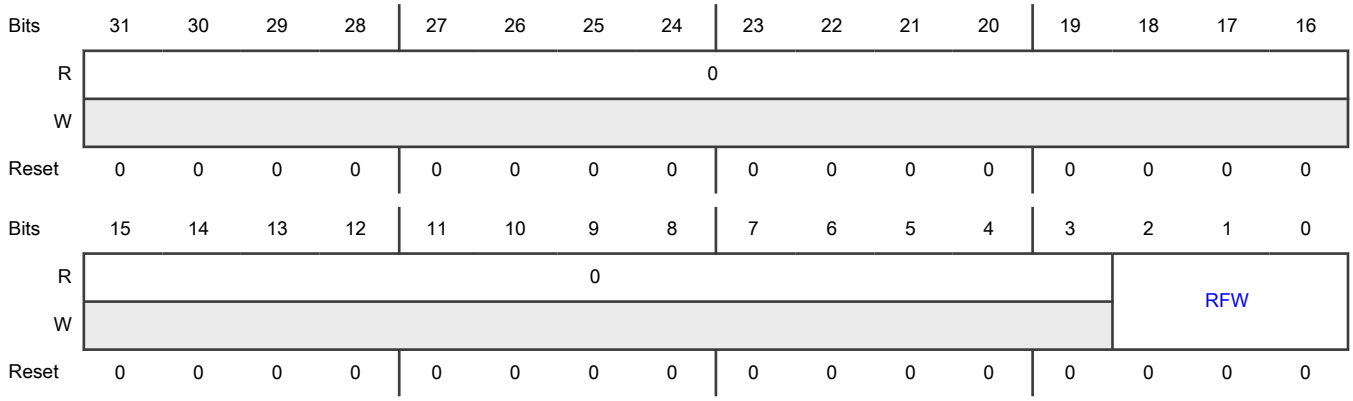
Offset

Register	Offset
RCR1	8Ch

Function

Configures the watermark level for all enabled receiver channels.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 RFW	Receive FIFO Watermark Configures the level of the receive FIFO watermark, in 32-bit FIFO words. 000b - 1 001b - 2 010b-110b - (RFW value + 1) 111b - 8

67.6.1.15 Receive Configuration 2 (RCR2)

Offset

Register	Offset
RCR2	90h

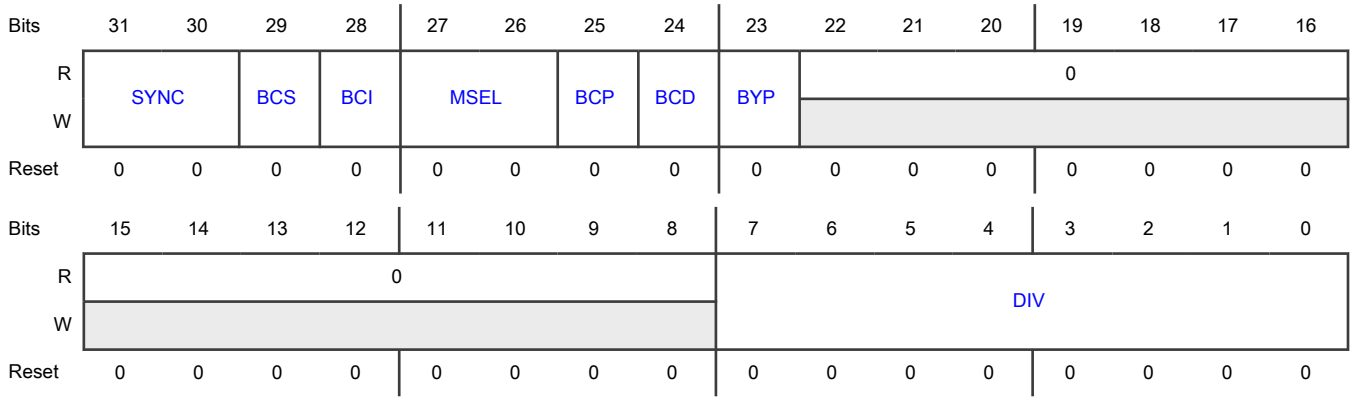
Function

Contains the SYNC mode and clock setting fields.

NOTE

Do not alter this register when RCSR[RE] is 1.

Diagram



Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures Asynchronous and Synchronous modes of operation. When configured for a Synchronous mode of operation, you must configure the transmitter or other SAI peripheral for asynchronous operation. 00b - Asynchronous mode 01b - Synchronous with transmitter 10b - Synchronous with another SAI receiver 11b - Synchronous with another SAI transmitter
29 BCS	Bit Clock Swap Swaps the bit clock used by the receiver. When the receiver is configured in Asynchronous mode and this field is 1, the transmitter bit clock (TX_BCLK) clocks the receiver. This setting allows the transmitter and receiver to share one bit clock, while the receiver continues to use the receiver frame sync (RX_SYNC). When you configure the receiver in Synchronous mode, you must write the same value to the transmitter BCS field and receiver BCS field. When both are 1, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but both use the transmitter frame sync (TX_SYNC). This field has no effect when synchronous to another SAI peripheral. 0b - Use the normal bit clock source 1b - Swap the bit clock source
28 BCI	Bit Clock Input Enables the internal logic to be clocked as if the bit clock is generated externally. When this field is 1 and when using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the receiver is delayed by the pad output delay. (The pad input clocks the receiver as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Use the Target mode timing from the data sheet for the receiver when this field is 1. In Synchronous mode, this field allows the receiver to use the Target mode timing from the data sheet, while the transmitter uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock or when synchronous to another SAI peripheral. **NOTE** When this field is 1, both the input buffer and output buffer must be enabled for the BCLK pad. 0b - Disable 1b - Enable
27-26 MSEL	MCLK Select Selects the audio controller clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Some controller clock options are not available for some chips. See the chip-specific information for the availability and chip-specific meaning of each option. **NOTE** Choose the same value for this field and for TCR2[MSEL]. 00b - Bus clock 01b - Controller clock (MCLK) option 1 10b - Controller clock (MCLK) option 2 11b - Controller clock (MCLK) option 3
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on the rising edge and sample inputs on the falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on the falling edge and sample inputs on the rising edge. 0b - Active high 1b - Active low
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Generated externally in Target mode 1b - Generated internally in Controller mode
23 BYP	Bit Clock Bypass Enables the bypass of the bit clock divider. When enabled, the internal bit clock is divide-by-one of the audio controller clock. When disabled, the internal bit clock is generated from the bit clock divider.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Choose the same value for this field and for TCR2[BYP]. 0b - Disable 1b - Enable
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Determines the value by which the audio controller clock is divided to generate the bit clock, when configured for an internal bit clock. The division value is (DIV + 1) × 2.

67.6.1.16 Receive Configuration 3 (RCR3)

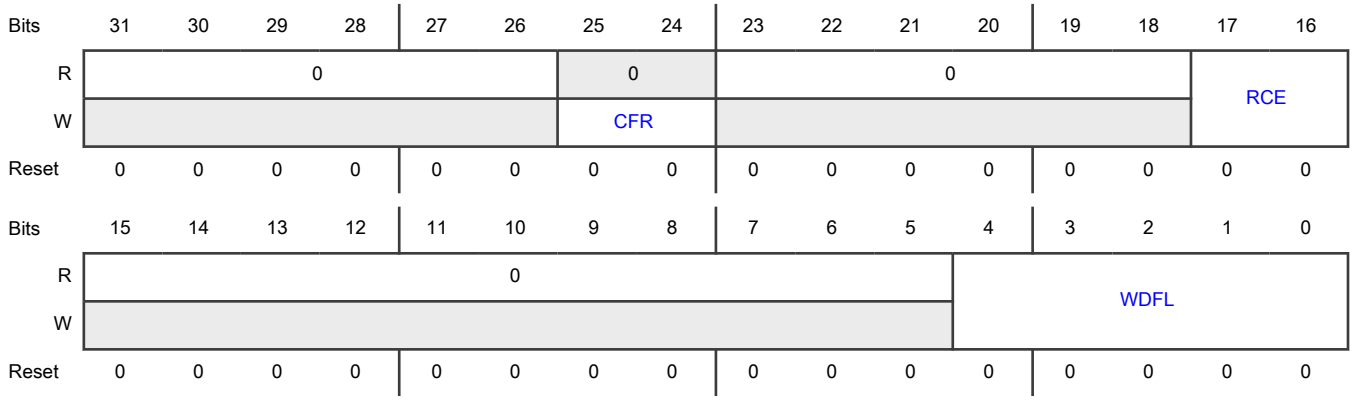
Offset

Register	Offset
RCR3	94h

Function

Contains the receive channel settings.

Diagram



Fields

Field	Function
31-26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
25-24 CFR	Channel FIFO Reset Resets the FIFO pointers for a specific channel. Reading this field always returns zero. Reset FIFO pointers only when a channel is disabled or the FIFO error flag is set. The width of this field = the number of receive channels (call it *n*). For example, if this field is two bits wide, bit position 24 refers to the receive channel 1 FIFO pointer and bit position 25 refers to the receive channel 2 FIFO pointer. Writing 1 to bit 24 resets the receive channel 1 FIFO pointer, and writing 1 to bit 25 enables the receive channel 2 FIFO pointer. Writing 1 to bit *n* resets receive channel *n* FIFO pointer. • 0b – No effect • 1b – Reset receive data channel *n* FIFO
23-18 —	Reserved
17-16 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. Changing this field takes effect immediately for generating the FIFO request and warning flags. It takes effect at the end of each frame for receive operations. The width of RCE = the number of receive channels (call it *n*). For example, if RCE is two bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Writing 1 to bit 16 enables receive channel 1, and writing 1 to bit 17 enables receive channel 2. Writing 1 to bit *n* enables receive channel *n*. **NOTE** When there is only a single channel, you do not need an individual channel FIFO reset (RCR3[CFR]). In that case, use the global FIFO reset (RCSR[FR]). • 0b – Disable receive data channel *n* • 1b – Enable receive data channel *n*
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Configures which word sets the word start flag (RCSR[WSF]). The value must be one less than the word number (for example, write zero to select the first word in the frame). If you configure this field to a value greater than RCR4[FRSZ], RCSR[WSF] is never set. 0_0000b - Word 1 0_0001b - Word 2 0_0010b-1_1110b - Word (WDFL value + 1) 1_1111b - Word 32

67.6.1.17 Receive Configuration 4 (RCR4)

Offset

Register	Offset
RCR4	98h

Function

Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when SAI continues receiving data after a FIFO error is detected. 0b - From the start of the next frame after the FIFO error flag is cleared 1b - From the same word that caused the FIFO error to become 1 after the FIFO warning flag is cleared
27-26 FCOMB	FIFO Combine Mode Enables FIFO Combine mode for specified operations. When FIFO Combine mode is enabled for FIFO reads, software reading any FIFO data register alternates the read among the enabled data channel FIFOs. For example, if two data channels are enabled:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The first read is performed to the first enabled data channel FIFO. • The second read is performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO Combine mode for FIFO reads resets the pointer back to the first enabled data channel. When FIFO Combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input alternates between the enabled data channel FIFOs. For example, if two data channels are enabled: • The first unmasked received word is stored in the first enabled data channel FIFO. • The second unmasked received word is stored in the second enabled data channel FIFO. Because the first word of the frame is always stored in the first enabled data channel FIFO, NXP recommends that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. 00b - Disable 01b - Enable on FIFO writes (from receive shift registers) 10b - Enable on FIFO reads (by software) 11b - Enable on FIFO writes (from receive shift registers) and reads (by software)
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 bits or 16 bits, only the first 8 bits or 16 bits are stored in the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer only increments when software reads the full 32-bit FIFO word. 00b - Disable 01b - Reserved 10b - Enable 8-bit FIFO packing 11b - Enable 16-bit FIFO packing
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words. 0_0000b - 1 0_0001b - 2 0_0010b-1_1110b - (FRSZ value + 1) 1_1111b - 32
15-13	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit-clock cycles. The value must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. You cannot configure this field to be longer than the first word of the frame. 0_0000b - 1 0_0001b - 2 0_0010b-1_1110b - (SYWD value + 1) 1_1111b - 32
7-6 —	Reserved
5 —	Reserved Write only zero to this field.
4 MF	MSB First Configures what is received first: LSB or MSB. 0b - LSB 1b - MSB
3 FSE	Frame Sync Early Determines when frame sync is asserted. 0b - First bit of the frame 1b - One bit before the first bit of the frame
2 ONDEM	On-Demand Mode Determines when the internal frame sync is generated. When this field is 1, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is 0. 0b - Generated continuously 1b - Generated when the FIFO warning flag is 0
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Active high 1b - Active low
0 FSD	Frame Sync Direction Configures the direction of the frame sync.

68.1.1 Module instances

This device has two instances of FlexCAN module, CAN0 and CAN1.

68.1.2 Maximum data rate

The maximum data rate for FlexCAN in this device is 10 Mbps. Refer to device's Data sheet for more information.

68.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in Flexible Data (FD) mode.

NOTE

In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

68.2.1 Block diagram

Figure 393 shows the main submodules implemented in FlexCAN.

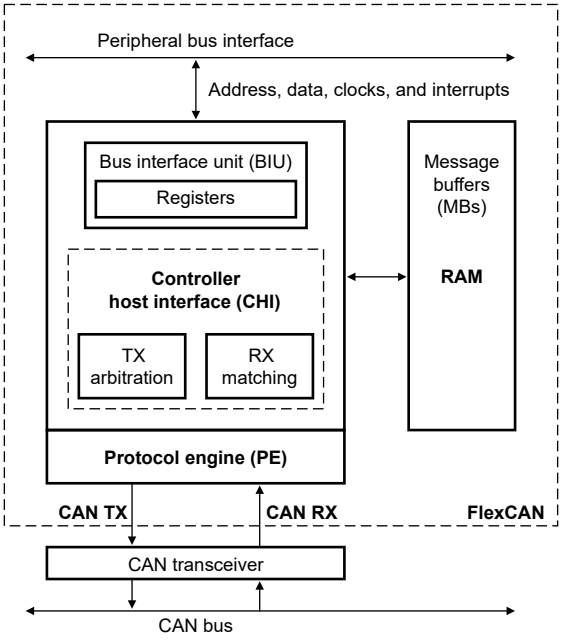

Figure 393. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling.
- CAN FD message detection

The Controller Host Interface (CHI) submodule manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

68.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Programmable bit rate (see chip-specific FlexCAN information for specific maximum rate configuration)

  - Content-related addressing
- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 12 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 16-bit free-running timer
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity or matching with received frames (Pretended Networking)
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful Legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful Enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 16 extended or 32 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask.
- Complete backward compatibility with previous FlexCAN version
- Pretended Networking functionality in low power: Stop mode

68.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 616). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 617).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

68.3.1 Modes of operation

FlexCAN has these functional modes:

Table 583. Functional modes

Mode	Description
Normal	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when Debug mode is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 584. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes
Pretended network support	Yes	No

FlexCAN can operate in these low-power modes:

Table 585. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.
Pretended Network (PN)	FlexCAN can operate in this mode with Stop mode. Before entering one of these low-power modes, you must write 1 to MCR[PNET_EN]. When in a low-power mode, CHI subblock clocks are shut down and CAN_PE subblock remains clocked. The receive process remains active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, a wake-up interrupt is issued to the system. When MCR[PNET_EN] becomes 1, the CPU must disable Self-Wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR).

68.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

68.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.

2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

68.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

It is not recommended to use Module Disable mode under Pretended Networking mode. Write 0 to MCR[MDIS] and wait for MCR[LPMACK] to become 0 before writing 1 to MCR[PNET_EN].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items may not be accessed:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

68.3.1.1.3 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up. Table 586 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 586. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

68.3.1.1.4 Pretended Networking (PN) mode

This special low-power mode receives wake-up messages with low power consumption. This mode can be selected to operate together with Stop mode. Before entering a low-power mode, MCR[PNET_EN] must be 1. After entering a low-power mode, the CHI subblock is shut down and the CAN_PE subblock is kept active. The receive process is still active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, FlexCAN issues a wake-up interrupt to the system.

To enter Pretended Networking mode, FlexCAN must be in Normal mode, not in Freeze or Module Disable mode. In Pretended Networking mode, FlexCAN keeps itself synchronized with the CAN bus in Stop mode. Then, when Stop mode is requested, FlexCAN:

1. Waits to be in the Idle state, or waits for the third bit of Intermission, then verifies that it is recessive.
2. Writes 1 to MCR[LPMACK].
3. Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

FlexCAN can exit Pretended Networking mode in one of these ways:

- The CPU removes the Stop mode request.
- FlexCAN waits until Bus Idle, or until the third bit of Intermission state, to write 0 to MCR[LPMACK].

The above exit events can be triggered:

- By FlexCAN, after detecting a wake-up event and issuing the respective interrupt.
- By the CPU itself, when another method wakes it up.

Consequently, FlexCAN waits until the Bus Idle state, or until the third bit of the Intermission state, to write 0 to MCR[LPMACK] and resume Normal mode. This procedure ensures that FlexCAN is synchronized to the CAN bus after exiting Pretended Networking mode. The CPU must wait for MCR[LPM_ACK] to become 0 before performing any access to FlexCAN.

When MCR[PNET_EN] becomes 1, the CPU must disable the self-wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR)).

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 584.

68.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].

b. Set Remote Transmission Request (if needed) via MB_CS[RTR].

c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 597.[3]

d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 619 for detailed information.

e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 616 and Table 617 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

68.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.

[3] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

68.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

68.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

68.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 587. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

68.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 588. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

68.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait For Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If a resynchronization occurs during Wait For Bus Idle, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

68.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 616 and Table 617 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 616. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA Operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

68.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. . The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 589.

Table 589. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

68.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

68.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR31)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

68.3.6 Receive process in Pretended Networking mode

Pretended Networking mode adds specific wake-up functionality in low-power mode (Stop mode). When Pretended Networking (PN) mode is enabled by writing 1 to MCR[PNET_EN], FlexCAN continues processing received CAN messages in low-power mode. FlexCAN is able to detect specific wake-up messages by filtering them against identifier (ID) and payload target values using preselected matching criteria.

NOTE

Wake-up functionality is not available for messages in CAN FD format. When in PN mode, CAN FD format messages are ignored.

PN registers are located in the 0B00h–0B7Ch address range and can be written only in Freeze mode. These registers are used for writing PN configuration (both control and target values) prior to entering PN mode. They are also used for reading wake-up flags and the received message ID and data when returning to Normal mode after wake-up. The CPU must wait for MCR[LPMACK] to become 0 before performing any access to FlexCAN PN registers.

PN control registers are described in Pretended Networking Control 1 (CTRL1_PN) and Pretended Networking Control 2 (CTRL2_PN). The control fields that configure the filtering criteria are:

- Payload filtering selection: CTRL*n*_PN[PLFS]
- ID filtering selection: CTRL*n*_PN[IDFS]
- Filtering combination selection: CTRL*n*_PN[FCS]

Table 590. PN target values

Value	Description
FLT_IDE	IDE target value used to filter the incoming message by its format (standard or extended)
FLT_RTR	RTR target value used to filter the incoming message by its type (data or remote frame)
FLT_DLC_HI and FLT_DLC_LO	Target DLC range used to filter the size of the payload of an incoming message
FLT_ID1	ID target value used to filter the incoming message ID (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in an ID range)
FLT_ID2	ID target value used as the upper limit in an ID range
PL1	Payload target value used to filter the incoming message payload (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in a payload range)
PL2	Payload target value used as the upper limit in a payload range

IDE, RTR, ID, and payload filters have their respective masks. The ones in these masks determine which bits are considered in equality comparisons. The zeroes in these masks determine which bits are don't care. ID and payload masks are used only for exact ID and exact payload comparisons.

68.3.6.1 ID filtering

The IDs of incoming messages can be filtered based on the following criteria:

- Match the exact ID value, found by comparing the ID field of the incoming message to the content of target Pretended Networking ID Filter 1 (FLT_ID1). The ID mask is used.
- Less than or equal to the maximum range of ID. That is, any message with ID value smaller than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.
- Greater than or equal to the minimum range of ID. That is, any message with ID value greater than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.

- Inside a range of IDs. Any message with an ID value greater than or equal to the content of target FLT_ID1 and smaller than or equal to the content of target Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK) is accepted. The ID mask is not used.

See CTRL1_PN[IDFS].

The above criteria for ID filtering must be coherent with FLT_IDE and FLT_RTR target values in Pretended Networking ID Filter 1 (FLT_ID1). Only RX frames that match the respective IDE and RTR bits to the contents of FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] are compared. When a range of IDs is selected (CTRL1_PN[IDFS] = 11), both FLT_ID1 and FLT_ID2 are referred to the same FLT_IDE and FLT_RTR fields in FLT_ID1.

The ID mask is applied only to the exact ID comparison filtering option (CTRL1_PN[IDFS] = 00) to determine which bits are considered in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range, and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are considered in comparison.

68.3.6.2 Payload filtering

Similar to the ID criteria, 64-bit data or payloads (PL) of incoming messages can be filtered based on the following criteria:

- A match with the exact payload value, found by comparing the payload field of the incoming message to the content of PL1. The payload mask is used.
- Less than or equal to the maximum range of payload. That is, any message with payload value smaller than or equal to the content of PL1 is accepted. The payload mask is not used.
- Greater than or equal to the minimum range of payload. That is, any message with payload value greater than or equal to the content of PL1 is accepted. The payload mask is not used.
- Inside a range of payloads. Any message with a payload value greater than or equal to the content of PL1 and smaller than or equal to the content of PL2 is accepted. The payload mask is not used.

See CTRL1_PN[PLFS].

The above criteria for payload filtering must be coherent with upper and lower limit values in Pretended Networking Data Length Code (DLC) Filter (FLT_DLC). The payload of an incoming message is filtered using the selected criteria only if the DLC value of the incoming message is inside a DLC range:

- Greater than or equal to FLT_DLC[FLT_DLC_LO] (lower limit)
- Lower than or equal to FLT_DLC[FLT_DLC_HI] (upper limit)

A DLC value outside the specified range results in a mismatch. If you configure FLT_DLC_LO = FLT_DLC_HI, only payloads of the specified quantity of bytes are filtered. DLC is not maskable.

When the inside range of payloads option is selected (CTRL1_PN[PLFS] = 11), both PL1 and PL2 are considered with the 8-byte data length. All data bytes excluded by the DLC of the received message are considered to have value zero.

The payload mask is only used in the exact match option (CTRL1_PN[PLFS] = 00). This mask determines which bits or bytes in the 8-byte data field of both incoming message and the contents of PL1 register are used for matching. Mask length must meet the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When FlexCAN receives a remote frame and CTRL1_PN[FCS] is configured to select payload comparison, payload filtering is not considered and the comparison results in a mismatch.

68.3.6.3 Other filtering

Incoming messages can also be filtered based on the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload for a predefined number of times. This number can be from 1 to 255. See Pretended Networking Control 1 (CTRL1_PN).

- No message matching the filtering criteria for ID or payload up to a timeout trigger. That is, non-reception of a matching message for a defined quantity of time. See Pretended Networking Control 2 (CTRL2_PN).

When the counter reaches the predefined timeout value, FlexCAN can generate a wake-up timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag. This behavior is specified in CTRL2_PN[MATCHTO].

The above filtering criteria can be used together as follows:

- Message ID filtering only
- Message ID filtering and Payload filtering
- Message ID filtering only occurring *n* times
- Message ID filtering and Payload filtering occurring *n* times

The timeout counter runs concurrently with the reception filtering process. Both engines (timeout counter and message filtering) are independent. If an incoming message matches the selected filter criteria, the timeout counter continues counting until the CPU wakes up. If the timeout counter reaches the target value, the message filtering process continues to filter incoming messages until the CPU wakes up. WU_MTC[MCOUNTER] reports the number of matched messages that occurred in Pretended Networking mode up to the moment the CPU wakes up.

In Pretended Networking mode, the wake-up event that may occur sets the respective wake-up flag (see Pretended Networking Wake-Up Match (WU_MTC)):

- WU_MTC[WUMF] indicates a successful match meeting the selected filtering criteria.
- WU_MTC[WTOF] indicates a timeout trigger.

Any of these flags generates interrupts to the CPU, provided the respective mask bits are enabled (CTRL1_PN[WUMF_MSK] = 1 or CTRL1_PN[WTOF_MSK] = 1).

There are four Wake-up Message Buffers (WMBs) used to store incoming messages in Pretended Networking mode. Up to four messages can be stored (see Wake-Up Message Buffer (WMB0_CS - WMB3_CS)).

When CTRL1_PN[NMATCH] = 1, only one message is received if the filtering criteria are matched. This message is stored in WMB0.

If CTRL1_PN[NMATCH] is between two and four, WMB1, WMB2, and WMB3 store the second, third, and fourth matching messages, respectively.

If CTRL1_PN[NMATCH] is greater than four, the last four matching messages are stored in the WMBs. The WMB index indicates the arrival order. The last message is stored in WMB3.

Only the valid data bytes of the incoming match message are stored in the data field of WMBs. The non-valid data bytes are read as zero. If DLC = 0 and RTR = 1, the data field is filled with zeroes. In any of the above cases, the wake-up interrupt is generated only when the filtering criteria are completed and CTRL1_PN[WUMF_MSK] = 1.

When a non-match wake-up event occurs (timeout or external) and WU_MTC[MCOUNTER] ≥ 4, the message stored in WMB0 does not have valid content. WMB0 is used as a buffer for the current message in the CAN bus. Messages received during Pretended Networking mode do not have time stamps, and the respective field in the WMB structure must be ignored.

In low-power mode (Stop), all processes are shut down except for the PN functionality inside the CAN_PE subblock, which remains clocked by the oscillator clock (see Clock domains and restrictions). FlexCAN continues to receive incoming messages, but only compares them to the predefined target values according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in Normal mode, are not performed in Pretended Networking mode.

FlexCAN in Pretended Networking reacts to messages on the CAN bus in the same manner as in Normal mode. It generates acknowledge bits, detect and count errors, and so on.

68.3.7 Move process

There are two types of move process: move-in and move-out.

68.3.7.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

68.3.7.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of Intermission field
- During the Bus Off state, when TX Error Counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

68.3.8 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

68.3.8.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

68.3.8.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

68.3.8.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

68.3.9 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 12 CAN FD messages. The region 2000h– 204Bh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—

Table continues on the next page...

Table continued from the previous page...

Step	Purpose	Programming	Notes
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 394 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

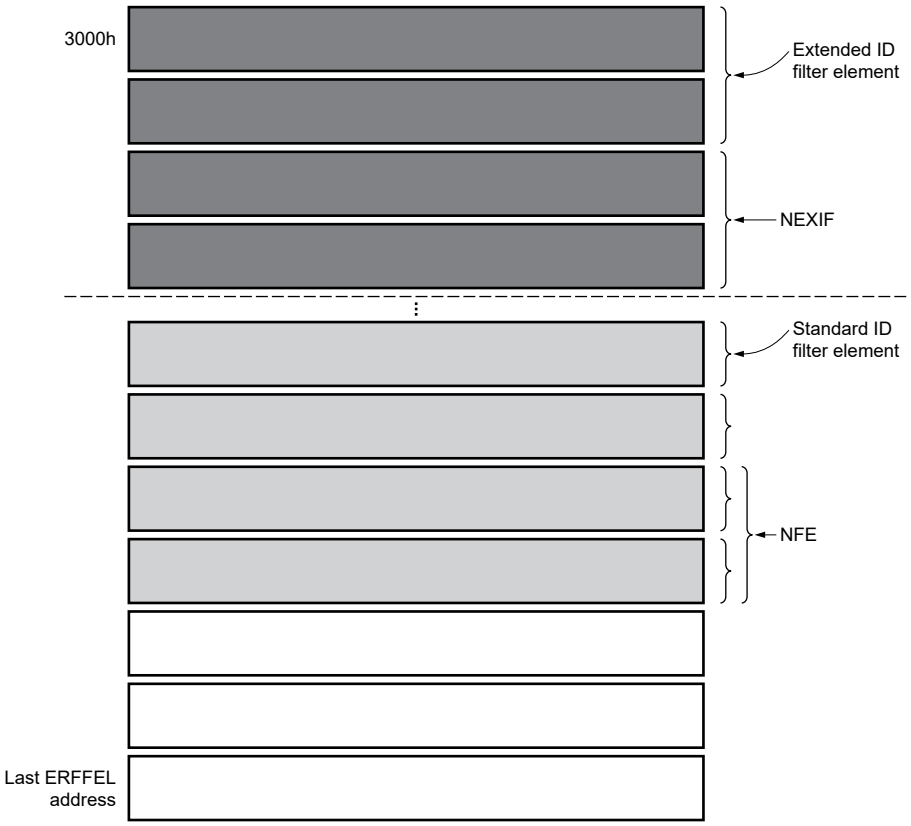

Figure 394. Number of enhanced RX FIFO filter elements

68.3.9.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 591.

Table 591. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR filter	STD ID filter		Reserved		RTR mask	STD ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 592.

Table 592. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTRfilter	STD ID Filter2		Reserved		RTR mask	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 593.

Table 593. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 594.

Table 594. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR filter	EXT ID filter	
Reserved		RTR mask	EXT ID mask	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 595.

Table 595. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28																										0
FSCH		RTR filter	EXT ID Filter2																										
Reserved		RTR mask	EXT ID filter 1																										

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 596.

Table 596. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28																										0
FSCH		RTR Filter2	EXT ID Filter2																										
Reserved		RTR Filter1	EXT ID filter 1																										

68.3.9.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 619.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight. In that case, the last enhanced RX FIFO address offset can be found in Table 629 and Table 630. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- Last address offset = TS_OFF = 2010h
- DMALW = 4

68.3.9.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

68.3.10 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 584 for information about the difference between FD and non-FD regarding this feature.

68.3.10.1 Legacy RX FIFO in DMA Operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 584 for information about the difference between FD and non-FD regarding this feature.

68.3.10.2 Clear Legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

68.3.11 CAN protocol-related features

68.3.11.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

68.3.11.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

68.3.11.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 395 illustrates the message formats for Classical and FD frames with either standard or extended ID.

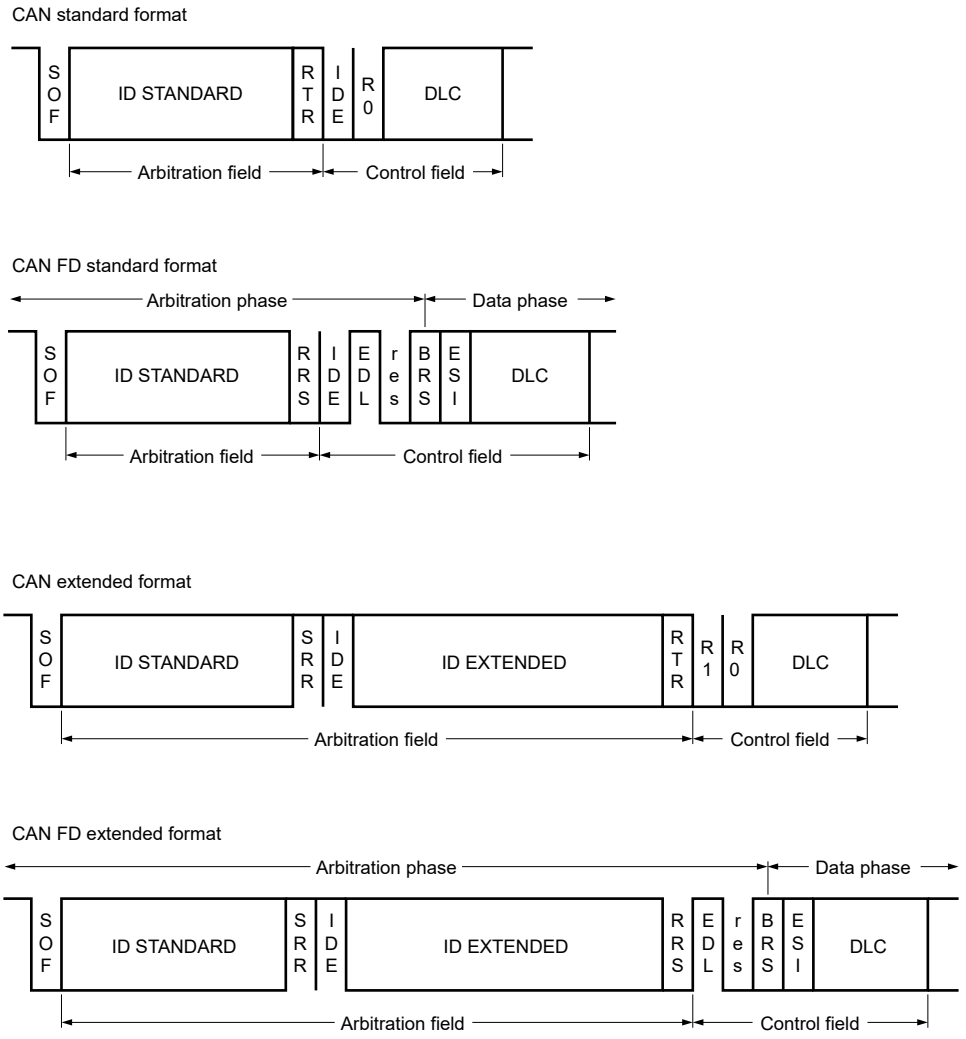

Figure 395. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

68.3.11.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 396 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

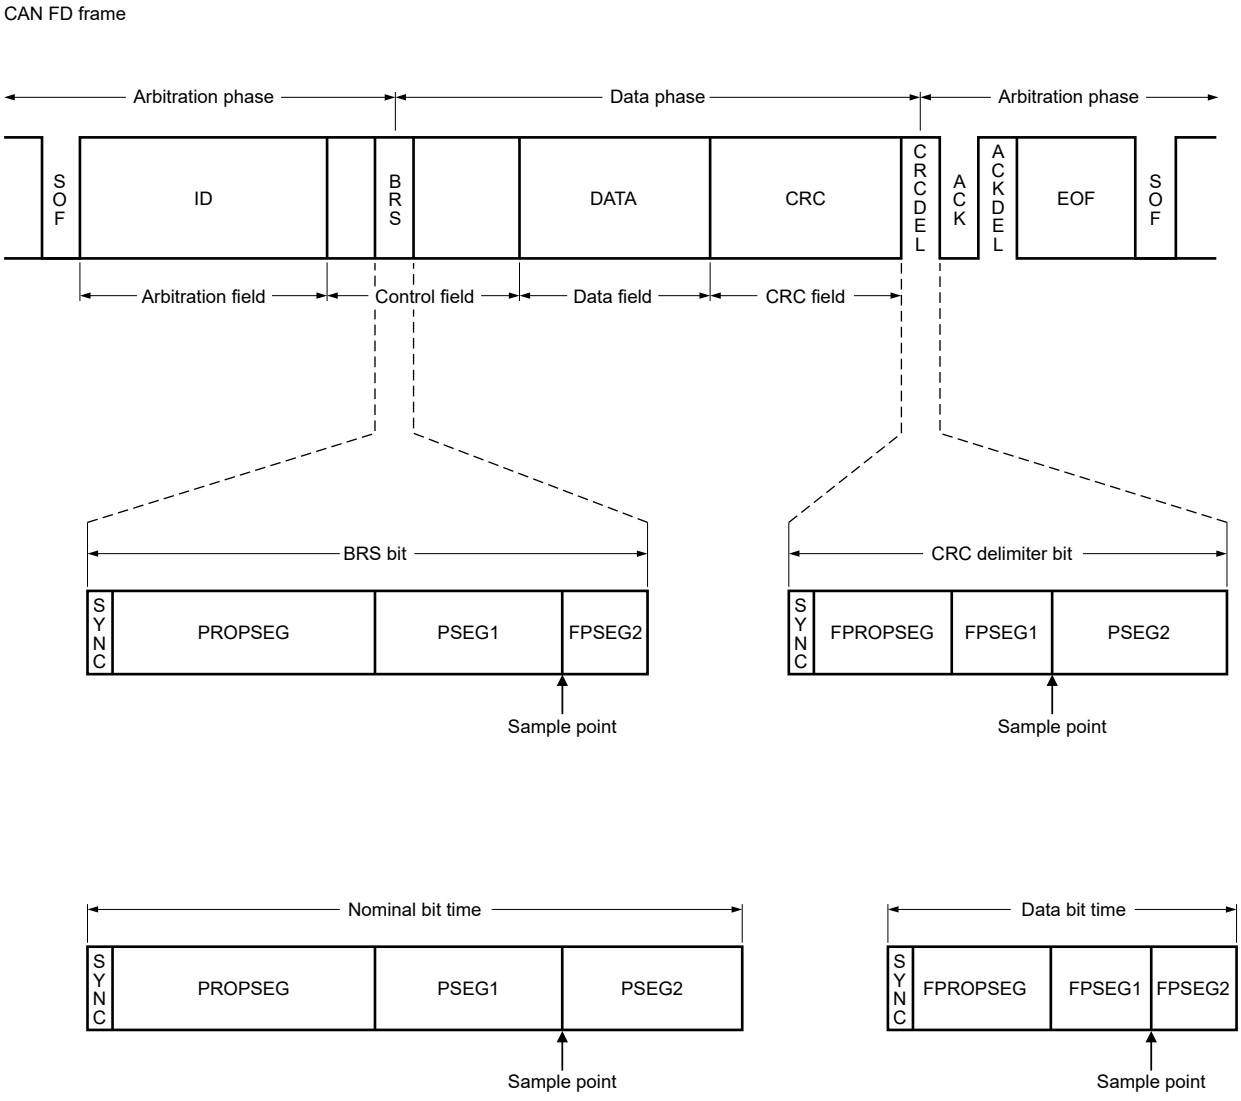

Figure 396. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

68.3.11.2.3 ESI in CAN FD

The value of the ESI bit is determined:

- By the error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node,
- Or by the original transmitting node when FlexCAN is acting as a gateway for the message.

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 597.

Table 597. Written versus transmitted values of ESI field

FlexCAN fault confinement status at start of frame	ESI bit of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

68.3.11.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

68.3.11.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

68.3.11.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

68.3.11.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 397). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

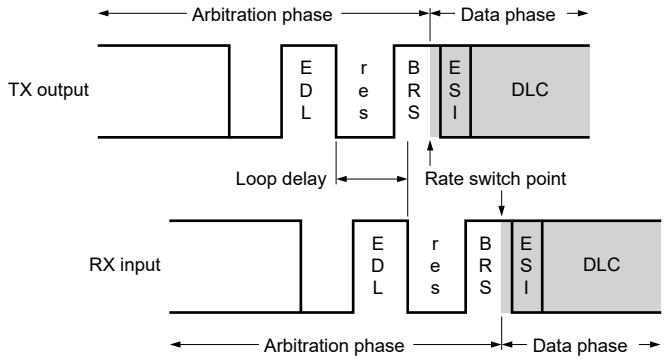

Figure 397. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
$$or$$
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \text{ if } ETDCEN$$

Equation 29. TDC offset calculation

Figure 398 shows the SSP position when these settings are used.

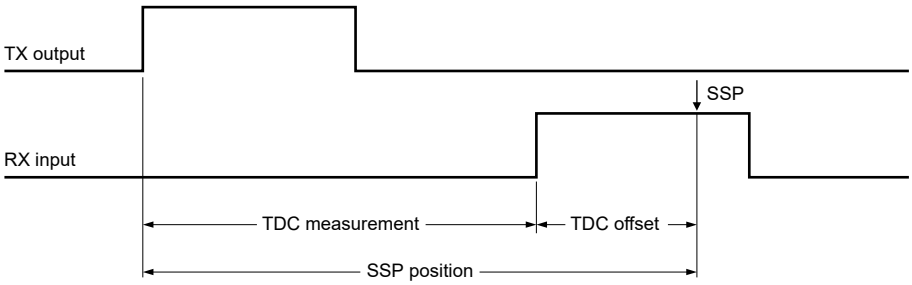

Figure 398. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 399 shows the secondary sample point position when the transceiver delay measurement is disabled.

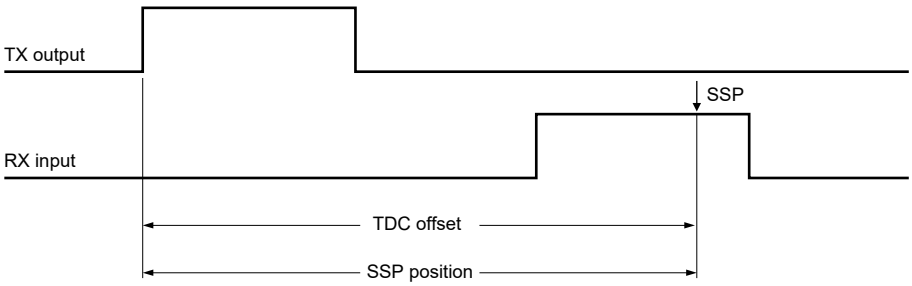

Figure 399. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

68.3.11.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

68.3.11.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

68.3.11.6 Timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field, providing network behavior regarding time.

The FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

68.3.11.7 Protocol timing

Figure 400 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

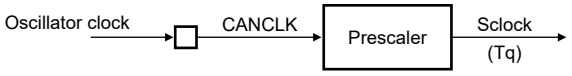

Figure 400. CAN engine clocking scheme

68.3.11.7.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]

- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial clock (Sclock). (See Equation 30.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 30. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 31. CAN bit time and baud rate

68.3.11.7.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 401. See also Figure 402 , Figure 403, and Table 598.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

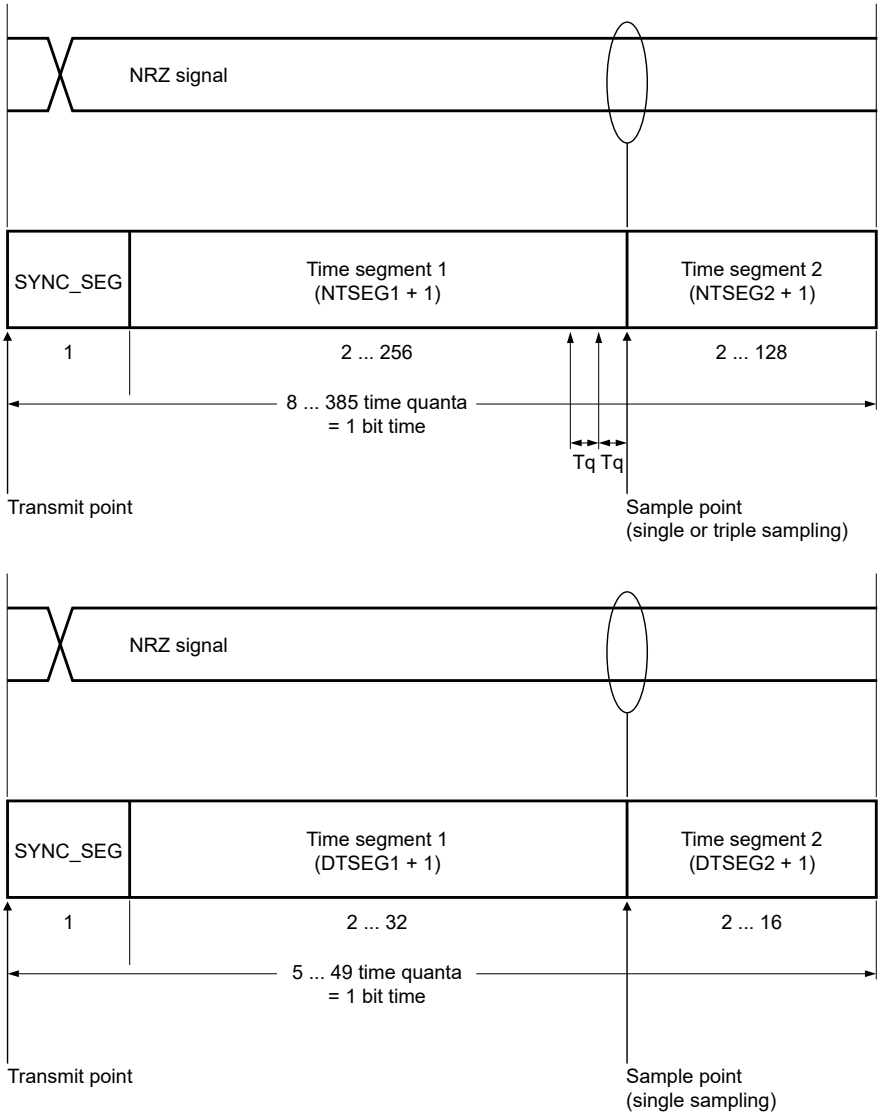

Figure 401. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses

FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

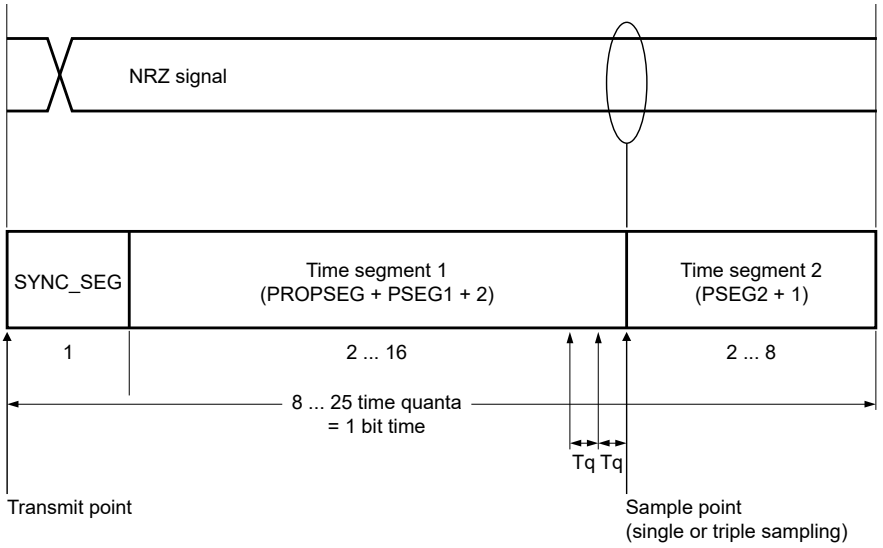

Figure 402. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

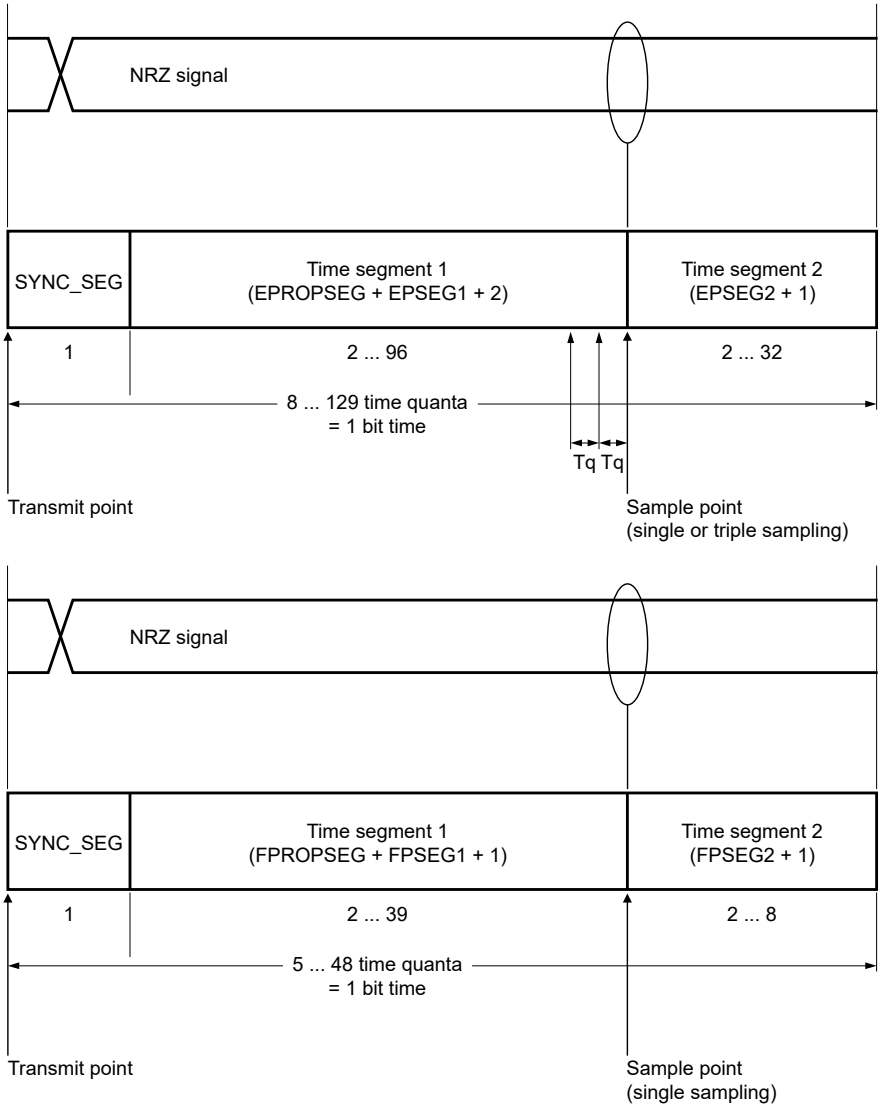

Figure 403. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 598. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 599 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 599. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

68.3.11.7.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 32. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 33. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 400), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

68.3.11.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

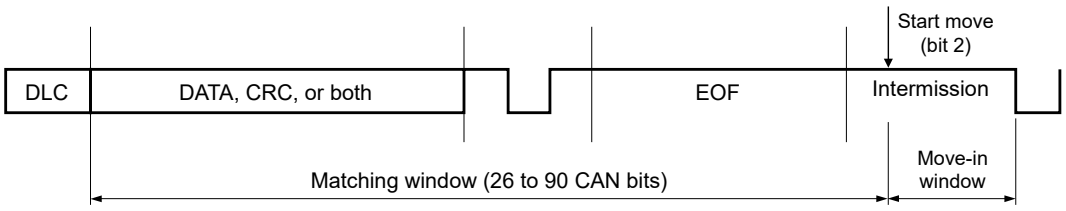

Figure 404. Matching and move-in time windows

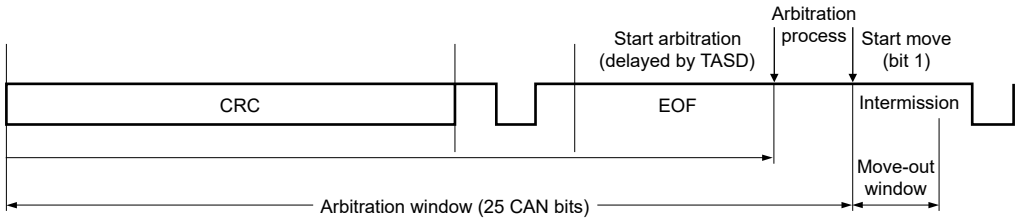

Figure 405. Arbitration and move-out time windows

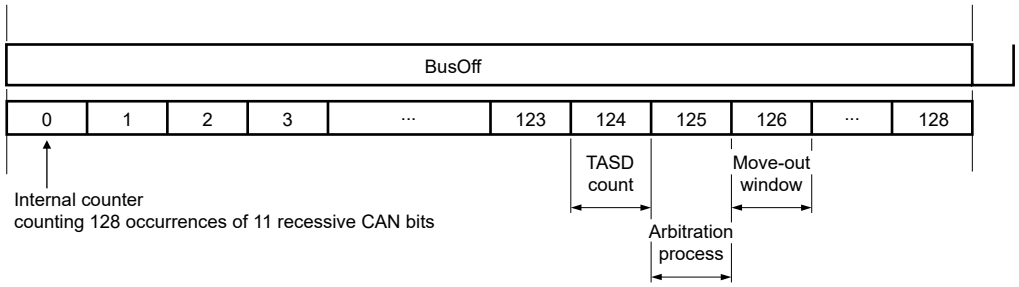

Figure 406. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

68.3.11.9 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 407, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

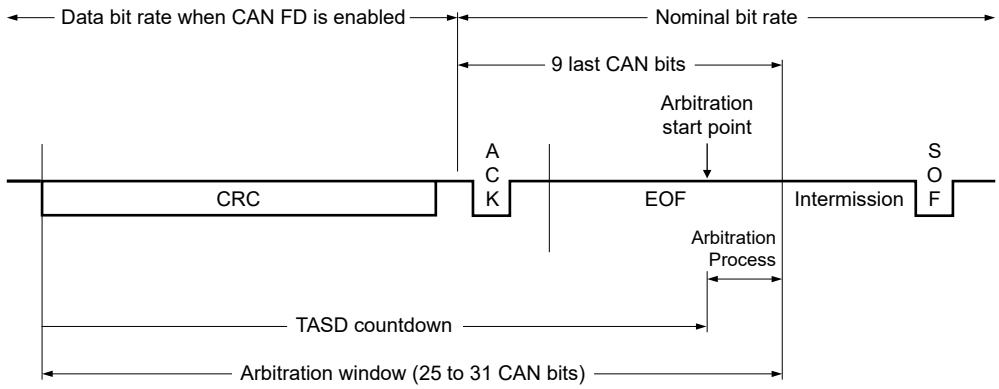

Figure 407. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 34. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 35. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 35.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 36. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 37. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

68.3.11.9.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 600. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 601. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)

- Bit rate in arbitration phase = 1 Mbaud

Table 602. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0

68.3.12 Clocks

The following table describes the clock sources for FlexCAN. See the chip clocking chapter for clock setting, configuration, and gating information.

Table 603. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

68.3.12.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 604.

Table 604. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16

Table continues on the next page...

Table 604. Minimum number of peripheral clocks per CAN bit for Classical CAN format (continued)

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	1	0	16
32	1	0	17
16	0	1	16
32	0	1	19

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 604 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

68.3.12.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 38. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 605. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 605. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53

Table continues on the next page...

Table 605. Number of fast CAN bits in a CAN FD frame (continued)

Minimum number of data bytes	DLC field	NumOfFastBits
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 39. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 40. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 41. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 42. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

Equation 43. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 605. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 44. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 45. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 46. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 47. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 606 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 606. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

68.3.13 Reset

You can reset FlexCAN in the following ways:

- Chip-level hard reset, which resets all memory-mapped registers asynchronously.
- Soft reset, in one of two ways:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 609.
  - Chip-level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

68.3.14 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - Wake Up Match
  - Wake Up Timeout
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag
- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast

- Wake Up
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

The interrupt sources for Pretended Networking (Wake-up by Match Flag and Wake-up by Timeout Flag) can be read in Pretended Networking Wake-Up Match (WU_MTC). The respective interrupt mask bits are located in Pretended Networking Control 1 (CTRL1_PN).

68.3.15 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used.
    For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.
    - The memory space 0090h–017Fh is available.
    - The space 0180h–087Fh is reserved.
    - The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
    - In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

    As a rule, free memory space for general purpose depends only on MCR[MAXMB].
  - If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

Table 607. Access permissions

Modes of operation	Normal	Freeze	Low-power

Reserved space (empty)[1]	Bus error	Bus error	Bus error

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

68.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 608 and described in the following subsections.

Table 608. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

68.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

68.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

68.5 Initialization and application information

68.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. If Pretended Networking mode is required, write 1 to MCR[PNET_EN].
    g. Enable the abort mechanism by writing 1 to MCR[AEN].
    h. Enable the local priority feature by writing 1 to MCR[LPRIOEN].
2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
    a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
    b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
    c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
    d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
    e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
    f. Determine the internal arbitration mode by programming CTRL1[LBUF].

3. Initialize the message buffers. (See Message buffer structure for message buffer details.)
    a. The control and status word of all message buffers must be initialized.
    b. If RX FIFO is enabled, the ID filter table must be initialized.
    c. Other entries in each message buffer should be initialized as required.
4. Initialize Receive Individual Mask (RXIMR0 - RXIMR31).
5. Write 1 to required interrupt mask bits in:
    - IMASK registers (for all message buffer interrupts)
    - Module Configuration (MCR) (for wake-up interrupt)
    - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
6. If Pretended Networking mode is enabled, configure the necessary registers for selective wake-up.
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

68.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

68.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 609. Register reset information

Register	Affected by hard reset	Affected by soft reset
Module Configuration (MCR)	Yes	Yes
Control 1 (CTRL1)	Yes	No

Pretended Networking Control 1 (CTRL1_PN)	Yes	Yes
Pretended Networking Control 2 (CTRL2_PN)	Yes	Yes
Pretended Networking Wake-Up Match (WU_MTC)	Yes	Yes
Pretended Networking ID Filter 1 (FLT_ID1)	Yes	Yes
Pretended Networking DLC Filter (FLT_DLC)	Yes	Yes
Pretended Networking Payload Low Filter 1 (PL1_LO)	Yes	Yes
Pretended Networking Payload High Filter 1 (PL1_HI)	Yes	Yes
Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK)	Yes	Yes
Pretended Networking Payload Low Filter 2 or Payload Low Mask (PL2_PLMASK_LO)	Yes	Yes
Pretended Networking Payload High Filter 2 or Payload High Mask (PL2_PLMASK_HI)	Yes	Yes
Pretended Networking Wake Up Message Buffer 0 (WMB0)	Yes	No
Pretended Networking Wake Up Message Buffer 1 (WMB1)	Yes	No

Table continues on the next page...

Table 609. Register reset information (continued)

Register	Affected by hard reset	Affected by soft reset
Pretended Networking Wake-Up Message Buffer 2 (WMB2)	Yes	No
Pretended Networking Wake-Up Message Buffer 3 (WMB3)	Yes	No
Enhanced CAN Bit Timing Prescalers (EPRS)	Yes	No
Enhanced Nominal CAN Bit Timing (ENCBT)	Yes	No
Enhanced Data Phase CAN bit Timing (EDCBT)	Yes	No
Enhanced Transceiver Delay Compensation (ETDC)	Yes	No
CAN FD Control (FDCTRL)	Yes	No
CAN FD Bit Timing (FDCBT)	Yes	No
CAN FD CRC (FDCRC)	Yes	Yes
Enhanced RX FIFO Control (ERFCR)	Yes	Yes
Enhanced RX FIFO Interrupt Enable (ERFIER)	Yes	Yes
Enhanced RX FIFO Status (ERFSR)	Yes	Yes
Enhanced RX FIFO	No	No
Enhanced RX FIFO Filter Element (ERFFEL)	No	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

68.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–27Fh allocates the thirty-two 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–2048h allocates the Enhanced RX FIFO output, and the address range from offset 204Ch–238Ch allocates the rest of Enhanced RX FIFO 11 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

68.6.2.1 CAN memory map

CAN0 base address: 400D_4000h

68.6.2.2 Module Configuration (MCR)

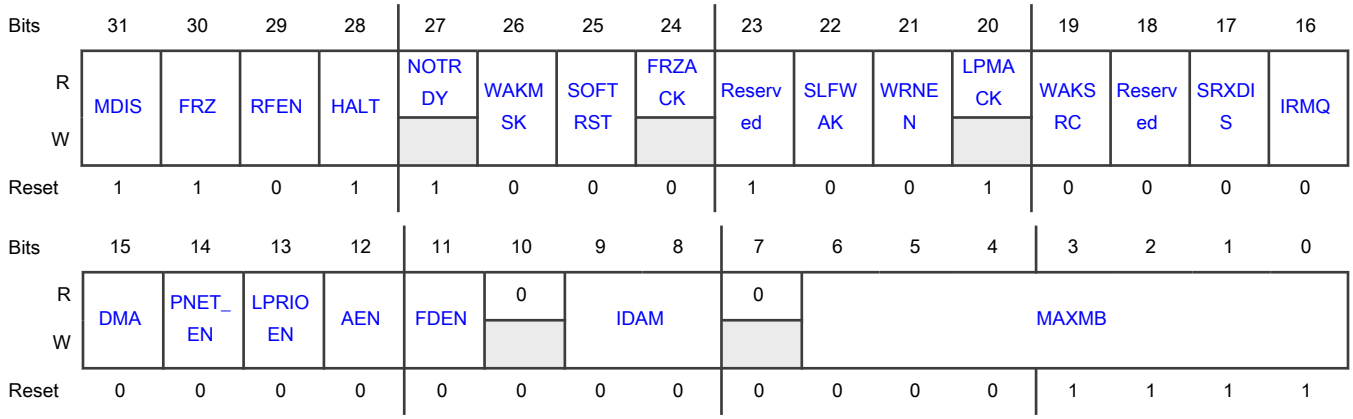
Offset

Register	Offset
MCR	0h

Function

Defines global system configurations, including the module operation modes and the maximum message buffer configuration.

Diagram



Fields

Field	Function
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0b - Enable 1b - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. 0b - Disable 1b - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 604. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. 0b - No request 1b - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1b - FlexCAN is in Disable mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0b - Disabled 1b - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0b - No reset 1b - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE FRZACK becomes 1 within 178 CAN bits following the Freeze mode request by the CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - Not in Freeze mode, prescaler running. 1b - In Freeze mode, prescaler stopped.
23 —	Reserved
22 SLFWAK	Self Wake-up Enables the Self Wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. When MCR[PNET_EN] = 1, this feature must be disabled. 0b - Disable 1b - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
20 LPMACK	Low-Power Mode Acknowledge Indicates whether FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits after the low-power mode request by the CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). When FlexCAN is in Pretended Networking mode, this field becomes 0 within 180 CAN bits after the low-power mode request removal.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not in a low-power mode 1b - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0b - No filter applied 1b - Filter applied
18 —	Reserved When writing to this field, always write the reset value.
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Enable 1b - Disable
16 IRMQ	Individual RX Masking and Queue Enable Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0b - Disable 1b - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
14 PNET_EN	Pretended Networking Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables Pretended Networking functionality. When in Stop mode, the PE subblock is kept operational. It can process RX message filtering as defined by the Pretended Networking configuration registers. See Receive process in Pretended Networking mode. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0b - Disable 1b - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0b - Disabled 1b - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015. **NOTE** If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 —	Reserved
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 604.

68.6.2.3 Control 1 (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. PhaseBuffer Segment 1 = (PSEG1 + 1) × Time Quanta.

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Interrupt disabled 1b - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Interrupt disabled 1b - Interrupt enabled
13 —	Reserved **NOTE** Writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0b - Disabled 1b - Enabled
11	TX Warning Interrupt Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
TWRNMSK	Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0b - One sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

68.6.2.4 Free-Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

The CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop, Pretended Networking, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

15-0 TIMER	Timer Value Contains the free-running counter value.

68.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

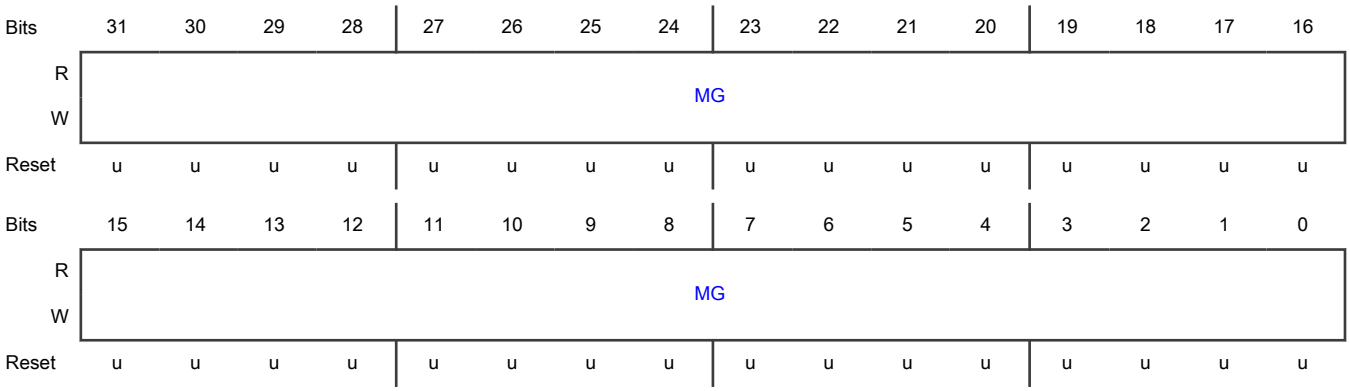
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]

<table>
<tr><th>Field</th><th>Function</th></tr>
<tr><td></td><td>

<tr><th rowspan="2">SMB[RTR] [1]</th><th rowspan="2">CTRL2[RRS]</th><th rowspan="2">CTRL2[EACEN]</th><th colspan="4">Message buffer filter fields</th></tr>
<tr><th>MB[RTR]</th><th>MB[IDE]</th><th>MB[ID]</th><th>Reserved</th></tr>
<tr><td>1</td><td>1</td><td>1</td><td>MG[31]</td><td>MG[30]</td><td>MG[28:0]</td><td>MG[29]</td></tr>
</table>
1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.
</td></tr>
</table>

68.6.2.6 Receive 14 Mask (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

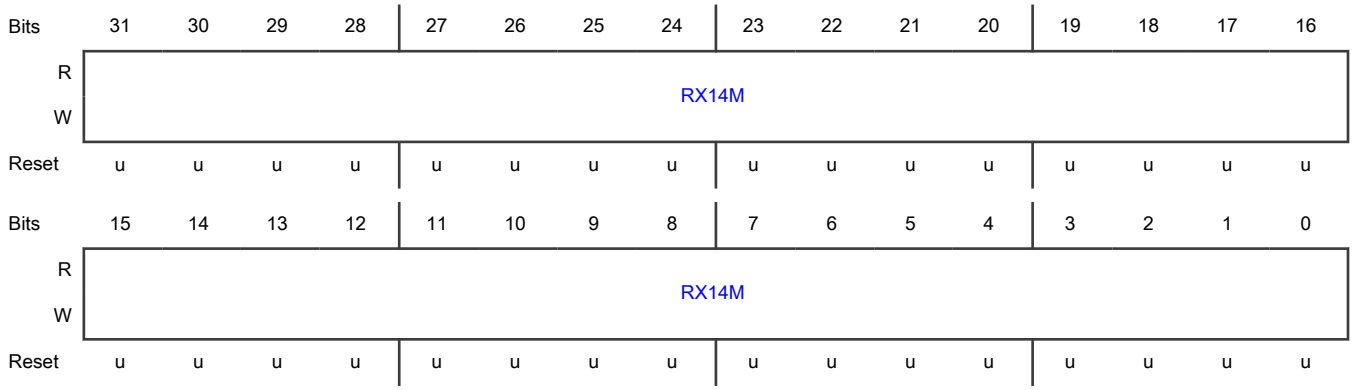
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

68.6.2.7 Receive 15 Mask (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

68.6.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

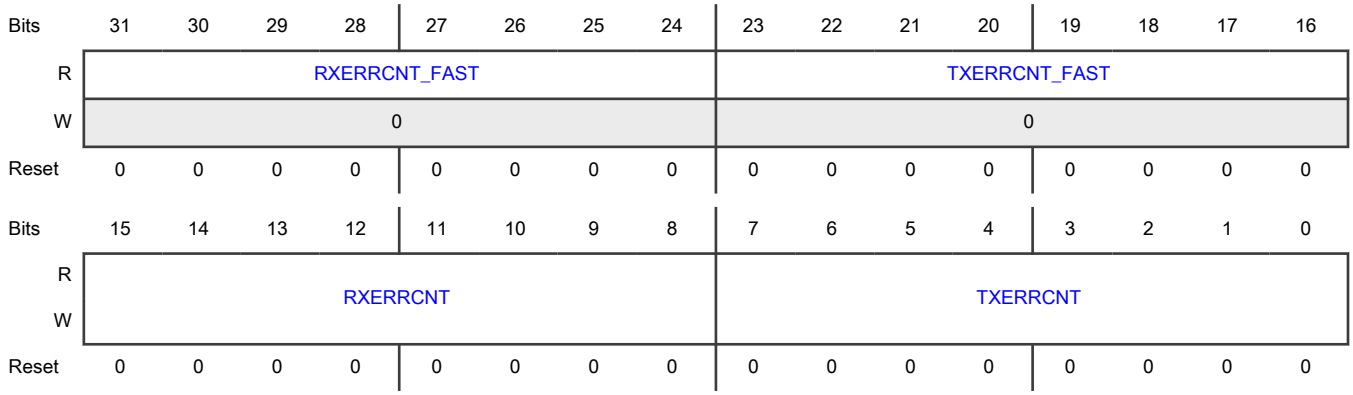
- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.
- When FlexCAN is in Pretended Networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors, and error flags are stored. TXERRCNT and TXERRCNT_FAST preserve their values and do not change, because no transmission occurs in Pretended Networking mode. Error counters and error flags that changed values in Pretended Networking mode

are updated in this register and in Error and Status 1 (ESR1) when FlexCAN returns to Normal mode. If FlexCAN is in Pretended Networking mode, the FAST error flags in ESR1 are not set.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.
7-0 TXERRCNT	Transmit Error Counter Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

68.6.2.9 Error and Status 1 (ESR1)

Offset

Register	Offset
ESR1	20h

Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.

2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 610. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Function
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as recessive is received as dominant.
30	Fast Bit0 Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
BIT0ERR_FAST	Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Fast Form Error Flag Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-24 —	Reserved
23 —	Reserved
22 —	Reserved
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No overrun 1b - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0b - No such occurrence. 1b - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0b - No such occurrence 1b - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status Flag Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0b - Not synchronized 1b - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is not updated. 0b - No such occurrence 1b - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is updated to reflect the RX error counter state. 0b - No such occurrence 1b - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending a error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This field is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. Additionally, this flag is updated when FlexCAN returns to Normal mode from Pretended Networking mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 610. 0b - Not IDLE

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 610. 0b - Not transmitting 1b - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0b - Not receiving 1b - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - Indicates setting of any error flag in the Error and Status register.
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates that a recessive-to-dominant transition was received on the CAN bus.

68.6.2.10 Interrupt Masks 1 (IMASK1)

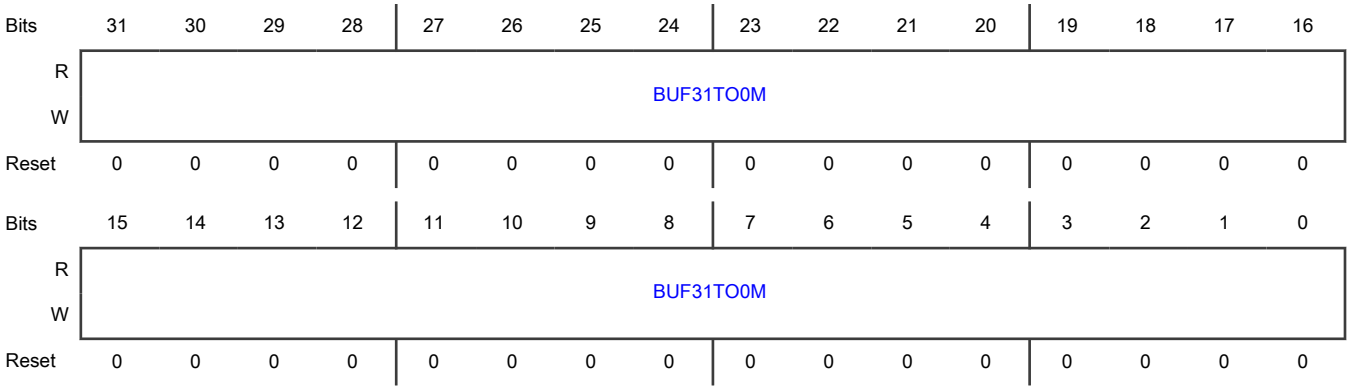
Offset

Register	Offset
IMASK1	28h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Diagram



Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request.

Table continues on the next page...

Field	Function
	0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

68.6.2.11 Interrupt Flags 1 (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

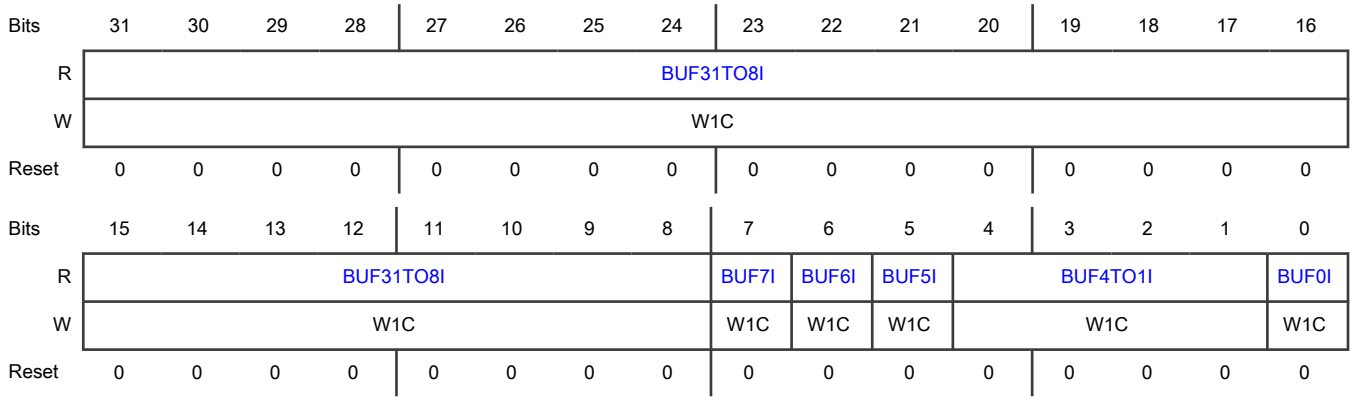
Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Diagram



Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0b - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1b - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0b - No occurrence of MB6 completing transmission or reception, or FIFO not almost full.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0b - No occurrence of completed transmission or reception, or no frames available 1b - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions. 0b - MB0 has no occurrence of successfully completed transmission or reception. 1b - MB0 has successfully completed transmission or reception.

68.6.2.12 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 611 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 611. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask
0h	8	MB 0–7	MB 8–31	Elements 0–7	None

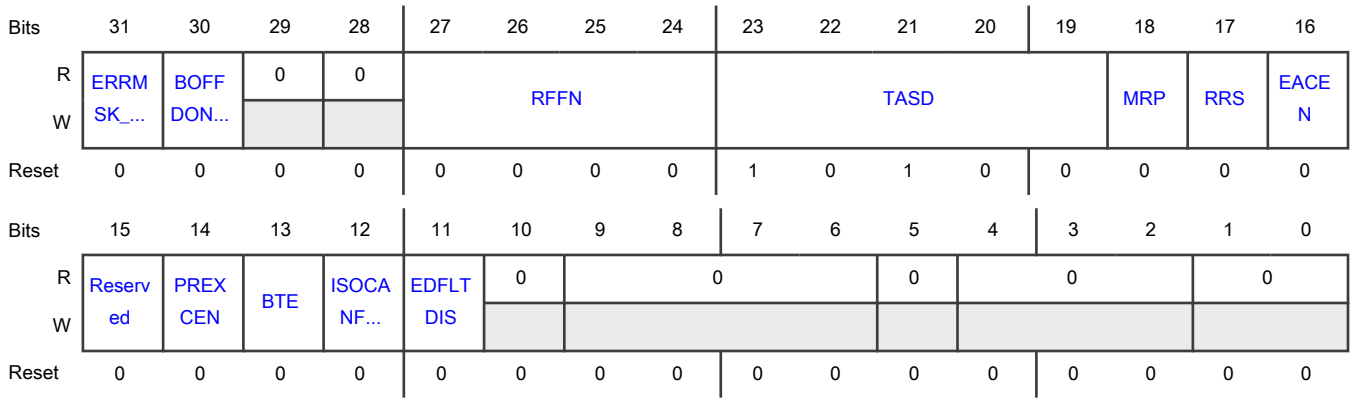
Diagram



Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0b - Disable 1b - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0b - Disable 1b - Enable
29 —	Reserved
28 —	Reserved
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 611. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19	Transmission Arbitration Start Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
TASD	Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0b - Generated 1b - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0b - Disable 1b - Enable
15 —	Reserved When writing to this field, always write the reset value.
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Disabled 1b - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0b - Disable 1b - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0b - Disable 1b - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0b - Enabled 1b - Disabled
10 —	Reserved

5 —	Reserved
4-2 —	Reserved
1-0 —	Reserved

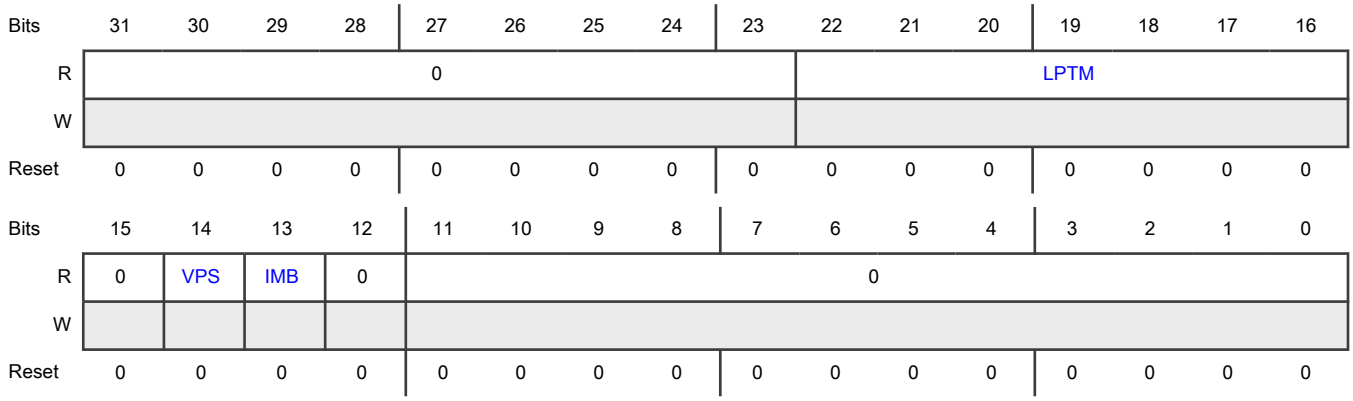
68.6.2.13 Error and Status 2 (ESR2)

Offset

Register	Offset
ESR2	38h

Function
Reports general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0b - Invalid 1b - Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0b - Message buffer indicated by ESR2[LPTM] is not inactive. 1b - At least one message buffer is inactive.
12 —	Reserved
11-0 —	Reserved

68.6.2.14 Cyclic Redundancy Check (CRCR)

Offset

Register	Offset
CRCR	44h

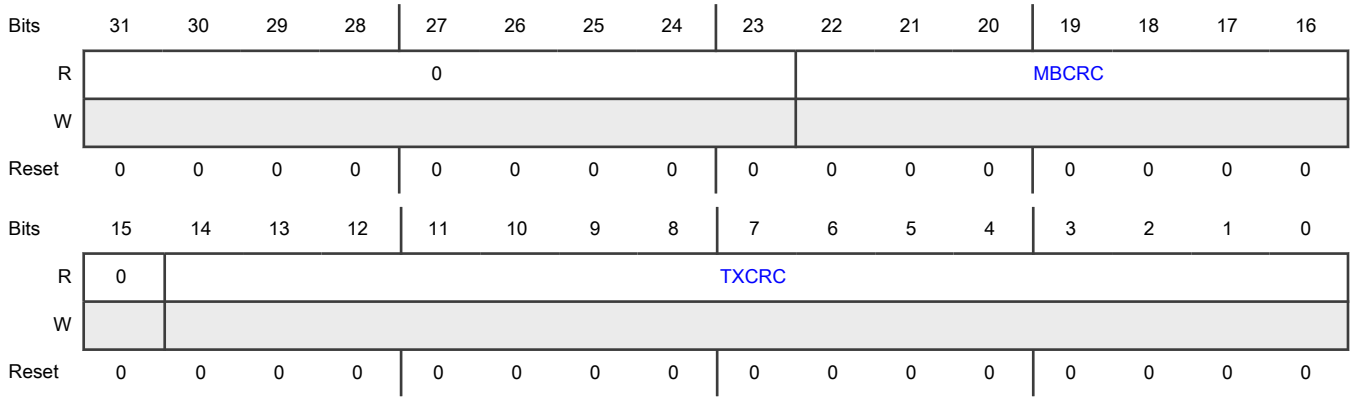
Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

68.6.2.15 Legacy RX FIFO Global Mask (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

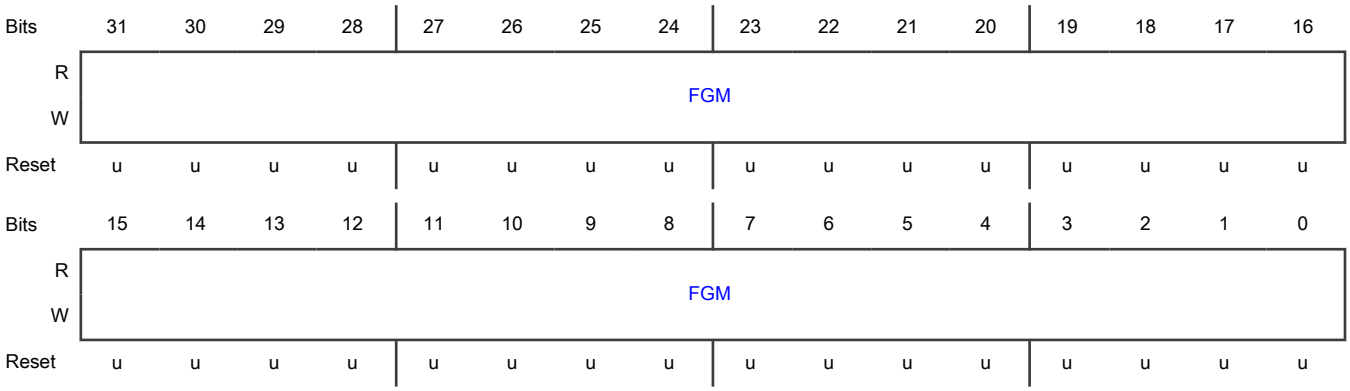
The following table shows how the FGM bits correspond to each IDAF field.

Table 612. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

68.6.2.16 Legacy RX FIFO Information (RXFIR)

Offset

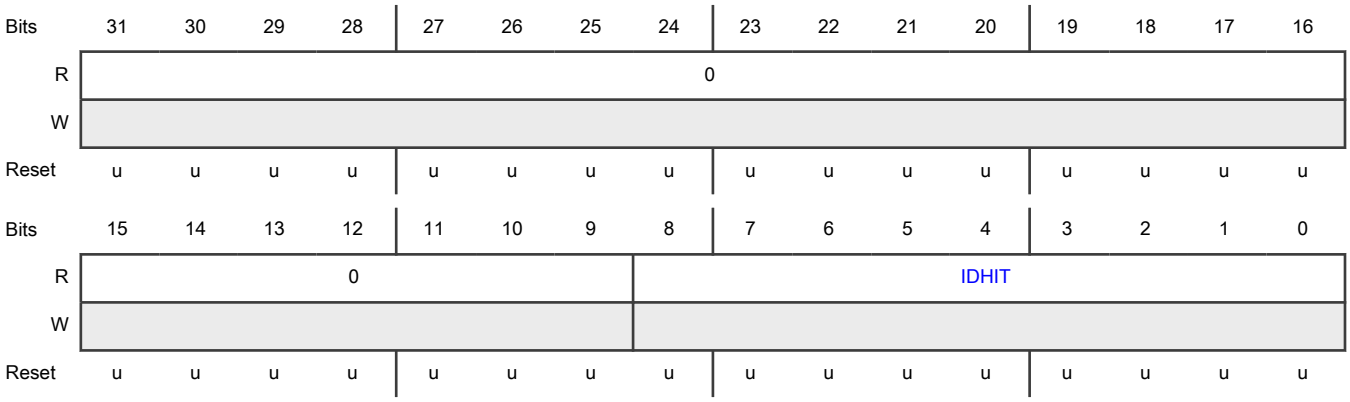
Register	Offset
RXFIR	4Ch

Function

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

68.6.2.17 CAN Bit Timing (CBT)

Offset

Register	Offset
CBT	50h

Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	EPROPSEG				EPSEG1				EPSEG2							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0b - Disable 1b - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

68.6.2.18 Receive Individual Mask (RXIMR0 - RXIMR31)

Offset

For n = 0 to 31:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

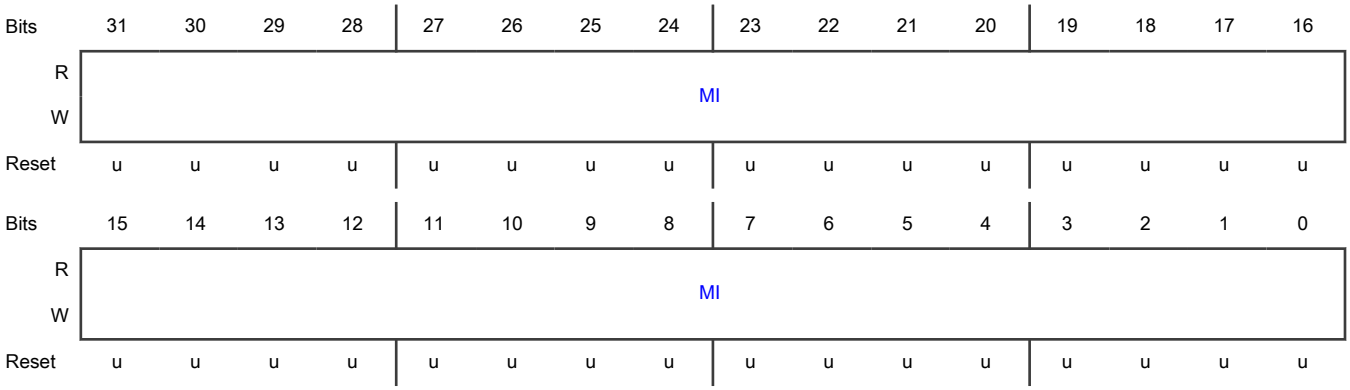
When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Diagram



Fields

Field	Function
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

68.6.2.19 Pretended Networking Control 1 (CTRL1_PN)

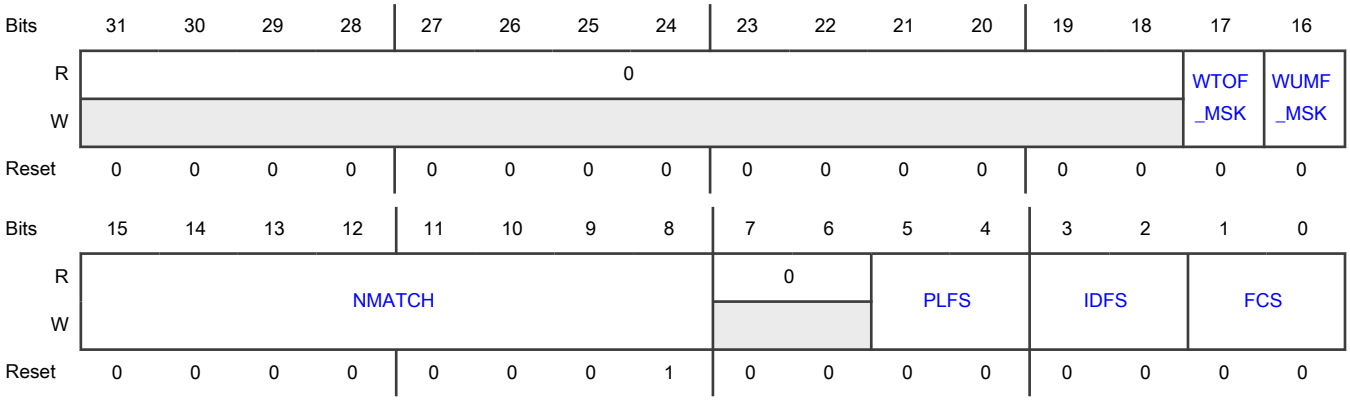
Offset

Register	Offset
CTRL1_PN	B00h

Function

Contains control bits for Pretended Networking mode filtering selection. Configure this register with the filter criteria to be used to receive wake-up messages. Fields in this register can be written in Freeze mode only, except for CTRL1_PN[WTOF_MSK] and CTRL1_PN[WUMF_MSK].

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF_MSK	Wake-up by Timeout Flag Mask Enables the generation of a wake-up event originated by a timeout. 0b - Disable 1b - Enable
16 WUMF_MSK	Wake-up by Matching Flag Mask Enables the generation of a wake-up event originated by a successful filtered RX message. 0b - Disable 1b - Enable
15-8 NMATCH	Number of Messages Matching the Same Filtering Criteria Defines the number of times a given message must match the predefined filtering criteria for ID or payload before generating a wake-up event. You can configure this quantity in the 1–255 range by using values 01h–FFh, respectively. 0000_0001b - Once 0000_0010b - Twice 1111_1111b - 255 times
7-6 —	Reserved
5-4 PLFS	Payload Filtering Selection Selects the level of payload filtering to be applied when FlexCAN is in Pretended Networking mode. When payload filtering is active, filtering does not accept remote messages (RTR = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Match payload contents to an exact target value 01b - Match a payload value greater than or equal to a specified target value 10b - Match a payload value smaller than or equal to a specified target value 11b - Match upon a payload value within a range of values, inclusive
3-2 IDFS	ID Filtering Selection Selects the level of ID filtering to be applied when FlexCAN is in Pretended Networking mode. In ID filtering, if FLT_ID2_IDMASK[IDE_MSK] = 1 and FLT_ID2_IDMASK[RTR_MSK] = 1, the IDE and RTR bits are considered part of the reception filter. 00b - Match ID contents to an exact target value 01b - Match an ID value greater than or equal to a specified target value 10b - Match an ID value smaller than or equal to a specified target value 11b - Match an ID value within a range of values, inclusive
1-0 FCS	Filtering Combination Selection Selects the filtering criteria to be applied when FlexCAN is in Pretended Networking mode. See Receive process in Pretended Networking mode for more details. 00b - Message ID filtering only 01b - Message ID filtering and payload filtering 10b - Message ID filtering occurring a specified number of times 11b - Message ID filtering and payload filtering a specified number of times

68.6.2.20 Pretended Networking Control 2 (CTRL2_PN)

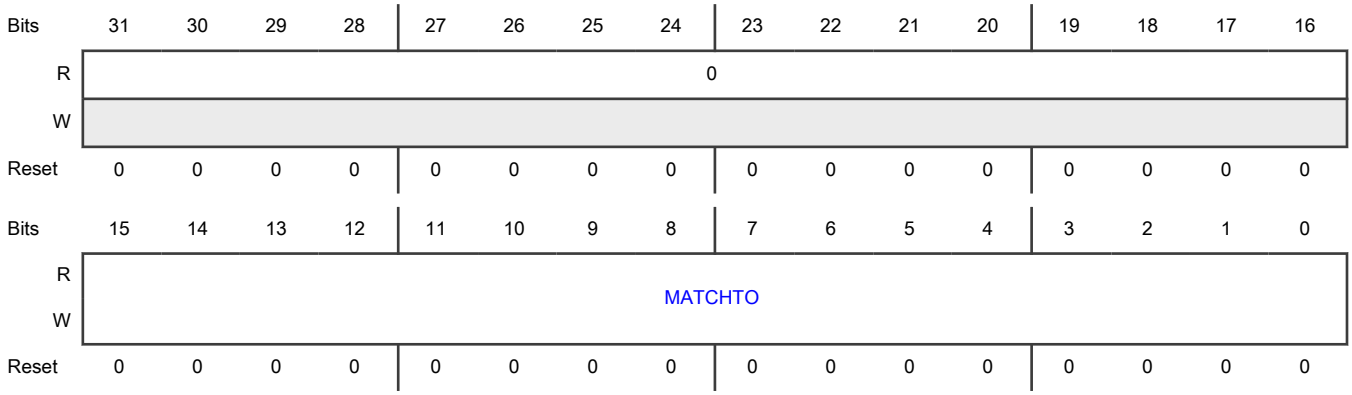
Offset

Register	Offset
CTRL2_PN	B04h

Function

Contains the configuration for the timeout value in Pretended Networking mode. You can only write to this register in Freeze mode.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MATCHTO	Timeout for No Message Matching the Filtering Criteria Defines a timeout value that generates a wake-up event if MCR[PNET_EN] = 1. If the timeout counter reaches the target value when FlexCAN is in Pretended Networking mode, a wake-up event is generated. The timeout limit can be configured from 1 to 65535 to control an internal 16-bit incrementing timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, where the period is 64 times the CAN Bit Time unit. Writing 0000h to this field disables the timeout.

68.6.2.21 Pretended Networking Wake-Up Match (WU_MTC)

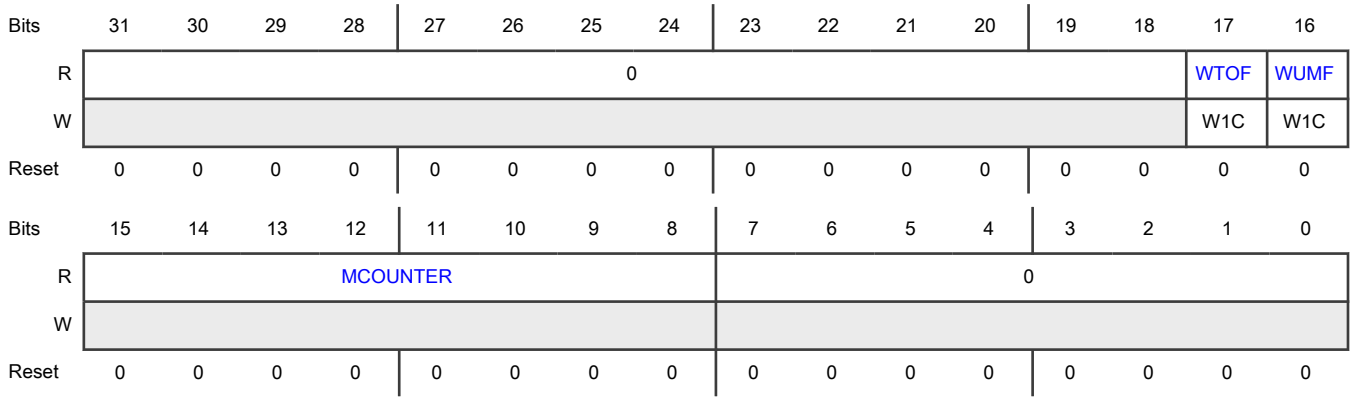
Offset

Register	Offset
WU_MTC	B08h

Function

Contains wake-up information related to the matching processes performed when FlexCAN receives frames in Pretended Networking mode.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF	Wake-up by Timeout Flag Bit Identifies whether FlexCAN has detected a timeout event during a time interval defined by CTRL2_PN[MATCHTO]. If CTRL1_PN[WTOF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
16 WUMF	Wake-up by Match Flag Identifies whether FlexCAN has detected a matching RX incoming message that meets the filtering criteria specified in Pretended Networking Control 1 (CTRL1_PN). If CTRL1_PN[WUMF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
15-8 MCOUNTER	Number of Matches in Pretended Networking Contains the number of times a given message has matched the predefined filtering criteria for ID or payload before a wake-up event. When FlexCAN enters Pretended Networking mode, this register is reset; soft reset does not affect it.
7-0 —	Reserved

68.6.2.22 Pretended Networking ID Filter 1 (FLT_ID1)

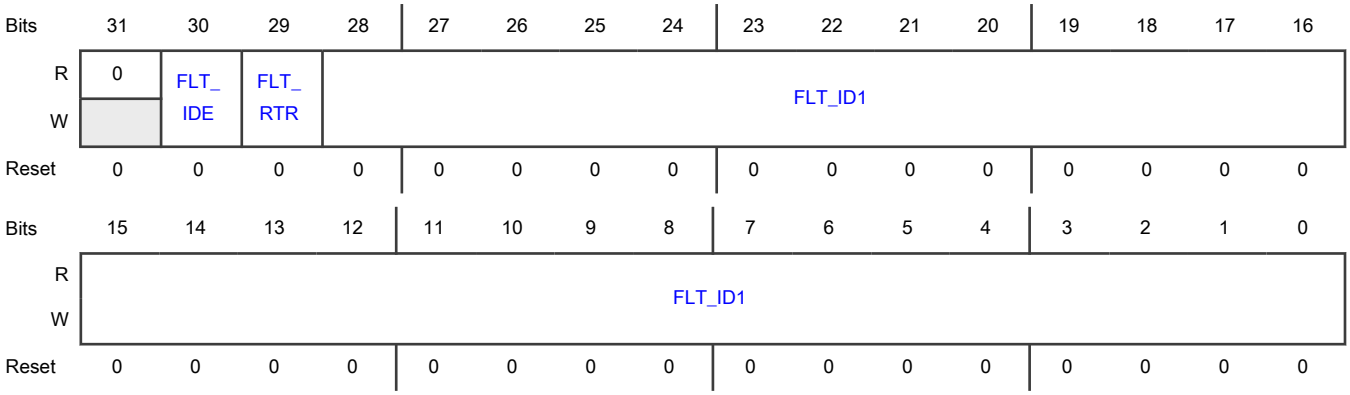
Offset

Register	Offset
FLT_ID1	B0Ch

Function

Contains FLT_ID1 target value, as well as IDE and RTR target values used to filter an incoming message ID. The FLT_ID1 is used for comparisons or as the lower limit value in an ID range detection. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31 —	Reserved
30 FLT_IDE	ID Extended Filter Identifies whether the frame format is standard or extended. It is used as part of the ID reception filter. 0b - Standard 1b - Extended
29 FLT_RTR	Remote Transmission Request Filter Identifies whether the frame is remote. It is used as part of the ID reception filter. 0b - Reject remote frame (accept data frame) 1b - Accept remote frame
28-0 FLT_ID1	ID Filter 1 for Pretended Networking filtering Defines either the 29 bits of an extended frame format, considering all bits, or the 11 bits of a standard frame format, considering only the leftmost 11 bits.

68.6.2.23 Pretended Networking Data Length Code (DLC) Filter (FLT_DLC)

Offset

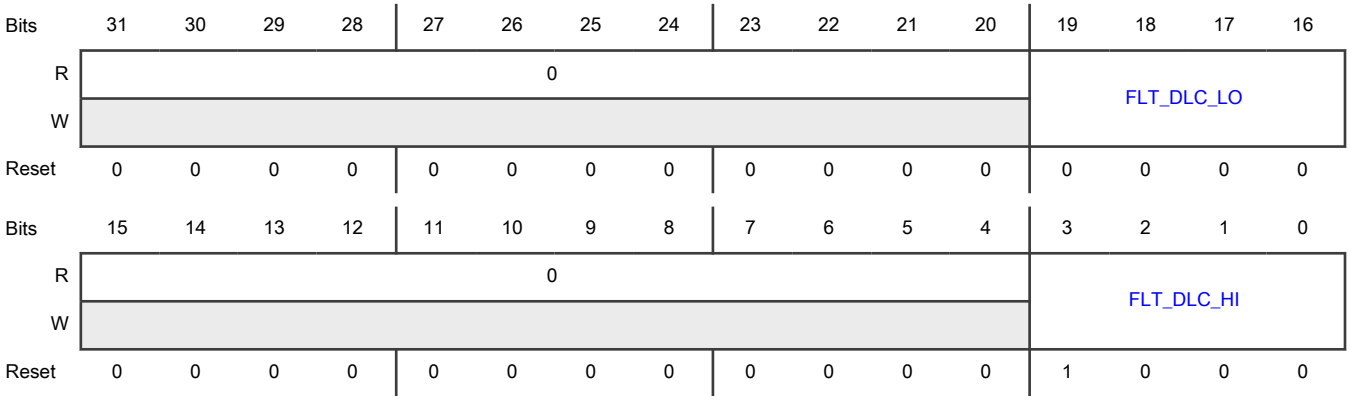
Register	Offset
FLT_DLC	B10h

Function

Contains the DLC inside a range of target values (FLT_DLC_LO and FLT_DLC_HI) used to filter an incoming message. The DLC range is used only for payload filtering. It can be written in Freeze mode only.

When a fixed quantity of data bytes is required, write the same value to FLT_DLC[FLT_DLC_LO] and FLT_DLC[FLT_DLC_HI]. See Receive process in Pretended Networking mode.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 FLT_DLC_LO	Lower Limit for Length of Data Bytes Filter Specifies the lower limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.
15-4 —	Reserved
3-0 FLT_DLC_HI	Upper Limit for Length of Data Bytes Filter Specifies the upper limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.

68.6.2.24 Pretended Networking Payload Low Filter 1 (PL1_LO)

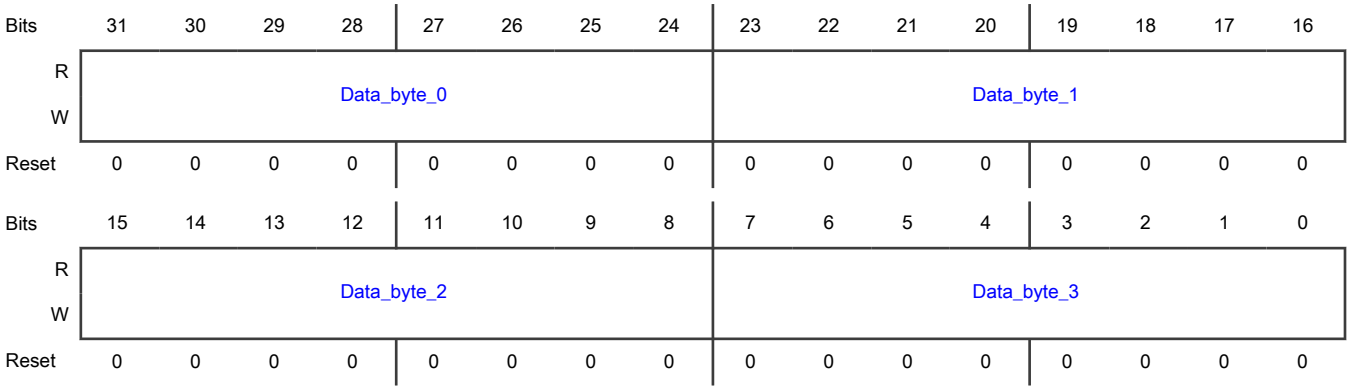
Offset

Register	Offset
PL1_LO	B14h

Function

Contains the low-order bits of the target value used to filter incoming message payload for payload filter 1. It is used for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_0	Data byte 0 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 0.
23-16 Data_byte_1	Data byte 1 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 1.
15-8 Data_byte_2	Data byte 2 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 2.
7-0 Data_byte_3	Data byte 3 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 3.

68.6.2.25 Pretended Networking Payload High Filter 1 (PL1_HI)

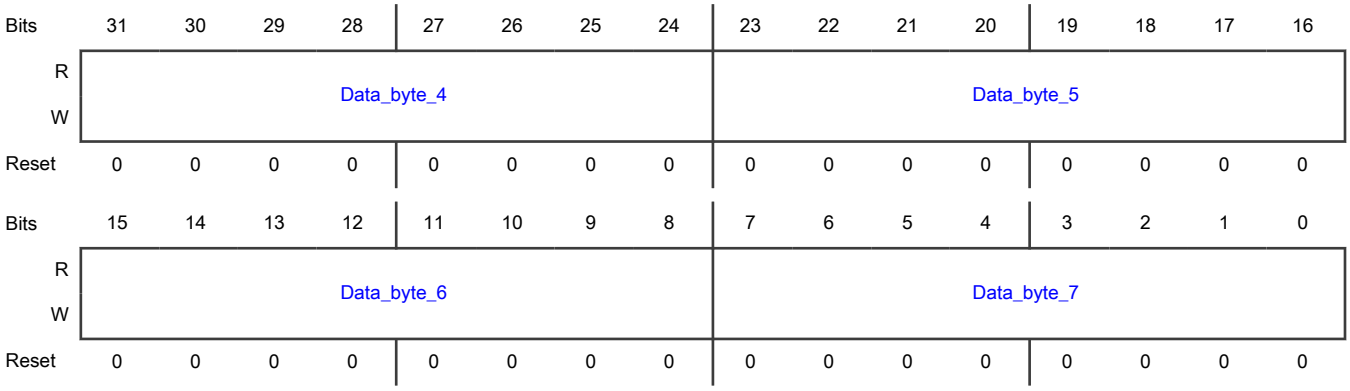
Offset

Register	Offset
PL1_HI	B18h

Function

Contains the high-order bits of the target value used to filter incoming message payload for payload filter 1. It is used either for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_4	Data byte 4 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 4.
23-16 Data_byte_5	Data byte 5 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 5.
15-8 Data_byte_6	Data byte 6 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 6.
7-0 Data_byte_7	Data byte 7 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 7.

68.6.2.26 Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK)

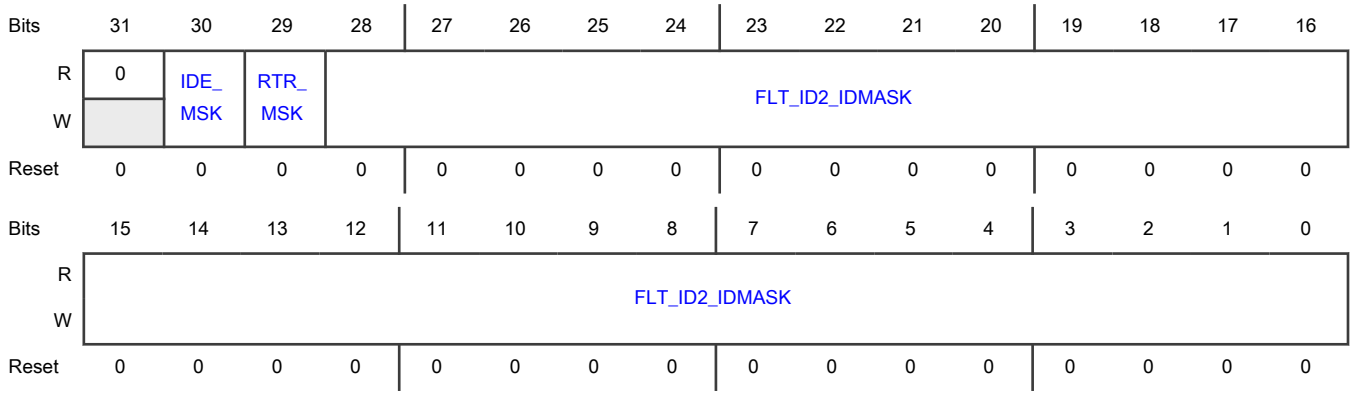
Offset

Register	Offset
FLT_ID2_IDMASK	B1Ch

Function

Contains FLT_ID2 target value used only as the upper limit value in ID range detection. When an exact ID filtering criterion is selected, this register stores the ID mask. IDE_MSK and RTR_MSK are used in both types of ID filtering (exact and range). These fields enable FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] to be used as part of the ID reception filter. This register can be written in Freeze mode only.

Diagram



Fields

Field	Function
31 —	Reserved
30 IDE_MSK	ID Extended Mask Indicates whether the frame format (standard or extended) is used as part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
29 RTR_MSK	Remote Transmission Request Mask Indicates whether the frame type (data or remote) is part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
28-0 FLT_ID2_IDMASK	ID Filter 2 for Pretended Networking Filtering or ID Mask Bits for Pretended Networking ID Filtering Defines filter values in range ID filtering: • Value in extended frame format (29 bits), considering FLT_ID2[28:0] • Value in standard frame format (11 bits), considering the FLT_ID2[28:18]. In this case, bits [17:0] are meaningless. Or, defines the mask values in exact ID filtering: • Values for extended frame format (29 bits), considering IDMASK[28:0] • Values for standard frame format (11 bits), considering IDMASK[28:18]. In this case, bits [17:0] are meaningless.

68.6.2.27 Pretended Networking Payload Low Filter 2 and Payload Low Mask (PL2_PLMASK_LO)

Offset

Register	Offset
PL2_PLMASK_LO	B20h

Function

Contains the low-order bits for Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the low-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 0
23-16 Data_byte_1	Data Byte 1 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 1
15-8 Data_byte_2	Data Byte 2 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 2
7-0 Data_byte_3	Data Byte 3 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 3

68.6.2.28 Pretended Networking Payload High Filter 2 and Payload High Mask (PL2_PLMASK_HI)

Offset

Register	Offset
PL2_PLMASK_HI	B24h

Function

Contains the high-order bits for the Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the high-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram

31-24 Data_byte_4	Data Byte 4 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 4.
23-16 Data_byte_5	Data Byte 5 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 5.
15-8 Data_byte_6	Data Byte 6 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 6.
7-0 Data_byte_7	Data Byte 7 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 7.

68.6.2.29 Wake-Up Message Buffer (WMB0_CS - WMB3_CS)

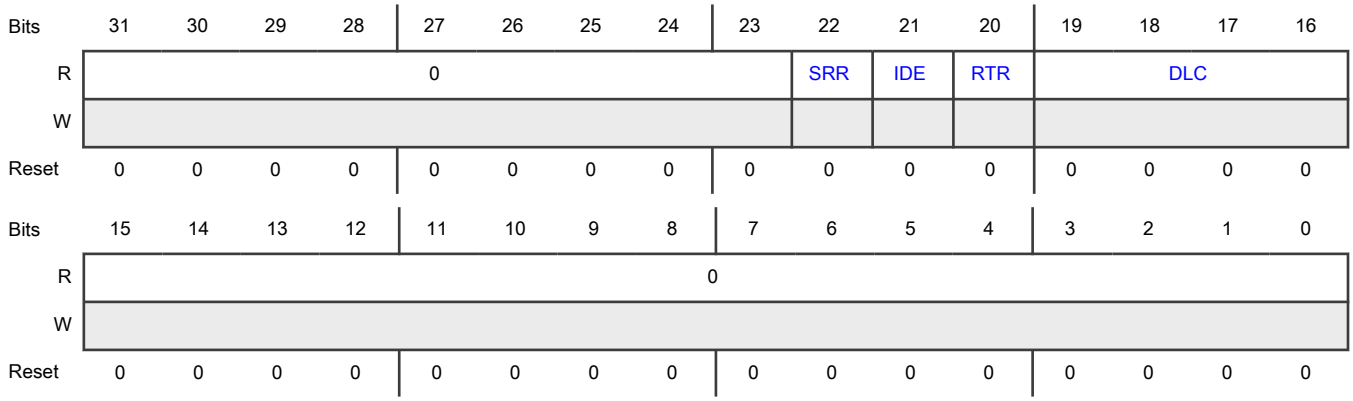
Offset

Register	Offset
WMB0_CS	B40h
WMB1_CS	B50h
WMB2_CS	B60h
WMB3_CS	B70h

Function

Stores the Control and Status information (IDE, RTR, and DLC fields) of an incoming RX message.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 SRR	Substitute Remote Request Identifies whether the request is dominant or recessive. This field is used only in extended format. You must write 1 to this field for transmission buffers. The value of this field is stored with the value received on the CAN bus for receiving buffers. If FlexCAN receives this field as dominant, it is interpreted as an arbitration loss. 0b - Dominant 1b - Recessive
21 IDE	ID Extended Bit Identifies whether the frame format is standard or extended.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Standard 1b - Extended
20 RTR	Remote Transmission Request Identifies whether the frame is remote or data 0b - Data 1b - Remote
19-16 DLC	Length of Data in Bytes Contains the length (in bytes) of the RX data received when FlexCAN is in Pretended Networking mode. FlexCAN writes this field, copied from the DLC (Data Length Code) field of the received frame. The DLC field indicates which data bytes are valid.
15-0 —	Reserved

68.6.2.30 Wake-Up Message Buffer for ID (WMB0_ID - WMB3_ID)

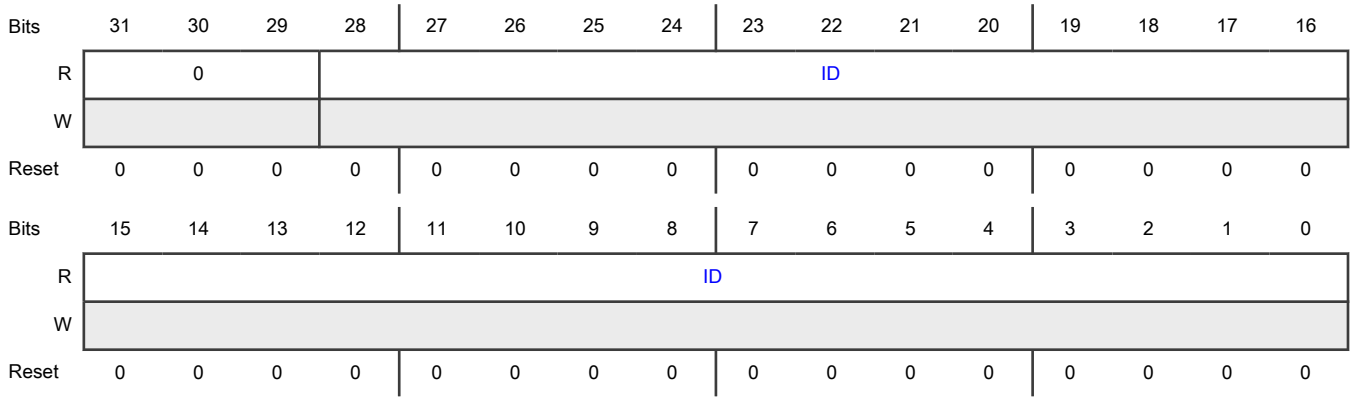
Offset

Register	Offset
WMB0_ID	B44h
WMB1_ID	B54h
WMB2_ID	B64h
WMB3_ID	B74h

Function

Stores the ID information of an incoming RX message.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-0 ID	Received ID in Pretended Networking Mode Stores the received ID, which is: • The 29 bits of the extended frame format (considering ID[28:0]) • The 11 bits of the standard frame format (considering ID[28:18] only; the remaining bits in the ID[17:0] range are meaningless).

68.6.2.31 Wake-Up Message Buffer for Data 0–3 (WMB0_D03 - WMB3_D03)

Offset

Register	Offset
WMB0_D03	B48h
WMB1_D03	B58h
WMB2_D03	B68h
WMB3_D03	B78h

Function

Stores data bytes 0–3 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Data_byte_0								Data_byte_1

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Data_byte_2								Data_byte_3							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains received payload corresponding to data byte 0 in Pretended Networking mode
23-16 Data_byte_1	Data Byte 1 Contains received payload corresponding to data byte 1 in Pretended Networking mode
15-8 Data_byte_2	Data Byte 2 Contains received payload corresponding to data byte 2 in Pretended Networking mode
7-0 Data_byte_3	Data Byte 3 Contains received payload corresponding to data byte 3 in Pretended Networking mode

68.6.2.32 Wake-Up Message Buffer Register Data 4–7 (WMB0_D47 - WMB3_D47)

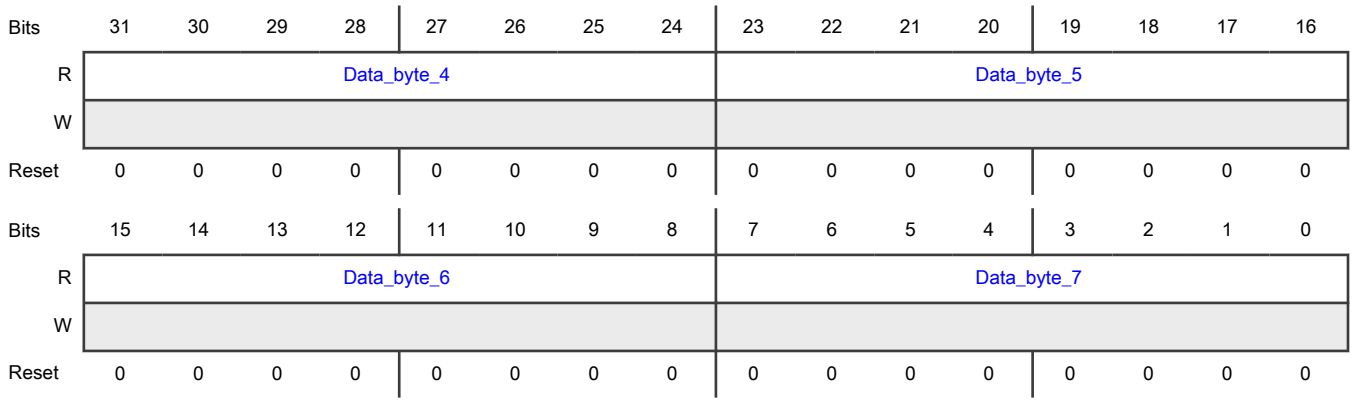
Offset

Register	Offset
WMB0_D47	B4Ch
WMB1_D47	B5Ch
WMB2_D47	B6Ch
WMB3_D47	B7Ch

Function

Stores the data bytes 4–7 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram



Fields

Field	Function
31-24 Data_byte_4	Data Byte 4 Contains received payload corresponding to data byte 4 in Pretended Networking mode
23-16 Data_byte_5	Data Byte 5 Contains received payload corresponding to data byte 5 in Pretended Networking mode
15-8 Data_byte_6	Data Byte 6 Contains received payload corresponding to data byte 6 in Pretended Networking mode
7-0 Data_byte_7	Data Byte 7 Contains received payload corresponding to data byte 7 in Pretended Networking mode

68.6.2.33 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

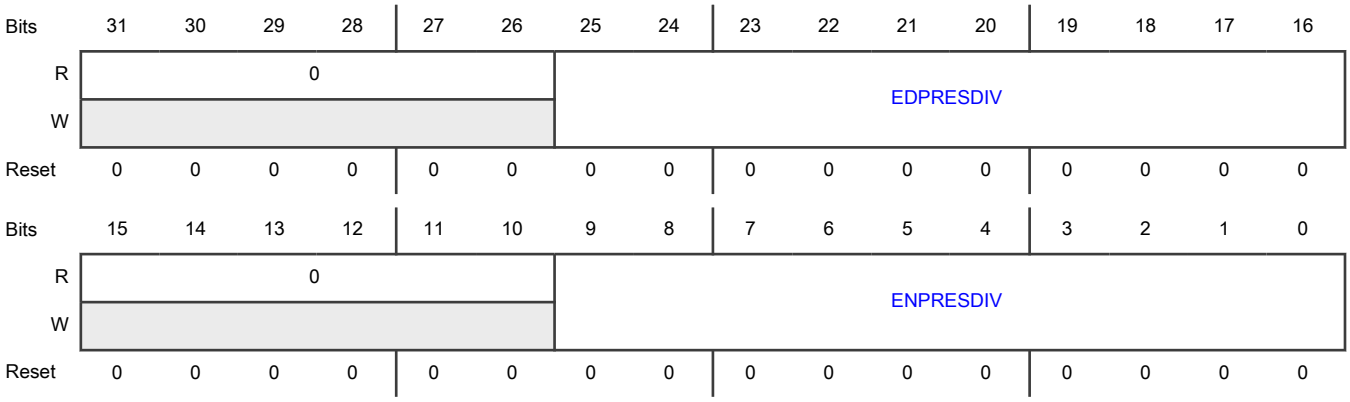
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

68.6.2.34 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

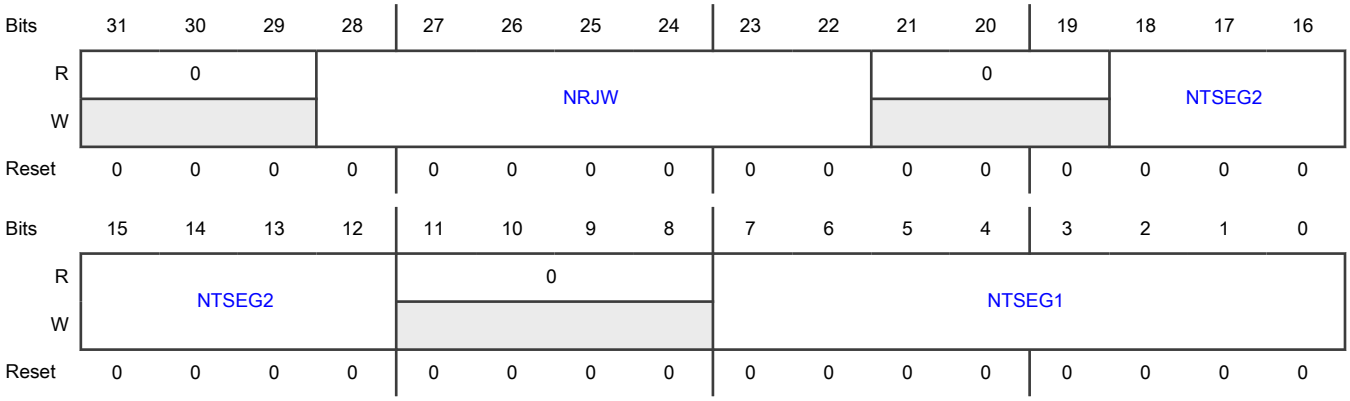
Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

68.6.2.35 Enhanced Data Phase CAN Bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

DTSEG1 must be at least two time quanta.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

68.6.2.36 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

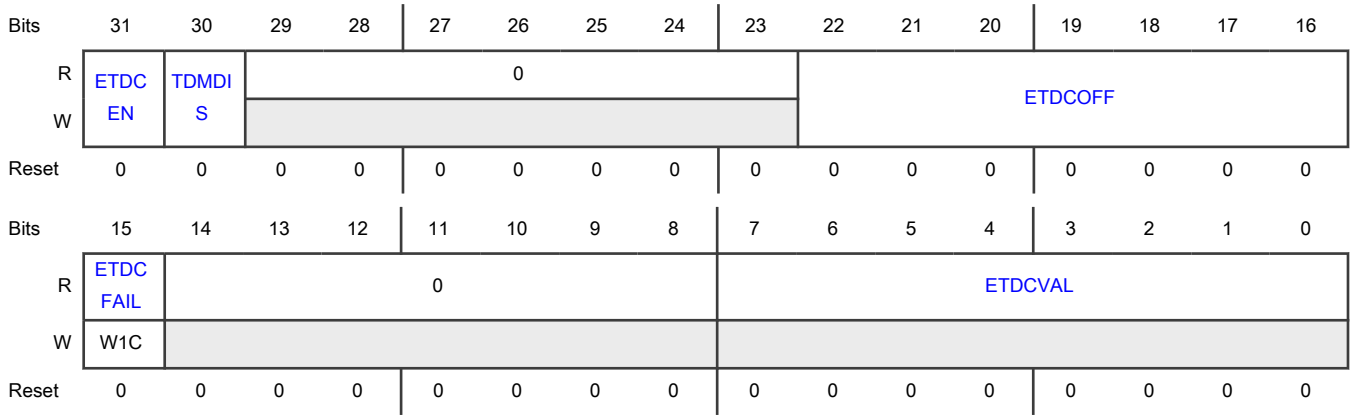
Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0b - Disable 1b - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0b - Enable 1b - Disable
29-23 —	Reserved
22-16	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
ETDCOFF	Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0b - In range 1b - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

68.6.2.37 CAN FD Control (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 613.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

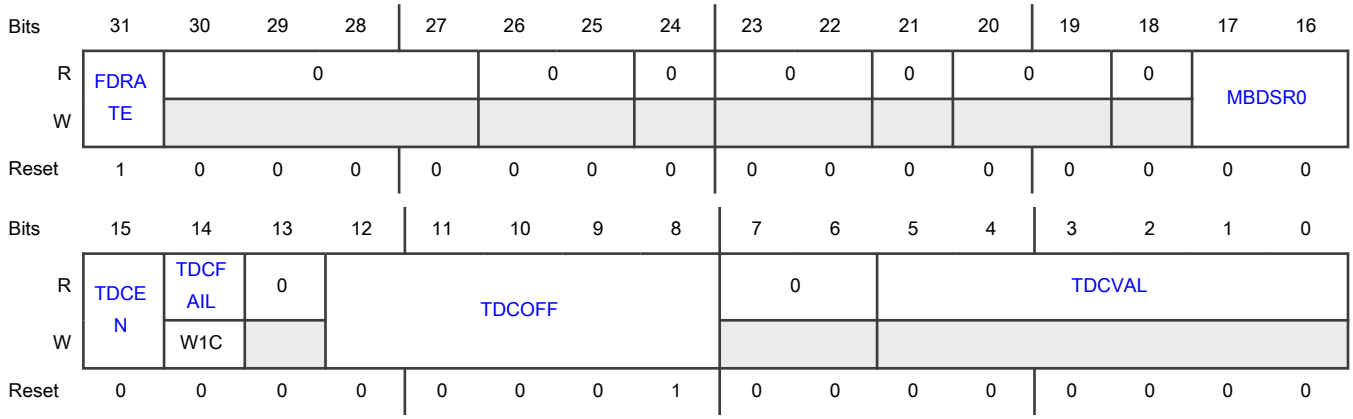
Table 613. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state. • The CAN bus is in the Bus Off state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0b - Disable 1b - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 —	Reserved
21 —	Reserved
20-19 —	Reserved
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - Disable 1b - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - In range 1b - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect. Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

68.6.2.38 CAN FD Bit Timing (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

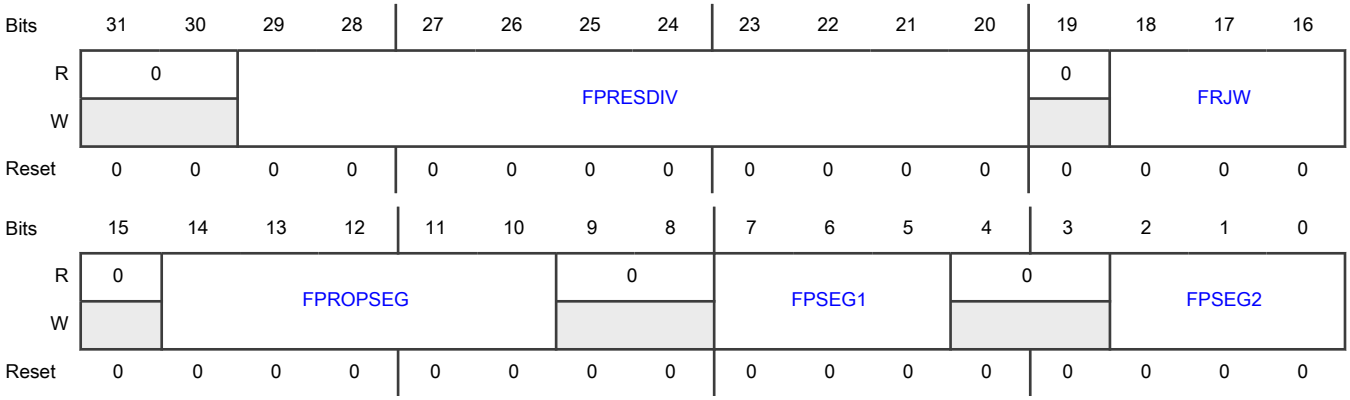
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

68.6.2.39 CAN FD CRC (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$\text{CRC_15} = \text{C599h: } (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$\text{CRC_17} = \text{3685Bh: } (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

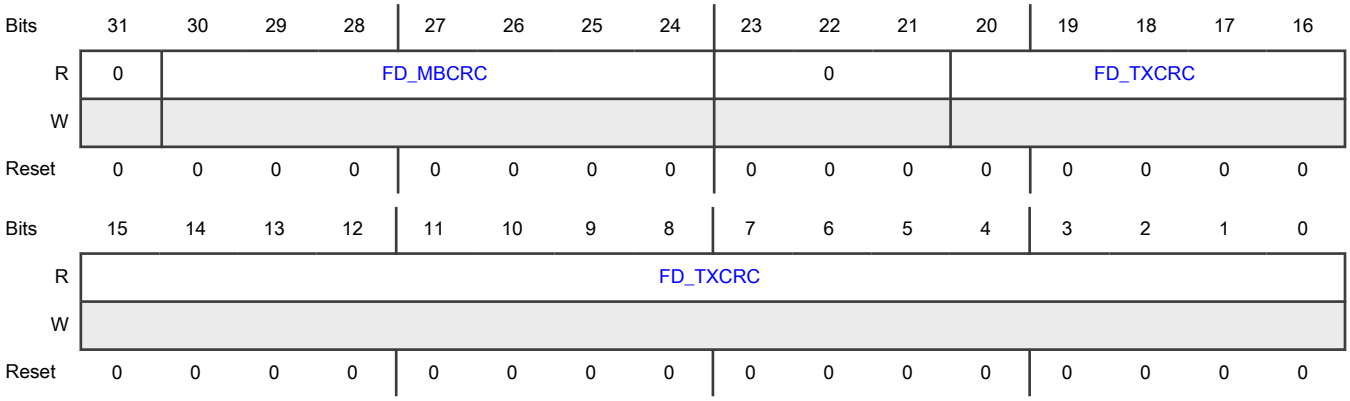
$$\text{CRC_21} = \text{302899h: } (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 48. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Diagram



Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

68.6.2.40 Enhanced RX FIFO Control (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

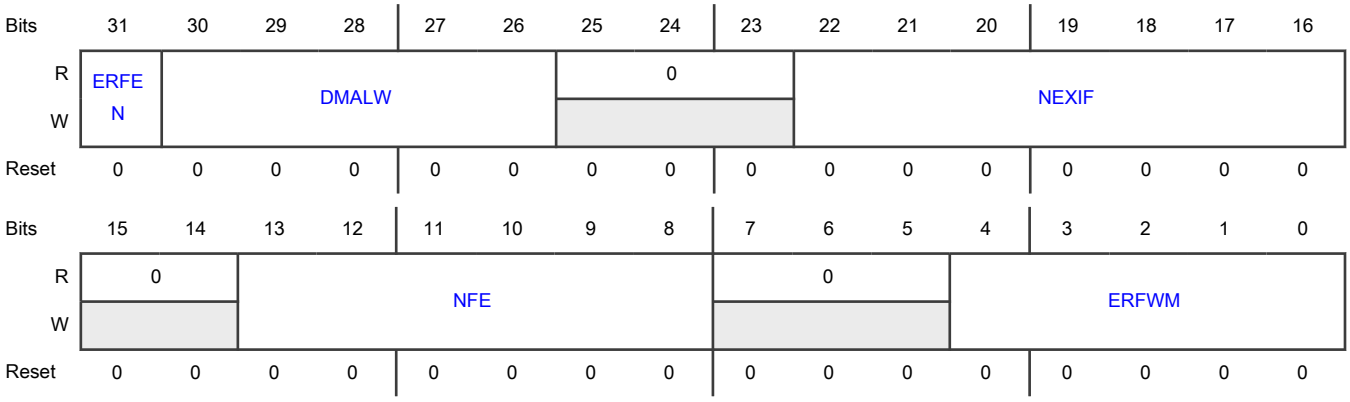
Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Diagram



Fields

Field	Function
31 ERFEN	Enhanced RX FIFO enable Enables the Enhanced RX FIFO. **NOTE** If MCR[RFEN] = 1, do not write 1 to this field. 0b - Disable 1b - Enable
30-26 DMALW	DMA Last Word Defines the last DMA address for each Enhanced RX FIFO element. This table shows the number of elements and the last address for each Enhanced RX FIFO element according to the value of DMALW.

DMALW	Number of 32-bit words transferred	Last FIFO address

Fields

Field	Function
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Overflow
29	Enhanced RX FIFO Watermark Indication Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERFWMI	Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - At least one message stored in Enhanced RX FIFO
27 ERFCLR	Enhanced RX FIFO Clear Writing one to this field during Freeze mode clears Enhanced RX FIFO content. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0b - No effect 1b - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0b - Not empty 1b - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0b - Not full 1b - Full
15 —	Reserved
14-6 —	Reserved
5-0 ERFEL	Enhanced RX FIFO Elements Indicates the number of CAN messages stored in the Enhanced RX FIFO.

68.6.2.43 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31)

Offset

For n = 0 to 31:

Register	Offset
ERFFELn	3000h + (n × 4h)

Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Fields

Field	Function
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

68.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–27Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 614. Message buffer structure example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

= Unimplemented or reserved

Table 615. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 616).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 616 and Table 617. See Functional description.

Table 616. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten

Table continues on the next page...

Table 616. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
					again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or other message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 617. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 618. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN

Table continues on the next page...

Table 618. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
		bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 616, Table 617, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 614). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 619).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

Table continues on the next page...

Table 618. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 619.

Table 619. DATA BYTE validity

DLC	Valid data bytes
0	None
1	DATA BYTE 0
2	DATA BYTE 0–1
3	DATA BYTE 0–2
4	DATA BYTE 0–3
5	DATA BYTE 0–4
6	DATA BYTE 0–5

13	DATA BYTE 0–31
14	DATA BYTE 0–47
15	DATA BYTE 0–63

68.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 620.

Table 620. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload

In this case, Table 621 indicates how the message buffers are arranged in RAM.

Table 621. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31

68.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

68.6.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 626. Legacy RX FIFO structure

	31 28 24	23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
	= Unimplemented or reserved							

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAF) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 627 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 627. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 296–)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std and ext = 31–24)		RXIDC_1 (std and ext = 23–16)		RXIDC_2 (std and ext = 15–8)			RXIDC_3 (std and ext = 7–0)	
		= Unimplemented or Reserved							

Table 628. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected. 0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

68.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–2048h contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 629. Enhanced RX FIFO structure

	31	30	29	28	24	23	22	21	20	19	18	17	16	15	8	7	6	0

15	2048h

Table 631. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does

Table continues on the next page...

Table 631. Field descriptions (continued)

Mnemonic	Field	Description
		not include the data field, regardless of the DLC field. See Table 619 for more details.
TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame.
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 632 shows how FlexCAN writes IDHIT according to each filter element.

Table 632. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

EMVSIM

69.1 Chip-specific EMVSIM information

Table 633. Reference links to related information

Topic	Related module	Reference
Full description	EMVSIM	EMVSIM
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

69.1.1 Module instances

This device contains two instances of the EMVSIM module, EMVSIM0 and EMVSIM1.

69.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

69.2 Overview

EMVSIM facilitates communication with smart cards that are compatible with these standards:

- EMV v4.3 (Book 1)
- ISO/IEC 7816-3

69.2.1 Block diagram

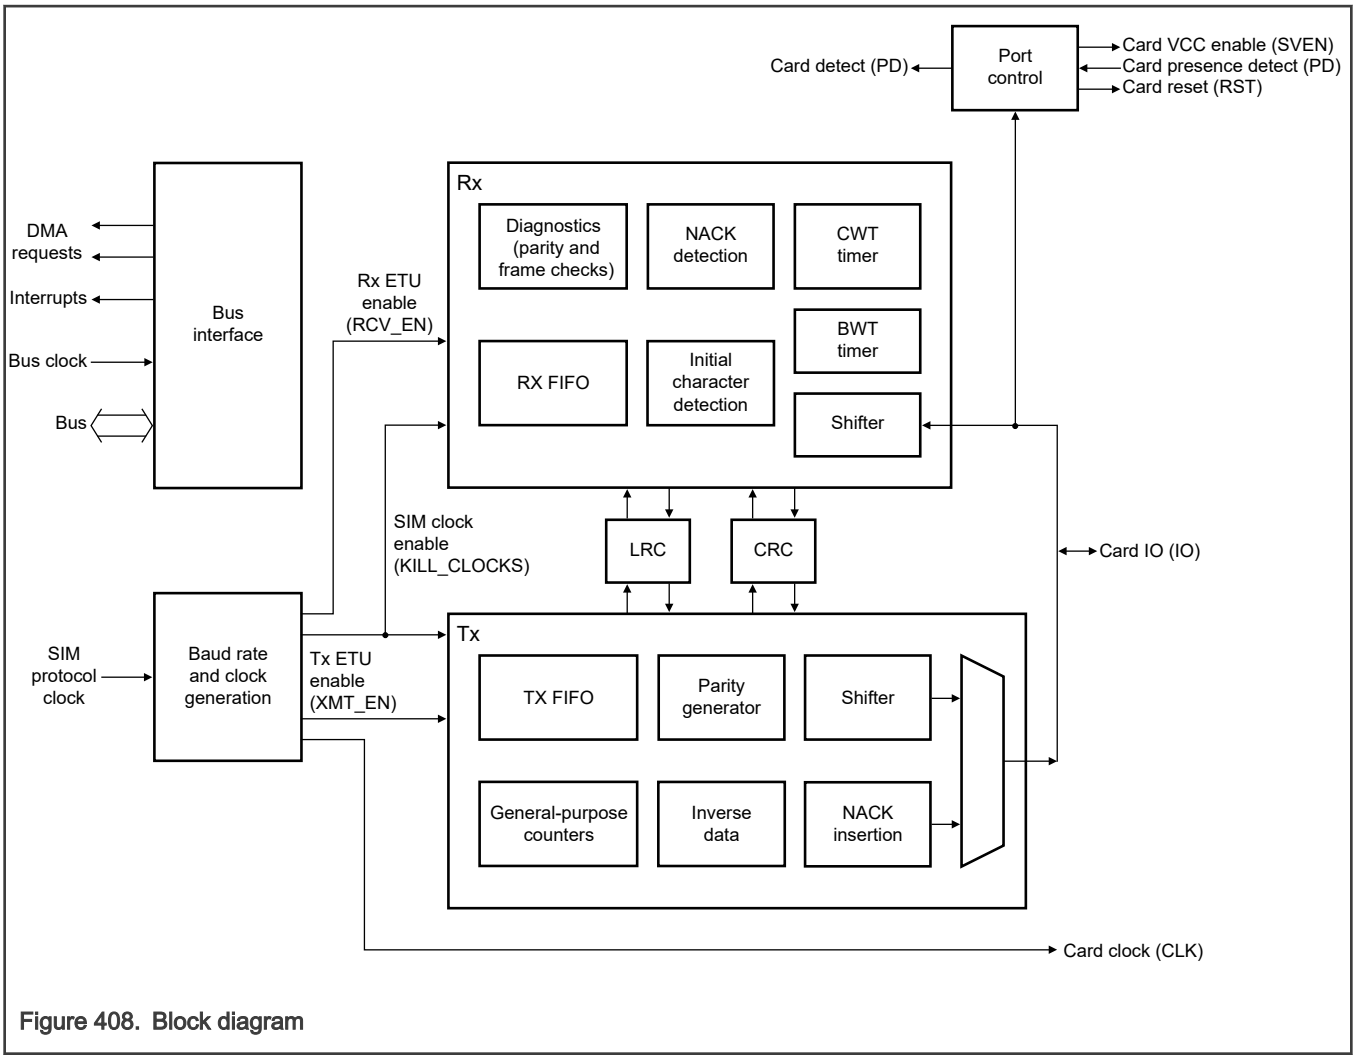

Figure 408. Block diagram

69.2.2 Features

- Independent clock for SIM logic (transmitter and receiver)
- Independent clock for register read-write interface
- 16-byte–deep FIFO for transmitter and receiver
- Automatic NACK generation on parity error and receiver FIFO overflow error
- Support for both inverse and direct conventions
- Retransmission of a byte on smart card NACK request with programmable threshold of re-transmissions
- Auto-detection of initial character in receiver, and setting of data format (inverse or direct)
- NACK detection in receiver
- Independent timers to measure:
  - Character wait time
  - Block wait time
  - Block guard time

- Two general-purpose counters available for use by software, with programmable clock selection for the counters
- DMA support for transferring data to and from FIFOs, with a programmable option to select interrupt or DMA
- Programmable prescaler generating the selected frequency for card clock and baud rate divisor, generating internal ETU clocks for a transmitter and receiver for any F/D ratio
- Manual control of all smart card interface signals
- Automatic power-down of port logic on smart card presence detection
- 8-bit LRC and 16-bit CRC generation for bytes sent out from transmitter, and checking incoming message checksum for receiver

69.3 Functional description

69.3.1 Bus interface

EMVSIM is a block that is configured via the chip's peripheral bus interface. EMVSIM has 32-bit–aligned memory-mapped registers that are used to configure and control its operations. You can write the transmit bytes or read the received bytes using either interrupt operation or DMA operation. EMVSIM can generate necessary DMA requests for the operation.

69.3.2 Smart card interface and control

EMVSIM controls all interface signals for the smart card. The smart card clock is generated by using the prescaler (CLKCFG[CLK_PRSC]) voltage enable through Port Control and Status (PCSR). The message bytes are transmitted and received on the card I/O device pin (IO) which is used in open drain configuration.

The smart card interface signals, except IO (controlled by the transmitter and receiver), are generated by the port control block. The port control block controls the assertion and de-assertion of the clock, reset, and SVEN signals to the smart card. It can do so manually (software explicitly writes the necessary bits) or by using auto power-down. In auto power-down, the module can itself power down the smart card when you configure it to do so by software. The port control block can also detect the presence of the smart card and generate the necessary interrupts to indicate its presence.

For more information about powering up and automatic power down, see Powering up and Automatic power-down sections.

69.3.2.1 Smart card presence detect

The smart card presence detect pin PD (see External signals) allows detecting the insertion or removal of a smart card. PCSR[SPDES] allows you to configure the software as to which edge of the PD pin causes a presence detect interrupt flag to be asserted.

When the smart card is removed, an internal pull-down is required on the PD pin to allow a high-to-low transition on this pin.

69.3.3 EMVSIM receiver

The EMVSIM receiver is designed to receive all message bytes and store valid bytes into the receive FIFO. It performs checks on incoming messages and tells the transmitter to enable NACK insertion for each message. In addition, the receiver automatically detects NACKs received when the transmitter is sending out message bytes.

The receiver includes a 16-byte deep FIFO to store the correctly received bytes from the smart card. You must configure software to ensure that it reads out the data from the FIFO, preventing any overflow when more bytes are sent from the card.

You can configure the receiver to detect the initial character. When configured to do so, the data format (direct or inverse convention) is also determined by the receiver. Then EMVSIM sets the appropriate field in the register map.

Internal timers in the receiver measure the various wait times (character, block, and guard). After receiving a byte, the receiver checks the byte for a parity error (in T = 0 mode) and framing error. It can then direct the transmitter to insert NACK on parity error detection. For a block of bytes received, the receiver checks for LRC or CRC errors (in T = 1 mode). See LRC and CRC for more LRC and CRC information. Other errors are stored as status for software to be aware of their occurrence. The status of the receiver operation is indicated to software via maskable interrupts.

69.3.3.1 Data sampling

The incoming data is internally synchronized and sampled by using a 16x oversampled clock, called the EMVSIM receiver logic clock. The frequency of this clock is 16 times the ETU clock (1/ETU period). The whole receiver works on this EMVSIM receiver logic clock.

69.3.3.2 Initial character detection

EMVSIM supports detection of the initial character and determines the data format when it is placed in the initial character mode by writing 1 to CTRL[ICM]. When placed in this mode, EMVSIM samples the input line and waits until it has detected one of the initial characters. After detecting one, EMVSIM writes 0 to CTRL[ICM]. It also writes the appropriate value to CTRL[IC], depending on the data format detected using the initial character.

The two possible data formats are inverse convention (Figure 409) and direct convention (Figure 410). Essentially, inverse convention differs from direct convention in that the order of the bits is flipped (in other words, MSB for LSB) and the data bits and parity bit are logically inverted. When receiving inverse convention data, the transformation of the data back to direct convention format is done in hardware, including the inversion of the data and parity bits.

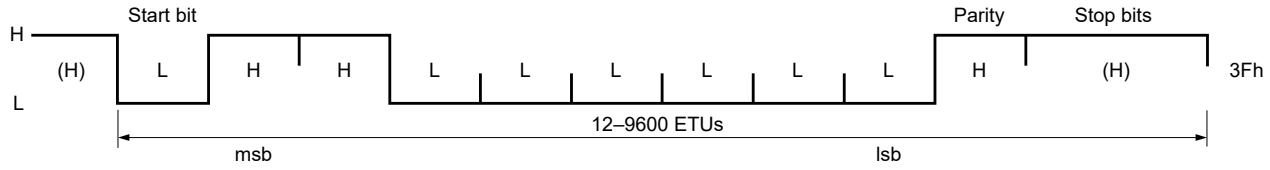

Figure 409. Initial character in inverse convention

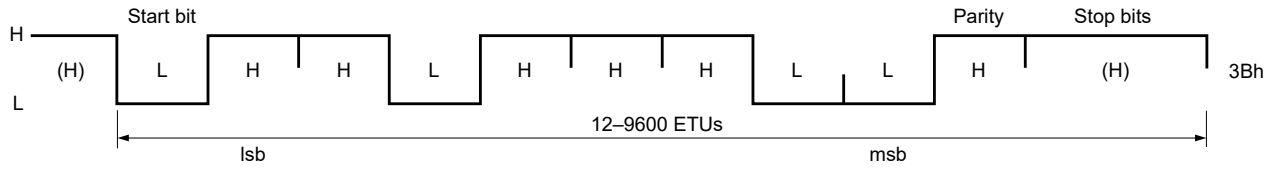

Figure 410. Initial character in direct convention

To place EMVSIM into initial character mode, write 1 to CTRL[ICM]. After a valid initial character is received, EMVSIM accordingly writes 1 to CTRL[IC] and writes 0 to CTRL[ICM]. You can read CTRL[IC] to determine which mode EMVSIM is currently using. The 3Bh (as decoded by direct convention) with parity bit high causes direct convention to be used (CTRL[IC] = 0), whereas a 3Fh (as decoded by inverse convention) with parity bit high causes inverse convention to be used (CTRL[IC] = 1).

The receiver remains in initial character mode until you disable it or until a valid initial character is detected. Upon detection of a valid character, the receiver enters data receive mode. NXP recommends that you use one of the general-purpose counters as a timeout during initial character mode.

When the receiver is in initial character mode, all bytes received continue to be placed into the receive FIFO whether they are valid initial characters or not. If a valid initial character is received that causes the data format being used to change, all subsequent bytes are decoded with that format before being placed into the FIFO, including the initial character byte itself. That is, if CTRL[IC] is low, and the correct initial character for setting inverse convention is received, that character and all subsequently received characters are stored in the FIFO after having been decoded using inverse convention (for example, the initial character is stored as 3Fh).

NOTE

There is a condition where a parity error in the initial byte for direct convention (3Bh) might be decoded as what appears to be a valid initial character for inverse convention (that is, 3Fh). EMVSIM does not recognize this as a valid initial character for inverse convention and writes 1 to RX_STATUS[PEF].

69.3.3.3 Receiver diagnostics

EMVSIM performs diagnostic checks on the incoming messages. These include:

- Parity checks
- Message frame checks

Parity error detection

The receiver is responsible for detecting parity errors in the received data. Data is always transmitted with even parity, except in inverse convention mode. In inverse convention mode, all data bits and the parity bit are complemented, making the data appear to be odd parity. The parity bit is defined as the tenth bit of the received data. The parity of the second through tenth received bits is calculated by the receiver parity logic. This logic determines if the parity of the nine received bits is correct.

When EMVSIM detects a parity error on a given byte, the parity error flag (RX_STATUS[PEF]) is asserted if NACK generation on errors is disabled (CTRL[ANACK] = 0). The parity error flag does not generate an interrupt to the system. However, EMVSIM can cause the transmitter to transmit a NACK (if CTRL[ANACK] = 1) and request retransmission of the current byte. Software does not need to enable the transmitter to perform this action.

Framing error detection

The receiver is responsible for detecting framing errors in the received data. Data is always transmitted with 2 STOP bits, except in 11 ETU mode, where there is one STOP bit. The STOP bits are defined as high state at the 11th and 12th bit positions in the received data. In either mode, the receiver expects to see a high at the 11th bit position in the received data. If a low is detected at the 11th bit position, the receiver indicates a framing error for that byte.

When a framing error is detected on a given byte, EMVSIM writes 1 to RX_STATUS[FEF]. A framing error cannot cause an interrupt, nor can it create a NACK pulse to the smart card asking for a retransmission of the corrupted data.

LRC and CRC

The receiver also checks the LRC or CRC on the incoming block of bytes (if LRC or CRC is enabled). The result of the CRC or LRC check is updated in the RX_STATUS register after the complete message block is received. See LRC and CRC for more LRC and CRC information.

69.3.3.4 NACK detection

During transmission of message bytes, the receiver automatically checks for NACKs sent by the smart card. The software does not need to enable the receiver for this purpose.

The NACK is detected by sampling the IO line at 11 ETUs after the falling edge of the start bit. After a NACK is detected, the transmitter is signaled. The transmitter then retransmits the current byte after two ETU intervals (as per ISO 7816 specification).

69.3.3.5 Using EMVSIM receiver with T = 1 smart cards

EMVSIM provides hardware support for T = 1 type smart cards. This type of card presents several requirements above and beyond the standard T = 0 cards. The features provided to meet the requirements that pertain to the EMVSIM receiver are:

Table 634. Receiver features and requirements

Feature	Description
11 ETU characters	T = 1 cards can transmit with character lengths of 11 ETUs (that is, one STOP bit). EMVSIM provides CTRL[RCVR_11] to configure the receiver state machine to accept 11 ETU characters.
Character wait time counter	The character waiting time (CWT) is defined as the time between the start bits of two consecutive characters received from the smart card. The value of CWT is from 12–32779 ETU. To identify when the smart card has exceeded CWT, EMVSIM provides a 16-bit counter with programmable comparator clocked at the ETU bit rate.

Table continues on the next page...

Table 634. Receiver features and requirements (continued)

Feature	Description
Block wait time	The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The block wait time must not exceed a value that you program. EMVSIM provides a 32-bit block wait timer that you can use to identify when the BWT has been exceeded.
Block guard time	The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The block guard must be greater than a value that you program. EMVSIM provides a 16-bit block guard timer that you can use to identify when the BGT has been exceeded.
Error detection code	T = 1 cards can specify LRC or CRC error detection codes to use. EMVSIM provides hardware support for both the LRC and CRC operations.

69.3.4 EMVSIM transmitter

The transmitter is responsible for:

- Reading the message bytes from the transmit FIFO
- Adding the LRC or CRC at the end of the message block
- Retransmitting any byte on reception of a NACK

It assists the receive operation by inserting NACKs when directed by the receiver.

The transmitter includes a 16-byte deep FIFO to store the bytes sent to the smart card. These bytes are sent to the smart card serially by the transmitter. The selected data format (inverse or direct conversion) is supported, and EMVSIM converts the byte into the correct data format before it is shifted out serially.

The transmitter also supports retransmission of the current byte on the reception of a NACK. The transmitter automatically inserts a NACK when the receiver indicates a parity or FIFO overflow error, if you have configured software to do so. The transmitter is not required to be enabled for this.

The transmitter also includes a timer to insert the programmable guard time between the transmitter bytes, and general purpose timers to allow software to perform certain measurements.

The status of the transmitter operation is provided to software via maskable interrupts.

69.3.4.1 Message transmission

The transmitter operation does not start until the transmit FIFO is empty. Software can configure EMVSIM and enable the transmitter, but no transmission starts until a byte has been written into the transmit FIFO. Writing zero to CTRL[XMT_EN] while the transmitter is in operation halts any transmission in progress, and flushes the transmit FIFO. See Transmit FIFO for more details.

The transmitter continuously transmits the messages from the transmit FIFO. Upon NACK detection, the transmitter resends the same byte until the transmitter NACK threshold limit is reached. When TX_STATUS[TNTE] = 1, then:

- EMVSIM halts the transmitter.
- All pending transfers are aborted.
- EMVSIM writes 1 to:
  - TX_STATUS[TCF]
  - TX_STATUS[ETCF]
  - TX_STATUS[TFE]
- All bytes remaining in the transmit FIFO are lost.

There is no way to restart the transmission on the next byte in the FIFO. The transmitter remains frozen until software writes 1 to TX_STATUS[TNTE]. The only way to clear TX_STATUS[TNTE] is to write a 1 to it.

It is possible to disable the detection of NACKs from the smart card by writing 0h to TX_THD[TNCK_THD]. By writing 1h to TNCK_THD, it is possible to disable all retransmissions while still setting TX_STATUS[TNTE] on the first NACK received. In general, TX_STATUS[TNTE] becomes 1 on the NACK that causes the threshold controlled by TX_THD[TNCK_THD] to be reached. This final NACK does not cause a retransmission, whereas all previous NACKs cause a retransmission.

If all bytes are successfully transmitted and the transmit FIFO is empty, then the transmitter sends the check byte (that is, LRC or CRC) if the XMT_CRC_LRC and CTRL[LRC_EN] or CTRL[CRC_EN] = 1. The transmitter sends each byte to the LRC or CRC block to allow check byte generation.

At the end of each byte, the transmitter inserts the programmed guard ETUs. See Transmit guard time for details.

69.3.4.2 NACK insertion

The transmitter is responsible for driving the output low during the STOP bit time to signify that an error was detected in the received data from the smart card. This logic responds to a NACK request generated by the receiver block.

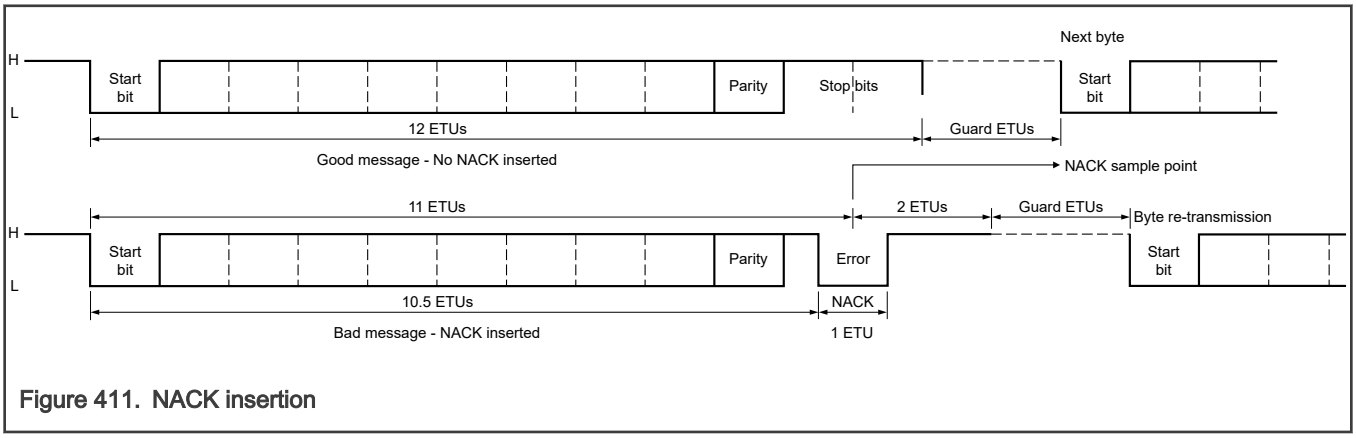

Figure 411. NACK insertion

The NACK generation logic is also responsible for keeping track of the number of NACKs received during a transmit operation. The receiver detects NACKs generated by the smart card, and then reports them to the transmit NACK logic. After the number of detected NACKs has reached the programmed threshold (TX_THD[TNCK_THD]), then:

- An interrupt flag (TX_STATUS[TNTE]) is generated.
- The transmit FIFO is flushed.
- The transmitter is disabled.

69.3.4.3 Using the EMVSIM transmitter with T = 1 smart cards

EMVSIM provides hardware support for T = 1 type smart cards. These type of cards present several requirements above and beyond the standard T = 0 cards. The features provided to meet the requirements that pertain to the EMVSIM transmitter are:

Table 635. Transmitter features and requirements

Feature	Description
11 ETU characters	The EMVSIM transmitter has a programmable guard time register that allows the programmer to specify the number of ETUs between character transmissions. Programming a value of 255 (FFh) in Transmitter Guard ETU Value (TX_GETU) sets the number of ETUs per character transmitted to 11.
Character waiting time	CWT is defined as the time between the start bits of two consecutive characters. The value of CWT within the range of 12–32779 ETU. The time between transmitted characters is controlled by the programmable guard time in Transmitter Guard ETU Value (TX_GETU). However, the time between

Table continues on the next page...

Table 635. Transmitter features and requirements (continued)

Feature	Description
	the last byte in the transmit FIFO and the next transmitted byte can be largely affected by software response time to the transmit interrupts. The EMVSIM transmitter provides a transmit FIFO threshold (TDTF) interrupt to signal the system when the expected number of characters has been transmitted from the transmit FIFO. The minimum CWT is achieved only if the software can respond to the TDTF interrupt and write new data to the transmit FIFO before the last character in the transmit FIFO has been sent.
Block waiting time	The block waiting time (BWT) is defined as the maximum time between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BWT is always greater than 1800 ETU. The EMVSIM transmitter provides two general purpose counters, either of which can be used to track the BWT. The BWT is purely determined by software response time to the transmit interrupts.
Block guard time	The block guard time (BGT) is defined as the minimum delay between the start bits of the last character of a transmitted block and the first character of the next received block. The value of BGT is 22 ETU. The EMVSIM module supports the BGT by providing the ability to generate an interrupt when the last byte is received, and transmitting within 2 ETU after XMT_EN = 1. The BGT is determined by the speed at which the software can react to an interrupt and enable the transmitter.
Error detection code	T = 1 cards can specify LRC or CRC error detection codes to be used. EMVSIM provides hardware support for both LRC and CRC operation.

69.3.5 LRC and CRC

EMVSIM also contains the 8-bit LRC block and 16-bit CRC block, which are common to the transmitter and receiver. Both the transmitter and the receiver can use the LRC and CRC blocks. They can insert the LRC or CRC into the byte stream or check the validity of the input stream using the LRC and CRC values received. Because transmit and receive operations are mutually exclusive, you can use LRC and CRC blocks that are shared by the transmitter and receiver.

69.3.5.1 LRC block

EMVSIM provides an 8-bit linear redundancy check (LRC) generator and checker. The block is provided for use with T = 1 smart cards that support LRC. This block can be enabled with CTRL[LRC_EN]. It performs an 8-bit exclusive-OR (XOR) on all received or transmitted characters.

At the end of the reception of a block of characters, the result is expected to be 00. If so, EMVSIM writes 1 to RX_STATUS[LRC_OK]. During transmission, the LRC block exclusive-ORs each character that is transmitted with the current value of the LRC. If CTRL[XMT_CRC_LRC] = 1, the transmitter automatically sends the LRC value as the final character when the transmit FIFO empties.

You can reset the LRC value in multiple ways:

- Writing 0 to CTRL[LRC_EN]
- Automatic reset by EMVSIM at the end of a transmission (either after the LRC byte is transmitted, or after the last character in the transmit FIFO is sent when CTRL[XMT_CRC_LRC] = 0)
- By EMVSIM when writing 1 to CTRL[XMT_EN]

Here is a summary of the configuration needed to use the LRC block:

- Write 1 to CTRL[LRC_EN] to enable the LRC block.
- Use CTRL[XMT_CRC_LRC] to enable the transmission of the LRC character after the last character in the transmit FIFO has been sent.

69.3.5.2 CRC block

EMVSIM provides a 16-bit cyclic redundancy check (CRC) generator and checker. This block is provided for use with T = 1 smart cards that support CRC. The block can be enabled with CTRL[CRC_EN]. This block performs a polynomial-based check on all received or transmitted characters. The polynomial used for calculating the CRC is $G(x) = x^{16} + x^{12} + x^5 + 1$. EMVSIM initializes the CRC register by writing all 1s to it before the data is shifted in. You can configure the CRC block to compute using the ISO 7816 CRC method or the 16-bit CCITT CRC method by selecting the following fields:

- CTRL[CRC_IN_FLIP]
- CTRL[CRC_OUT_FLIP]
- CTRL[INV_CRC_VAL]

To select the CCITT CRC method, write 1 to:

- CTRL[CRC_IN_FLIP]
- CTRL[CRC_OUT_FLIP]
- CTRL[INV_CRC_VAL]

To select the normal CRC (ISO 7816 CRC) method, write:

- 0 to CRC_IN_FLIP
- 0 to CRC_OUT_FLIP
- 1 to INV_CRC_VAL

During transmission, the CRC block updates the current value of the CRC, using each character. If CTRL[XMT_CRC_LRC] = 1, the CRC value is automatically formatted according to the selected CRC method (CCITT or normal). The transmitter then sends it as the final two characters when the transmit FIFO empties. At the end of the reception of a block of characters, the residual from the CRC calculation is compared and EMVSIM writes 1 to RX_STATUS[CRC_OK].

NOTE

Any other value of CRC_IN_FLIP, CRC_OUT_FLIP, and INV_CRC_VAL causes the CRC value to be formatted accordingly; however, the CRC is not compliant with the standard CRC used in smart cards.

You can change the CRC value in multiple ways:

- Writing 0 to CTRL[CRC_EN]
- Automatic reset by EMVSIM at the end of a transmission (either after the CRC characters are transmitted, or after the last character in the transmit FIFO is sent when CTRL[XMT_CRC_LRC] = 0)
- By EMVSIM when writing 1 to CTRL[XMT_EN]

Here is a summary of the configuration needed to use the CRC block:

- Write the correct values to CTRL[CRC_IN_FLIP], CTRL[CRC_OUT_FLIP], and CTRL[INV_CRC_VAL] to select the appropriate CRC method (CCITT or normal).
- Write 1 to CTRL[CRC_EN] to enable the CRC block.
- Write 1 to CTRL[XMT_CRC_LRC] to enable the transmission of the CRC characters after the last character in the transmit FIFO has been sent.

69.3.6 Message handling

EMVSIM has FIFOs on both the transmit side and the receive side for handling all message bytes.

69.3.6.1 Transmit FIFO

A 16-byte deep FIFO is implemented in the transmitter. The transmit FIFO can be written to by software, but an attempt to read it returns zeros. To manage clock synchronization, each write access has wait states inserted by EMVSIM, but this is transparent

to the software. You can write to the transmit FIFO when the transmitter is enabled; however, the transmitter does not start transmitting while the FIFO is empty. A write to the transmit FIFO initiates the transmit operation.

Software can store more bytes to the transmit FIFO until the programmed threshold is reached. You can enable DMA operation by writing 1 to CTRL[TX_DMA_EN]. EMVSIM asserts a DMA request that remains asserted until the number of bytes in the FIFO reaches the programmed threshold value (TX_THD[TDT[3:0]]).

The transmit FIFO can be flushed by writing 1 to CTRL[FLSH_TX]. A transmit NACK threshold error (TX_STATUS[TNTE]) halts the transmitter, and flushes the transmit FIFO. The flush operation resets the transmit read and write pointers to equal values. Everything in the transmitter block is reset by the transmit flush operation. This does not include the control registers associated with the transmitter. The transmit data threshold flag (TX_STATUS[TDTF]) is not cleared by the FLSH_TX operation.

69.3.6.2 Receive FIFO

A 16-byte deep FIFO is implemented in the receiver. Because more than 16 bytes can be received in the FIFO, you must configure the software to ensure that it regularly reads the receive FIFO. You can read the receive FIFO by software via normal CPU accesses on interrupt (INT_MASK[RX_DATA_IM]) or via DMA by writing 1 to CTRL[RX_DMA_EN]. Software cannot write to this register. A write access may terminate in a transfer error.

The receiver loads the receive FIFO when it receives an error-free message byte with correct parity. The FIFO stores the message byte only. When the number of total bytes in the receive FIFO equals the programmed threshold value (RX_THD[RDT[3:0]]), EMVSIM writes 1 to RX_STATUS[RDTF]. An interrupt is asserted if INT_MASK[RDT_IM] = 0. If DMA access to RX_FIFO is enabled, then the DMA request to read the receive FIFO is asserted when the threshold flag is set and clears when all the bytes are read out from the receive FIFO.

The receive FIFO can be flushed by writing 1 to CTRL[FLSH_RX]. The flush operation resets the receiver except for the receiver control registers.

NOTE

Because the registers and the receiver logic are in different clock domains, you must configure the software to allow clock synchronization time when sampling RX_STATUS[RDTF]. One proposed method is:

- Read one byte at a time (from the receive FIFO) when RX_STATUS[RDTF] = 1.
- Allow a time of 3 bus clock cycles after the receive FIFO read.
- Check the status of RX_STATUS[RDTF].
- Repeat as necessary.

Alternatively, you could set the receiver threshold to be one more than is actually needed.

Receive FIFO Overflow Detection: When a byte is received, and the receive FIFO:

- Has not been read
- Already contains 16 bytes

then EMVSIM asserts a FIFO overflow error (EMVSIM writes 1 to RX_STATUS[RFO]). The received byte is discarded, leaving the FIFO with the first 16 bytes received.

If CTRL[ONACK] = 1, the transmitter generates a NACK for the overflow condition every time it receives a new byte that cannot be stored in the receive FIFO. EMVSIM continually sends NACKs until the receive FIFO is read or the NACK transmit threshold is reached.

69.3.7 Protocol timers

EMVSIM has several 16-bit and 32-bit timers that allow the software to perform protocol timing checks and measurements, such as:

- Transmit guard time
- Character wait time
- Block wait time

- Block guard time
- Work wait time

In addition to these timers, EMVSIM also contains two 32-bit general purpose counters that software can use for any specific time measurement application.

69.3.7.1 Transmit guard time

The transmit guard time is the number of ETUs inserted by the transmitter between each character that it transmits. You control the number of ETUs by programming Transmitter Guard ETU Value (TX_GETU). The guard time is measured as the time (in ETUs) between the STOP bits of the previous character and the start bit of the next character.

For a guard time programmed as FFh in TX_GETU[GETU], the transmitter inserts one STOP bit instead of two.

69.3.7.2 Character wait time

The EMVSIM receiver block includes a 16-bit counter that counts the number of bit times (ETUs) between received characters (that is, the time between start bits in consecutive characters that are received). When enabled, the CWT counter does not start counting until after the start bit(s) of a valid character have been received.

The counter is synchronized to the receive character bit positions so that an accurate count of the number of ETUs between characters can be made. The CWT has a 16-bit programmable comparator. Software can write the expected number of ETUs between characters to the comparator. If the time between characters exceeds this value, an interrupt flag is set and an interrupt is generated if the mask = 0.

You can configure the CWT like this:

- Program Character Wait Time Value (CWT_VAL) to the value that needs to be enforced.
- Activate the CWT function by writing 1 to CTRL[CWT_EN].
- Enable the CWT_ERR interrupt by writing 0 to INT_MASK[CWT_ERR_IM].
- If an interrupt occurs, then the software must read Receive Status (RX_STATUS) to determine if the error was caused by a CWT_ERR violation. The software must clear the CWT_ERR interrupt by writing 1 to RX_STATUS[CWT_ERR].
- Software can disable the CWT counter by writing 0 to CTRL[CWT_EN] at any time.

69.3.7.3 Block wait time and block guard time

A 32-bit timer is used to measure both block wait time (BWT) and block guard time (BGT). The BWT and BGT timer is used to measure the delay between:

- The leading edge of the last character of the block received by the card
- The leading edge of the first character of the next block sent by the card

If the time that has been measured is larger than the value in Block Wait Time Value (BWT_VAL), then INT_MASK[BWT_ERR_IM] automatically transitions to 1 and an interrupt is generated. If the time is less than the value in Block Guard Time Value (BGT_VAL), then INT_MASK[BGT_ERR_IM] automatically transitions to 1 and an interrupt is generated.

The block wait timer can be configured as follows:

- Program the BWT_VAL and BGT_VAL registers to the values that need to be enforced.
- Activate the block wait timer by writing 1 to CTRL[BWT_EN].
- Enable the BWT_ERR and BGT_ERR interrupts by writing 0 to INT_MASK[BWT_ERR_IM] and INT_MASK[BGT_ERR_IM].
- If an interrupt occurs, then the software must read the RX_STATUS register to determine if the error was caused by a BWT_ERR violation or by a BGT_ERR violation. The software should clear the interrupt status field by writing a 1 to either RX_STATUS[BWT_ERR] or RX_STATUS[BGT_ERR] respectively.
- Software can disable the BWT counter by writing 0 to CTRL[BWT_EN] at any time.

NOTE

BWT should be enabled after all bytes have been written to the transmit FIFO. This is necessary to avoid the condition where writes to the transmit FIFO are very slow (more than 1 ETU time apart) and if BWT is enabled earlier, then a BWT error might trigger falsely.

69.3.7.4 Work wait time

There is no separate counter to measure the work wait time (WWT). Work wait time is a combination of BWT and CWT. To measure WWT, software must configure both Character Wait Time Value (CWT_VAL) and Block Wait Time Value (BWT_VAL) to the value to be enforced. When measuring WWT the BGT timer is not used, so it should be masked (inactive) by INT_MASK[BGT_ERR_IM].

Here is the sequence to program EMVSIM to send and receive data while checking WWT:

- Program both the CWT_VAL and the BWT_VAL registers to the WWT (work wait time) value that needs to be enforced. Write 0 to Block Guard Time Value (BGT_VAL) (this is the default value).
- Activate both the CWT and BWT functions by writing 1 to CTRL[CWT_EN] and to CTRL[BWT_EN].
- Enable the CWT_ERR and BWT_ERR interrupts by writing 0 to INT_MASK[CWT_ERR_IM]] and INT_MASK_IM[BWT_ERR_IM].
- Program EMVSIM to enable either the receiver or the transmitter, depending on the application.
- If an interrupt occurs, then the software should consider it a WWT violation if any of these fields are asserted:
  - RX_STATUS[CWT_ERR]
  - INT_MASK[CWT_ERR_IM]
  - RX_STATUS[BWT_ERR]

  Program the software to clear the CWT_ERR or BWT_ERR interrupt by writing a 1 either to RX_STATUS[BWT_ERR] or to RX_STATUS[CWT_ERR].

69.3.7.5 General purpose counters

EMVSIM provides two 16-bit counters that it uses when timing events during smart card communication. The clock source for the counter is selectable between three sources:

- Card clock
- Receiver clock (16 times the ETU clock)
- ETU clock (for the transmitter)

Select the clock input with CLKCFG[GPCNT0_CLK_SEL] and CLKCFG[GPCNT1_CLK_SEL]. The counter is enabled as soon as you select the input clock. The counter starts immediately after the input clock begins running. You can use software to control the three input clock sources by using:

- PCSR[SCEN]
- CTRL[RCV_EN]
- CTRL[XMT_EN]

To run the counters from the card clock source, the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0
- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- PCSR[SCEN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 01

The counter begins to count at the card clock rate as soon as these conditions are met.

To run the counters from the receive clock source, the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0
- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 10

The counter begins to count at the receive clock rate as soon as these conditions are met.

To run the counters from the ETU (transmit) clock source the following conditions must be met:

- CTRL[KILL_CLOCKS] = 0
- CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1
- CLKCFG[GPCNT0/1_CLK_SEL] = 11

The counter begins to count at the ETU clock rate as soon as these conditions are met.

You can reset the counters by writing 00 to GPCNT0/1_CLK_SEL. A 16-bit comparator value (GPCNT0/1_VAL register) allows the software to select a count value. When that count value is reached, then you can set the interrupt flags (TX_STATUS[KGPCNT0_TO] and TX_STATUS[KGPCNT1_TO]). An interrupt is generated if the mask (INT_MASK[GPCNT0_IM] or INT_MASK[GPCNT1_IM]) = 0.

Use the following sequence to configure both general purpose timers:

1. Program the counter comparator using the GPCNT0/1_VAL register.
2. Enable the conditions described above using the CTRL register.
3. Select a clock source for the general purpose counter using the CLKCFG register.
4. Enable interrupts in the INT_MASK register.

69.3.8 Answer-to-reset (ATR) detection

The first communication that occurs between the smart card and EMVSIM is a block of data that the smart card sends to EMVSIM. This communication happens after the card is powered up and the card reset is removed (see Smart card interface and control). This block of data is called the answer-to-reset (ATR). To receive the ATR, you must configure EMVSIM for 12 ETU character reception. According to the ISO 7816-3 spec, both T = 0 and T = 1 cards communicate initially using 12 ETU character durations.

For more information about ATR detect configuration, see the Configuration for ATR detect section.

69.3.9 Clocks

The key functional blocks in EMVSIM that control the interactions with the smart card are:

- Clocking
- Transmitter
- Receiver

These blocks function on a clock that is different from, and asynchronous to, the register read/write clock. In order for the transmitter and receiver to function properly, the respective configuration must be complete before you enable the transmitter or receiver.

The clocking module generates the following clocks:

- Card clock (output to smart card)
  - The prescaler (CLKCFG[CLK_PRSC]) generates the card clock in the range of 1–5 MHz with near 50% duty cycle.
- Internal clocks for the transmitter and receiver (internal clocks control the ETU period and the sampling and driving of data on the IO line)
  - The receive operation uses an internal oversampled clock that oversamples the received input at 16 times the ETU rate.

— The baud divider (Baud Rate Divisor (DIVISOR)) generates the internal ETU clocks for transmitter and receiver.

69.3.10 Modes

EMVSIM has two modes of operation:

- Stop mode: All EMVSIM clocks shut down in Stop mode except the smart card clock. It is still active when CTRL[STOP_EN] = 1.
- Doze mode: If CTRL[DOZE_EN] = 1, all EMVSIM clocks shut down when the transmit FIFO is empty. Otherwise, a Doze instruction has no effect on EMVSIM.

69.3.11 Reset

CTRL[SW_RST] is used to reset the entire EMVSIM module. The result is the same as a hardware reset. There is also PCSR[SRST], which is used to control the state of the reset line to the smart card. It can be forced low by hardware during the auto power-down sequence.

69.3.12 Interrupts

EMVSIM has one interrupt output. It is generated by any of the following conditions:

- Parity error flag
- Block guard time error flag
- Block wait time error flag
- Received NACK threshold error flag
- Character wait time error flag
- Receive data threshold interrupt flag
- Receive data interrupt flag
- Receive FIFO overflow flag
- General purpose counter 1 timeout flag
- General purpose counter 0 timeout flag
- Transmit data threshold flag
- Transmit FIFO full flag
- Transmit complete flag
- Early transmit complete flag
- Transmit FIFO empty flag
- Transmit NACK threshold error flag

69.3.13 DMA

The EMVSIM DMA supports transferring data from and to FIFOs.

Software can enable DMA operation by writing 1 to CTRL[TX_DMA_EN]. When this field = 1, EMVSIM asserts a DMA request that remains asserted until the number of bytes in the FIFO reaches the programmed threshold value (TX_THD[TDT]).

EMVSIM enables DMA read access when CTRL[RX_DMA_EN] = 1. When this field = 1, EMVSIM asserts a DMA request to read the Rx FIFO when the threshold flag (TX_STATUS[TDTF]) = 1. EMVSIM writes 0 to TX_STATUS[TDTF] when all the bytes have been read from the Rx FIFO.

69.4 External signals

EMVSIM interfaces to the external card (smart card) through:

- Card clock
- Card reset
- Card V_{CC} enable
- I/O pins

The transmitter output from the module, and the receiver input to the module, are connected to the same I/O pin and are used in open-drain configuration.

NOTE

You must connect a pullup resistor to the I/O pin on board to allow proper functioning.

The following table shows the user-accessible signals available on EMVSIM. See the chip-level specification to find out which signals are connected to the external pins.

Table 636. External signals

Signal	Description	I/O
CLK	Card clock—clock to smart card	O
RST	Card reset—reset signal to smart card	O
SVEN	Card power enable—Controls power to smart card	O
IO	Card data line—Bidirectional data line	I/O
PD	Card presence detect—Indicates presence or removal of card	I

69.5 Initialization

The first thing to do is to configure the interface signals, allowing transmit or receive operation to begin. The following steps describe a typical way to enable the smart card:

1. Configure the prescaler by programming the selected value in CLKCFG[CLK_PRSC] to generate the card clock. The card clock frequency is calculated as f_{SIM} / (CLKCFG[CLK_PRSC]) (where f_{SIM} is the EMVSIM clock frequency).

   You must set the prescaler value so that the maximum card clock frequency specifications, as stated in EMV and ISO-7816 specifications, are not exceeded.
2. Configure DIVISOR[DIVISOR_VALUE]. This value determines the ETU period that the transmitter or receiver uses.
3. Enable power to the smart card by writing 1 to PCSR[SVCC_EN].
4. Enable the smart card clock by writing 1 to PCSR[SCEN].
5. Release the smart card reset by writing 1 to PCSR[SRST].
6. Program the power-down functionality, that is, whether auto power-down of the smart card is required or not.
7. There are two ways to select the data format type for EMVSIM. Use only one of them.
   - Select the data format (inverse or direct) by writing the appropriate value to CTRL[IC].
   - Write 1 to CTRL[ICM] to allow automatic detection of the initial character. EMVSIM updates CTRL[IC] to the selected data format when a valid initial character has been detected.
8. Configure EMVSIM to run in Stop mode by writing 1 to CTRL[STOP_EN], and in Doze mode by writing 1 to CTRL[DOZE_EN], as needed.
9. Enable DMA request generation for the transmitter or receiver as appropriate.

After the configuration is complete, you can configure the receiver or transmitter, depending on the operation to be carried out on the smart card.

NOTE

You must not change CTRL[XMT_EN] and CTRL[RCV_EN] in the same write cycle. Software should attempt separate write accesses to the CTRL register for updating these fields, one by one. For example, if XMT_EN = 1 and RCV_EN = 0, then enable the receiver like this: the first write to the CTRL register should make XMT_EN = 0, and the second write to the CTRL register should make RCV_EN = 1.

The transmit and receive operations are mutually exclusive. You must not enable them together.

69.5.1 Configuring the receiver

Here is a list of configurations that you need to perform (after Initialization) in order to configure the EMVSIM receiver for operation:

1. Enable NACK generation capability.
   - To generate NACK on parity errors and invalid initial characters, write 1 to CTRL[ANACK].
   - To generate NACK on receiver FIFO overflow error, write 1 to CTRL[ONACK].
2. Configure thresholds.
   - Configure the threshold for NACK generation by writing the appropriate value to RX_THD[RNCK_THD].
   - Configure the threshold for data by writing the appropriate value to RX_THD[RDT].

   These are the thresholds at which the RTE and RDTF flags are set, respectively.
   - If auto power-down is needed on RTE flag assertion, then write 1 to PCSR[SAPD] to initiate the smart card power-down.
3. Configure the timeout values for the CWT Counter, the Block Wait Timer Counter, and the Block Guard Time Counter. [Identify topics to link to for reference.]
4. Enable necessary interrupts by writing 0 to the appropriate fields in Clock Configuration (CLKCFG).
5. Configure the general purpose counter as needed and select the correct clock source (CLKCFG[GPCNT0_CLK_SEL] or CLKCFG[GPCNT1_CLK_SEL]).
6. Enable the receiver by writing 1 to CTRL[RCV_EN].
7. The receiver enters Initial Character Detection mode if CTRL[ICM] = 1 or enters normal receive mode if CTRL[ICM] = 0.
8. Enable either LRC block or CRC block.

69.5.2 Configuring the transmitter

Here is a list of the configurations that you need to perform (after the Initialization step) in order to configure the EMVSIM transmitter for operation:

1. Select a retransmission threshold for NACKed characters in Transmitter Threshold (TX_THD). This is the threshold at which TX_STATUS[TNTE] is set by using TX_THD[TNCK_THD].
2. Configure the guard time between the transmitted characters by writing the appropriate value to TX_GETU[GETU].
3. Select the appropriate data threshold in TX_THD.
4. Enable necessary interrupts by writing 0 to the appropriate fields in Interrupt Mask (INT_MASK).
5. Configure the general purpose counter as needed and select the correct clock source (CLKCFG[GPCNT0_CLK_SEL] or CLKCFG[GPCNT1_CLK_SEL]).
6. Enable the transmitter by writing 1 to CTRL[XMT_EN].
7. Enable LRC and CRC as needed.[more detail]

8. Program bytes to be transmitted into the transmit FIFO. If DMA is enabled, then a DMA request is asserted automatically.

NOTE

You can write to the transmit FIFO after the transmitter is enabled (CTRL[XMT_EN] = 1). Writing to the transmit FIFO when the transmitter is disabled is not successful and write access is ignored.

69.6 Application information

69.6.1 Powering up

The first step in communicating with a smart card is to provide the card with power and a clock signal. After the card is detected as present (using the presence detect features, or by some other method), you should power up the smart card according to the power-up sequence provided in the ISO 7816-3 specification.

1. Apply voltage to the smart card by writing 1 to PCSR[SVCC_EN].
2. Select the appropriate clock frequency for the smart card by programming Clock Configuration (CLKCFG) and Baud Rate Divisor (DIVISOR).
3. Enable the clock to the smart card by writing 1 to PCSR[SCEN].
4. The card exits reset state by writing 1 to PCSR[SRST].

69.6.2 Automatic power-down

Smart cards require a proper sequence of operations to power down. The power-down sequence as per ISO 7816 specifications is:

1. Smart card reset (RST) pin transitions from high to low.
2. Smart card clock (CLK) is turned off to low.
3. Smart card IO (IO) is transitioned from high impedance to low.
4. Smart card voltage enable (SVCC_EN) is turned off (pin driven low).

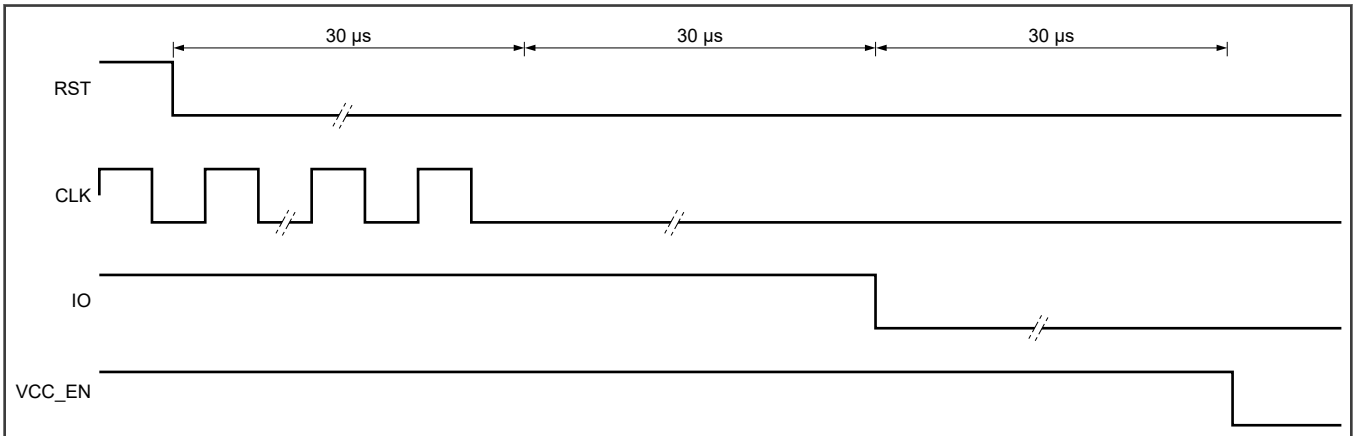

Figure 412. Auto power-down sequence

These operations can be done manually by software which writes to the appropriate fields (PCSR[SCEN], PCSR[SRST], and PCSR[SVCC_EN]), or automatically by hardware under the following conditions:

- You write 1 to PCSR[SPD]
- Assertion of RX_STATUS[RTE]
- Assertion of PCSR[SPDIF] when configured to detect card removal

NOTE

PCSR[SPDES] determines which edge transition of the smart card presence detect pin (PD) is used for smart card presence detection. Presence detection can be used to determine if the card has been inserted or removed. The occurrence of the edge specified by PCSR[SPDES] causes EMVSIM to do the following:

- PCSR[SPDIF] automatically transitions to 1
- If PCSR[SPDIM] = 0, generate an interrupt to the CPU
- If PCSR[SAPD] = 1, begin an auto power-down sequence

If smart card insertion is expected, you can write 0 to PCSR[SAPD] low to avoid the auto power-down sequence from falsely triggering. You can use PCSR[SPDP] to determine the current state of the smart card presence detect pin.

The auto power-down operation requires a low-frequency clock (usually a 32 kHz clock source) to be active on the device.

The auto power-down sequence writes 0 to the following fields upon power-down sequence completion:

1. PCSR[SPD]
2. PCSR[SCEN]
3. PCSR[SRST]
4. PCSR[SVCC_EN]
5. CTRL[XMT_EN] and CTRL[RCV_EN]

69.6.3 Configuration for ATR detect

The following steps provide a suggested approach for configuring EMVSIM to receive the ATR.

1. Write 0 to CTRL[RCVR_11].
2. Write 1 to CTRL[ANACK] to enable NACK generation. The ISO 7816-3 spec allows the EMVSIM module to NACK any communication errors that occur during the initial communication at 12 ETU.

   NOTE

   The Europay MasterCard and VISA (EMV) cards are similar to T = 1, but do not allow EMVSIM to NACK during the initial communication.

3. Enable RDTF and RFO interrupts by writing 0 to INT_MASK[RDT_IM] and INT_MASK[RFO_IM]. These interrupts are enabled to notify the software when characters are received. You can set a threshold for the number of characters to receive before generating an interrupt.
4. Set the desired threshold for received characters by writing RX_THD[RDT].

You must set up EMVSIM to perform in initial character mode during ATR detection. This causes the hardware to identify the first valid character sent during the ATR as an initial character. This character automatically configures the hardware for the data convention used by the smart card.

Set Initial Character mode by writing 1 to CTRL[ICM].

The ISO 7816-3 spec requires that smart cards meet certain timing restrictions. One of these is the time from the deassertion of the card reset to the beginning of the ATR sequence. The general purpose counter of EMVSIM can be used to verify that the smart card begins its ATR within the 400–40,000 card clock cycle range.

1. Write the general purpose counter timeout value with 9C40h by programming General Purpose Counter 0 Timeout Value (GPCNT0_VAL) and General Purpose Counter 0 Timeout Value (GPCNT0_VAL).
2. Enable the general purpose counter interrupt by writing 0 to INT_MASK[GPCNT0_IM] and INT_MASK[GPCNT1_IM].
3. Enable the general purpose counter by writing 01 to CLKCFG[GPCNT0_CLK_SEL] and to CLKCFG[GPCNT1_CLK_SEL] so that the card clock is used for counting.

The ISO 7816-3 spec states that the maximum allowed time between two characters during the ATR is 9600 ETUs (initial waiting time). You must set up the CWT counter to detect any errors for this condition.

1. Set the CWT counter comparator to 9600 using Character Wait Time Value (CWT_VAL).
2. Enable the CWT counter interrupt by writing 0 to INT_MASK[CWT_ERR_IM].
3. Enable the CWT counter by writing 1 to CTRL[CWT_EN].

The last step in preparing for ATR reception is to enable the receiver.

Write 1 to CTRL[RCV_EN].

EMVSIM generates interrupts after a threshold number of characters is received. The software must react to these interrupts and read the characters from the receive FIFO (RX_BUF) until the complete ATR has been received. If a general purpose counter interrupt occurs before the final ATR character is received, then the card should be deactivated according to the ISO 7816-3 spec (see Smart card interface and control). Otherwise, when a valid ATR is received, the software determines from the ATR information what are the specific characteristics for this card (see the ISO 7816-3 spec for details).

69.6.3.1 Programming considerations for T = 0 smart cards

For type T = 0 cards, you must program the software to adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values in Baud Rate Divisor (DIVISOR) based on the values of 'F' and 'D' received in the ATR.
- Adjust the guard time between characters by changing the value of TX_GETU[GETU].
- Adjust NACK capability by modifying the values of CTRL[ONACK] and CTRL[ANACK].
- Adjust the stop clock polarity by modifying the value of PCSR[SCSP].
- Adjust the level of transmit NACK retransmissions allowed by modifying the value of TX_THD[TNCK_THD].
- Adjust the level for the receive NACK threshold by modifying RX_THD[RNCK_THD].

If a negotiation with the smart card is needed, the software sends a PPS response to the smart card. To send the response, the following steps should be performed:

- Set the transmit FIFO threshold level by writing to TX_THD[TDT].
- Clear all transmit interrupt flags in Transmitter Status (TX_STATUS) by writing 1 to every bit in the register.
- Enable the transmit interrupts by writing 0 to the mask fields in Interrupt Mask (INT_MASK). If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the smart card.
- Enable the transmitter by writing 1 to CTRL[XMT_EN].
- Write the characters to be sent as response (maximum of 16) to the transmit FIFO using Transmit Data Buffer (TX_BUF).

At this point, EMVSIM transmits the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt is set when the number of characters remaining in the FIFO equals the threshold. The software can then write an additional number of characters to be sent without interrupting transmission to the smart card.

After the transmission is complete, EMVSIM should be completely configured for standard operation with the T = 0 smart card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

69.6.3.2 Programming considerations for T = 1 smart cards

For type T = 1 cards, you must program the software to adjust the following parameters according to the information in the ATR:

- Adjust the baud rate by changing the values in Baud Rate Divisor (DIVISOR) based on the values of 'F' and 'D' received in the ATR.
- Adjust the guard time between characters by changing the value of TX_GETU[GETU]. Writing FFh to TX_GETU[GETU] configures the SIM transmitter for 11 ETU transmissions.

- Disable NACK capability by writing 0 to CTRL[ONACK] and CTRL[ANACK]. T = 1 cards do not allow NACKs.
- Adjust the stop clock polarity by modifying the value of PCSR[SCSP].
- Set the character wait time counter timeout value to the value specified in the ATR by using Character Wait Time Value (CWT_VAL).
- Enable the character wait time counter interrupt by writing 0 to INT_MASK[CWT_ERR_IM].
- Enable the character wait time counter by writing 1 to CTRL[CWT_EN].
- Enable CRC or LRC error checking according to the ATR information by writing 1 to either CTRL[CRC_EN] or CTRL[LRC_EN]. These fields must never be equal to 1 at the same time.

For T = 1 cards, the ATR is sent using a T = 0 type of structure (12 ETU, no LRC or CRC). If a negotiation with the smart card is needed, the software sends a PPS response to the smart card. Otherwise, the protocol is initiated with a block transfer from EMVSIM. In order to send the response or the first block, the following steps must be performed:

- Set the transmit FIFO threshold level by writing to TX_THD[TDT].
- Clear all transmit interrupt flags in Transmitter Status (TX_STATUS) by writing 1 to every bit in the register.
- Enable the transmit interrupts by writing 0 to the mask bits in Interrupt Mask (INT_MASK). If more than 16 characters are to be sent, it is suggested that the TDTF interrupt be used to signify when to write more characters to the transmit FIFO. This results in the most efficient transfer times to the smart card.
- Enable the transmission of the error checking characters (LRC or CRC) by writing 1 to CTRL[XMT_CRC_LRC].

NOTE

If the card supports PPS, the software may not be allowed to send the LRC/CRC information until the PPS exchange is complete. If so, do not write 1 to CTRL[XMT_CRC_LRC] during the PPS exchange.

- Enable the transmitter by writing 1 to CTRL[XMT_EN].
- Write the characters to be sent as response (maximum of 16) to the transmit FIFO using Transmit Data Buffer (TX_BUF).

At this point, EMVSIM transmits the characters in the transmit FIFO. If more than 16 characters are to be sent, the transmit threshold interrupt is enabled when the number of characters remaining in the FIFO equals the threshold. The software can then write an additional number of characters to be sent without interrupting transmission to the smart card.

After the transmission is complete, EMVSIM should be completely configured for standard operation with the T = 1 smart card. The software can continue to service RDTF interrupts for received characters, and TDTF interrupts for transmitted characters.

69.7 Memory map and registers

69.7.1 EMVSIM register descriptions

EMVSIM memory consists of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. A write access to reserved locations generates a transfer error. A read access to reserved locations also generates a transfer error, and the read data bus shows all zeroes. The module does not check for the correctness of programmed values in the registers—therefore, software must ensure that correct values are written.

7-0 RX_FIFO_DEPTH	Receive FIFO Depth Contains value of parameter for receive FIFO depth in bytes.

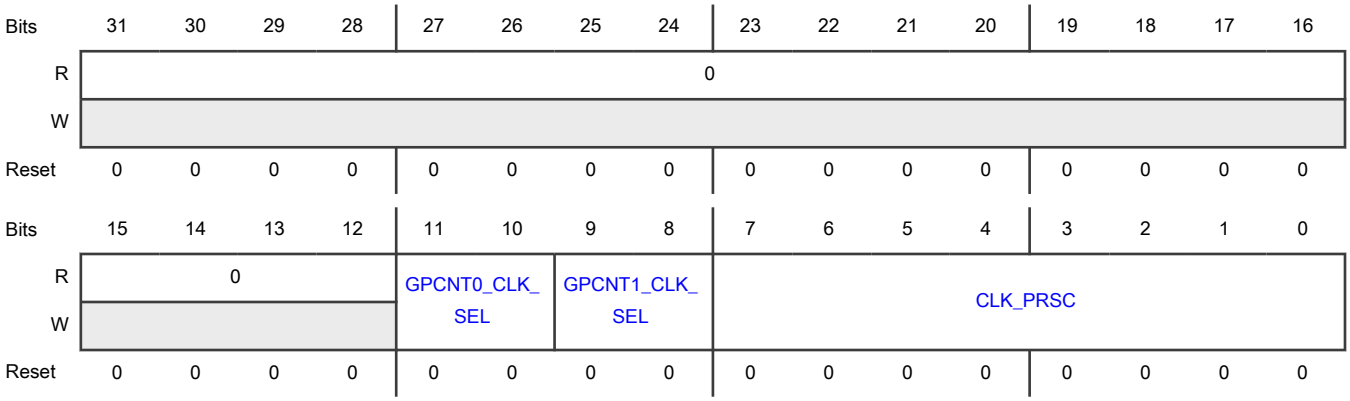
69.7.1.4 Clock Configuration (CLKCFG)

Offset

Register	Offset
CLKCFG	8h

Function
Provides configuration details to enable the correct clock frequency of EMVSIM clocks.

Diagram



Fields

Field	Function
31-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-10 GPCNT0_CLK_SEL	General Purpose Counter 0 Clock Select Selects which clock source is used by EMVSIM general purpose counter 0. The only way to reset the counter is to write 0 to this field. The counter begins counting as soon as the clock input is selected and the clocks are active. These input clocks are enabled through other EMVSIM fields (CTRL[KILL_CLOCKS], CTRL[RCV_EN], and CTRL[XMT_EN]). The counter is active if CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1. 00b - Disable/reset 01b - Card clock 10b - Receive clock 11b - ETU clock (transmit clock)
9-8 GPCNT1_CLK_SEL	General Purpose Counter 1 Clock Select Selects which clock source is used by EMVSIM general purpose counter 1. The only way to reset the counter is to write 0 to this field. The counter begins counting as soon as the clock input is selected and the clocks are active. These input clocks are enabled through other EMVSIM fields (CTRL[KILL_CLOCKS], CTRL[RCV_EN], and CTRL[XMT_EN]). The counter is active if CTRL[RCV_EN] = 1 or CTRL[XMT_EN] = 1. 00b - Disable/reset 01b - Card clock 10b - Receive clock 11b - ETU clock (transmit clock)
7-0 CLK_PRSC	Clock Prescaler Value Contains the prescaler value that you can use to select the card clock frequency. The card clock frequency is the EMVSIM protocol (or logic) clock divided by this prescaler value. Update the prescaler value only when card clock is disabled and the transmitter and receiver are not operational. When this field = 0 or 1, EMVSIM uses the maximum prescaler value (FFh). For all other values of this field, the prescaler value is the value of this field.

69.7.1.5 Baud Rate Divisor (DIVISOR)

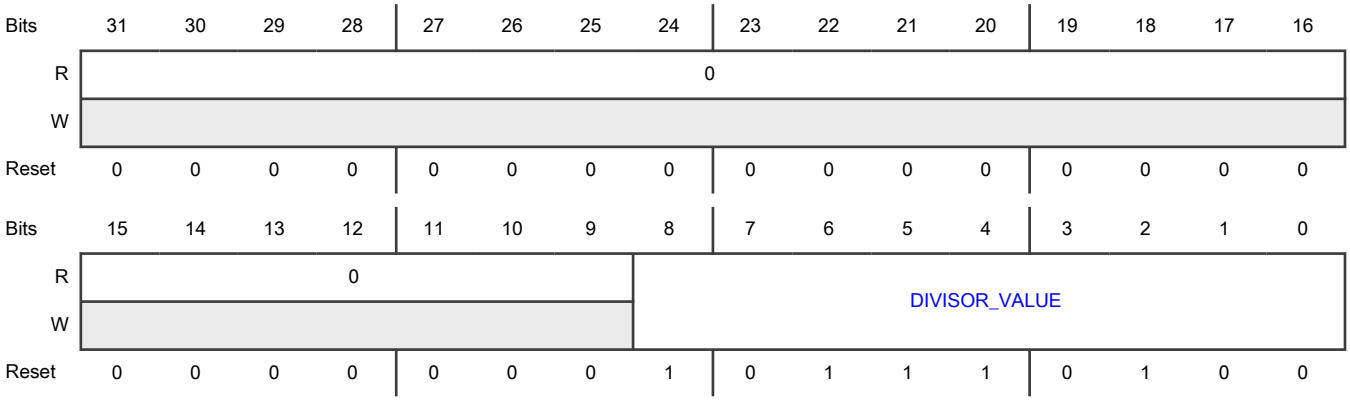
Offset

Register	Offset
DIVISOR	Ch

Function

Configures the divisor value to generate the baud-rate clock. The baud-rate clock drives the card clock and also generates the transmit and receive clocks and their respective ETUs.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 DIVISOR_VALUE	Divisor (F/D) Value Contains the divisor value. The value written to this register is used to generate the ETU bit period that is used by the transmitter and receiver. The divisor value is the integer result of the F/D value. 1 ETU = F / D x 1 / f • The ETU is the elementary time unit, the nominal time to transmit a bit (0 or 1). • F is the clock rate conversion integer. • D is the baud rate adjustment integer. • f is the frequency of the communication clock used between the controller and the smart card. You can change the value in this register when there is no active transaction with the smart card. When you program this field, the fractional part of F/D must be rounded off to the nearest integer. 0_0000_0000b-0_0000_0100b - Invalid. As per ISO 7816 specification, the minimum value of F/D is 5. 0_0000_0101b-0_1111_1111b - Divisor value F/D. For example, 101110100b = the divisor value for F = 372 and D = 1.

69.7.1.6 Control (CTRL)

Offset

Register	Offset
CTRL	10h

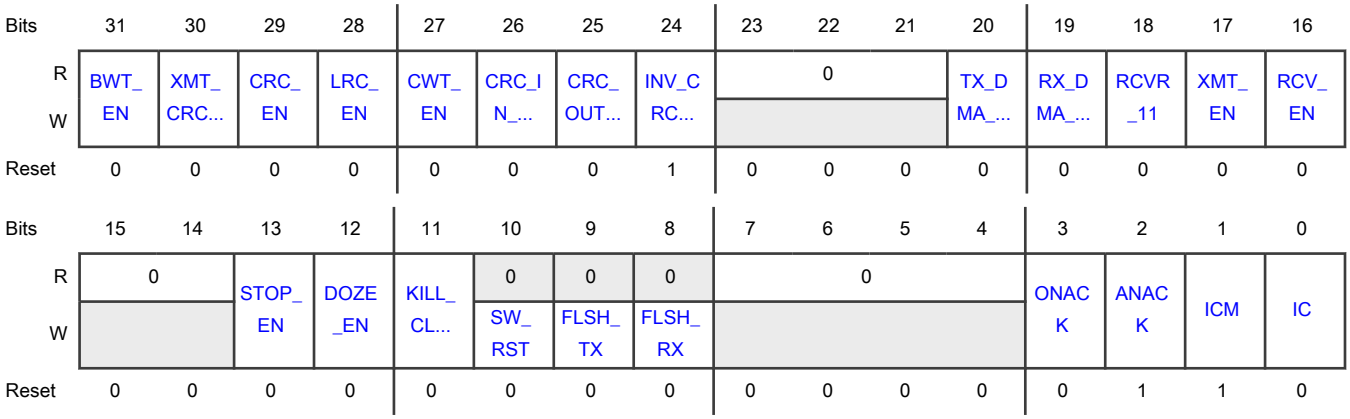
Function

Provides EMVSIM configuration details.

NOTE

You must not change XMT_EN and RCV_EN fields in the same write cycle. Program the software to write separate accesses to them, performing each update one at a time.

Diagram



Fields

Field	Function
31 BWT_EN	Block Wait Time Counter Enable Enables the BWT and BGT functions. You can then individually select the BWT and BGT functions using the interrupt mask. 0b - Disable 1b - Enable
30 XMT_CRC_LRC	Transmit CRC or LRC Enable Specifies whether to transmit the redundancy checking data (LRC or CRC) at the end of a transmission (that is, when the FIFO becomes empty). 0b - Do not transmit 1b - Transmit
29 CRC_EN	CRC Enable Enables 16-bit cyclic redundancy checking, using calculation of the 16-bit CRC value for both receiver and transmitter. The result of the calculation is continuously compared to the expected remainder and is reflected in RX_STATUS[CRC_OK]. Writing 0 to this field resets the current CRC residual value in the EMVSIM hardware. 0b - Disable 1b - Enable
28 LRC_EN	LRC Enable Enables 8-bit linear redundancy checking, using calculation of the 8-bit LRC value for both receiver and transmitter. The result of the calculation is continuously compared to zero and is reflected in RX_STATUS[LRC_OK]. Writing 0 to this field resets the current LRC value in the EMVSIM hardware.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
27 CWT_EN	CWT Counter Enable Enables the character wait time counter. Writing 0 to this field resets the counter to zero. 0b - Disable 1b - Enable
26 CRC_IN_FLIP	CRC Input Byte's Bit Reversal Or Flip Control Controls whether the bits in the CRC input byte are reversed before CRC calculation. When this field = 1, the bits within the input byte for CRC are reversed from 7:0 to 0:7. When this field = 0, then the bits in the input byte are not reversed (that is, 7:0 remains 7:0). For CCITT CRC calculation, this field must = 1. For any other CRC using the same polynomial, write to this field accordingly. 0b - Not reversed 1b - Reversed
25 CRC_OUT_FLIP	CRC Output Value Bit Reversal Or Flip Control Controls whether the bits in the CRC output bytes are reversed. When this field = 1, the bits in the two bytes used for CRC output change from 15:0 to {8:15,0:7}. When this field = 0, then the bits in the output bytes are not reversed. For CCITT CRC calculation, this field must = 1. For any other CRC using the same polynomial, write to this field accordingly. 0b - Not reversed 1b - Reversed
24 INV_CRC_VAL	Invert CRC Output Value Bits Controls whether the bits within the CRC Output value are inverted (1's complement). For CCITT CRC calculation, you must write 1 to this field. For any other CRC using the same polynomial, write to this field accordingly. 0b - Not inverted 1b - Inverted
23-21 —	Reserved
20 TX_DMA_EN	Transmit DMA Enable Enables assertion of a DMA write request when the transmit FIFO is empty. The request is held asserted until the transmit FIFO reaches the programmed data threshold value. A transmit data threshold interrupt is not generated when this field is asserted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not asserted 1b - Asserted
19 RX_DMA_EN	Receive DMA Enable Enables assertion of a DMA read request when the receive FIFO reaches the programmed data threshold value. The request is held asserted until all the programmed threshold bytes are read out. A receiver data interrupt is not generated when this field is asserted. 0b - Not asserted 1b - Asserted
18 RCVR_11	Receiver 11 ETU Mode Enable Configures the EMVSIM receiver for 11 ETU operation (that is, 1 stop bit). This field is provided for support of T = 1 cards. If this field = 0, the receiver is configured for 12 ETU operation mode. If this field = 1, the receiver is configured for 11 ETU operation mode. 0b - 12 ETU operation 1b - 11 ETU operation
17 XMT_EN	Transmitter Enable Enables the EMVSIM transmitter block. You can set it to 0 during the auto–power-down sequence. **Note:** Writing 1 to this field resets the CRC and LRC values. 0b - Disable 1b - Enable
16 RCV_EN	Receiver Enable Enables the EMVSIM receiver block. After the transmitter has completed its operation, you must use this field to enable the receiver. You can write 0 to it during the auto–power-down sequence. 0b - Disable 1b - Enable
15-14 —	Reserved
13 STOP_EN	STOP Enable Configures the operation of EMVSIM when a processor Stop instruction is executed. This field provides support for smart cards that do not allow the smart card clock to be stopped while power is applied. If this field = 0, a Stop instruction shuts down all EMVSIM clocks. If this field = 1, a Stop instruction shuts down all clocks except the smart card clock. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 DOZE_EN	Doze Enable Configures the operation of EMVSIM when a processor Doze instruction is executed. If this field = 0, a Doze instruction gates all internal EMVSIM clocks as well as the smart card clock when the transmit FIFO is empty. If this field = 1, a Doze instruction has no effect on EMVSIM. 0b - Disable 1b - Enable
11 KILL_CLOCKS	Kill Internal Clocks Enables the clock input to EMVSIM. This field gates all clocks, including the smart card clock, regardless of the state of the Stop bit described above. This field has no effect on the register read/write clock. Only the EMVSIM logic clock is gated. 0b - Enable 1b - Disable
10 SW_RST	Software Reset Resets the entire EMVSIM. This action has the same result as a hardware reset. This field is self-clearing and always reads 0. You must allow a minimum of four protocol clock cycles before attempting to access EMVSIM after a software reset. 0b - Normal 1b - Reset
9 FLSH_TX	Flush Transmitter Operates as an EMVSIM transmitter reset. The receive portion of EMVSIM is not affected. This field is self-clearing and always reads 0. 0b - Normal 1b - Reset
8 FLSH_RX	Flush Receiver Operates as an EMVSIM receiver reset. The transmit portion of EMVSIM is not affected. This field is self-clearing and always reads 0. 0b - Normal 1b - Reset
7-4 —	Reserved
3 ONACK	Overrun NACK Enable Enables NACK generation when the receive FIFO is full and another message is ready for writing into the FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
2 ANACK	Auto NACK Enable Enables NACK generation for parity errors in received messages or when invalid initial characters are received in ICM mode. 0b - Disable 1b - Enable
1 ICM	Initial Character Mode Enables initial character mode. Hardware automatically clears this field after a valid initial character is received. 0b - Disable 1b - Enable
0 IC	Inverse Convention Configures EMVSIM to use either inverse convention or direct convention for its data format. You can control this field by software, but hardware normally sets it as a result of the interpretation of the initial character when in ICM mode. 0b - Direct 1b - Inverse

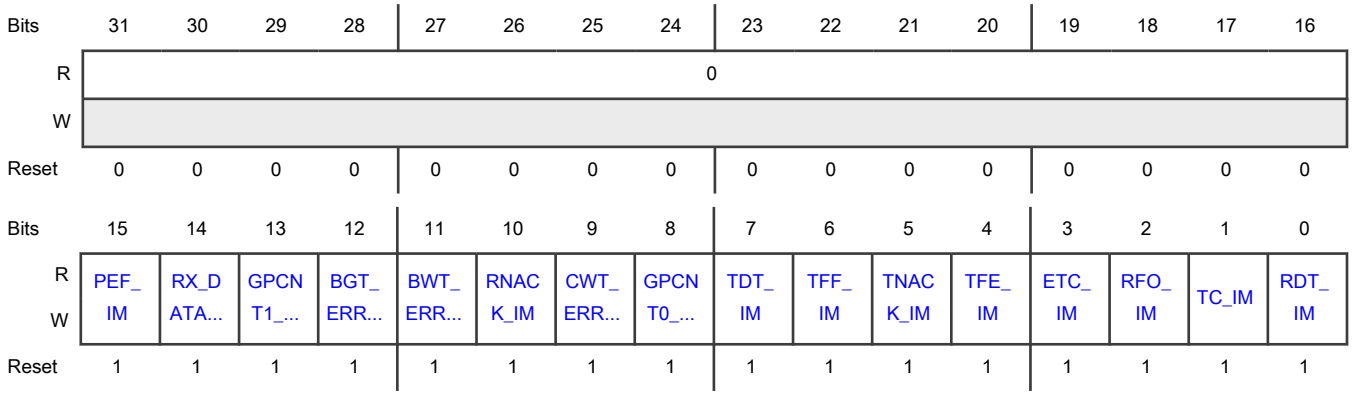
69.7.1.7 Interrupt Mask (INT_MASK)

Offset

Register	Offset
INT_MASK	14h

Function
Provides interrupt masking configuration details.

Diagram



Fields

Field	Function

9 CWT_ERR_IM	Character Wait Time Error Interrupt Mask Enables RX_STATUS[CWT_ERR] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
8 GPCNT0_IM	General Purpose Timer 0 Timeout Interrupt Mask Enable/s TX_STATUS[GPCNT0_TO] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
7 TDT_IM	Transmit Data Threshold Interrupt Mask Enables TX_STATUS[TDTF] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
6 TFF_IM	Transmit FIFO Full Interrupt Mask Enables TX_STATUS[TFF] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
5 TNACK_IM	Transmit NACK Threshold Interrupt Mask Enables TX_STATUS[TNTE] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
4 TFE_IM	Transmit FIFO Empty Interrupt Mask Enables TX_STATUS[TFE] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
3 ETC_IM	Early Transmit Complete Interrupt Mask Enables TX_STATUS[ETCF] to generate EMVSIM interrupts. 0b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Masked
2 RFO_IM	Receive FIFO Overflow Interrupt Mask Enables RX_STATUS[RFO] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
1 TC_IM	Transmit Complete Interrupt Mask Enables RX_STATUS[TCF] to generate EMVSIM interrupts. 0b - Enable 1b - Masked
0 RDT_IM	Receive Data Threshold Interrupt Mask Enables RX_STATUS[RDTF] to generate EMVSIM interrupts. 0b - Enable 1b - Masked

69.7.1.8 Receiver Threshold (RX_THD)

Offset

Register	Offset
RX_THD	18h

Function
Provides receiver threshold configuration details.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W

R	0				RNCK_THD				Reserved				RDT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-12 —	Reserved
11-8 RNCK_THD	Receiver NACK Threshold Value Specifies the number of consecutive NACKs transmitted by EMVSIM, for a given character, before the receive threshold error flag (RX_STATUS[RTE]) is triggered. A value of 0 indicates that RX_STATUS[RTE] is never 1. When EMVSIM receives a valid character, the internal counter keeping track of the NACK count resets to zero for the subsequent byte being received. If CTRL[ANACK] = 0, then this field has no effect. 0000 - Zero threshold: RTE is not 1 0001 - RTE is triggered after 1 NACK is transmitted 0010 - RTE is triggered after 2 NACKs are transmitted 0011 - RTE is triggered after 3 NACKs are transmitted ... 1111 - RTE is triggered after 15 NACKs are transmitted
7-4 —	Reserved
3-0 RDT	Receiver Data Threshold Value Determines the number of bytes that must exist in the receive FIFO to trigger the receive data threshold interrupt flag (RX_STATUS[RDTF]). This value must not exceed the total number of bytes that can be stored in the receive FIFO.

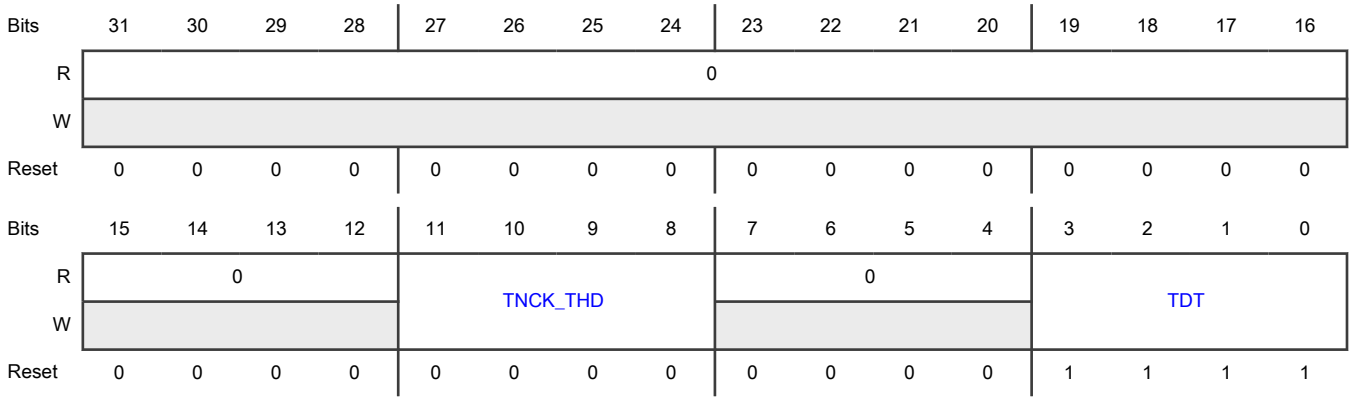
69.7.1.9 Transmitter Threshold (TX_THD)

Offset

Register	Offset
TX_THD	1Ch

Function
Provides transmitter threshold configuration details.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 TNCK_THD	Transmitter NACK Threshold Value Sets the NACK threshold for the transmitter. After the threshold number set by TNCK_THD has been reached for the current byte being transmitted, the error flag (TX_STATUS[TNTE] is set. Writing 1 to TX_STATUS[TNTE] causes the remaining transmissions queued in the transmit FIFO to be canceled, and no more transmissions can occur until software clears TX_STATUS[TNTE]. To trigger TX_STATUS[TNTE], a given byte being transmitted must reach the TNCK_THD threshold itself. Transmit NACKs accumulated on one byte are not carried over to the next. 0000 - Error flag is never set; retransmission after NACK reception is disabled 0001 - Error flag is set after 1 NACK is received; 0 retransmissions occur 0010 - Error flag is set after 2 NACKs are received; at most 1 retransmission occurs 0011 - Error flag is set after 3 NACKs are received; at most 2 retransmissions occur ... 1111 - Error flag is set after 15 NACKs are received; at most 14 retransmissions occur
7-4 —	Reserved
3-0 TDT	Transmitter Data Threshold Value Sets the threshold value for the transmit FIFO at which TX_STATUS[TDTF] is set. When the number of bytes in the transmit FIFO is less than or equal to TDT, EMVSIM writes 1 to TX_STATUS[TDTF].

69.7.1.10 Receive Status (RX_STATUS)

Offset

Register	Offset
RX_STATUS	20h

Function
Provides receive status details.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				RX_CNT				0				RX_WPTR

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 RX_CNT	Receive FIFO Byte Count Indicates the number of bytes stored in the receive FIFO. 0000b - FIFO empty
23-20 —	Reserved
19-16 RX_WPTR	Receive FIFO Write Pointer Value Contains the value of the write pointer of the receive FIFO.
15-14 —	Reserved
13 FEF	Frame Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates if the current received byte did not have proper STOP bits. This does not cause a NACK transmission. This field does not cause an interrupt assertion. It is simply an indication that a framing error has occurred. 0b - No error 1b - Error
12 PEF	Parity Error Flag Indicates if a received byte had a parity error or not. A parity error causes transmission of NACK if CTRL[ANACK] = 1 and this field is not asserted. When ANACK is not = 1, PEF is asserted. This field also does not assert when CTRL[ICM] = 1; however, parity is checked in CTRL[ICM] = 1 mode. It is simply an indication that a parity error has occurred. 0b - No error 1b - Error
11 BGT_ERR	Block Guard Time Error Flag Indicates if the block guard time was too small or sufficient. The threshold is set by BGT_VAL[BGT]. 0b - Sufficient 1b - Too small
10 BWT_ERR	Block Wait Time Error Flag Indicates if the block wait time has been exceeded. The threshold is set by BWT_VAL[BWT]. 0b - Not exceeded 1b - Exceeded
9 RTE	Received NACK Threshold Error Flag Indicates whether the number of consecutive NACKs generated by EMVSIM, in response to receive parity errors for the byte being received, equals the value programmed in RX_THD[RNCK_THD]. This field is never set unless CTRL[ANACK] = 1. CTRL[SAPD] must be 1 to enable the threshold error to trigger the auto power-down sequence. Clearing this field also resets the internal counter for consecutive NACKs being transmitted for a given byte. If this field = 0, the number of NACKs generated by the receiver is less than the value programmed in RX_THD[RNCK_THD]. If this field = 1, the number of NACKs generated by the receiver is equal to the value programmed in RX_THD[RNCK_THD]. 0b - Less than 1b - Equal to
8 CWT_ERR	Character Wait Time Error Flag Indicates when the time between received characters is equal to or greater than the value programmed in CWT_VAL[CWT]. If this field = 0, no character wait time violation has occurred. If this field = 1, a character wait time violation has occurred. 0b - No CWT violation

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - CWT violation
7 CRC_OK	CRC Check OK Flag Indicates when the calculated 16-bit CRC value matches the expected value for the current input data stream. The value is calculated across all received characters and begins when CTRL[CRC_EN] becomes 1. The current CRC residual can be reset by three mechanisms: • Write 0 to CTRL[CRC_EN]. • Write 1 to CTRL[XMT_EN]. • Automatically by hardware when TX_STATUS[ETCF] becomes 1 at the end of a transmission. 0b - Current CRC value does not match remainder. 1b - Current calculated CRC value matches the expected result.
6 LRC_OK	LRC Check OK Flag Indicates when the calculated 8-bit LRC value is correct for the current input data stream. The value is calculated across all received characters and begins when CTRL[LRC_EN] becomes 1. You can reset the current LRC residual by three mechanisms: • Write 0 to CTRL[LRC_EN]. • Write 1 to CTRL[XMT_EN]. • Automatically by hardware when TX_STATUS[ETCF] becomes 1 at the end of a transmission. If this field is 0, then the current LRC value does not match the remainder. If this field is 1, then the current calculated LRC value matches the expected result (that is, zero). 0b - No match 1b - Match
5 RDTF	Receive Data Threshold Interrupt Flag Asserts an interrupt when total bytes in the receive FIFO are equal to or greater than the programmed receive threshold (RX_THD[RDT]). EMVSIM writes 1 to this field any time the number of unread bytes in the receive FIFO is equal to or greater than the value of the threshold. This flag can be cleared (= 0) by reading enough bytes out of the receive FIFO to bring the number of bytes remaining in the FIFO below the threshold. Another way to clear this flag is to set RX_THD[RDT] higher than the number of unread bytes currently in the FIFO. This flag creates an interrupt if INT_MASK[RDT_IM] = 0. If this flag = 0, the number of unread bytes in the receive FIFO is less than the threshold. If this flag = 1, the number of unread bytes in the receive FIFO is greater or than equal to the threshold. 0b - Less than threshold 1b - Greater than or equal to threshold
4 RX_DATA	Receive Data Interrupt Flag Asserts an interrupt when a new data byte is received and entered into the receive FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No new byte 1b - New byte
3-1 —	Reserved
0 RFO	Receive FIFO Overflow Flag Indicates that EMVSIM was unable to store received data due to already unread bytes in the FIFO (FIFO full or almost full). It does not necessarily indicate that data has been lost. If CTRL[ONACK] = 1, EMVSIM generates a NACK pulse on bytes that would otherwise cause a loss of data due to a full FIFO. These bytes should be retransmitted by the smart card, which implies that no data has actually been lost. In this case, this RFO flag is just an indicator that the situation has occurred, which may be helpful in system debug. For the case where ONACK is not set, a set RFO flag does indicate a loss of data, because all bytes received with this field = 1 are indeed lost (including the byte that caused RFO to be set). The RFO flag causes an interrupt if INT_MASK[RFO_IM] is enabled (RFO_IM=0). 0b - No overrun error 1b - Overrun error

69.7.1.11 Transmitter Status (TX_STATUS)

Offset

Register	Offset
TX_STATUS	24h

Function

Provides transmitter status details.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				TX_CNT				0				TX_RPTR			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0						GPCNT1_...	GPCNT0_...	TDTF	TFF	TCF	ETCF	TFE	0		TNTE
W							W1C	W1C		W1C	W1C	W1C	W1C			W1C
Reset	0	0	0	0	0	0	0	0	1	0	1	1	1	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 TX_CNT	Transmit FIFO Byte Count Indicates the number of bytes stored in the transmit FIFO. 0000b - FIFO empty
23-20 —	Reserved
19-16 TX_RPTR	Transmit FIFO Read Pointer Contains the value of the read pointer of the transmit FIFO.
15-10 —	Reserved
9 GPCNT1_TO	General Purpose Counter 1 Timeout Flag Indicates when the value in General Purpose Counter 1 equals the value in GPCNT1_VAL[GPCNT1]. If this field is 0, the GPCNT1 time has not been reached, or this field has been written to 0. If this field = 1, the general purpose counter has reached the GPCNT1 value. 0b - GPCNT1 not reached, or flag cleared 1b - GPCNT1 reached
8 GPCNT0_TO	General Purpose Counter 0 Timeout Flag Indicates when the value in General Purpose Counter 0 equals the value in GPCNT0_VAL[GPCNT0]. If this field is 0, the GPCNT0 time has not been reached, or this field has been written to 0. If this field = 1, the general purpose counter has reached the GPCNT0 value. 0b - GPCNT0 not reached, or flag cleared 1b - GPCNT0 reached
7 TDTF	Transmit Data Threshold Flag Indicates that the total number of bytes in the transmit FIFO is less than or equal to the programmed transmit data threshold (TX_THD[TDT]). EMVSIM writes 1 to this field any time the number of bytes in the transmit FIFO is less than or equal to the value set by TX_THD[TDT]. This flag can be cleared by writing enough bytes into the transmit FIFO to make the number of bytes in the FIFO greater than the threshold. Another way to clear this flag is to set the threshold lower than the number of bytes currently in the FIFO. This flag creates an interrupt if INT_MASK[TDT_IM] = 0. 0b - Threshold exceeded or this field written to 0 1b - Threshold not exceeded
6 TFF	Transmit FIFO Full Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates when the transmit FIFO has been written with the maximum number of bytes that it can store. Subsequent writes may be ignored. This flag can only be cleared by writing 1 to it or by writing 1 to CTRL[SW_RST]. 0b - Not full 1b - Full
5 TCF	Transmit Complete Flag Indicates whether the EMVSIM transmitter is ready for a new transmission. This flag becomes set when the guard time has expired after the last byte in the transmit FIFO (if CTRL[XMT_CRC_LRC] = 0) or the LRC or CRC byte (if CTRL[XMT_CRC_LRC] = 1) has been transmitted. This flag creates an interrupt if INT_MASK[TC_IM] = 1. 0b - Pending or incomplete 1b - Complete
4 ETCF	Early Transmit Complete Flag Indicates that the EMVSIM transmitter has finished sending the last byte in transmit FIFO (if CTRL[XMT_CRC_LRC] = 0) or finished sending the LRC or CRC byte (if CTRL[XMT_CRC_LRC] = 1). This field differs from TCF because it is set before the guard time of the last byte has elapsed. This flag creates an interrupt if INT_MASK[ETC_IM] = 0. 0b - Pending or incomplete 1b - Complete
3 TFE	Transmit FIFO Empty Flag Indicates that the EMVSIM transmit FIFO has been emptied. This field becomes 1 when the last byte in the transmit FIFO has been successfully transferred out of the EMVSIM transmitter to the smart card. It also becomes 1 when TNTE = 1. This flag creates an interrupt if INT_MASK[TFE_IM] = 0. 0b - Not empty 1b - Empty
2-1 —	Reserved
0 TNTE	Transmit NACK Threshold Error Flag Indicates that the transmit NACK threshold has been reached. When this field = 1, EMVSIM performs no further transmissions until this field = 0. Any data transmissions still pending in the transmit FIFO are aborted, and TCF, ETCF, and TFE flags are written to 1. This flag creates an interrupt if INT_MASK[TNACK_IM] = 0. 0b - Threshold not reached 1b - Threshold reached

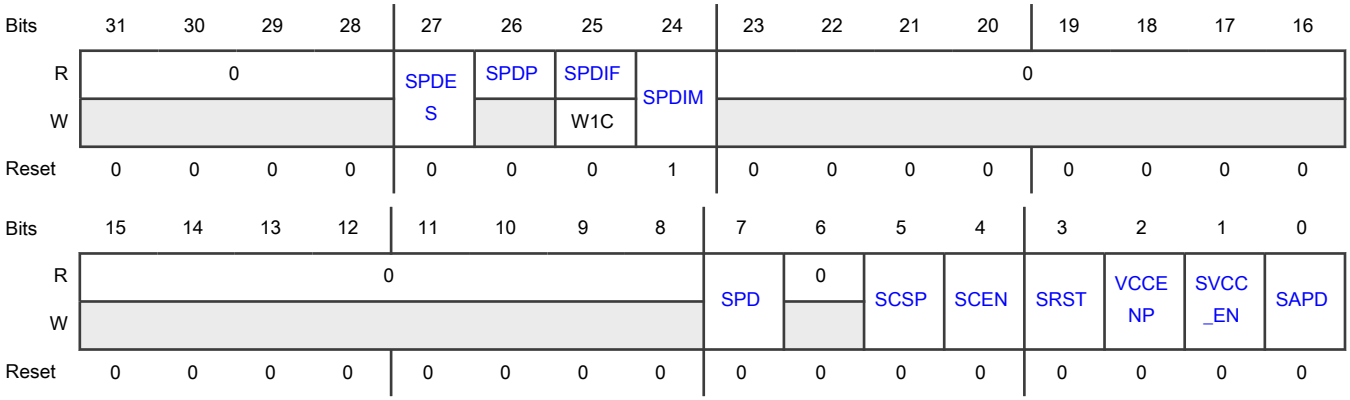
69.7.1.12 Port Control and Status (PCSR)

Offset

Register	Offset
PCSR	28h

Function
Provides control and status details related to the smart card port.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 SPDES	SIM Presence Detect Edge Select Controls which edge of the Smart Card Presence Detect pin is used to detect the presence of the smart card. 0b - Falling edge 1b - Rising edge
26 SPDP	Smart Card Presence Detect Pin Status Reflects the state of the Smart Card Presence Detect pin. It is not a latched register bit, but instead a synchronized version of the state of the pin itself. 0b - Logic low 1b - Logic high
25 SPDIF	Smart Card Presence Detect Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Contains the status flag to indicate that an insertion or removal of a smart card has been detected on the port. This field can create an interrupt to the MCU if SPDIM is 0, or initiate the auto power-down sequence if SAPD is 1. 0b - No insertion or removal 1b - Insertion or removal
24 SPDIM	Smart Card Presence Detect Interrupt Mask Enables the interrupt mask for the presence detect interrupt flag (SPDIF). If this field is 0, the SIM presence detect interrupt is enabled. If this field is 1, the SIM presence detect interrupt is masked. 0b - Enable 1b - Mask
23-8 —	Reserved
7 SPD	Auto Power-Down Control Starts the auto power-down sequence, if the auto power-down feature has been enabled by writing 1 to the SAPD field. This field automatically becomes 0 when power-down is complete. If this field is 1, either it starts auto power-down or else the power-down sequence is already in progress. 0b - No 1b - Yes
6 —	Reserved
5 SCSP	Smart Card Clock Stop Polarity Controls the polarity of the idle EMVSIM clock when the clock is disabled by the SCEN field. If this field is 0, the clock is logic 0 when stopped by SCEN. If this field is 1, the clock is logic 1 when stopped by SCEN. 0b - Logic 0 1b - Logic 1
4 SCEN	Clock Enable for Smart Card Enables the clock to the smart card. It can be forced low by hardware during the auto power-down sequence. 0b - Disable 1b - Enable
3 SRST	Reset Smart Card Controls the state of the reset line to the smart card. It can be forced low by hardware during the auto power-down sequence. Smart card reset signals are active low.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Assert 1b - Deassert
2 VCCENP	VCC Enable Polarity Control Controls the polarity of the SVEN output pad via the SVCC_EN field. When this field is 1, it inverts the value of the SVCC_EN field of this register and output to the SVEN output pad of this chip. If this field is 0, SVCC_EN is active high. The polarity of SVCC_EN is unchanged. If this field is 1, SVCC_EN is active low. The polarity of SVCC_EN is inverted. 0b - Active high 1b - Active low
1 SVCC_EN	Vcc Enable for Smart Card Controls the state of the SVEN pin on the smart card port. The SVEN pin controls the smart card Vcc enable in the power management device. It can be forced low by hardware during the auto power-down sequence. This field is XORed with the VCCENP field to control the polarity of the SVEN output pad. 0b - Disable 1b - Enable
0 SAPD	Auto Power Down Enable Enables the auto power-down feature. You must write 1 to this field before the auto power conditions are met. This field returns to 0 at the end of the auto power-down sequence. You can initiate the auto power-down function by: • Writing 1 to the SPD field by software • Writing 1 to RX_STATUS[RTE] • Writing 1 to SPDIF when the interrupt is used for detecting card removal You can still initiate a manual power-down through software by writing 1 to: • SCEN • SRST • VCC_EN This action will be effective no matter what the value of this field is. 0b - Disable 1b - Enable

69.7.1.13 Receive Data Read Buffer (RX_BUF)

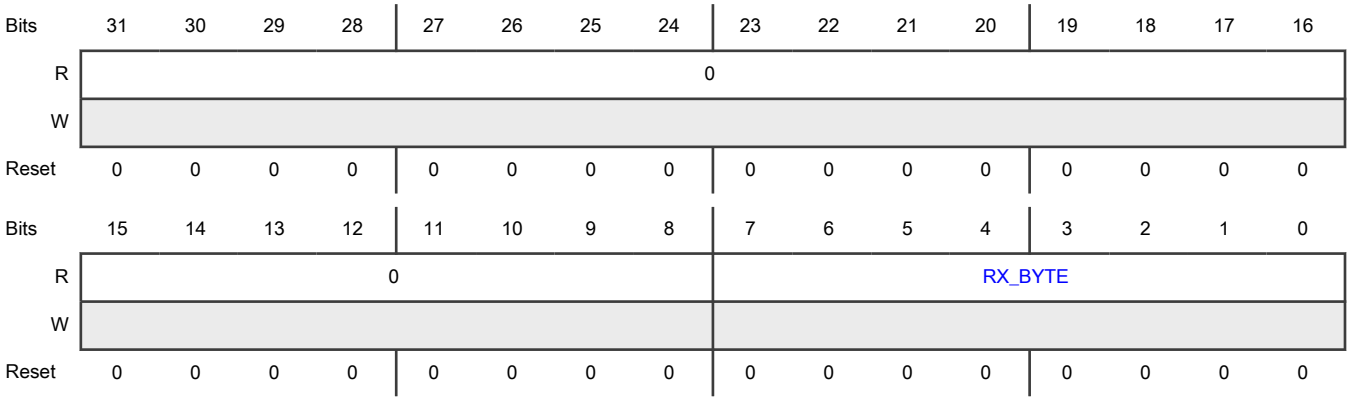
Offset

Register	Offset
RX_BUF	2Ch

Function

Provides the byte value from the top of the receive FIFO.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RX_BYTE	Receive Data Byte Read Provides the byte value from the top of the receive FIFO. Each read access to this register increments the read pointer of the receive FIFO.

69.7.1.14 Transmit Data Buffer (TX_BUF)

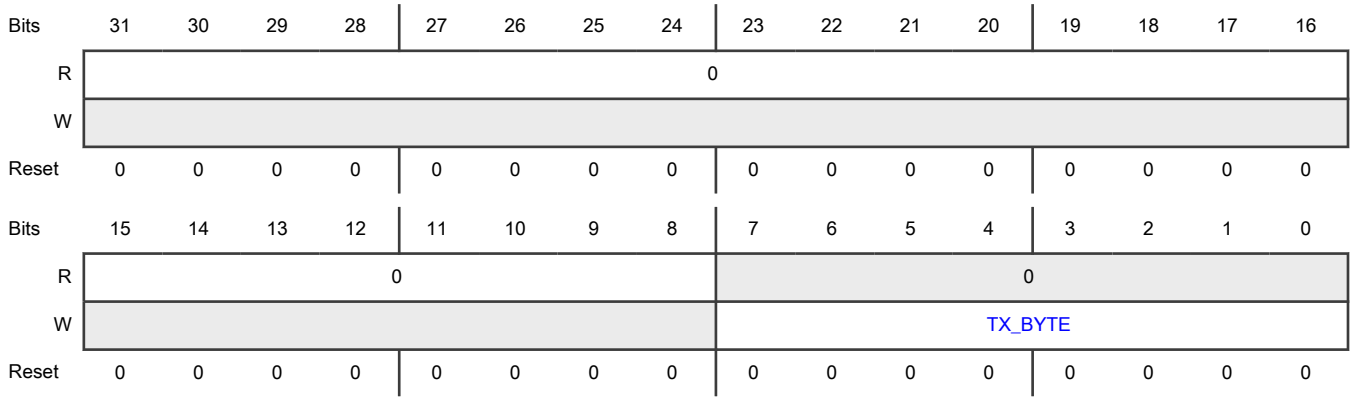
Offset

Register	Offset
TX_BUF	30h

Function

Fills the transmit FIFO with the bytes to be transmitted.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TX_BYTE	Transmit Data Byte Fills the transmit FIFO with the bytes to be transmitted. The transmit FIFO can be written to only when the transmitter is enabled. Writing to this register while the transmitter is disabled leads to ignoring all write accesses to this register. Reads to this register return zeros. **NOTE** Writing more data to the transmit FIFO than it can hold causes a transmit FIFO full (TFF) error.

69.7.1.15 Transmitter Guard ETU Value (TX_GETU)

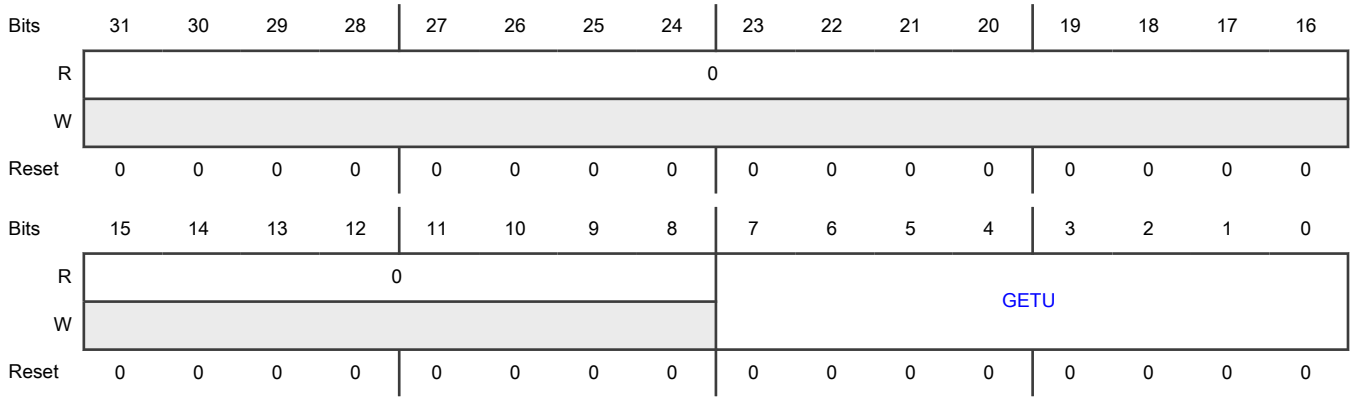
Offset

Register	Offset
TX_GETU	34h

Function

Controls the number of additional elementary time units (ETUs) inserted between bytes transmitted by the transmitter.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 GETU	Transmitter Guard Time Value in ETU Controls the number of additional elementary time units (ETUs) inserted between bytes transmitted by the EMVSIM transmitter. An ETU is equivalent to one bit time at the given baud rate (for example, the length of a start bit). The guard time has no effect on the EMVSIM receiver. A value of 00h inserts no additional ETUs, while a value of FEh inserts 254 additional ETUs. A value of FFh subtracts one ETU by reducing the number of stop bits from two to one. 00000000 - No additional ETUs inserted 00000001 - 1 additional ETU inserted ... 11111110 - 254 additional ETUs inserted 11111111 - Subtracts one ETU by reducing the number of stop bits from two to one

69.7.1.16 Character Wait Time Value (CWT_VAL)

Offset

Register	Offset
CWT_VAL	38h

Function

Specifies the number of ETU times allowed between characters.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-0 CWT	Character Wait Time Value Specifies the number of ETU times allowed between characters. The default value is FFFFh.

69.7.1.17 Block Wait Time Value (BWT_VAL)

Offset

Register	Offset
BWT_VAL	3Ch

Function

Specifies the maximum time between the time from the start bit of the last byte sent from EMVSIM to the start bit of the first byte sent from the smart card.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BWT

R	BWT															
W																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Fields

Field	Function
31-0 BWT	Block Wait Time Value Specifies the maximum block wait time value. The time from the start bit of the last byte sent from EMVSIM to the start bit of the first byte sent from the smart card must be less than the value in this register. If it is not, then EMVSIM writes 1 to the BWT_TO flag.

69.7.1.18 Block Guard Time Value (BGT_VAL)

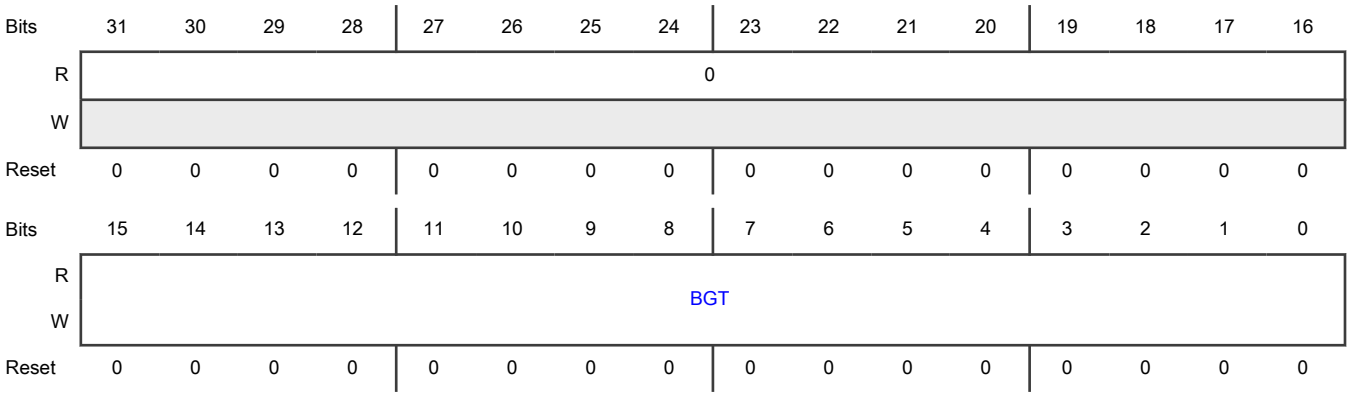
Offset

Register	Offset
BGT_VAL	40h

Function

Contains the block guard time. The time from the start bit of the last byte sent from EMVSIM to the start bit of the first byte sent from the smart card must be greater than this value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 BGT	Block Guard Time Value Contains the block guard time value. The time from the start bit of the last byte sent from EMVSIM to the start bit of the first byte sent from the smart card must be greater than this value. If it is not, then EMVSIM writes 1 to the BGT flag.

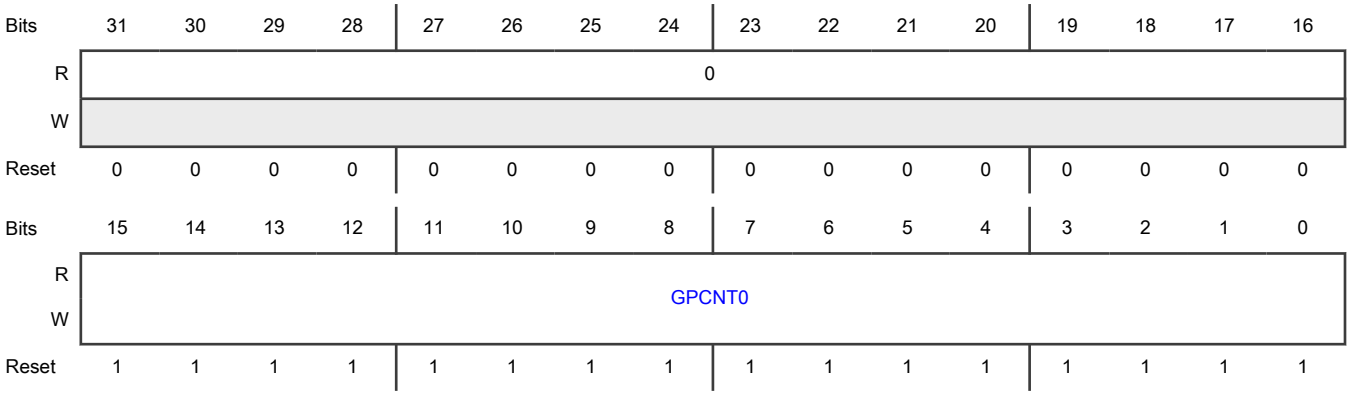
69.7.1.19 General Purpose Counter 0 Timeout Value (GPCNT0_VAL)

Offset

Register	Offset
GPCNT0_VAL	44h

Function
Contains a value to be compared to general purpose counter 0.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 GPCNT0	General Purpose Counter 0 Timeout Value Contains a value to be compared to general purpose counter 0. After the general purpose counter reaches this value, EMVSIM writes 1 to TX_STATUS[GPCNT0_TO]. This counter is intended for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration.

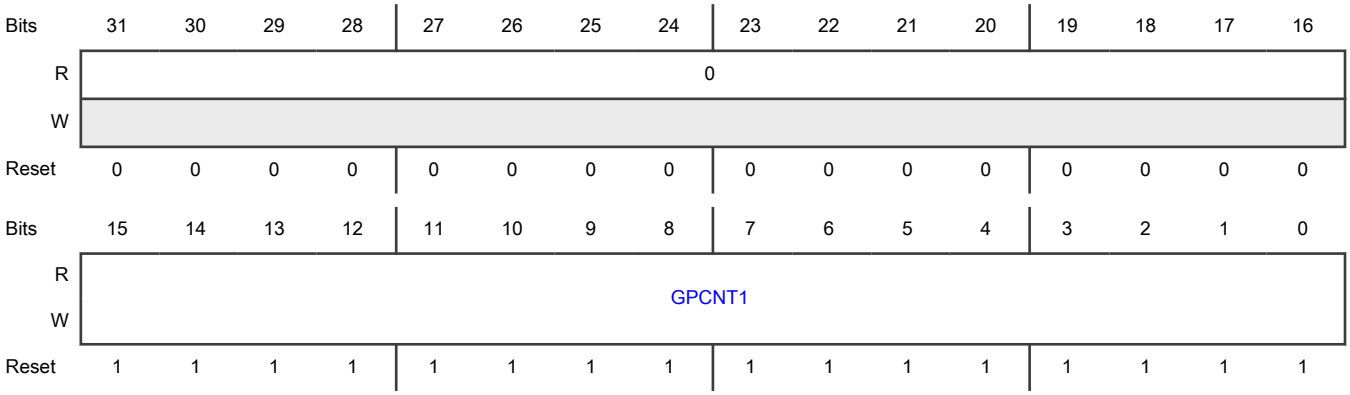
69.7.1.20 General Purpose Counter 1 Timeout Value (GPCNT1_VAL)

Offset

Register	Offset
GPCNT1_VAL	48h

Function
Contains a value to be compared to general purpose counter 1.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 GPCNT1	General Purpose Counter 1 Timeout Value Contains a value to be compared to general purpose counter 1. After the general purpose counter reaches this value, EMVSIM writes 1 to TX_STATUS[GPCNT1_TO]. This counter is intended for any events that must be monitored for duration based on the card clock, receiver sample rate, or ETU rate (transmit clock). Example: ATR arrival time and ATR duration.

Chapter 70
Ethernet QoS (ENET)

70.1 Chip-specific ENET information

Table 637. Reference links to related information

Topic	Related module	Reference
Full description	ENET	Ethernet QoS
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

70.1.1 Module instances

This device has one instance of the Ethernet QoS module, ENET0.

70.1.2 Initialization

The Ethernet controller is configured as follows:

- Clock: In the SYSCON AHB Clock Control 2 (AHBCLKCTRL2) register, set ENET field, to enable the bus clock.
- Reset: In the SYSCON Peripheral Reset Control 2 (PRESETCTRL2) register, set ENET_RST field, to reset the Ethernet controller when needed.
- The Ethernet interrupts are connected to interrupt slots # 139, # 140, and # 141 in the NVIC. The Ethernet wake-up interrupt Ethernet wake-up packet indicator is connected to slot # 140 in the NVIC. See Nested Vectored Interrupt Controller (NVIC).
- Set the Ethernet mode to RMII or MII in the Ethernet PHY Interface Select (ENET_PHY_INTF_SEL) register in SYSCON.
- Set the sideband flow control for each channel.

70.2 Overview

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The Ethernet module enables a host to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2008 standard. The Ethernet interface contains a full-featured 10 Mbps or 100 Mbps Ethernet Media Access Controller (MAC) designed to provide optimized performance through the use of DMA hardware acceleration.

Features include control registers, full-duplex or half-duplex operation, flow control, control frames, hardware acceleration for transmit retry, receive packet filtering, and wake-up on LAN activity, supporting both wake-up and magic packet frames. Automatic frame transmission and reception with Scatter-Gather DMA off-load many operations from the CPU.

The Ethernet module is an AHB master connected to the AHB multilayer matrix and has access to internal SRAM and memory connected to the External Memory Controller for Ethernet data, control, and status information. A multi-layer AHB matrix connects the CPU buses and other bus masters to peripherals in a flexible manner that optimizes performance by allowing peripherals on different slaves ports of the matrix to be accessed simultaneously by different bus masters.

The Ethernet module interfaces with an off-chip Ethernet PHY using the Media Independent Interface (MII) or Reduced MII (RMII) protocol and with the on-chip Media Independent Interface Management (MIIM) serial bus.

70.2.1 Block Diagram

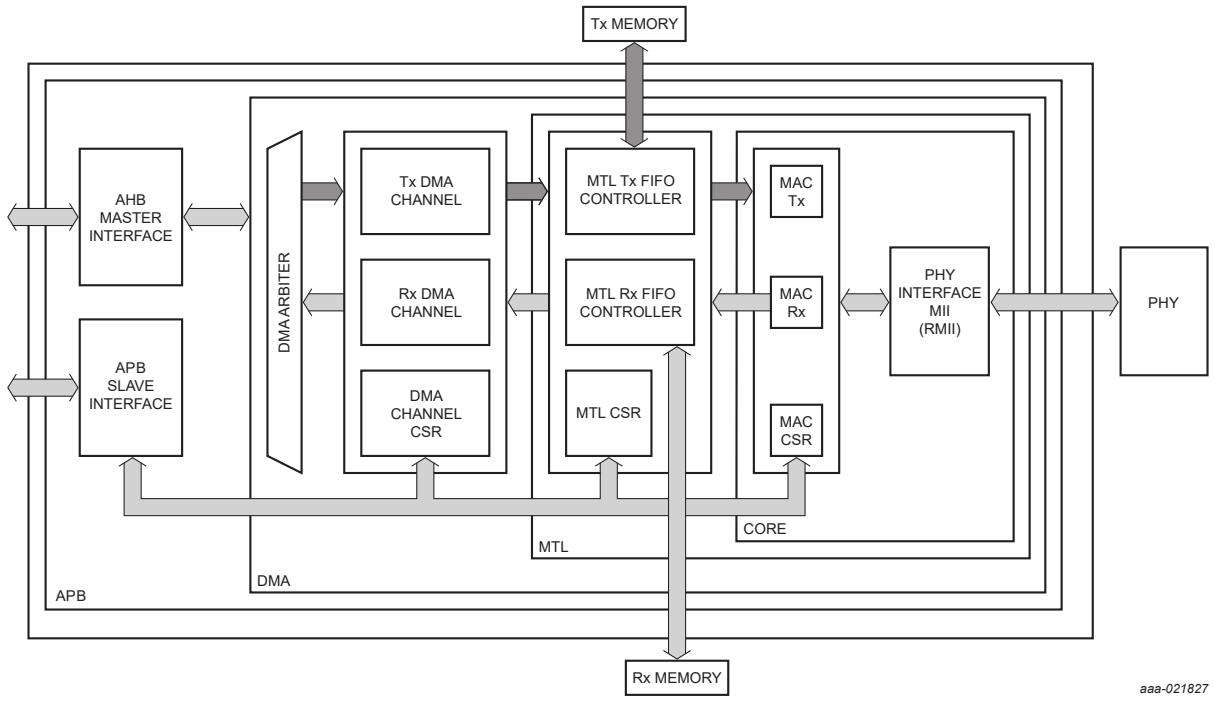


Figure 413. Ethernet block diagram

70.2.2 Features

key features of ENET module are:

- 10/100 Mbit/s
- Ethernet MAC IEEE 8023-2008
- DMA support
- IEEE 1588-2008 v2 timestamping driven by external PHY clock
- IEEE 1588 advanced timestamp support (IEEE 1588-2008 v2)
- Energy efficient Ethernet (IEEE 8023az-2010) for MII PHY
- Power management remote wake-up frame and magic packet detection
- Supports both MII and RMII (ver12) PHY
- Supports MDIO (Clause 22 and Clause 45) master interface to manage and configure PHY
- IP checksum offload support for TCP, UDP, or ICMP payloads encapsulated over IP
- Supports both full-duplex and half-duplex operation
  - Supports CSMA/CD Protocol for half-duplex operation
  - Supports IEEE 8023x pause packets and priority flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Backpressure support for half-duplex operation
  - Automatic transmission of zero-quanta pause frame on de-assertion of flow control input in full-duplex operation

70.3 Functional description

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

70.3.1 Power management and low power modes

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wake-up frames and magic packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and magic packets received by the MAC. The PMT block sits on the receiver path of the MAC and is enabled with remote wake-up frame enable and magic packet enable. These enables are in the PMT control and status register and are programmed by the application.

When the power-down mode is enabled in the PMT, then all received frames are dropped by the Ethernet core and they are not forwarded to the application. The Ethernet comes out of the power-down mode only when either a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

70.3.1.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 MAC sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE. The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides of the link can disable some functionality to save power during periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY. The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

70.3.1.1.1 Transmit path functions

In the transmit path, the software must set the LPIEN bit of the MAC LPI control status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER(LST) field of MAC LPI timers control register. The PHY link status bit of the LPI control and status register indicates the link status of the PHY.

According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the transmit clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts transmit enable (TX_EN).
2. Asserts transmit error (TX_ER). Sets TXD[3:0] to 0x1 The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
3. Updates the status (TLPIEN bit of MAC LPI control status register and generates an interrupt. To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:
4. Stops transmitting the LPI pattern and start transmitting the IDLE pattern
5. Starts the LPI TW TIMER
6. Updates the LPI exit status (TLPIEX bit of the MAC LPI control status register and generates an interrupt

The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC LPI Timers control register.

70.3.1.1.2 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period or has a packet to transfer. These modes are enabled and controlled by the MAC LPI control status register.

When the LPITXA (bit 19) and LPITXEN (bit 16) of the MAC LPI control status register are set, the MAC transmitter enters the LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clears the LPITXEN bit as soon as any of the functions in the TX path (DMA, MTL, or MAC) becomes non-idle due to initiation of a packet transfer. In addition to the above, when bit 20 (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only when the transmit path remains in an idle state (no activity) for the time indicated by the value in MAC LPI Entry Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of the LPI IDLE state by programming the LPITXEN bit.

70.3.1.1.3 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV. The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.
4. The MAC updates the RLPIEN bit of the MAC LPI control status register and immediately generates an interrupt.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC LPI control status register and generates an interrupt immediately. The sideband signal (synchronous to Rx clock) is also asserted.

70.3.1.1.4 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control register:

- LPI LS Timer
  - The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of the MAC_LPI_Control_Status register. The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in bits 25:16 of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1,023 ms.
- LPI TW Timer
  - The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in bits 15:0 of MAC register 53 (LPI timers control register). The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of a microsecond. The LPI TW TIMER is 16-bits wide. Therefore, the software can program up to 65,535 µs.

70.3.1.1.5 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The low-power interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC LPI control status register.

70.3.1.2 Power management and wake-up

The power management (PMT) block supports the reception of magic packets as wake up packets, as well as the reception of network (remote) wake-up packets as wake up packets.

70.3.1.2.1 Magic packet detection

The magic packet frame is based on a method that uses Advanced Micro Device's magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

Only magic packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wake-up requirements. Magic packets that pass the address filtering (unicast or broadcast)are checked to determine whether they meet the remote wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times.

The application enables magic packet wake-up by writing a 1 to bit 1 of the PMT control and status register. The PMT block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected.

If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- ...CRC

Magic packet detection is updated in the PMT control and status register for magic packet received. A PMT interrupt to the application triggers a read to the PMT CSR to determine whether a magic packet frame is received. When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet is received and the corresponding detection is enabled.

70.3.1.2.2 Remote wake-up detection

The PMT block supports the reception of network (remote) wake-up packets as wake-up packets.

When the MAC is in sleep mode and the remote wake-up bit is enabled in PMT control and status register (0x00C0), normal operation is resumed after receiving a remote wake-up frame. The application writes all eight wake-up filter registers by performing a sequential write to address (0x00C4). The application enables remote wake-up by writing a 1 to bit 2 of the PMT control and status register.

PMT supports 16 programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of filter command, and if filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter byte mask determines which bytes of the frame must be examined. The 31st bit of the byte mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT control and status register for every remote wake-up frame received. A PMT interrupt to the application triggers a read to the PMT control and status register to determine the reception of a wake-up frame.

70.3.1.2.3 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. When software resets the PWRDWN bit in the remote wake-Up packet detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a remote wake-up packet is received and the corresponding detection is enabled. The PMT block is available in the receive path of MAC.

70.3.1.3 System considerations during power-down

MAC neither gates nor stops clocks when power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with ENET_RX_CLK during power-down mode because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during deep-sleep mode.

The PMT interrupt is asserted when a valid wake-up frame is received. This signal is generated in the receive clock domain.

The recommended power-down and wake-up sequences are as follows.

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when transmit interrupt (see DMA channel status register bit TI) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC configuration register.
3. Wait until the receive DMA empties all the frames from the Rx FIFO. This can be done by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable power-down mode by appropriately configuring the PMT registers.
5. Enable the MAC receiver and enter power-down mode.
6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter sleep mode.
7. On receiving a valid wake-up frame, the MAC asserts the PMT interrupt signal and exits the power-down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

70.3.2 Flow control

This section describes the flow control for transmit and receive paths.

70.3.2.1 Transmit flow control

The transmit flow control involves transmitting pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end. To independently enable transmit flow control for each Rx Queue, set the TFE bit in the corresponding MAC queue Tx flow control register. The transmit flow control involves transmitting pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

70.3.2.1.1 Flow control in full-duplex mode

In full-duplex mode, one of the following packet types are used for flow control:

- IEEE 802.3x pause packets.
- Priority flow control (PFC) packets.

The PFC packets are used only when the enable data center bridging option is selected. The PFCE bit of MAC_Rx_Flow_Ctrl register determines whether PFC packets or IEEE 802.3x pause control packets are used for flow control. If the PFCE bit is set, the MAC sends the PFC packets.

describes the fields of a pause packet.

Table 638. Pause packet fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC	Control opcode Contains 0001 for IEEE 802.3x pause control packets; 0101 for PFC packets
PT	Contains pause time specified in the PT field of the MAC_Tx_FLOW_CTRL Q# register

When the FCB bit is set, the MAC generates and transmits a single pause packet. If the FCB bit is set again after the pause packet transmission is complete, the MAC sends another pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously transmitted pause packet, the application should program the pause time register with the appropriate value and then again set the FCB bit. Similarly, when the mti_flowctrl_i signal is asserted, the MAC generates and transmits a single pause packet. If the mti_flowctrl_i signal remains asserted at a configurable number of slot times before the pause time runs out, the MAC transmits a second pause packet. This process is repeated as long as the mti_flowctrl_i signal remains active. If the mti_flowctrl_i signal goes inactive prior to the sampling time, the MAC transmits a pause packet with zero-pause time (if the DZPQ bit in MAC_Q#_Tx_Flow_Ctrl register is set to 0) to indicate to the remote end that the receive buffer is ready to receive new data packets.

For PFC packets, you can specify the priority, pause time, and other controls for a queue in MAC_Q#_Tx_Flow_Ctrl register. The MAC supports independent flow control for each Rx Queue. There is one trigger input for each Rx Queue. Therefore, when multiple triggers come simultaneously, the MAC sends one PFC packet for each trigger. Based on the hardware trigger or software trigger through respective queues, the MAC sends a PFC packet with programmed pause time and priority. If multiple priorities are programmed in the same Rx Queue, multiple priorities are set for the PFC packet with the same pause time values. A separate pause timer is available for each Rx Queue.

70.3.2.1.2 Flow control in half-duplex mode

In half-duplex mode, the MAC uses the deferral mechanism for flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station back off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

The following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_TX_FLOW_CTRL_Q0 register
- DM bit of the MAC configuration register flow control is similar for all queues.

Flow control is similar for all queues.

Table 639. Tx MAC flow control

EFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs backpressure when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs backpressure when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs backpressure when Rx Queue level crosses the threshold set by bits 10:8 of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the pause packet when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	1	The MAC transmitter sends the pause packet when bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a pause packet when Rx Queue level crosses the threshold set by bits 10:8 of MTL_RxQ0_Operation_Mode register.

70.3.2.2 Receive flow control

In the receive path, the flow control is functional only in the full-duplex mode. If any pause packet is received in the half-duplex mode, the packet is considered as a normal control packet. To enable the pause flow control Set the RFE bit in the MAC Rx flow control register.

70.3.3 Transmit and Receive FIFOs

The Transmit FIFO (Tx FIFO) buffers the data transferred from the host controller to the Ethernet module. Similarly, the Receive FIFO (Rx FIFO) stores the Ethernet frames received from the line until they can be transferred to the host controller. These are asynchronous FIFOs because they also transfer the data between the host controller clock and the MAC line clocks. Tx memory and Rx memory are required to be two-ported RAM of 35-bit width for 32-bit data bus widths, respectively. The extra bits are used for storing the byte-enable information.

When multiple queues are selected, all Tx Queue share the Tx FIFO memory and all Rx Queue share the Rx FIFO memory. The application can program the size of the FIFO memory allocated to each Tx or Rx Queue.

70.3.4 Multiple channels and queues support

The Ethernet module supports up to 2 queues and channels on Tx and Rx paths. The number of Tx channels are equal to the number of Tx Queues.

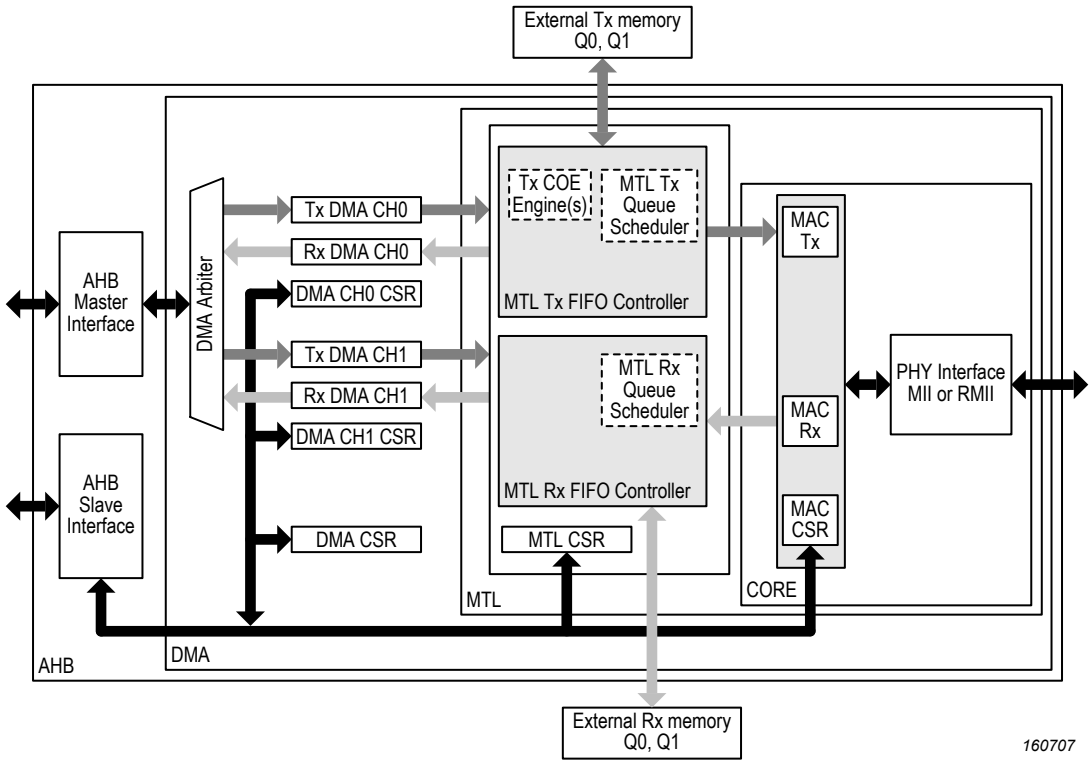

Figure 414. Multiple channels and queues

70.3.4.1 Support in the transmit path

Ethernet module supports up to two Tx Queues. The fixed priority scheme is the default priority scheme for the DMA channels. In a fixed priority scheme, the channel with the highest priority always wins the arbitration when it requests the bus. Channel 0 has a lower priority than channel 1. In weighted strict priority (WSP), the weight corresponds to the number of burst transfers given to a channel in one arbitration cycle. The unused burst transfers of one or more channels are reallocated based on the priority. The channel with the highest priority gets the unused burst transfer time before it is allocated to a channel with the next highest priority.

In weighted round-robin (WRR), all channels are serviced in round-robin order according to the weights settings. The TCW field of the corresponding DMA channel transmit control register provides the weight for each transmit channel. The configured weights correspond to the number of burst transfers given to a channel in one arbitration cycle. The unused or excess burst transfers are distributed equally to all channels.

70.3.4.2 Support in the receive path

In the Rx direction, the MTL Rx controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL RxQ control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

70.3.4.3 Priority scheme for Tx DMA and Rx DMA

In the DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DMA arbiter supports two types of arbitration: fixed priority and weighted round-robin. The DA bit of the DMA mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

If the Tx DMA and Rx DMA of a channel are enabled, the user can specify which DMA gets the bus when the channel gets control of the bus. User can set the priority between the corresponding Tx DMA and Rx DMA by using the TXPR field of the DMA

mode register. For round-robin arbitration, the user can use the PR field of the DMA mode register to specify the weighted priority between the Tx DMA and Rx DMA.

Table 640. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit11	Bit 1	Priority Scheme
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests.
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Tx has priority over Rx in ratio 3:1
0	1	1	0	0	Tx has priority over Rx in ratio 4:1
1	0	0	0	0	Tx has priority over Rx in ratio 5:1
1	0	1	0	0	Tx has priority over Rx in ratio 6:1
1	1	0	0	0	Tx has priority over Rx in ratio 7:1
1	1	1	0	0	Tx has priority over Rx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests.
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

Bits 14, 13, 12, 11, and 1 are not valid if one of the paths (transmit or receive) is not present in a channel. The transmit and receive paths are always present in channel 0.

70.3.4.4 Multiple queues and channels support in Ethernet MTL

The Ethernet module supports up to two Tx and Rx Queues. You can control a Tx Queue through the corresponding MTL TxQ operation mode register. Also, you can control an Rx Queue through the corresponding MTL RxQ operation mode register.

70.3.4.5 Rx Queue to DMA mapping

The packets in the MTL Rx Queues can be routed to any one of the two DMA channels by programming the MTL RxQ DMA map registers for queues 0, 1. The following types of Rx Queue to DMA mapping is possible through programming:

1. Static mapping

2. Dynamic (per packet) mapping

70.3.4.5.1 Static mapping

In this mode, all the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bits 3:0) and Q0DDMACH (bit 7 = 0) of the MTL RxQ DMA Map0 register. Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each queue.

70.3.4.5.2 Dynamic (per packet) mapping

In this mode, the destination DMA channel of a packet that is read from an Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL RxQ DMA map register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC Core receiver for each packet, based on Ethernet DA-based DMA Selection. The DA address of the received packet is compared against the programmed DA values in MAC address registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number. If the above operations is unable to make a successful match/decision, then the packet is routed to DMA channel 0 by default.

70.3.4.6 Rx side routing from MAC to queues

The MAC routes the Rx packets to the Rx Queues based on the following packet types:

1. AV control packets
2. Untagged IEEE 1588 PTP over Ethernet packets

The AV control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in the MAC RxQ Ctrl1 register, and the corresponding Rx Queue is enabled for AV through the corresponding RXQEN field in MAC RxQ Ctrl0 register.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the AVPTPQ field in MAC RxQ Ctrl1 register and the corresponding Rx Queue is enabled for AV through the corresponding RXQEN field in the MAC RxQ Ctrl0 register. This type of Rx packet routing is available when the AV feature and multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet types for routing, it will be routed through Rx Queue 0.

70.3.4.7 Rx side arbitration between DMA and MTL

After completing the current packet processing, the DMA channel controller fetches the next descriptor. After the descriptor fetching is complete, the DMA channel controller evaluates the amount of data to be transferred to the Rx buffer based on the programmed PBL and Rx buffer length. Accordingly, it requests the MTL to transfer the data. After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL operation mode register) and the weights programmed in the corresponding queue receive control register. The arbitration is done among queues for which DMA is ready to serve. After the Rx Queue is selected, the PBL (Programmable Burst Length) amount of data is read out from that queue and is routed to the Rx DMA channel based on the Rx channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for processing from at least one DMA channel.

70.3.4.8 Tx side arbitration between DMA and MTL

Because the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it. The main reason for this strategy is to optimize and increase the efficiency of the DMA data transfer, as well as to simplify the TX checksum engines in the MTL.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue when a Tx DM A starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

70.3.4.9 Audio Video Bridging

The Ethernet module supports the AV data transfer in 100 Mbps modes. The AV feature enables the transmission of time-sensitive traffic over bridged local area networks (LANs). The following standards define various aspects of the AV feature implementation:

1. IEEE 802.1Qav-2009: Allows the bridges to provide time-sensitive and loss-sensitive real-time audio-video data transmission (AV traffic). It specifies the priority regeneration and controlled bandwidth queue draining algorithms that are used in bridges and AV traffic sources.
2. IEEE 802.1Qat-2009: Allows the network resources to be reserved for specific traffic streams traversing a bridged local area network.
3. IEEE 802.1AS-2011: Specifies the protocol and procedures used to ensure that the synchronization requirements are met for time-sensitive applications such as audio and video across bridged and virtual-bridged LANs consisting of LAN media where the transmission delays are fixed and symmetrical. For example, IEEE 802.3 full-duplex links include the maintenance of synchronized time during normal operation followed by addition, removal, or failure of network components and network reconfiguration.

70.3.4.9.1 Transmit path functions

When the AV feature is selected, the transmit paths of Queue 0 and the highest enabled queue are enabled by default. The transmit path of Queue 0 supports the strict-priority algorithm, and it is used for best-effort traffic. For a queue, the strict-priority algorithm determines that a packet is available for transmission if the queue contains one or more packets. When the threshold mode for MTL Tx FIFO is enabled, the strict-priority algorithm determines that a packet is available for transmission if the queue contains a partial packet of size equal to the programmed threshold limit.

The transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

1. The queue contains one or more packets.
2. The credit for the queue is positive as per the algorithm.

The credit-based shaper algorithm can be disabled for all queues or lower-priority queues. For example, you can disable the credit-based shaper algorithm for Queue 1 and Queue 2 or only for Queue 1. Do not disable the credit-based shaper algorithm for Queue 2 and enable it for Queue 1. When you disable the credit-based shaper algorithm for a queue, the channel uses the default strict-priority algorithm. Each transmit DMA has a separate descriptor chain for fetching the transmit data. The transmit channel that gets access to the system bus depends on the DMA arbiter.

The transmit path has a shared FIFO (MTL layer) for each queue, as shown in Multiple channels and queues support. The data fetched by the DMA is put in the respective part of the FIFO. The MTL Tx Queue Scheduler controls which part of the FIFO data is transmitted by the MAC. If the credit-based shaper algorithm is enabled for a queue, the corresponding queue is selected for transmission if the following conditions are true:

1. If the packet is available in the channel and has a positive or zero credit.
2. If the higher priority queue has no packet waiting in the FIFO.

If the credit-based shaper algorithm is disabled for all queues, the packet to be transmitted from a queue is selected based on the priority scheme.

70.3.4.9.2 Receive path functions

When the AV feature is selected, the receive path of Queue 0 is enabled by default. All traffic is received on this channel. You can enable the receive paths of additional queues. By enabling the receive paths of multiple channels, you can demultiplex the received data to send the packets into separate receive channels.

To differentiate between the AV and non-AV traffic, the MAC provides a status that indicates if it is an AV packet and its corresponding VLAN Priority tag value. This status is updated in the extended status field of the receive descriptor as explained in "receive descriptor". All received packets with the Ether Type field of 0x22F0 are detected as AV packets. The AV packets can be of the following two types:

1. AV data packets: The AV data packets are always tagged. The tagged AV data packets are received based on the programmed priority value. To specify the channel to which an AV packet with a given priority must be sent, program bits 15:8 in the transmit flow control register of the corresponding queue.
2. Similar to the AV data packets, the tagged AV control packets are received based on the programmed priority value.

In addition to the AV packets, can be received the untagged PTP packets on any queue. By default, the PTP packets (tagged or untagged) are received on Queue 0. To receive these packets on any other queue, you need to program bits 6:4 of the MAC Rx Queue control1 register (MAC_RXQ_CTRL1).

70.3.4.9.3 Credit based shaper algorithm

The MTL queue scheduler uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.The following sections provide information about how you can implement the credit-based shaper algorithm:

1. Credit value
2. idleSlopeCredit and sendSlopeCredit Values
3. Bandwidth status

70.3.4.9.3.1 Credit value

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values.

Table 641. Credit value Per transmit cycle example

Mode	Values	Description
100 Mbps	portTransmitRate = 100 Mbps	
	idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class)	credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted.
	sendSlope = 30 Mbps	credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth available on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The Ethernet block supports another mode in which the credit can build up in advance for a queue in which no packet is available in the respective part of the FIFO. This enables sending a burst of high-priority traffic in a queue as soon as the data is available. You can enable this mode with bit 1 of the CBS control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

70.3.4.9.3.2 idleSlopeCredit and sendSlopeCredit Values

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1,024, such as, 2.8 x 1,024 = 2,867 and 1.2 x 1,024 = 1,229. In addition, the software must program the hiCredit and loCredit values, scaled by 1,024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the

values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12,000 x 1,024 bits and two's complement of 3,036 x1,024, respectively.

70.3.4.9.3.3 Bandwidth status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previously programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in bits 6:4 of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue. A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 the credit-based shaper algorithm (with reserved bandwidth of 50%) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0.

70.3.4.9.4 Slot number function with Audio Video Bridging

In AV mode the slot number function to schedule the data fetching from the system memory by the DMA. This feature is useful when the source AV data needs to be transmitted at specific intervals. Slot number can be programmed to a particular slot at which the DMA should fetch the data from system memory in the transmit descriptor Word 3 (TDES3). This 4-bit field allows the application to schedule data up to 16 slots of 125 µs each. This field is applicable only for the AV channels. When the DMA fetches a Tx descriptor, it compares the slot number of the Tx descriptor with the internally generated reference slot interval. The slot interval is a counter that is updated every 125 µs of the IEEE 1588 system time. In addition, the slot interval counter is initialized to zero when the second field of the system time is incremented, that is, the sub-second counter rolls over. The DMA fetches the data only if it matches the current slot or the next slot. The DMA remains in the descriptor fetch state till there is a match.

To enable the DMA to fetch the data only if it matches the current slot or the next two slots, you can program bit 1 of the slot function control and status register of the corresponding DMA channel. You can enable the check for slot number by setting bit 0 of the slot function control and status register of the corresponding DMA channel. When this check is not enabled, the packets are fetched immediately after the descriptor is read. In addition, bits 19:16 indicate the value of the reference slot number in DMA.

If the slot number in the descriptor is less than the reference slot number, the DMA takes it as a future slot.

See AV feature.

70.3.4.10 Queue modes

You can enable a Tx Queue for generic, AV, or all types of traffic. When you select multiple Tx Queues, the queues are enabled for generic queuing using WRR or WSP algorithms. The queuing is based on the CBS or SP algorithms.You can enable an Rx Queue for generic, AV, or all types of traffic. A particular queue enabled for generic or AV based routing is determined by the RXQEN field of corresponding queue. When you select the enable audio video bridging option, AV is enabled for all selected Rx Queues.

The AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC Rx Queue control 1 register (MAC_RXQ_CTRL1). The priority should be assigned in the following order:

1. AV queue (high priority)
2. Best-effort queue (low priority)

The software should put packets with correct priorities in the respective programmed queue on Tx side. The MAC uses the programmed priorities for blocking the Tx Queues when a PFC packet is received. If a single queue is selected for multiple priorities and PFC is enabled, the entire queue is paused if one or more priorities in the queue are paused.

70.3.5 TCP/IP offloading

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. Therefore, the MAC has a checksum offload engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. By using the Checksum Offload features, the software can offload the task of checksum insertion and checking to the hardware. This feature helps in improving the throughput.

In the transmit path MAC calculates the checksum and inserts it in the Tx packet. In the receive path, MAC verifies the received checksum with the internally calculated checksum and provides the status.

70.3.5.1 Transmit checksum offload engine

The MAC has a checksum offload engine (COE) to support checksum calculation and insertion in the transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in improving the throughput. The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits 17:16).

The checksum for TCP, UDP, or ICMP is calculated over a complete packet and then inserted into its corresponding header field. It must be made sure that the Tx FIFO is deep enough to store a complete packet before that packet is transferred to the MAC transmitter. The reason is that when space is not available to accept the programmed burst length of data, then the MTL Tx FIFO starts reading to avoid dead-lock. When reading starts, the COE fails and consequently, all succeeding packets may get corrupted because of improper recovery. Therefore, you must enable the checksum insertion only in the packets that are less than the following number of bytes in size:

- TXFIFO_SIZE – ((PBL + 6)*(DATAWIDTH/8))

The PBL is the programmed burst length in the DMA Bus mode register.

70.3.5.1.1 IP header checksum engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit header checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the type field of Ethernet packet has the value 0x0800 and the version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

70.3.5.1.2 TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP checksum engine processes the IPv4 or IPv6 header and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the checksum field of the input packet. This engine includes the checksum field in the checksum calculation and then replaces the checksum field with the final calculated checksum.
- The engine ignores the checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation and overwrites the checksum field with the final calculated value.

The result of this operation is indicated by the payload checksum error status bit in the transmit status vector (bit 12 in). This engine sets the payload checksum error status bit when it detects that the packet is forwarded to the MAC transmitter engine in the store and forward mode without the end of packet (EOP) is written to the FIFO, or when the packet ends before the number of bytes indicated by the payload length field in the IP header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 642. Transmit checksum offload engine functions for different frame types

Frame type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6 frame	No	No
IPv4 frame is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K frames is enabled in MAC) but less than or equal to the frame size constraint specified in	Yes	Yes
IPv6 frame is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K frames is enabled in MAC) but less than or equal to the frame size constraint specified in	N/A	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 frame has IP options (IP header is longer than 20 bytes)	Yes	Yes
Frame is an IPv4 fragment	Yes	No
IPv6 frame with the following next header fields in main or extension headers:	N/A	
• Hop-by-hop options (in IPv6 main header)		Yes
• Hop-by-hop options (in IPv6 extension header)		No
• Destinations options		Yes
• Routing (with segment left 0)		No
• Routing (with segment left > 0)		No
• TCP, UDP, or ICMP		Yes
• Authentication		Yes
• Any other next header field in main or extension headers		No
IPv4 frame has TCP header with Options fields.	Yes	Yes
IPv4 Tunnels: • IPv4 frame in an IPv4 tunnel • IPv6 frame in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv4 frame has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled).	Yes	Yes
IPv6 frame has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled).	N/A	Yes

Table continues on the next page...

Table 642. Transmit checksum offload engine functions for different frame types (continued)

Frame type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	N/A	No

70.3.5.2 Receive checksum offload engine

The MAC has a checksum offload engine (COE) to support packet error detection in the receive path. In the receive path, MAC verifies the received checksum with the internally calculated checksum and provides the status. Here, both IPv4 and IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for values 0x0800 or 0x86DD respectively in the Type field of the received Ethernet packet.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP header error bit is set for any mismatch between the indicated payload type (Ethernet type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header). This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a payload checksum error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 643. Receive checksum offload engine functions for different frame types

Frame type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Non-IPv4 or IPv6	No	No
IPv4 frame is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K packets is enabled in the MAC)	Yes	Yes
IPv6 frame is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K frames is enabled in the MAC)	N/A	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 frame has IP options (IP header is longer than 20 bytes)	Yes	Yes
Frame is an IPv4 fragment	Yes	No
IPv6 frame with the following next header fields in main or extension headers:	N/A	
Hop-by-hop options (in IPv6 main header)		Yes

Table continues on the next page...

Table 643. Receive checksum offload engine functions for different frame types (continued)

Frame type	Hardware IP header checksum insertion	Hardware TCP/UDP checksum insertion
Hop-by-hop options (in IPv6 extension header)		No
Destinations options		Yes
Routing (with segment left 0)		Yes
Routing (with segment left > 0)		No
TCP, UDP, or ICMP		Yes
Any other next header field in main or extension headers		No
IPv4 frame has TCP header with Options fields.	Yes	Yes
IPv4 Tunnels: • IPv4 frame in an IPv4 tunnel • IPv6 frame in an IPv4 tunnel	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No
IPv6 Tunnels: • IPv4 frame in an IPv6 tunnel • IPv6 frame in an IPv6 tunnel	N/A	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN tag or S-VLAN tag when enabled)	N/A	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	N/A	No

70.3.6 Loopback mode

The MAC supports loopback of transmitted packets to its receiver. To enable this feature, program the LM bit of the MAC configuration register. Loopback mode can be enabled for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding interface block.

70.3.6.1 Guidelines for using loopback mode

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (CRS) or collision (col) signal inputs get sampled which may result in issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), the Tx and Rx clocks should be externally generated and should provide these clocks to the MAC.
- Do not loop back big packets. Big packets may get corrupted in the loopback FIFO.

The transmit and receive clocks can have an asynchronous timing relationship. Therefore, an asynchronous FIFO is used to make the loopback path of the PHY transmit data to the receive path.

The depth of FIFO is nine. The FIFO is free-running to write on the write clock and read on every read clock.

At the start of each packet readout of the FIFO, the write and read pointers get re-initialized to have an offset of 4. This avoids overflow or underflow during a packet transfer. This also ensures that the overflow or underflow occurs only during the IPG period between the packets. The FIFO depth of five or nine is sufficient to prevent data corruption Therefore, bigger packets should not be looped back because they may get corrupted in this loopback FIFO. At the end of every received packet, the receive protocol engine module generates received packet status and sends it to the receive packet controller module. The control, missed packet, and filter fail status are added to the receive status in the receive packet controller module. The MAC does not process ARP or PMT packets that are looped back.

70.3.7 PHY interfaces

70.3.7.1 Station management agent

The host controller can access the PHY registers through the Station Management Agent (SMA) module. SMA is a two-wire station management interface (MIM).

SMA module supports accessing up to 32 PHYs. The host controller can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module.

70.3.8 IEEE 1588 timestamps

The IEEE 1588 standard defines a protocol, Precision Time Protocol (PTP), that enables precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The Ethernet module supports both the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2) standards. The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588-2008 supports PTP transported over Ethernet. The Ethernet provides programmable support for both standards. It supports the following features:

- Supports both timestamp formats.
- Provides an option to take a snapshot of all packets or only PTP type packets.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent.
- Provides an option to select the node to be a master or slave for ordinary and boundary clocks.
- Identifies the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

70.3.8.1 Clock types

The Ethernet controller supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock
- Boundary clock
- End-to-end transparent clock
- Peer-to-peer transparent clock

70.3.8.1.1 Ordinary clock

The ordinary clock in a domain supports a single copy of the protocol. The ordinary clock has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecommunications applications, the ordinary clock can be associated with a timing demarcation device.

The ordinary clock can be a grandmaster or a slave clock. The ordinary clock supports the following features:

- Maintains the data sets such as timestamp values.

Table 644. Ordinary clock: PTP messages for snapshot

Master	Slave
Delay_Req	SYNC

For an ordinary clock, you can take the snapshot of either one of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the control bit (TSVER2ENA) and selecting the snapshot mode in MAC_TIMESTAMP_CONTROL.

70.3.8.1.2 Boundary clock

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy, and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the core helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:

- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

Therefore, the features of the ordinary clock are also applicable to the boundary clock.

70.3.8.1.3 End-to-end transparent clock

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between slave clocks and the master clock. The end-to-end transparent clock forwards all messages like a normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the ingress port to the egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet inside the end-to-end transparent clock is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both ingress and egress ports only for the messages mentioned in the table below.

You can take the snapshot by setting the snapshot select bits (SNAPTYPSEL) to 10 in MAC_TIMESTAMP_CONTROL.

Table 645. End-to-end transparent clock: PTP messages for which a snapshot is taken for transparent clock implementation

SYNC
FOLLOW_UP

70.3.8.1.4 Peer-to-peer transparent clock support

In this type of clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. Hence support for taking a snapshot for the event messages related to Pdelay is added.

Table 646. End-to-end transparent clock: PTP messages for which a snapshot is taken for transparent clock implementation

SYNC
Pdelay_Req
Pdelay_Resp

The transparent clock corrects only the sync and follow-up message. As discussed earlier this can be achieved using the message status provided.

The type of clock to be implemented is configurable through the control register. To ensure that the snapshot is taken only for the messages indicated in the table for the corresponding clock type, the TSEVNTENA (enable timestamp snapshot for event messages) bit has to be set.

70.3.8.2 Delay request-response mechanism

The system or network is classified into master and slave nodes for distributing the timing/clock information. The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

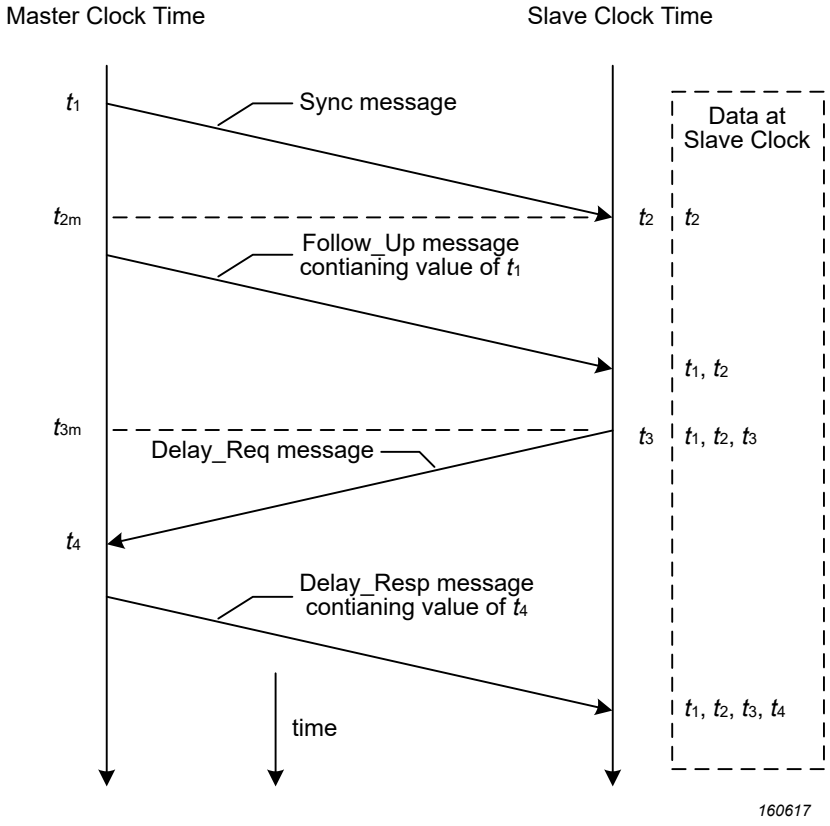

Figure 415. Networked time synchronization

The PTP uses the following process:

1. The master broadcasts the PTP sync messages to all its nodes. The sync message contains the master.s reference time information. The time at which this message leaves the master.s system is t1. This time must be captured, for Ethernet ports, at MII.
2. The slave receives the sync message and also captures the exact time, t2, using its timing reference.

3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master, noting the exact time, t3, at which this frame leaves the MII.
5. The master receives the message, capturing the exact time, t4, at which it enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.

Most of the PTP implementation is done in the software above the UDP layer. However, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

70.3.8.3 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports peer-to-peer PTP (Pdelay) message in addition to sync, delay request, follow-up, and delay response messages. The below figure shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

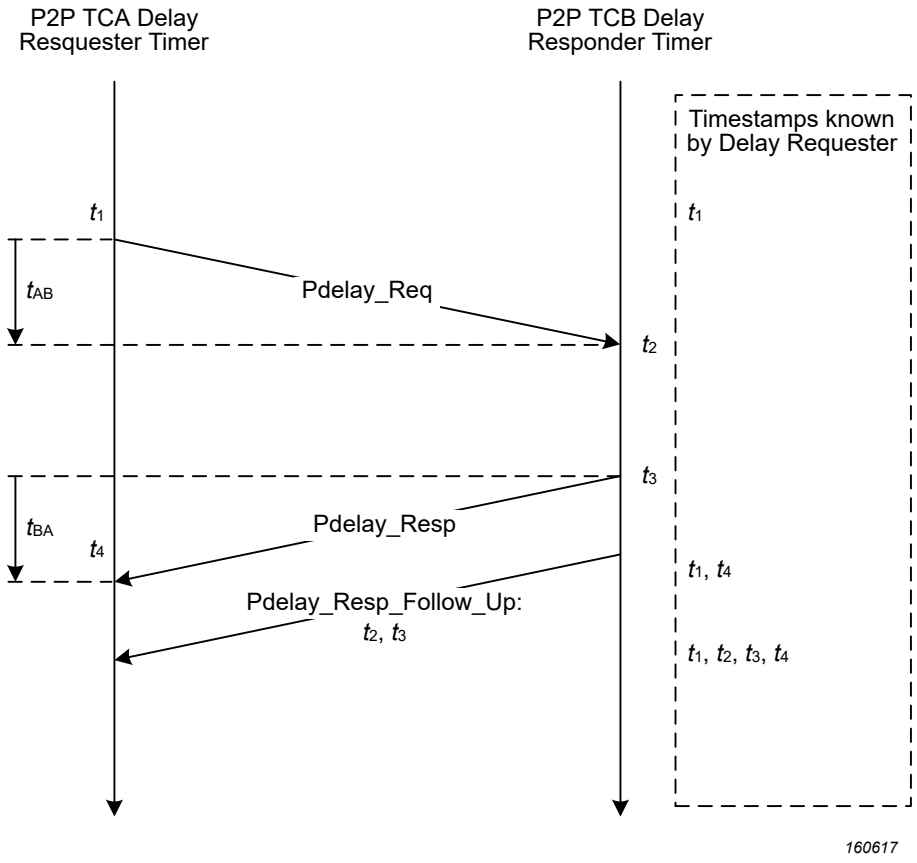

Figure 416. Propagation delay calculation in clocks supporting peer-to-peer path correction

The propagation delay is calculated in the following way:

1. Port-1 issues a Pdelay_Req message and generates a timestamp, t1, for the Pdelay_Req message.
2. Port-2 receives the Pdelay_Req message and generates a timestamp, t2, for this message.
3. Port-2 returns a Pdelay_Resp message and generates a timestamp, t3, for this message.

To minimize errors because of any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. The Port-2 returns any one of the following:

- The difference between the timestamps t2 and t3 in the Pdelay_Resp message.
- The difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message.
- The timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.

4. Port-1 generates a timestamp, t4, on receiving the Pdelay_Resp message.
5. Port-1 uses all four timestamps to compute the mean link delay.

70.3.8.4 Frequency range of the reference timing clock

The timestamp information is transferred across asynchronous clock domains, that is, from MAC clock domain to application clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of II and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (1 ns resulting in 1 GHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the MII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends upon the operating mode and operating speed of the MAC as shown in Table 4-1.

Table 647. Minimum PTP clock frequency cycle

Mode	Minimum gap between two SFDs	Minimum PTP frequency
100-Mbps full-duplex operation	+ 24 clocks of min IFG + 16 clocks of preamble) 168 MII clocks (128 clocks for a 64-byte frame	(3 * PTP) + (4 * MII) ≤ 168 * MII that is, ~0.5 MHz ((168 – 4) * 40 ns ÷ 3 = 2,180 ns period)

70.3.8.5 PTP processing and control

shows the common message header for the PTP messages. This format is taken from IEEE standard 1588-2008 (Revision of IEEE Std. 1588-2002).

There are some fields in the Ethernet payload that you can use to detect the PTP packet type and control the snapshot to be taken. These fields are different for the following PTP frames:

- PTP Frames Over IPv4
- PTP Frames Over IPv6
- PTP Frames Over Ethernet

70.3.8.5.1 PTP frames over IPv4

The table below provides information about the fields that are matched to control snapshot for the PTP packets sent over UDP over IPv4 for IEEE 1588 version 1 and 2. The octet positions for the tagged frames are offset by 4. This is based on Annex D of IEEE 1588-2008 standard and the message format defined in End-to-end transparent clock.

Table 649. IPv4-UDP PTP frame fields required for control and status

Field matched	Octet position	Matched value	Description
MAC Frame Type	12, 13	0x0800	IPv4 datagram
IP version and Header Length	14	0x45	IP version is IPv4
Layer 4 Protocol	23	0x11	UDP
IP Multicast Address (IEEE 1588 version 1)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (or 0x82 or 0x83 or 0x84)	Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132
IP Multicast Address (IEEE 1588 version 2)	30, 31, 32, 33	0xE0, 0x00, 0x01, 0x81 (Hex) 0xE0, 0x00, 0x00, 0x6B (Hex)	PTP-Primary multicast address: 224.0.1.129 PTP-Pdelay multicast address: 224.0.0.107
UDP Destination Port	36, 37	0x013F, 0x0140	0x013F – PTP event message [1] 0x0140 – PTP general messages
PTP control Field (IEEE version 1)	74	0x00/0x01/0x02/0x03/0x04	0x00 – SYNC, 0x01 – Delay_Req

1. The address match of destination addresses (DA) programmed in MAC address 1 to 31 is used if the control bit 18 (TSENMACADDR: enable MAC address for PTP frame filtering) of the timestamp control register is set.
2. IEEE standard 1588-2008, Annex F
3. The Ethernet controller does not consider the PTP version 1 messages with peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

70.3.8.6 Transmit path functions

The MAC captures a timestamp when the start frame delimiter (SFD) of a frame is sent on MII. The frames for which you want to capture timestamps are controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame.

The MAC does not process the transmitted frames to identify the PTP frames. You need to specify the frames for which you want to capture timestamps.

Use the control bits in the transmit descriptor (see). The MAC returns the timestamp to the software inside the corresponding transmit descriptor, thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES6 and TDES7 fields. The TDES7 field holds the 32 least significant bits of the timestamp.

70.3.8.7 Receive path functions

The MAC captures the timestamp of all frames received on the MII. The MAC does not process the received frames to identify the PTP frames in the default mode, that is, when the advanced timestamp feature is not selected.

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the MAC_Timestamp_Control register.

- Enable snapshot for all packets.
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp.
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet.
- Enable timestamp snapshot for the received packet for IPv4 or IPv6.
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP).

- Enable the node to be a master or slave and select the snapshot type This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software inside the corresponding receive descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

70.3.8.8 IEEE 1588-2008 advanced timestamps

In addition to the basic timestamp features (see) the Ethernet controller supports the following advanced timestamp features defined in the IEEE 1588-2008 standard:

- Supports the IEEE 1588-2008 (version 2) timestamp format.
- Provides an option to take snapshots of all frames or only PTP type frames.
- Provides an option to take snapshots of only event messages.
- Provides an option to take the snapshot based on the clock type: ordinary, boundary, end-to-end, and peer-to-peer.
- Provides an option to select the node to be a master or slave for ordinary and boundary clock.
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status.
- Provides an option to measure sub-second time in digital or binary format.

70.3.8.8.1 Reference timing source

The Ethernet controller supports the 48-bit seconds field reference timing sources featured in the IEEE 1588-2008 standard.

The Ethernet controller supports 80-bit timestamping. The timestamp has the following fields:

- UInteger48 secondsField

  The seconds field is the integer portion of the timestamp in units of seconds and is 48-bits wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000 0000 0002.

- UInteger32 nanosecondsField

  The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000 0001.

  The nanoseconds field supports the following two modes:

  — Digital rollover mode: The maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.

  — Binary rollover mode: The nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

You can set these modes by using the bit 9 (TSCTRLSSR) of MAC_TIMESTAMP_CONTROL.

When you select the advanced timestamp feature, the timestamp maintained in the core is still 64-bit wide. The overflow to the upper 16-bits of seconds register happens once in 130 years. You can read the values of the upper 16-bits of the seconds field from the CSR register.

70.3.8.9 System time register module

The 64-bit time is maintained in this module and updated using the input reference clock.

This time is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the MII.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the timestamp update register. For initialization, the system time counter is written with the value in the timestamp update registers, while for system time correction, the offset value is added to or subtracted from the system time.In the fine correction method, a slave clock's frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals. In this method, an accumulator sums up

the contents of the addend register, as shown in Figure 4-2. The arithmetic carries that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

This algorithm is shown in :

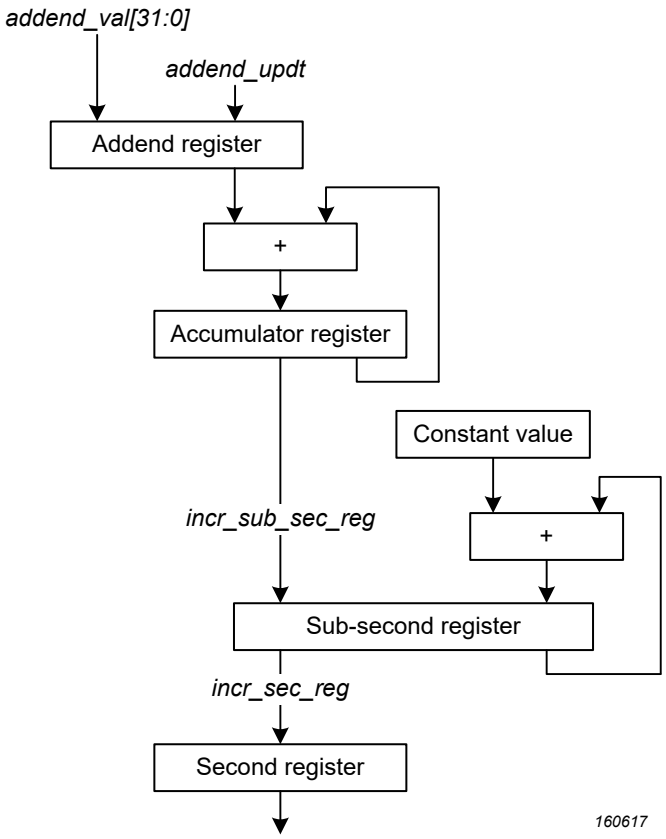

Figure 417. System update using fine method

The system time update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock is, for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to be set in the register is 2^{32} / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 2^{32} / 1.30, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B 7672. When the clock drift is nil, the default addend value of 0xC1F0 7C1F (2^{32} / 1.32) must be programmed.

In , the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20 ns steps).

The software must calculate the drift in frequency based on the sync messages and update the addend register accordingly.

Initially, the slave clock is set with FreqCompensationValue0 in the addend register. This value is:

FreqCompensationValue0 = 2^{32} / FreqDivisionRatio

The frequency division (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency.

If MasterToSlaveDelay is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time $MasterSyncTime_n$ the master sends the slave clock a sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as:

  $MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n$

- The master clock count for current sync cycle, $MasterClockCount_n$ is given by:

  $MasterClockCount_n = MasterClockTime_n - MasterClockTime_{n-1}$ (assuming that MasterToSlaveDelay is the same for sync cycles n and n - 1)

- The slave clock count for current sync cycle, $SlaveClockCount_n$ is given by:

  $SlaveClockCount_n = SlaveClockTimen_n - SlaveClockTime_{n-1}$

- The difference between master and slave clock counts for current sync cycle, $ClockDiffCount_n$ is given by:

  $ClockDiffCount_n = MasterClockCount_n - SlaveClockCount_n$

- The frequency-scaling factor for slave clock, $FreqScaleFactor_n$ is given by:

  $FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n$

- The frequency compensation value for addend register, $FreqCompensationValue_n$ is given by:

  $FreqCompensationValue_n = FreqScaleFactor_n * FreqCompensationValue_{n-1}$

In theory, this algorithm achieves lock in one sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more sync cycles.

70.3.9 DMA controller description

The DMA has independent transmit and receive engines and a CSR space. The transmit engine transfers data from the system memory to the device port (MTL), while the receive engine transfers data from the device port to the system memory. The DMA controller uses descriptors to efficiently move data from source to destination with minimal host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the host CPU for situations such as frame transmit and receive transfer completion, and other normal/error conditions.

The DMA and the host driver communicate through two data structures:

- Control and status registers (CSR).
- Lists and data buffers.

The DMA transfers data frames received by the MAC to the receive buffer in the system memory, and transmit data frames from the transmit buffer in the system memory. Descriptors that reside in the system memory act as pointers to these buffers. There are two descriptor lists; one for reception, and one for transmission.The DMA supports up to two Tx and two Rx descriptor lists (or DMA channels). The base address of each list is written to the respective Tx descriptor list address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. This offset can be controlled by the DSL field of DMA_CH0_CTRL/DMA_CH1_CTRL registers.

The number of descriptors in the list is programmed in the respective Tx (or Rx) descriptor ring length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the list address register to create a descriptor ring. The descriptors lists reside in the host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptors. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when the end-of-frame is detected. data chaining can be enabled or disabled.

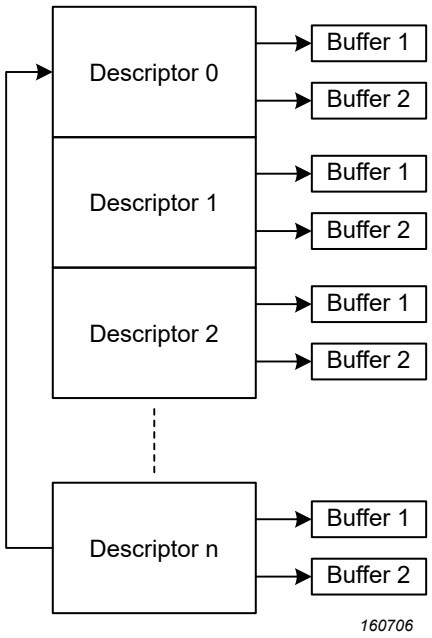

Figure 418. Ring structure

The transmit and receive engines enter the running state and attempt to acquire descriptors from the respective descriptor lists. The receive and transmit engines then begin processing receive and transmit operations. The transmit and receive processes are independent of each other and can be started or stopped separately.

70.3.9.1 Host bus burst access

The DMA attempts to execute fixed-length Burst transfers on the AHB master interface if configured to do so (FB bit of DMA system bus mode register 0). The maximum burst length is indicated and limited by the PBL field (DMA register 0[13:8]). The receive and transmit descriptors are always accessed in the maximum possible (limited by PBL or 16 x 8/bus width) burst size for the 16 bytes to be read.

The transmit DMA initiates a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. Otherwise (no fixed length burst), it transfers data using INCR (undefined length) and SINGLE transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL Receive FIFO or when the end of frame (when it is less than the configured burst length) is detected in the Receive FIFO. The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. If the end of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed to complete the fixed burst. Otherwise (FB bit of DMA_ SYSBUS_MODE register is reset), it transfers data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16) because the AHB interface does not support more than INCR16.

70.3.9.2 Host data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start addresses for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers

with addresses aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example: buffer read

If the transmit buffer address is 0x0000 0FF2 (for 32-bit data bus), and 15 bytes need to be transferred, then the DMA reads five full words from address 0x0000 0FF0, but when transferring data to the MTL Tx Queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures it transfers a full 32-bit data to the MTL Transmit FIFO unless it is the end-of-frame.

Example: buffer write

If the receive buffer address is 0x0000 0FF2 (for 64-bit data bus) and 16 bytes of a received frame need to be transferred, then the DMA writes 3 full words from address 0x0000 0FF0. But the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data.

70.3.9.3 Buffer size calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC core. If a descriptor is marked as first (FS bit of TDES2 is set), then the DMA marks the first transfer from the buffer as the start of the frame. If a descriptor is marked as last (LS bit of TDES2), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. When the FS bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA channel receive control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in bits 14:1 of receive control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (FL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of the next packet with a new descriptor.

Even when the start address of a receive buffer is not aligned to the system bus's data width, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes because of the start address offset.

70.3.9.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB host interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (DA bit of DMA mode register is reset), the arbiter allocates the data bus in the ratio set by the PR bits of DMA mode register, when both transmit and receive DMAs are requesting for access simultaneously. When the DA bit is set, the receive DMA always gets priority over the transmit DMA for data access by default. When the TXPR bit (bit 11 of DMA mode register) is also set, then the transmit DMA gets priority over the receive DMA.

70.3.9.5 Transmission

70.3.9.5.1 TxDMA operation: Default (non-OSF) mode

The transmit DMA engine in default mode proceeds as follows:

1. The host sets up the transmit descriptor (TDES0-TDES3) and sets the OWN bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data.
2. The application advances the descriptor tail pointer offset value of the transmit channel.
3. While in the run state, the DMA runs an arbitration cycle to select the next Tx DMA channel from which the packets requiring transmission should be processed.
4. The DMA fetches the descriptor from the application memory.
5. If the DMA detects one of the following conditions, the transmission from that channel is suspended and bit 2 and bit 16 of the status register of the corresponding DMA channel are set and the Tx engine proceeds to step 11.
   - The descriptor is flagged as owned by the application (TDES3[31] = 0).
   - The descriptor tail pointer is equal to the current descriptor pointer in ring descriptor list mode.
   - An error condition occurs.
6. If the acquired descriptor is flagged as owned by DMA (TDES3[31] = 1), the DMA decodes the transmit data buffer address from the acquired descriptor.
7. The DMA fetches the transmit data from the host memory and transfers the data to the MTL for transmission.
8. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3, 4, and 5 are repeated until the end-of-Ethernet-frame data is transferred to the MTL.
9. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value obtained from MTL is written to the transmit descriptor (TDES0 and TDES1) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES3). Because the OWN bit is cleared during this step, the host now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES0 and TDES1.
10. Bit 0 of the status register of the corresponding channel is set after completing transmission of a packet that has interrupt on completion (TDES2[31]) set in its last descriptor. The DMA engine returns to Step 3.
11. when it receives a transmit poll demand and the underflow interrupt status bit is cleared. If the application stopped the DMA by clearing bit 0 of the transmit control register of the corresponding DMA channel, the DMA enters the stop state.

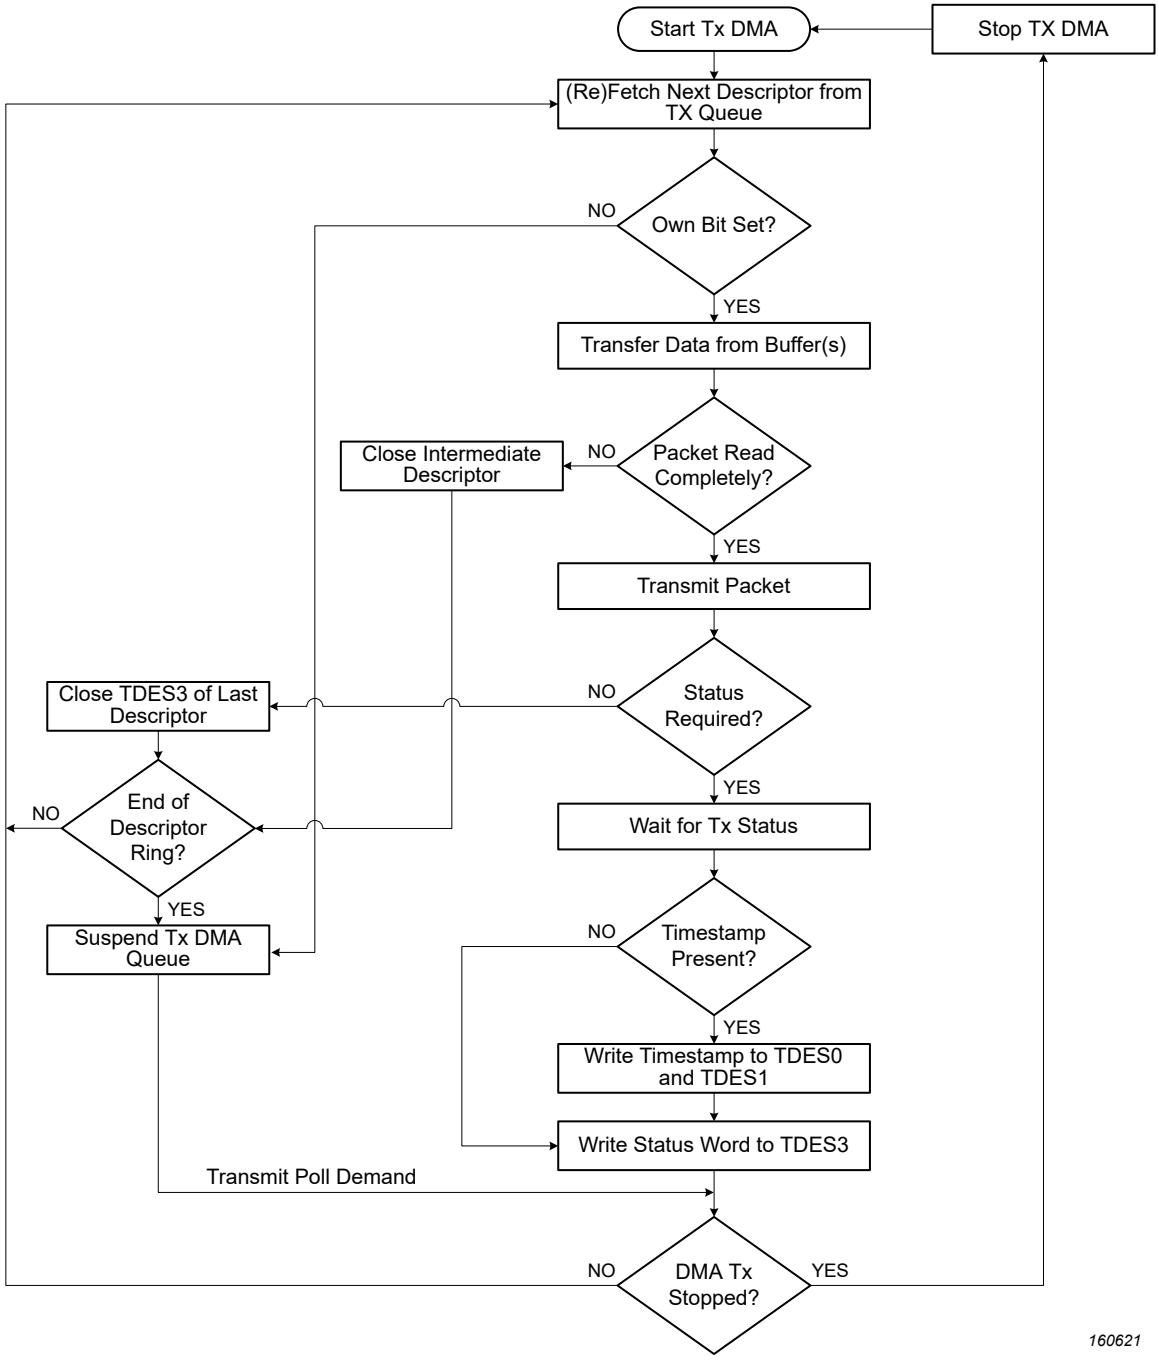

Figure 419. Transmit DMA operation in default mode

70.3.9.5.2 TxDMA operation: OSF mode

In the run state, if bit 4 is set in the transmit control register of the corresponding DMA channel, the transmit process can simultaneously acquire two packets without closing the status descriptor of the first frame. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In OSF mode, the run state transmit DMA operates in the following sequence:

1. The DMA operates as described in steps 1 to 7of the TxDMA (default mode).

2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into suspend mode and skips to Step 7.
4. The DMA fetches the transmit frame from the host memory and transfers the frame to the MTL until the end-of-frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and timestamp. Once the status is available, the DMA writes the timestamp to TDES0 and TDES1, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared OWN bit, to the corresponding TDES3, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3.
6. If enabled, the transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 3 (when status is normal). If the previous transmission status shows an underflow error, the DMA goes into suspend mode (Step 7).
7. In suspend mode, if a pending status and timestamp are received from the MTL, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES3. It then sets relevant interrupts and returns to suspend mode. If no status is pending and the application stopped the DMA by clearing bit 0 of the transmit control register of the corresponding DMA channel, the DMA enters the stop state.
8. The DMA can exit suspend mode and enter the run state (go to Step 1 or Step 2 depending on pending status) only after receiving a transmit poll demand in transmit descriptor tail pointer register of the corresponding channel.

As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than 2 different descriptors for correct and proper operation.

The basic flow is described in the figure below.

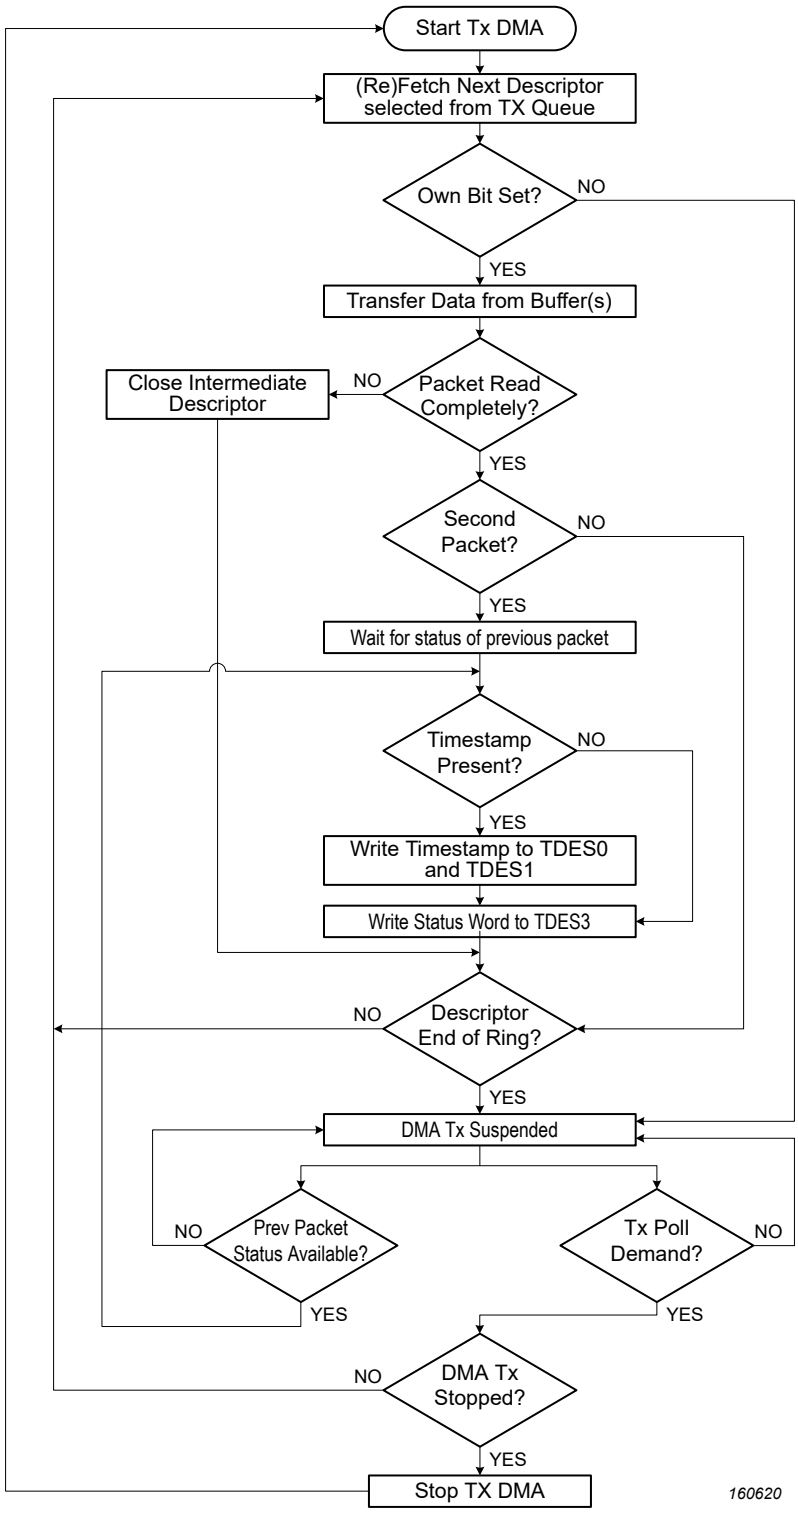

Figure 420. Transmit DMA operation in OSF mode

70.3.9.5.3 Timestamp correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the

network. Because the reference timing source (the PTP clock clk_ptp_ref_i) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.

Ingress Correction: On the receive side, the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (ingress correction value) programmed in the ingress correction register. The value that needs to be programmed in the ingress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding INGRESS_SYNC_CORR to the synchronized timestamp value as:

INGRESS_SYNC_CORR = - (2*PTP_CLK_PER)

The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value(INGRESS_LATENCY) with the captured timestamp as:

Ingress Correction = INGRESS_SYNC_CORR - INGRESS_LATENCY

Ingress correction is performed by programming the TSIC field in the MAC timestamp ingress correction register. The ingress correction is always negative and has a unit of nanoseconds. The value is represented in complement form as follows:

When the TSCTRLSSR bit in the MAC_Timestamp_Control register is set, this has an accuracy of 1 ns. It is represented by setting bit 31 to 1 and bits 30:0 containing

10^9 - <ingress_correction_value> represented in binary. For example, if the required correction value is -5 ns, then the programmed value is 0xBB9A_C9FB. When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 ns. It is represented by setting bit 31 to 1 and bits 30:0 containing

2^{31} - <ingress_correction_value> represented in binary.

Egress correction:

On the transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (egress correction value) programmed in the egress correction register. The value that needs to be programmed in the egress correction register is calculated as follows:

The timestamp correction because of synchronization is compensated by adding EGRESS_SYNC_CORR to the synchronized timestamp value as follows:

When enable one step timestamp feature is selected,

EGRESS_SYNC_CORR = (1*PTP_CLK_PER + 4*TX_CLK_PER)

Otherwise,

EGRESS_SYNC_CORR = -(2*PTP_CLK_PER)

The egress latency correction between the recommended capture point and the internal timestamp snapshot point is done by adding the latency value (EGRESS_LATENCY) with the captured timestamp as follows:

Egress Correction = EGRESS_SYNC_CORR + EGRESS_LATENCY

Egress correction is performed by programming the TSEC field in the MAC timestamp egress correction register. The egress correction can be positive or negative and has a unit of nanoseconds. Negative values are represented in complement form as follows:

When the TSCTRLSSR bit in the MAC_Timestamp_Control register is set, this has an accuracy of 1 ns.

If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <egress_correction_value> represented in binary. The value must not exceed 0x 3B9A_C9FF. If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 10^9 - <egress_correction_value> represented in binary.

For example, if the required correction value is -5 ns, then the programmed value should be 0xBB9A_C9FB

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, this has an accuracy of ~0.466 nS. If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing <egress_correction_value> represented in binary. The

maximum value is 0x7FFF_FFFF. If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing 2^{31} - <egress_correction_value> represented in binary.

70.3.9.5.4 Transmit frame processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and type/len fields contain valid data. If the transmit descriptor indicates that the MAC core must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the first descriptor (TDES3[29]) and the last descriptor (TDES3[28]), respectively.

As transmission starts, the first descriptor must have (TDES3[29]) set. When this occurs, frame data transfers from the host buffer to the MTL Tx Queue. Concurrently, if the current frame has the last descriptor (TDES3[28]) clear, the transmit process attempts to acquire the next descriptor. The transmit process expects this descriptor to have TDES3[29] clear. If TDES3[28] is clear, it indicates an intermediary buffer. If TDES3[28] is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the transmit descriptor 3(TDES3) word of the descriptor that has the last descriptor bit set in transmit descriptor 3 (TDES3[28]). At this time, if the interrupt on completion (TDES2[31]) was set, bit 0 of the status register of the corresponding DMA channel is set, the next descriptor is fetched, and the process repeats.

The actual frame transmission begins after the MTL Tx Queue has reached either a programmable transmit threshold (DMA operation mode register, bits 6:4), or a full frame is contained in the FIFO. There is also an option for store and forward mode (MTL operation mode register, bit 1). In this mode, the descriptors are released (OWN bit TDES0[31] clears) when the DMA finishes transferring the frame.

To ensure proper transmission of a frame and the next frame, you must specify a non-zero buffer size for the transmit descriptor that has the last descriptor (TDES3[28]) set.

70.3.9.5.5 Transmit polling suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the host (TDES3[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a poll demand command by writing the tail pointer register.
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate transmit descriptor 3 (TDES3) bit is set.
- The DMA detects that the tail pointer is equal to the current descriptor closed by it. To resume, the software driver must modify the tail pointer register.

If the second condition occurs, bit 14 of the status register of the corresponding DMA channel is set.

In all three cases, the position in the transmit list is retained. The retained position is that of the descriptor following the last descriptor closed by the DMA.

The driver must explicitly issue a transmit poll demand command after rectifying the suspension cause.

70.3.9.5.6 Transmit channel arbitration

An arbiter provides access to multiple DMAs trying to access the bus interface unit (BIU). Figure 3-21 shows the arbitration process.

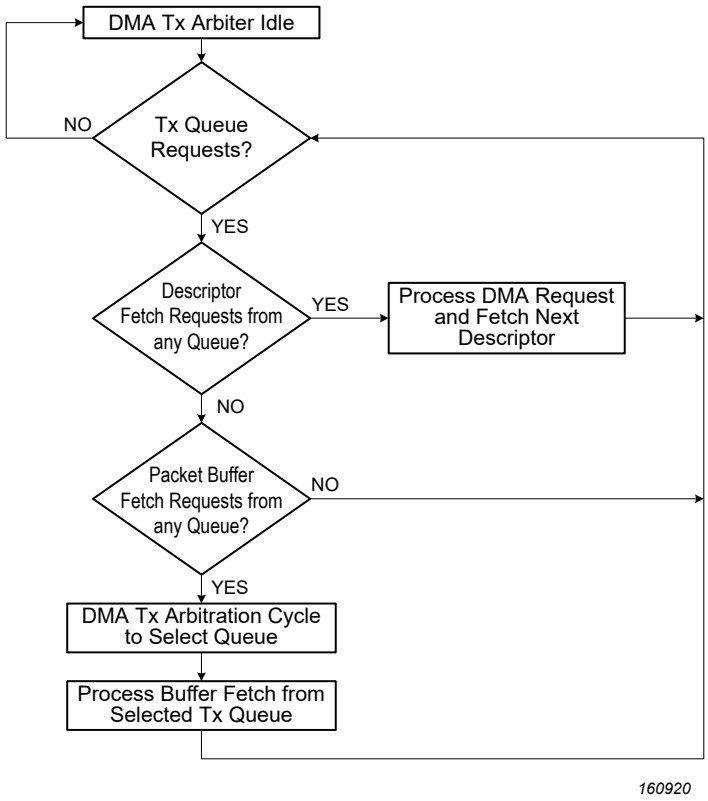

Figure 421. DMA transmit channel arbitration process

When there is any request in the Tx Queue, the DMA arbiter checks the type of the request: packet buffer fetch or descriptor fetch request. The descriptor fetch requests have higher priority than the buffer requests. Therefore, when there is a descriptor fetch request, the DMA arbiter acknowledges the DMA channel that is requesting a descriptor fetch. If there is no descriptor fetch request, the arbiter looks for packet buffer fetch requests.

The DMA arbiter acknowledges the descriptor fetch request of one DMA channel at a time. Descriptor fetch requests are granted using a fixed priority with the higher channel having higher priority (channel 1 having priority over channel 0, channel 2 having priority over channel 1 and so on). For packet buffer fetches, the DMA arbiter uses the programmed channel weight and priority to decide which channel to acknowledge. The DMA arbiter performs a burst-by-burst arbitration based on one of the following algorithms:

- Weighted strict priority (WSP): In WSP arbitration mode, the arbiter first processes channel 7 (or the last enabled channel) and then channel 6, channel 5, and so on. If any channel does not have a frame to transmit, the weight of that channel gets reassigned to channel7 (or last enabled channel). If channel 7 has no frames to transmit, the remaining weight is assigned to channel 6 and so on.
- Weighted round-robin (WRR): In WRR arbitration mode, the arbiter first selects the channel with the highest weight programmed, and then the channel with the next highest weight, and so on. If any channel does not have a frame to transmit, the weight of that channel gets equally distributed to all channels that have frames to transmit.
- Fixed priority (FP): In fixed priority mode, channel 0 has the lowest priority and the last selected channel has the highest priority. The weight programmed in the transmit control register of a channel is ignored.

In WSP or WRR arbitration, the channel weight corresponds to the number of DMA burst transfers for which the DMA arbiter grants the bus to a channel. When a channel completes all the DMA burst transfers, the arbiter grants the bus to the next channel.

70.3.9.5.7 Reception

In the receive path, the DMA reads a packet from the MTL Rx Queue and writes it to the frame data buffers of the corresponding DMA channel. The receive DMA engine's reception sequence is shown in and proceeds as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the OWN bit (RDES3[31]). The host must set the correct value in the receive descriptor tail pointer register of the corresponding DMA channel.
2. is set, the DMA enters the run state. While in the run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the suspend state and jumps to step 11.
3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of the current descriptor.
5. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.
6. Incoming frames are processed and placed in the acquired descriptor's data buffers.
7. The DMA takes the status of the received frame from the MTL and writes the status word to the current descriptor with the OWN bit cleared and the last descriptor bit set.
8. The DMA writes the frame length to RDES3. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 timestamp feature is enabled, the DMA stores the timestamp (if available).
10. If more descriptors are available in the Rx DMA descriptor ring, go to step 3; otherwise, go to the suspend state (step 11).
11. The receive DMA exits the Suspend state when a receive poll demand is given and the application advances the receive tail pointer register of a channel. The engine proceeds to step 2 and fetches the next descriptor.

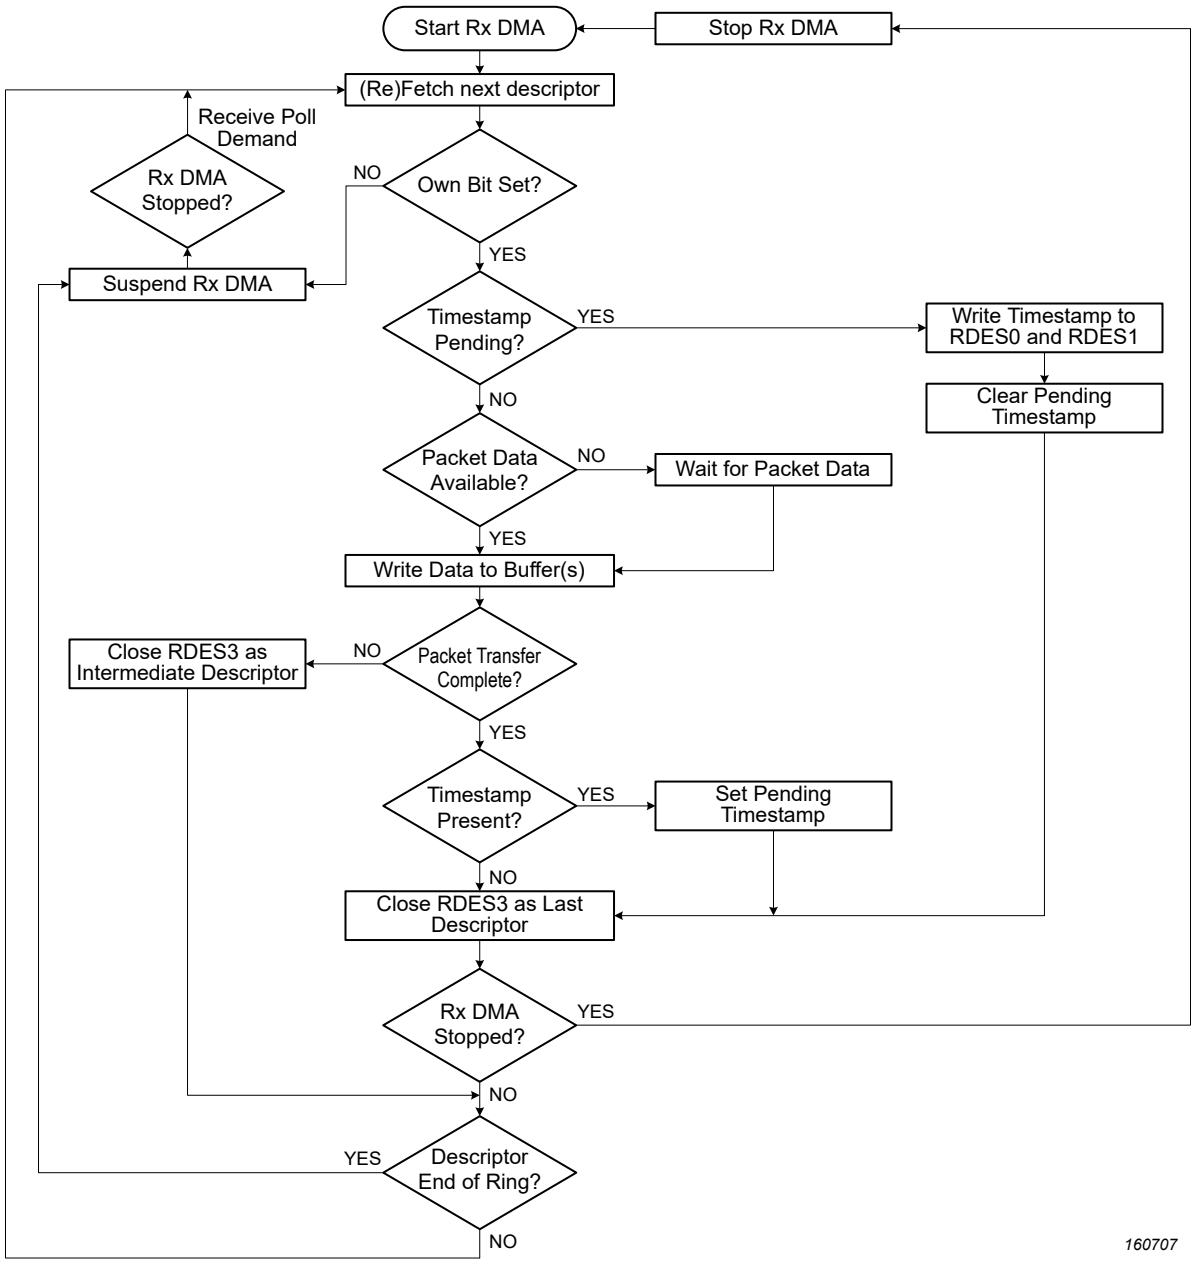

Figure 422. Receive DMA operation

70.3.9.5.8 Receive descriptor acquisition

The receive engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- It is set immediately after being placed in the run state.
- The descriptor tail pointer register value is ahead of the current descriptor acquired by the Rx DMA.
- The controller has completed frame reception, but the current receive descriptor is not yet closed.
- A receive poll demand is issued.

70.3.9.5.9 Receive frame processing

The MAC transfers the received frames to the host memory only when the frame passes the address filter and frame size is greater than or equal to configurable threshold bytes set for the Receive FIFO of MTL, or when the complete frame is written to the queue in store and forward mode.

If the frame fails the address filtering, it is dropped in the MAC block itself (unless receive all bit 31 is set in the MAC frame filter register;). Frames that are shorter than 64 bytes, because of the collision or premature termination, can be purged from the MTL Rx Queue.

When the DMA application interface AHB becomes ready, it transfers the data and sets the following: If the packet fits in a single descriptor, the DMA sets both the last descriptor (RDES3[28]) and the first descriptor (RDES3[29]). If the packets fit into more than one descriptor, the DMA sets the first descriptor (RDES3[29]) to delimit the packet. The descriptors are released when the OWN (RDES[31]) bit is reset to 0, either as the data buffer fills up or as the last segment of the frame is transferred to the receive buffer. The received packets status is updated in the last descriptor.

If interrupt enabled on completion (RDES3[30]) bit is set in any of the descriptors between the first and last descriptor of the packet and bit 6 of interrupt enable register of corresponding DMA channel is set, the DMA sets bit 6 of status register of corresponding DMA channel. The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host or when there are no more descriptors in the ring. When the DMA finds a descriptor owned by the application and if bit 7 of interrupt enable register of the corresponding DMA channel is set, the receive process sets bit 7 of status register of the corresponding DMA channel and then enters the suspend state. The position in the receive list is retained.

70.3.9.5.10 Interrupts

Interrupts can be generated as a result of various events. The DMA interrupt status register contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, normal and abnormal, as described in the DMA status channel status register The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events. Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal is de-asserted. Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated.

For example, receive interrupt bit 6 of the DMA channel status register indicates that one or more packets were transferred to the application buffer. The driver must scan all descriptors, from the last recorded position to the first one, owned by the DMA to determine how many packets are received. The interrupt pin is asserted because of any event in this status register only if the corresponding interrupt enable bit is set in DMA interrupt enable register.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the DMA interrupt status register for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs after the driver has cleared the appropriate bit in the DMA status register.

70.3.9.5.11 Error response to DMA

For any data transfer initiated by a DMA channel, if the slave replies with an error response, that DMA stops all operations and updates the error bits and the fatal bus error bit in the status register of corresponding DMA channel. That DMA controller can resume operation only after soft resetting or hard resetting the core and re-initializing the DMA. The rest of the DMA channels are not affected by such errors.

70.3.10 Ethernet descriptors

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The descriptors supported by Ethernet module are described in subsequent sections.

Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

There is no limit for number of descriptors that can be used for a single packet.

70.3.10.1 Descriptor structure

Ethernet module supports the ring structure for DMA descriptor.

In Ring structure, descriptors are separated by the word, dword, or lword number programmed in the DSL field of the DMA channel control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- DMA channel transmits descriptor ring length register(DMA_CH0_TXDESC_RING_LENGTH and DMA_CH1_TXDESC_RING_LENGTH).
- DMA channel receives descriptor ring length register (DMA_CH0_RX_CONTROL2 and DMA_CH1_RX_CONTROL2).

The descriptor tail pointer register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current descriptor pointer == descriptor tail pointer;

The DMA goes into the suspend mode when this condition occurs. The application must perform a write to the descriptor tail pointer register and update the tail pointer so that the following condition is true:

Current descriptor pointer < descriptor tail pointer;

The DMA automatically wraps around the base address when the end of ring is reached. See

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to descriptor base address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to descriptor base address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

The DMA writes the header length in RDES2 of the first receive descriptor (RDES3[29] (FD bit) is set) for the packet. The packet length is written in RDES3 of the last receive descriptor (RDES3[28] (LD bit) set). The buffer length for the payload is set by the driver through the RBSZ field in the corresponding DMA channel register 2 (receive control register). The DMA fills receive buffers fully in all except the last descriptor.

The header length is taken to be the value based on the bits programmed in the MAC extended configuration register HDSMS field (bits 22:20).

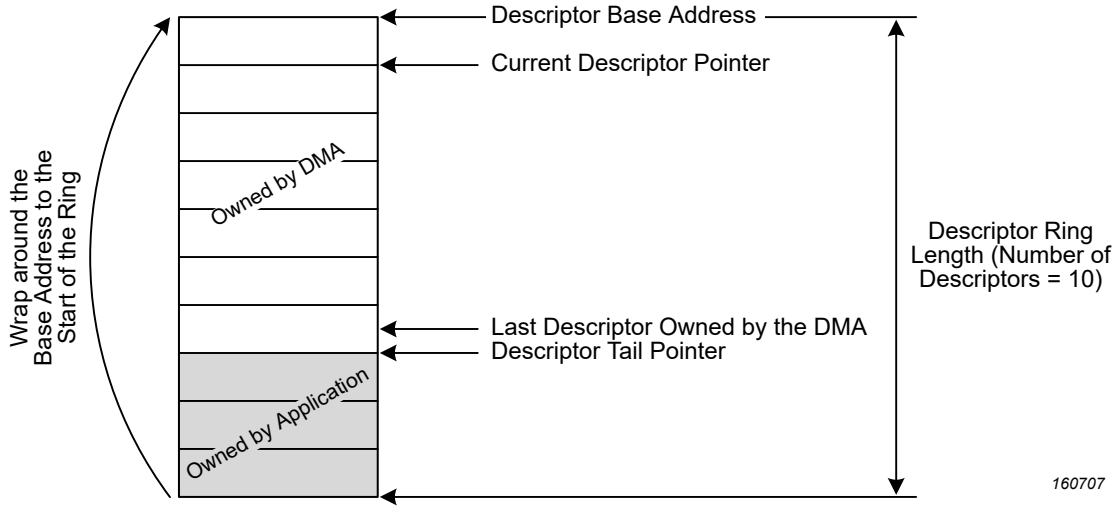

Figure 423. Descriptor ring

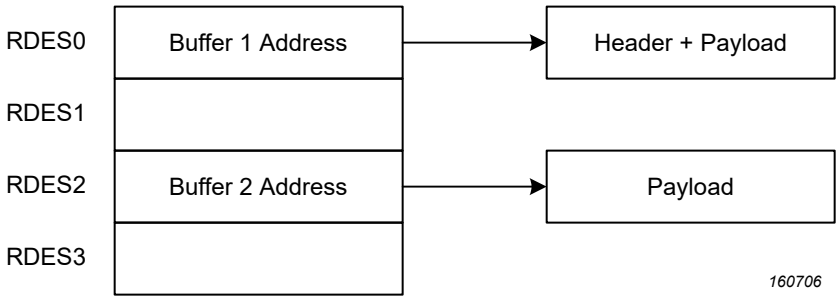

Figure 424. Descriptor structure

70.3.10.2 Descriptor endianness

The data bus can be configured for little-endian format.

70.3.10.3 Transmit descriptor

The DMA in Ethernet core requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields that can be used to control the MAC operation on per-transmit packet basis. The transmit normal descriptor has two formats: read format and write-back format.

70.3.10.3.1 Transmit normal descriptor (read format)

The data bus can be configured for either little-endian or big-endian format. The below figure shows the read format for a transmit normal descriptor.

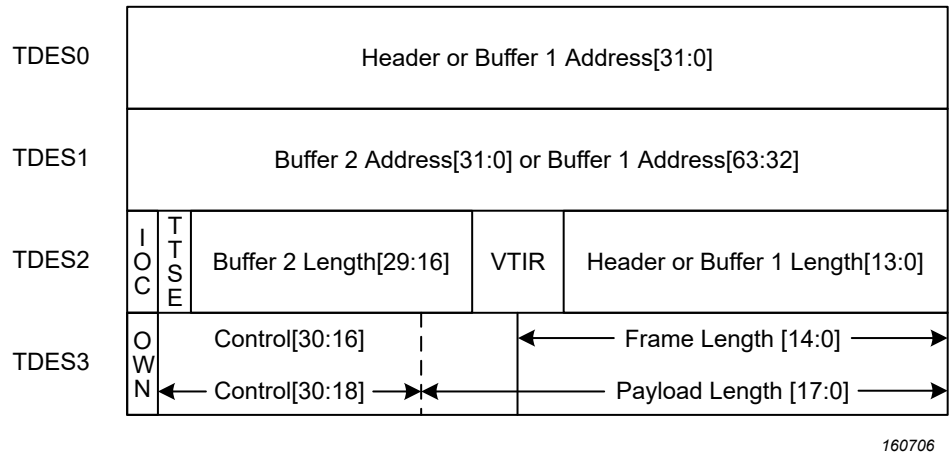

Figure 425. Transmitter descriptor read format

Table 652. Transmit descriptor word 0(TDES0)

Bit	Symbol	Description
31:0	BUF1AP	Buffer 1 address pointer or TSO header address pointer. These bits indicate the physical address of buffer 1. These bits indicate the TSO header address pointer when the following bits are set: TSE bit of TDES3 FD bit of TDES3

Table 653. Transmit descriptor word 1(TDES1)

Bit	Symbol	Description
31:0	BUF2AP	Buffer 2 or buffer 1 address pointer. This bit indicates the physical address of buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the buffer 1 address pointer.

Table 654. Transmit descriptor word 2 (TDES2)

Bit	Symbol	Description
13:0	B1L	Buffer 1 length. This field is equal to buffer 1 length.
15:14	-	Reserved.
29:16	B2L	Buffer 2 length. The driver sets this field. When set, this field indicates buffer 2 length.

Table continues on the next page...

Table 654. Transmit descriptor word 2 (TDES2) (continued)

Bit	Symbol	Description
30	TTSE	Transmit timestamp enable. This bit enables the IEEE1588 timestamping for transmit packet referenced by the descriptor.
31	IOC	Interrupt on completion. This bit sets the TI bit in the DMA channel status register after the present packet has been transmitted.

Table 655. Transmit descriptor word 3 (TDES3)

Bit	Symbol	Description
14:0	FL	Frame length. This field is equal to the length of the frame to be transmitted in bytes. This field is equal to the total length of the frame to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length
15	-	Reserved.
17:16	CIC	Checksum insertion control. These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 0x0: Checksum insertion disabled. • 0x1: Only IP header checksum calculation and insertion are enabled. • 0x2: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 0x3: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware.
18	-	Reserved.
22:19	SLOTNUM	Slot number control bits in AV mode. These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field. DMA channel slot function control status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]:

Table continues on the next page...

Table 655. Transmit descriptor word 3 (TDES3) (continued)

Bit	Symbol	Description
		2'b00: Do not include the source address 2'b01: Include or insert the source address. For reliable transmission, the application must provide frames without source addresses. 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
27:26	CPC	CRC pad control. This field controls the CRC and pad insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of bits 27:26: • 0x0: CRC and pad insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 0x1: CRC insertion (disable pad insertion) The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the transmit buffer, that is, the packet being transferred from the transmit buffer is of length greater than or equal to 60 bytes. • 0x2: Disable CRC insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the transmit buffer. • 0x3: CRC replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the transmit buffer.
28	LD	Last descriptor. When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
29	FD	First descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
30	CTXT	Context type. This bit should be set to 0 for normal descriptor
31	OWN	Own bit. When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).

70.3.10.3.2 Transmit normal descriptor (write-back format)

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding transmit packet.

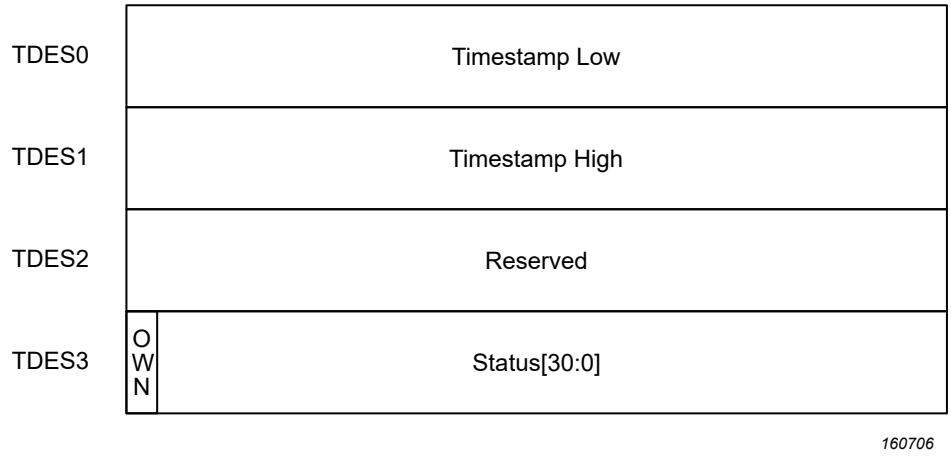

Figure 426. Transmitter descriptor write-back Format

70.3.10.3.3 TDES0 normal descriptor (write-back format)

This format is only applicable to the last descriptor of a packet.

Table 656. TDES0 normal descriptor (write-back Format)

Bit	Symbol	Description
31:0	TTSL	Transmit packet timestamp low. The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the last segment bit (LS) in the descriptor is set and the timestamp status (TTSS) bit is set.

70.3.10.3.4 TDES1 normal descriptor (write-back format)

This format is only applicable to the last descriptor of a packet.

Table 657. TDES1 normal descriptor (write-back format)

Bit	Symbol	Description
31:0	TTSH	Transmit packet timestamp high. The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding receive packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the last segment bit (LS) in the descriptor is set and timestamp status (TTSS) bit is set.

70.3.10.3.5 TDES2 normal descriptor (write-back format)

This format is only applicable to the last descriptor of a packet.

Table 658. TDES2 normal descriptor (write-back format)

Bit	Symbol	Description
31:0	--	Reserved.

70.3.10.3.6 TDES3 normal descriptor (write-back format)

This format is only applicable to the last descriptor of a packet.

Table 659. TDES3 normal descriptor (write-back format)

Bit	Symbol	Description
0	IHE	IP header error. When IP header error is set, this bit indicates that the checksum offload engine detected an IP header error. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet type field indicates an IPv4 payload.
1	DB	Deferred bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
2	UF	Underflow error. This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions: The DMA encountered an empty transmit buffer while transmitting the packet The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL interrupt status register.
3	ED	Excessive deferral. This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times if DC bit is set in the MAC configuration register.
7:4	CC	Collision count/ This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
8	EC	Excessive collision. This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC configuration register, this bit is set after first collision and the transmission of the packet is aborted.
9	LC	Late collision. This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including preamble in MII mode). This bit is not valid if underflow error is set.
10	NC	No carrier.

Table continues on the next page...

Table 659. TDES3 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
		This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
11	LOC	Loss of carrier. This bit indicates that loss of carrier occurred during packet transmission. This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
12	PCE	Payload checksum error. This bit indicates that the checksum offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the payload length field of the IP header, or the MTL starting to forward the packet to the MAC transmitter in store and forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store and forward mode.
13	FF	Packet flushed. This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.
14	JT	Jabber timeout. This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC configuration register is not set.
15	ES	Error summary. This bit indicates the logical OR of the following bits: • TDES3[0]: IP header error • TDES3[14]: jabber timeout • TDES3[13]: packet flush • TDES3[12]: payload checksum error • TDES3[11]: loss of carrier • TDES3[10]: no carrier • TDES3[9]: late collision • TDES3[8]: excessive collision • TDES3[3]: excessive deferral • TDES3[2]: underflow error
16	-	Reserved.
17	TTSS	Tx timestamp status. This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the transmit packet. This field is valid only when the last segment control bit (TDES3[28]) in a descriptor is set.
27:18	-	Reserved.

Table continues on the next page...

Table 659. TDES3 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
28	LD	Last descriptor. This bit is set 1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
29		First descriptor This bit indicates that the buffer contains the first segment of a packet.
30	CTXT	Context type. This bit should be set to 0 for normal descriptor.
31	OWN	Own bit. When this bit is set, it indicates that the Ethernet DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 0.

70.3.10.4 Receive descriptor

The DMA in the Ethernet module attempts to read a descriptor only if the tail pointer is different from the base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC. Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the Rx FIFO in MTL becomes full and starts dropping packets.

All RX descriptors are prepared by the software and given to the DMA as normal descriptors with the content as shown in receive normal descriptor (read format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the receive normal descriptor (write-back format).

In the receive descriptor (read format), if the buffer address field is all 0s, the Ethernet block does not transfer data to that buffer and skips to the next buffer or next descriptor.

In the receive descriptor (read format), if the buffer address field is all 0s, Ethernet does not transfer data to that buffer and skips to the next buffer or next descriptor.

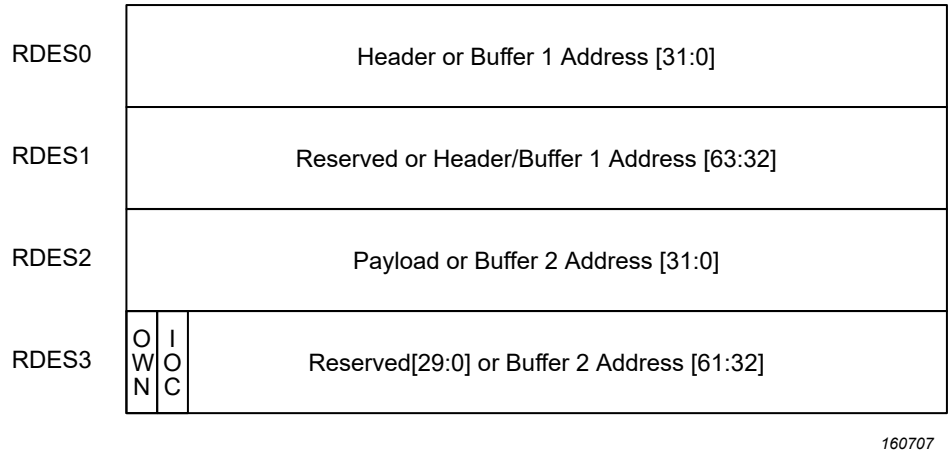

Figure 427. Receive normal descriptor (read format)

70.3.10.4.1 Receive normal descriptor (read format)

Table 660. RDES0 normal descriptor (read format)

Bit	Symbol	Description
31:0	BUF1AP	Header or buffer 1 address pointer. These bits indicate the physical address of buffer 1. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

Table 661. RDES1 normal descriptor (read format)

Bit	Symbol	Description
31:0	-	Reserved.

Table 662. RDES2 normal descriptor (read format)

Bit	Symbol	Description
31:0	BUF2AP	Buffer 2 address pointer. These bits indicate the physical address of buffer 2. The RxDMA uses the LS bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

Table 663. RDES3 normal descriptor (read format)

Bit	Symbol	Description
23:0	-	Reserved.
24	BUF1V	Buffer 1 address valid. When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by buffer 1 address in RDES1 can be used by the DMA to write received packet data.
25	BUF2V	Buffer 1 address valid. When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by buffer 1 address in RDES1 can be used by the DMA to write received packet data.
29:26	-	Reserved.
30	IOC	Interrupt enabled on completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.

Table continues on the next page...

Table 663. RDES3 normal descriptor (read format) (continued)

Bit	Symbol	Description
31	OWN	Own bit. When this bit is set, it indicates that the Ethernet module's DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception. • The buffers associated with the descriptor are full.

70.3.10.4.2 Receive normal descriptor (write-back format)

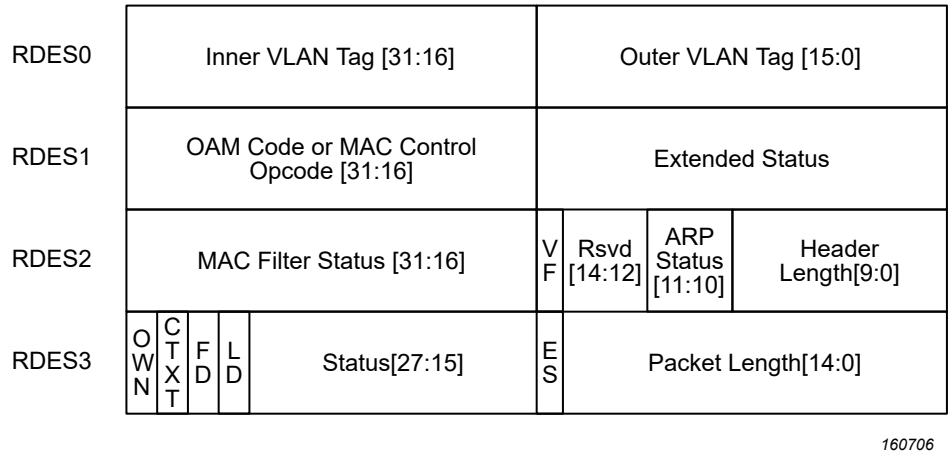

Figure 428. Receive descriptor write-back format

70.3.10.4.3 RDES0 normal descriptor (write-back format)

Table 664. RDES0 normal descriptor (write-back format)

Bit	Symbol	Description
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.

70.3.10.4.4 RDES1 normal descriptor (write-back format)

The status fields in write-back format are valid only for the last descriptor (RDES3[28] is set).

Table 665. RDES1 normal descriptor (write-back format)

Bit	Symbol	Description
2:0	PT	Payload type. These bits indicate the type of payload encapsulated in the IP datagram processed by the receive checksum offload engine (COE): • 0x0: Unknown type or IP/AV payload not processed • 0x1: UDP • 0x2: TCP • 0x3: ICMP • 0x4: IGMP if IPV4 header present bit is set else Reserved • 0x5: AV untagged control packet • 0x6: AV tagged data packet • 0x7: AV tagged control packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 0x0.
3	IPHE	IP header error. When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either bit 5 or bit 4 is set.
4	IPV4	IPV4 header present. This bit indicates that an IPV4 header is detected.
5	IPV6	IPv6 header present. This bit indicates that an IPV6 header is detected.
6	IPCB	IP checksum bypassed. This bit indicates that the checksum offload engine is bypassed.
7	IPCE	IP payload error. When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
11:8	PMT	PTP message type. These bits are encoded to give the type of the message received:

Table continues on the next page...

Table 665. RDES1 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
		• 0x0: No PTP message received • 0x1: SYNC (all clock types) • 0x2: Follow_Up (all clock types) • 0x3: Delay Req (all clock types) • 0x4: Delay Resp (all clock types) • 0x5: Pdelay Req (in peer-to-peer transparent clock) • 0x6: Pdelay Resp (in peer-to-peer transparent clock) • 0x7: Pdelay Resp follow-up (in peer-to-peer transparent clock) • 0x8: Announce • 0x9: Management • 0xA: Signaling • 0xF: PTP packet with Reserved message type • Others: Reserved
12	PFT	PTP packet type. This bit indicates that the PTP message is sent directly over Ethernet.
13	PV	PTP version. This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format.
14	TSA	Timestamp available. When timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the last descriptor bit (RDES3[28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
15	TD	Timestamp dropped. This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow
31:16	OPC	OAM sub-type code, or MAC control packet opcode OAM sub-type code. If bits 18:16 of RDES3 are set to 0x7, this field contains the OAM sub-type and code fields. MAC control packet opcode If bits 18:16 of RDES3 are set to 0x6, this field contains the MAC control packet opcode field.

70.3.10.4.5 RDES2 normal descriptor (write-back format)

Table 666. RDES2 normal descriptor (write-back format)

Bit	Symbol	Description
15:0	-	Reserved.
16	SAF	SA address filter fail. When this bit is set, it indicates that the packet failed the SA filter in the MAC.
17	DAF	Destination address filter fail. When this bit is set, it indicates that the packet failed the DA filter in the MAC.

Table continues on the next page...

Table 666. RDES2 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
18	-	Reserved. Always 0.
26:19	MADRM	MAC address match. When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.
31:20	--	Reserved.

70.3.10.4.6 RDES3 normal descriptor (write-back format)

Table 667. RDES3 normal descriptor (write-back format)

Bit	Symbol	Description
14:0	PL	Packet length. These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and either the descriptor error (RDES3[13]) or overflow error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the last descriptor and error summary bits are not set, this field indicates the accumulated number of bytes that are transferred for the current packet.
15	ES	Error summary. When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC error • RDES3[19]: dribble error • RDES3[20]: receive error • RDES3[22]: watchdog timeout • RDES3[21]: overflow error • RDES3[23]: giant packet This field is valid only when the LD bit of RDES3 is set.
18:16	LT	Length/type field. This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 0x0: The packet is a length packet • 0x1: The packet is a type packet. • 0x3: The packet is a ARP request packet type • 0x4: The packet is a type packet with VLAN tag • 0x5: The packet is a type packet with double VLAN tag

Table continues on the next page...

Table 667. RDES3 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
		• 0x6: The packet is a MAC control packet type • 0x7: The packet is a OAM packet type • 0x2: Reserved
19	DE	Dribble bit error. When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII mode.
20	RE	Receive error. When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the MII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
21	OE	Overflow error. When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store and forward mode, all partial packets are dropped completely in Rx FIFO.
22	RWT	Receive watchdog timeout. When this bit is set, it indicates that the receive watchdog timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
23	GP	Giant packet. When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9,018 or 9,022 bytes if jumbo packet enable is set). Giant packet indicates only the packet length. It does not cause any packet truncation.
24	CE	CRC error. When this bit is set, it indicates that a cyclic redundancy check (CRC) error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive status RDES0 valid. When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive status RDES1 valid. When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
27	RS2V	Receive status RDES2 valid. When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.

Table continues on the next page...

Table 667. RDES3 normal descriptor (write-back format) (continued)

Bit	Symbol	Description
28	LD	Last descriptor. When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
29	FD	First descriptor. When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet.
30	CTXT	Receive context descriptor. When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0x0 to this bit for normal receive descriptor.
31	OWN	Own bit. When this bit is set, it indicates that the Ethernet module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full

70.3.11 Initialization Information

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.It contains the following sections:

- Initializing DMA
- Initializing MTL registers
- Initializing MAC

70.3.11.1 Initializing DMA

Follow these steps to initialize the DMA controller:

1. Assert a software reset by setting bit 0 of the DMA mode register. This resets all of the MAC internal registers and logic.
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA SYSBUS mode register :
   - AAL
   - Fixed burst or undefined burst
   - Burst mode values for AHB bus interface.
4. Create a descriptor list for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3).
5. Program the transmit length registers DMA_CH0_TXDESC_RING_LENGTH, DMA_CH1_TXDESC_RING_LENGTH, DMA_CH0_RX_CONTROL2 and DMA_CH1_RX_CONTROL2. The ring length programmed must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor DMA_CH0_TXDESC_LIST_ADDR, DMA_CH1_TXDESC_LIST_ADDR, DMA_CH0_RXDESC_LIST_ADDR,

and DMA_CH1_RXDESC_LIST_ADDR. Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors DMA_CH0_TXDESC_TAIL_POINTER, DMA_CH1_TXDESC_TAIL_POINTER and DMA_CH0_RXDESC_TAIL_POINTER, DMA_CH1_RXDESC_TAIL_POINTER.

7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSF in case of TxDMA, RBSZ in case of RxDMA. DMA_CH0_CTRL, DMA_CH1_CTRL DMA_CH0_TX_CTRL, DMA_CH1_TX_CTRL, DMA_CH0_RX_CTRL, DMA_CH1_RX_CTRL.
8. Enable the interrupts by programming the DMA_CH0_INTERRUPT_ENABLE, DMA_CH1_INTERRUPT_ENABLE registers.
9. Start the receive and transmit DMAs by setting SR (bit 0) of the DMA_CH0_RX_CTRL, DMA_CH1_RX_CTRL and ST (bit 0) of the DMA_CH0_RX_CTRL, DMA_CH1_RX_CTRL register.

70.3.11.2 Initializing MTL

Complete the following steps to initialize the MTL registers:

1. Program the Tx scheduling (SCHALG) and receive arbitration algorithm (RAA) fields in MTL operation mode register to initialize the MTL operation in case of multiple Tx and Rx Queues.
2. Program the Rx Queue to DMA mapping in MTL Rx Queue and DMA channel mapping register.
3. Program the following fields to initialize the mode of operation in the MTL TxQ0 operation mode register
   - Transmit store and forward (TSF) or transmit threshold control (TTC) in case of threshold mode
   - Transmit Queue enable (TXQEN) to value 0x2 to enable Transmit Queue 0
   - Transmit Queue Size (TQS).
4. Program the following fields to initialize the mode of operation in the MTL RxQ0 operation mode register
   - Receive store and forward (RSF) or RTC in case of threshold mode
   - Flow control activation and deactivation thresholds for MTL Receive FIFO (RFA and RFD).
   - Error packet and undersized good packet forwarding enable (FEP and FUP)
   - Rx Queue size (RQS).
5. Repeat steps 3 and 4 for MTL Tx and Rx Queue 1.

70.3.11.3 Initializing MAC

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_Address0_High and MAC_Address0_Low. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC frame filter register
   - Receive all
   - Promiscuous mode
   - Unicast, multicast, broadcast, and control frames filter settings.
3. Program the following fields for proper flow control in the MAC transmit flow control register
   - Pause time and other pause frame control bits
   - Transmit flow control bits.
   - Flow control busy.
4. Program the MAC_Interrupt_Enable register as required, and if applicable, for your configuration.

5. Program the appropriate fields in the MAC_Configuration register, for example, Inter-packet gap while transmission and jabber disabled.
6. Set bit 0 and 1 in the MAC configuration registers to start the MAC transmitter and receiver.

70.3.11.3.1 Host bus burst access

The DMA attempts to execute fixed-length burst transfers on the AHB master interface if configured to do so (FB bit of DMA register 0). The maximum burst length is indicated and limited by the PBL field (DMA register 0[13:8]). The receive and transmit descriptors are always accessed in the maximum possible (limited by PBL or 16 x 8/bus width) burst-size for the 16-bytes to be read.

The transmit DMA initiates a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. Otherwise (no fixed-length burst), it transfers data using INCR (undefined length) and SINGLE transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the receive FIFO. The DMA indicates the start address and the number of transfers required to the AHB master interface. When the AHB interface is configured for fixed-length burst, then it transfers data using the best combination of INCR4/8/16 and SINGLE transactions. If the end-of frame is reached before the fixed-burst ends on the AHB interface, then dummy transfers are performed in order to complete the fixed-burst. Otherwise (FB bit of DMA_SYS_BUS_MODE register is reset), it transfers data using INCR (undefined length) and SINGLE transactions.

When the AHB interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the AHB initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the AHB interface does not support more than INCR16.

70.3.11.3.2 Host data buffer alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example: buffer read

If the transmit buffer address is 0x0000 0FF2 (for 32-bit data bus), and 15 bytes need to be transferred, then the DMA reads five full words from address 0x00000FF0, but when transferring data to the MTL transmit FIFO, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures it transfers a full 32-bit data to the MTL transmit FIFO, unless it is the end-of-frame.

Example: buffer write

If the receive buffer address is 0x0000 0FF2 (for 64-bit data bus) and 16 bytes of a received frame need to be transferred, then the DMA writes 3 full words from address 0x0000 0FF0. But the first 2 bytes of first transfer and the last 6 bytes of the third transfer have dummy data.

70.3.11.3.3 Buffer size calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by buffer size field of TDES1) towards the MAC core. If a descriptor is marked as first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of a frame. If a descriptor is marked as last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. If a descriptor is not marked as last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of the next frame with a new descriptor.

Even when the start address of a receive buffer is not aligned to the system bus's data width, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual usable space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

70.3.11.3.4 DMA arbiter

The arbiter inside the DMA module performs the arbitration between the transmit and receive channel accesses to the AHB master interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (DA bit of DMA_MODE register) is also set, then the transmit DMA gets priority over the receive DMA.

70.3.12 Application Information

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.It contains the following sections:

- Performing normal receive and transmit operation
- Stopping and starting transmission
- Programming guidelines for multi-channel multi-queuing
- Programming guidelines for MII link state transitions
- Programming guidelines for IEEE 1588 timestamping
- Programming guidelines for AV feature
- Programming guidelines for energy-efficient Ethernet

70.3.12.1 Performing normal receive and transmit operation

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the host (either transmit or receive).
2. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH0_TXDESC_TAIL_PTR / DMA_CH1_TXDESC_TAIL_PTR and DMA_CH0_RXDESC_TAIL_PTR DMA_CH1_RXDESC_TAIL_PTR). Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process DMA current host transmit register Table 854 and DMA current host receive register.
4. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (register DMA current host transmit buffer address register and DMA current host receive buffer address register.

70.3.12.2 Stopping and Starting Transmission

Complete the following steps to pause the transmission for some time. The steps are provided for channel 0. The similar step can be used for other channels.

1. Disable the transmit DMA by clearing bit 0 (ST) of The DMA channel 0 transmit control Table 843 and The DMA channel 1 transmit control registers.
2. Wait for any previous frame transmissions to complete. It can be checked by reading the appropriate bits of the MTL TxQ0 debug register (TRCSTS is not 01 and TXQSTS = 0).
3. Disable the MAC transmitter and MAC receiver by clearing bit (RE) and bit 1(TE) of the MAC configuration register.
4. Disable the receive DMA, after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL TxQ0 debug register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL TxQ0 debug register, and RXQSTS is 0 in MTL RxQ0 debug register
6. To restart the operation, first start the DMAs, and then enable the MAC transmitter and receiver.

NOTE

Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. The Software should change these parameters only when the MAC transmitter and receiver are not active. Similarly the DMA related configuration should not be changed when transmit and receive DMA are in active.

70.3.12.3 Multi-channel multi-queuing

70.3.12.3.1 Transmit

Complete the following steps for transmit.

1. Program the Tx Queue size in the TQS field of MTL TxQ0 operation mode register if queue 0 is used or MTL TxQ1 operation mode register if queue1 is used. Based on the value programmed in TQS field, the size of the queue is determined. In the transmit operation, the number of channels is equal to the number of queues. Due to this reason, the channel to queue mapping is fixed.
2. For a queue to be used, the queue needs to be enabled in TXQEN in the corresponding MTL TxQ operation mode register (MTL TxQ0 operation mode register or MTL TxQ1 operation mode register).
3. The scheduling method needs to be programmed in SCHALG of the MTL operation mode register.
4. Program the corresponding quantum weight register as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TxQ1_ETS_Control, MTL_TxQ1_SendSlopeCredit, MTL_TxQ1_HiCredit, and MTL_TxQ1_LoCredit registers also need to be programmed as required. These registers are not available for Q0.

70.3.12.3.2 Receive

Complete the following steps for transmit.

1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable both the Rx Queues 0 and 1 in the fields RXQ0EN and RXQ1EN in the MAC Rx Queue control0 register for AV.
3. The MAC routes the Rx packets to the Rx Queues based on the following packet types:
4. AV PTP Packets: Based on the programming of AVPTPQ in MAC Rx Queue control register.
5. AV untagged control packets: Based on the programming of AVCPQ in MAC Rx Queue control 1 register.
6. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping

7. Program the RAA field of MTL operation mode register to select the arbitration algorithm to decide which RxQ is read out from the Rx FIFO memory.
8. Program the MTL RxQ control register to decide the weights and the packet arbitration for each RxQ.
9. Set corresponding DADMACH bit in MTL Rx Queue and DMA channel mapping register to select dynamic mapping of packets in each Rx Queue.
10. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of the DCS field in the lowest MAC address register.

1. Program the Receive queue size in the RQS field of MTL_RxQ[n]_Operation_Mode Register. Based on the value programmed in the RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 4 in the fields RXQ0EN to RXQ4EN in MAC_RxQ_Ctrl0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_Rx_Control Register and corresponding RXQ[n]_EN in MAC_RxQ_Ctrl0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on the following packet types:
    a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RxQ_Ctrl1 Register.
    b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RxQ_Ctrl1 Register.
    c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RxQ_Ctrl1 Register to indicate to MAC which queue should get the DCB packets.
    d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ4-0 of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 4.
    e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers.

NOTE

The priorities set in PSRQ4-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
    a. Program the RAA field of MTL_Operation_Mode register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
    b. Program the MTL_RxQ[n]_Control to decide the weights and the packet arbitration for each RxQ.
    c. If static mapping is programmed in MTL_RxQ_DMA_Map[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
    d. Set RXQ[n]DADMACH bit in MTL_RxQ_DMA_Map0 Register to select dynamic mapping of packets in each RxQueue.
    e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of the DCS field in the lowest MAC Address Register.

70.3.12.4 MII link state transitions

70.3.12.4.1 Transmit and receive clocks are running when the link is down

1. Disable the transmit DMA (if applicable) by clearing bit 0 (ST) of the DMA channel control registers (both CH0 and CH1). or
2. Disable the MAC receiver by clearing bit 0(RE) of the MAC configuration register.
3. Wait for any previous frame transmissions to complete. It can be checked this by reading the appropriate bits of MTL_TXQ0_DBG register (TRCSTS is not 01). or Flush the Tx FIFO for faster empty operation.

4. Disable the MAC transmitter by clearing bit 1(TE) of the MAC configuration register.
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in (MTL_TXQ0_DBG register and RXQSTS is 0 in MTL_RxQ0_DBG register).
6. After the link is up, read the PHY registers to know the latest configuration and accordingly program the MAC registers.
7. Restart the operation by starting the Tx DMA, and then enabling the MAC transmitter and receiver. The Rx DMA not need to be disabled. As the receiver is disabled, the FIFO does not get any data in the Rx FIFO.

Complete the following steps when the link is down but the transmit and receive clocks are running: The steps are provided for channel 0.

70.3.12.4.2 Transmit and receive clocks are stopped when the link is down

Complete the following steps when the link is down but the transmit and receive clocks are stopped: The steps are provided for channel 0.

1. Disable the MAC transmitter and receiver by clearing bits RE and TE of MAC configuration register. This will not take effect immediately as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait for the completion of the transfer of any partial frame if any at time of stopping of transmit/receive clock. This can be checked by reading the MAC debug register (should be all zero).Some old packets may still remain in the Tx FIFO as the MAC transmitter is stopped.
4. Read the PHY registers to know the latest operating mode and accordingly program the MAC registers.
5. Restart the MAC transmitter and receiver by setting RE and TE bits.

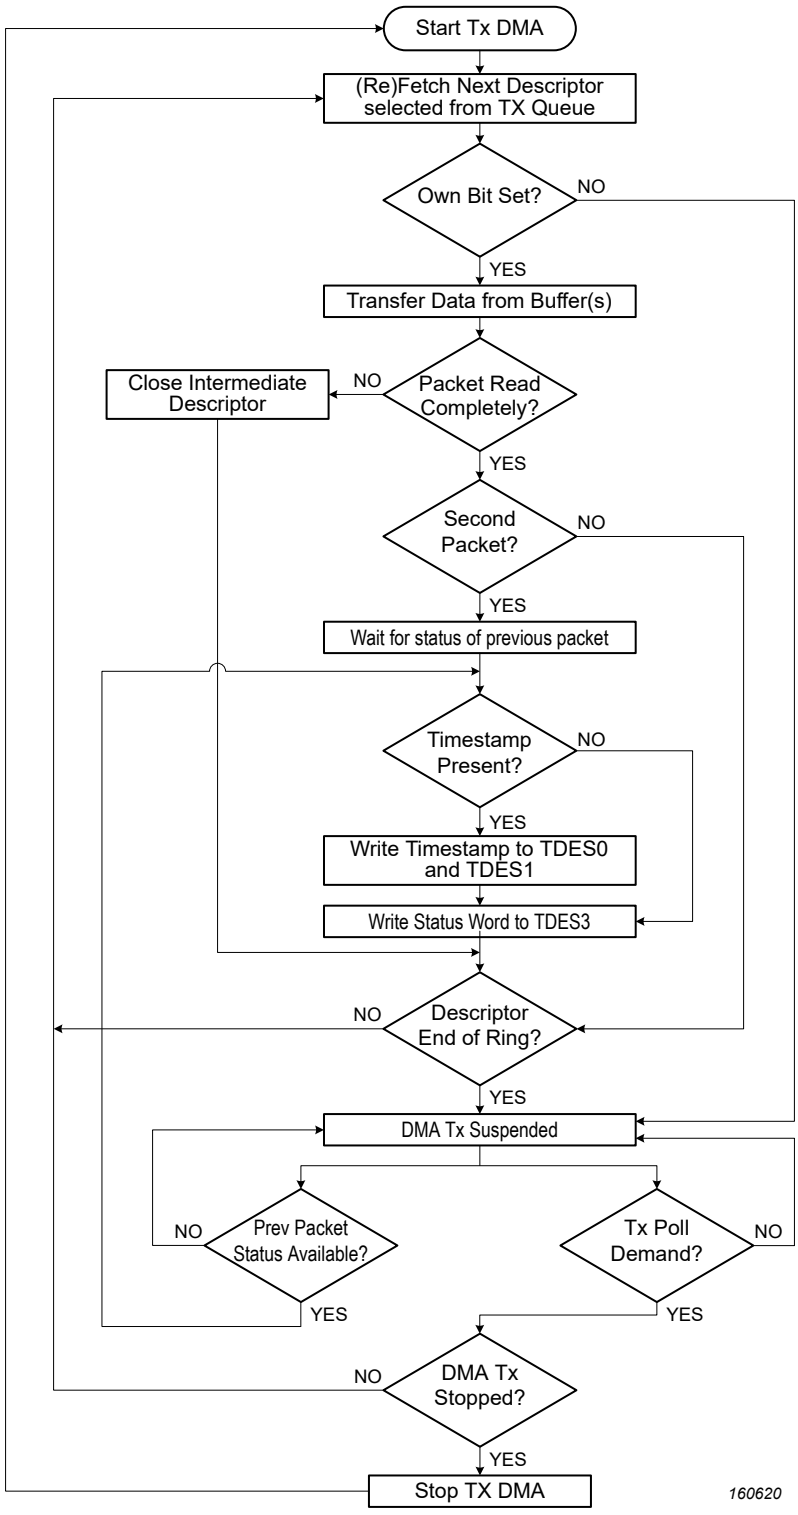

Figure 429. Transmit DMA operation in OSF mode

70.3.12.5 IEEE 1588 timestamping

70.3.12.5.1 Initialization guideline for system time generation

The timestamp feature can be enabled by setting bit 0 of the MAC timestamp control register. However, the timestamp counter must be initialized after this bit is set. Complete the following steps during Ethernet initialization:

1. Mask the timestamp trigger interrupt by clearing the bit 16 of MAC interrupt enable register.
2. Set bit 0 of the MAC timestamp control register to enable timestamping.
3. Program MAC sub-second increment register based on the PTP clock frequency.
4. If a fine correction approach is used, program MAC timestamp addend register and set bit 5 of MAC timestamp control register.
5. Poll the MAC timestamp control register until bit 5 is cleared.
6. Program bit 1 of MAC timestamp control register to select the fine update method (if required).
7. Program MAC system time seconds update register and MAC system time nanoseconds update register with the appropriate time value.
8. Set bit 2 in the MAC timestamp control register. The timestamp counter starts operation as soon as it is initialized with the value written in the timestamp update registers.
9. Enable the MAC receiver and transmitter for proper timestamping.

If timestamp operation is disabled by clearing bit 0 of the MAC timestamp control register, you need to repeat all these steps to restart the timestamp operation.

70.3.12.5.2 System time correction

To synchronize or update the system time in one process (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the timestamp update registers (MAC system time seconds update register and MAC system time nanoseconds update register.
2. Set bit 3 (TSUPDT) of the MAC timestamp control register. The value in the timestamp update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm explained in, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC timestamp addend register with the new value and set bit 5 of the MAC timestamp control register.
3. Wait for the time for which you want the new value of the addend register to be active. You can do this by enabling the timestamp trigger interrupt after the system time reaches the target value.
4. Enable the timestamp interrupt in bit 12 of MAC interrupt enable register.
5. Set bit 4 in MAC timestamp control register.
6. When this trigger causes an interrupt, read MAC interrupt status register.
7. Reprogram MAC timestamp addend register with the old value and set bit 5 again.

70.3.12.6 AV feature

70.3.12.6.1 Initializing the DMA

Complete the following steps to initialize the DMA:

1. Assert a software reset by setting bit 0 in DMA mode register. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).

2. Wait for the completion of the reset process (poll bit 0 of the DMA_Mode, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SYSBUS_MODE register:
    a. AAL
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). When OSF mode is used, at least two TX descriptors are required. For more information about descriptors, see Descriptor structure.
5. Make sure that the driver software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= 1) and DMA_CH(#i)_RX_CONTROL2 (for i = 0; i <= 1)). The ring length programmed must be at least 4.

NOTE

The descriptor address from the start to the end of the ring must not cross the 4GB boundary.

7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RxDesc_List_Address (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RxDesc_Tail_Pointer (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1))

NOTE

For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TxDesc_List_HAddress, DMA_CH[n]_RxDesc_List_HAddress).

The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

8. Program the following fields to initialize the mode of operation in the MTL_TxQ0 operation mode register.
    - Transmit store and forward (TSF)
    - Transmit threshold control (TTC)
    - Transmit Queue enable (TXQEN) to value 0x2 to enable Transmit Queue 0
    - Transmit Queue size (TQS)
9. Enable the interrupts by programming the DMA_CH0_INTERRUPT_ENABLE and register.
10. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
11. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

70.3.12.6.2 Enabling slot number checking

The slot number check feature can be used to specify the intervals at which the DMA channels mapped to AV queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the Ethernet memory. Complete the following steps to enable the slot number checking:

1. Enable timestamping by following the steps described in "Initialization Guideline for System Time Generation".

2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).
3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

70.3.12.6.3 Enabling average bits per slot reporting

The MTL TxQ ETS status register of a particular AV channel provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. Complete the following steps to enable average bits per slot reporting:

1. of a channel to generate the average bits per slot interrupt.
2. of a channel on each interrupt.

The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated every 125 microseconds.

When not required, you can disable this interrupt to stop the interrupt flooding. The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL TxQ ETS status register indicates that a new value is updated in the ABS field.

70.3.12.7 Energy efficient Ethernet

70.3.12.7.1 Entering and exiting the Tx LPI mode

Complete the following steps during Ethernet core initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX CLK stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode.)
3. Program Bits[25:16] and Bits[15:0] in MAC_LPI_TIMERS_CONTROL register.
4. Read the link status of the PHY chip by using the MDIO interface and update bit 17 of the MAC LPI control status register accordingly. This update should be done whenever the link status in the PHY chip changes.
5. Program the MAC_1US_TIC_COUNTER as per the frequency of the clock used for accessing the CSR slave port.
6. Program the MAC_LPI_ENTRY_TIMER register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
7. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_CONTROL_STATUS register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
8. Program the MAC_1US_TIC_COUNTER as per the frequency of the clock used for accessing the CSR slave port.
9. Program the MAC_LPI_ENTRY_TIMER register (LPIET) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
10. Set LPITE and LPITXA (bit[20:19]) of MAC_LPI_CONTROL_STATUS register to enable the auto-entry into LPI and auto-exit of MAC from LPI state.
11. Set Bit 16 of MAC_LPI_CONTROL_STATUS register to make the MAC Transmitter enter the LPI state. The MAC enters the LPI mode after completing all scheduled packets and remains IDLE for the time indicated by LPIET. It sets the TLPIEN (bit[0]) after entry to LPI state before step 12.
12. When a packet is scheduled for transmission (when the TxDMA comes out of IDLE state or when a packet is presented at ATI or MTI interface), the MAC Transmitter exits LPI state automatically. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.

13. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
14. MAC Transmitter re-enters LPI state if it remains IDLE for LPIET time and sets the TLPIEN bit and the entry-exit cycle continues.
15. Reset LPITXEN in case the application wants to over-ride the auto-entry/exit modes and make the MAC Transmitter exit the LPI state directly.
16. Start the receive and transmit DMA by setting bit 0 of the DMA channel 0, channel 1 transmit control register and bit 0 of DMA channel 0, channel 1 receive control register.

NOTE

To ensure MAC enter the LPI state only after completion of transmission of all the queued frames in the Tx FIFO, you should set Bit 19 in MAC_LPI_Control_Status register.

To switch off the GMII Transmit Clock during the LPI state, use the sbd_tx_clk_gating_ctrl_o signal for gating the clock input.

70.3.12.7.2 Enabling Slot Number Checking

The slot number check feature can be used to specify the intervals at which the DMA channels mapped to AV queues fetches the frames from the AHB system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the Ethernet memory. Complete the following steps to enable the slot number checking:

1. Enable timestamping by following the steps described in Initialization guideline for system time generation.
2. Make sure that the SLOTNUM field (bits 22:19) of the TDES3 normal descriptor (read format) contains a valid slot number. The current reference slot number can be read from the DMA channel 0 and channel 1 slot function control register
3. Set bit 0 (ESC) of the slot function control and status register of a channel to enable the slot number checking

70.4 Signals

NOTE

Table 668. Ethernet Signals

Pin function	Direction	Description
MIIM interface		
MDIO	I/O	Ethernet MIIM data input and output.
MDC	O	MIIM clock.
RMII interface		
RXD[1:0]	I	Receive data.
TXD[1:0]	O	Transmit data.
RX_DV	I	Receive data valid.
TX_EN	O	Ttransmit data enable.

Table continues on the next page...

Table 668. Ethernet Signals (continued)

Pin function	Direction	Description
MII interface		
RXD[3:0]	I	Receive data.
TXD[3:0]	O	Transmit data.
COL	I	Collision detect.
CRS	I	Carrier sense.
TX_ER	O	Transmit error.
TX_CLK	I	Transmit clock.
RX_CLK	I	Receive clock.
RX_ER	I	Receive error.
TX_EN	O	Transmit enable.

70.5 Memory Map and register definition

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section includes the eNET module memory map and detailed descriptions of all registers.

NOTE

After a write operation, when a register content is being transferred to a different clock domain, user needs to wait at least for four cycles of the destination clock (PHY Receive clock, PHY Transmit clock, or PTP clock) before writing to the same register.

70.5.1.2 MAC Configuration (MAC_CONFIGURATION)

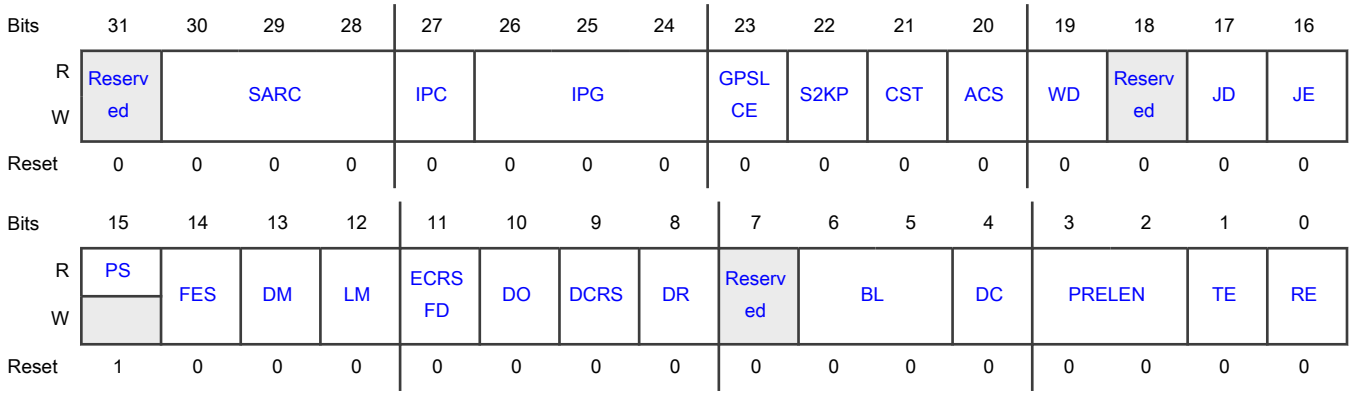
Offset

Register	Offset
MAC_CONFIGURATION	0h

Function

The MAC Configuration Register establishes the operating mode of the MAC.

Diagram



Fields

Field	Function
31 —	Reserved
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the IP, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000b - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010b - Contents of MAC Addr-0 inserted in SA field 011b - Contents of MAC Addr-0 replaces SA field

Table continues on the next page...

Table continued from the previous page...

Field	Function
	110b - Contents of MAC Addr-1 inserted in SA field 111b - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0b - IP header/payload checksum checking is disabled 1b - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. This function (IPG less than 96 bit times) is valid only when MAC_EXT_CONFIGURATION[EIPGEN] bit is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_Ext_Configuration register. 000b - 96 bit times IPG 001b - 88 bit times IPG 010b - 80 bit times IPG 011b - 72 bit times IPG 100b - 64 bit times IPG 101b - 56 bit times IPG 110b - 48 bit times IPG 111b - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_Ext_Configuration register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet). The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018

Table continues on the next page...

Table continued from the previous page...

Field	Function
	bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0b - Giant Packet Size Limit Control is disabled 1b - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Giant Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0b - Support upto 2K packet is disabled 1b - Support upto 2K packet is Enabled
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. 0b - CRC stripping for Type packets is disabled 1b - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. 0b - Automatic Pad or CRC Stripping is disabled 1b - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0b - Watchdog is enabled 1b - Watchdog is disabled
18	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
17 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0b - Jabber is enabled 1b - Jabber is disabled
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0b - Jumbo packet is disabled 1b - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). 0b - For 1000 or 2500 Mbps operations 1b - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. 0b - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0 1b - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0b - Half-duplex mode 1b - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Loopback is disabled 1b - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0b - ECRSFD is disabled 1b - ECRSFD is enabled
10 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0b - Enable Receive Own 1b - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0b - Enable Carrier Sense During Transmission 1b - Disable Carrier Sense During Transmission
8 DR	Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0b - Enable Retry 1b - Disable Retry
7 —	Reserved
6-5 BL	Back-Off Limit

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00b - k = min(n,10) 01b - k = min(n,8) 10b - k = min(n,4) 11b - k = min(n,1)
4 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288-bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII or MII. The defer time is not cumulative. For example, if the transmitter defers for 10,000-bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and a collision happens. Because of the collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0b - Deferral check function is disabled 1b - Deferral check function is enabled
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00b - 7 bytes of preamble 01b - 5 bytes of preamble 10b - 3 bytes of preamble 11b - Reserved
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII or MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Transmitter is disabled 1b - Transmitter is enabled
0 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII or MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII or MII interface. 0b - Receiver is disabled 1b - Receiver is enabled

70.5.1.3 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

Offset

Register	Offset
MAC_EXT_CONFIGURATION	4h

Function

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in CONFIGURATION register, gives the minimum IPG greater than 96-bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104-bit times 8'h01 - 112-bit times 8'h02 - 120-bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in CONFIGURATION register together as minimum IPG greater than 96-bit times in steps of 8-bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in CONFIGURATION register as minimum IPG less than or equal to 96-bit times in steps of 8-bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0b - Extended Inter-Packet Gap is disabled 1b - Extended Inter-Packet Gap is enabled
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_ADDRESS(#i)_HIGH register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of ADDRESS(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Packet Duplication Control is disabled 1b - Packet Duplication Control is enabled
18 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0b - Unicast Slow Protocol Packet Detection is disabled 1b - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0b - Slow Protocol Detection is disabled 1b - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0b - CRC Checking is enabled 1b - CRC Checking is disabled
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_CONFIGURATION register.

70.5.1.4 MAC Packet Filter (MAC_PACKET_FILTER)

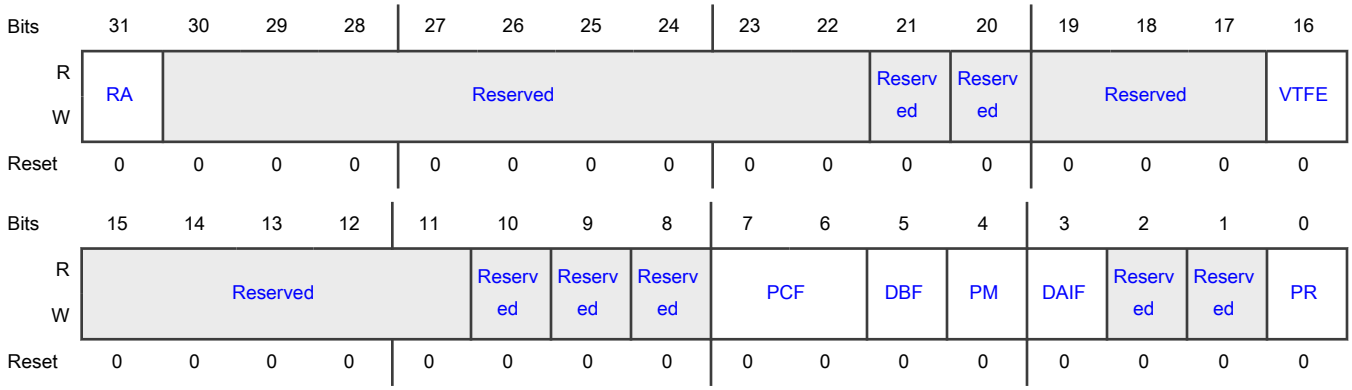
Offset

Register	Offset
MAC_PACKET_FILTER	8h

Function

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Diagram



Fields

Field	Function
31 RA	Receive All When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0b - Receive All is disabled 1b - Receive All is enabled
30-22 —	Reserved
21 —	Reserved
20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0b - VLAN Tag Filter is disabled 1b - VLAN Tag Filter is enabled
15-11 —	Reserved
10 —	Reserved
9 —	Reserved
8 —	Reserved
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00b - MAC filters all control packets from reaching the application 01b - MAC forwards all control packets except Pause packets to the application even if they fail the address filter 10b - MAC forwards all control packets to the application even if they fail the address filter 11b - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0b - Enable Broadcast Packets 1b - Disable Broadcast Packets
4 PM	Pass All Multicast

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0b - Pass All Multicast is disabled 1b - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0b - DA Inverse Filtering is disabled 1b - DA Inverse Filtering is enabled
2 —	Reserved
1 —	Reserved
0 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0b - Promiscuous Mode is disabled 1b - Promiscuous Mode is enabled

70.5.1.5 Watchdog Timeout (MAC_WATCHDOG_TIMEOUT)

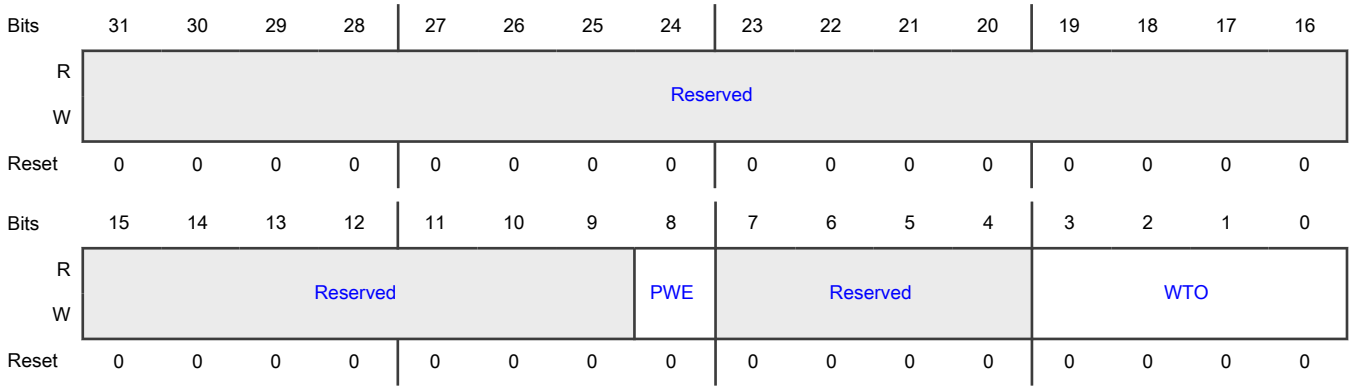
Offset

Register	Offset
MAC_WATCHDOG_TIMEOUT	Ch

Function

The Watchdog Timeout register controls the watchdog timeout for received packets.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_CONFIGURATION register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_CONFIGURATION register. 0b - Programmable Watchdog is disabled 1b - Programmable Watchdog is enabled
7-4 —	Reserved
3-0 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_CONFIGURATION register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0000b - 2 KB 0001b - 3 KB 0010b - 4 KB 0011b - 5 KB 0100b - 6 KB 0101b - 7 KB 0110b - 8 KB

70.5.1.6 MAC VLAN Tag Control (MAC_VLAN_TAG_CTRL)

Offset

Register	Offset
MAC_VLAN_TAG_CTRL	50h

Function

This register is the redefined format of the MAC VLAN Tag Register. It is used for indirect addressing. It contains the address offset, command type and Busy Bit for CSR access of the Per VLAN Tag registers.

Fields

Field	Function
31	Enable Inner VLAN Tag in Rx Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0b - Inner VLAN Tag in Rx status is disabled 1b - Inner VLAN Tag in Rx status is enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
27 ERIVLT	Enable Inner VLAN Tag Enable Inner VLAN Tag When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching. 0b - Inner VLAN tag is disabled 1b - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0b - Double VLAN Processing is disabled 1b - Double VLAN Processing is enabled
25 —	Reserved
24 EVLRXS	Enable VLAN Tag in Rx status Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status. 0b - VLAN Tag in Rx status is disabled 1b - VLAN Tag in Rx status is enabled
23	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
22-21 EVLS	Enable VLAN Tag Stripping on Receive 00b - Do not strip 01b - Strip if VLAN filter passes 10b - Strip if VLAN filter fails 11b - Always strip
20 DOVLTC	Disable VLAN Type Check When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit. The VLAN filter is bypassed when VLAN Type of received packet do not match the programmed VLAN Type in the VLAN filter. 0b - VLAN Type Check is enabled 1b - VLAN Type Check is disabled
19 ERSVLM	Enable Receive S-VLAN Match When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. The ERIVLT bit determines the VLAN tag position considered for filtering or matching. 0b - Receive S-VLAN Match is disabled 1b - Receive S-VLAN Match is enabled
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0b - S-VLAN is disabled 1b - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0b - VLAN Tag Inverse Match is disabled 1b - VLAN Tag Inverse Match is enabled
16 ETV	Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged

Table continues on the next page...

Table continued from the previous page...

Field	Function
	packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN hash filtering. 0b - 12-bit VLAN Tag Comparison is disabled 1b - 12-bit VLAN Tag Comparison is enabled
15-0 VL	VLAN Tag Identifier for Receive Packets This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field: Bits[15:13]: User Priority Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) Bits[11:0]: VLAN Identifier (VID) field of VLAN tag When the ETV bit is set, only the VID is used for comparison. If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.

70.5.1.7 VLAN Tag Inclusion or Replacement (MAC_VLAN_INCL)

Offset

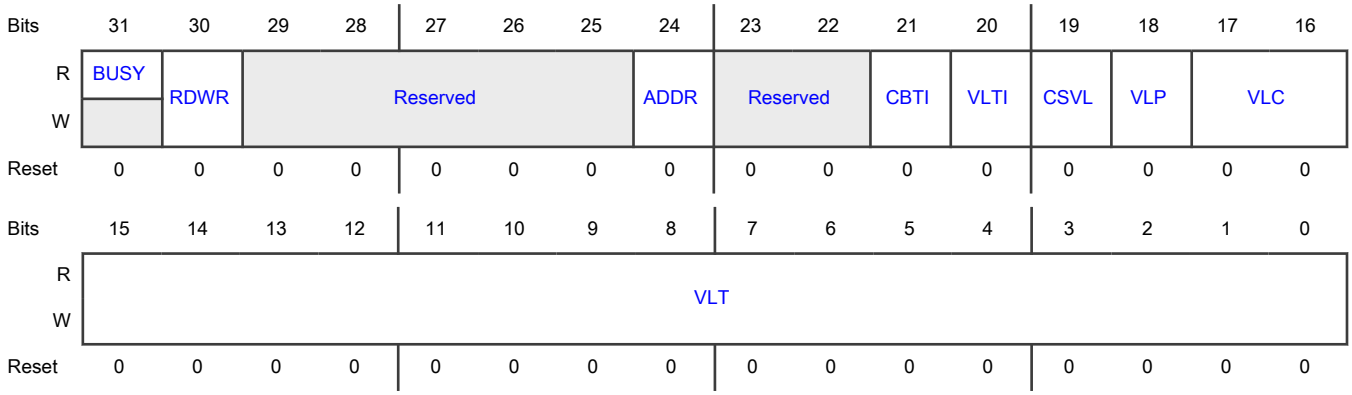
Register	Offset
MAC_VLAN_INCL	60h

Function

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the transmit packets.

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the transmit packets. It also contains the VLAN tag insertion controls.

Diagram



Fields

Field	Function
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0b - Busy status not detected 1b - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0b - Read operation of indirect access 1b - Write operation of indirect access
29-25 —	Reserved
24 ADDR	Address Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 CBTI	Channel based tag insertion When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0b - Channel based tag insertion is disabled 1b - Channel based tag insertion is enabled
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: The Tx descriptor 0b - VLAN Tag Input is disabled 1b - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted or replaced 1b - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0b - VLAN Priority Control is disabled 1b - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets VLAN Tag Control in Transmit Packets 2'b00: No VLAN tag deletion, insertion, or replacement 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. 2'b10: VLAN tag insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: Bits[15:13]: User priority Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

70.5.1.8 MAC Inner VLAN Tag Inclusion or Replacement (MAC_INNER_VLAN_INCL)

Offset

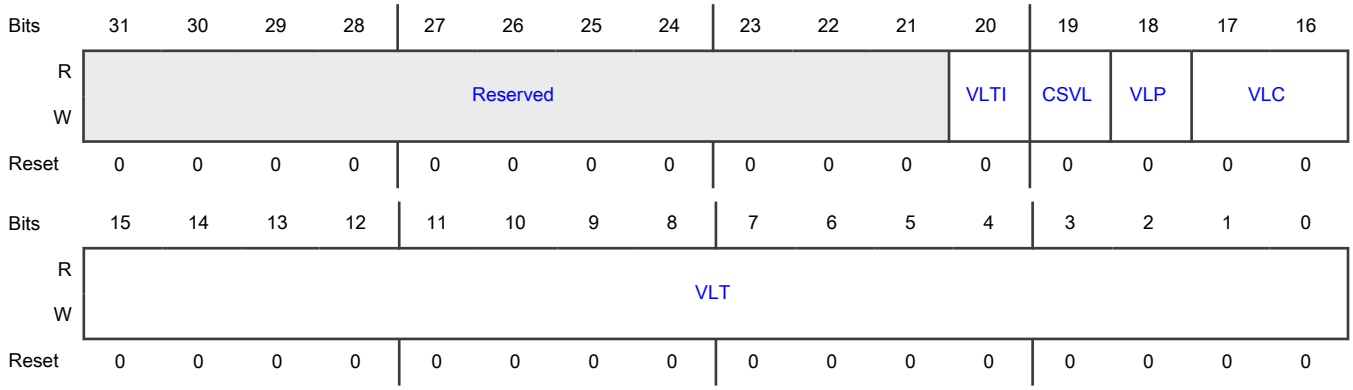
Register	Offset
MAC_INNER_VLAN_INCL	64h

Function

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the transmit packet.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the transmit packet. It also contains the inner VLAN tag insertion controls.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor 0b - VLAN Tag Input is disabled 1b - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 17th and 18th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 17th and 18th bytes of transmitted packets. 0b - C-VLAN type (0x8100) is inserted 1b - S-VLAN type (0x88A8) is inserted
18 VLP	VLAN Priority Control VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and the VLC field is ignored. 0b - VLAN Priority Control is disabled 1b - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets VLAN Tag Control in Transmit Packets 2'b00: No VLAN tag deletion, insertion, or replacement

Table continues on the next page...

Table continued from the previous page...

Field	Function
	2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). **NOTE** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00b - No VLAN tag deletion, insertion, or replacement 01b - VLAN tag deletion 10b - VLAN tag insertion 11b - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: Bits[15:13]: User Priority Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

70.5.1.9 MAC Q0 Tx Flow Control (MAC_Q0_TX_FLOW_CTRL)

Offset

Register	Offset
MAC_Q0_TX_FLOW_CTRL	70h

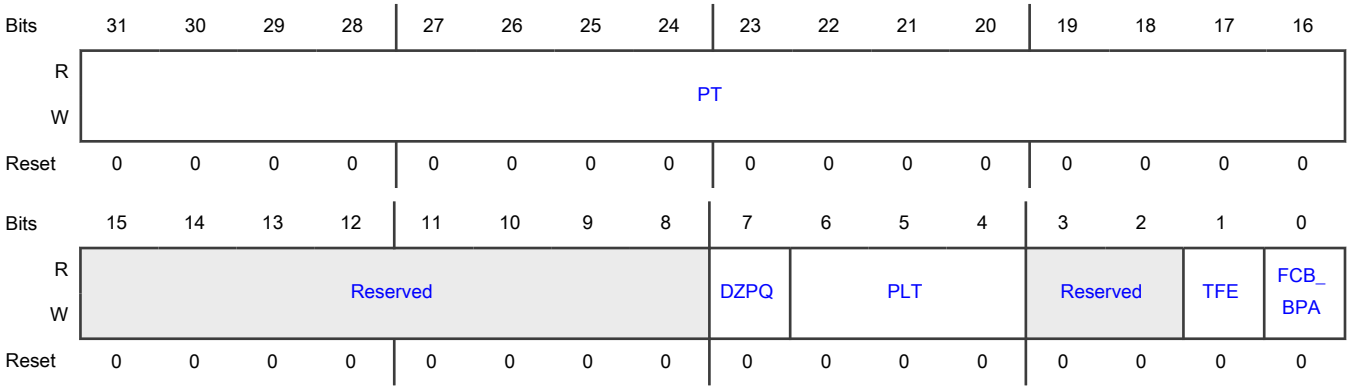
Function

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC.

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Q0_RX_FLOW_CTRL register is enabled, this register controls the generation of the Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_Q0_RXQ_CTRL2 register.

Diagram



Fields

Field	Function
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0b - Zero-Quanta Pause packet generation is enabled 1b - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000b - Pause Time minus 4 Slot Times (PT -4 slot times) 001b - Pause Time minus 28 Slot Times (PT -28 slot times) 010b - Pause Time minus 36 Slot Times (PT -36 slot times) 011b - Pause Time minus 144 Slot Times (PT -144 slot times) 100b - Pause Time minus 256 Slot Times (PT -256 slot times) 101b - Pause Time minus 512 Slot Times (PT -512 slot times) 110b - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0b - Transmit Flow Control is disabled 1b - Transmit Flow Control is enabled
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You must not write to this register until this bit is cleared. Half-Duplex Mode:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flow Control Busy or Backpressure Activate is disabled 1b - Flow Control Busy or Backpressure Activate is enabled

70.5.1.10 MAC Rx Flow Control (MAC_RX_FLOW_CTRL)

Offset

Register	Offset
MAC_RX_FLOW_CTRL	90h

Function

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-9 —	Reserved
8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_Address0_High and MAC_Address0_Low. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0b - Unicast Pause Packet Detect disabled 1b - Unicast Pause Packet Detect enabled
0 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time. 0b - Receive Flow Control is disabled 1b - Receive Flow Control is enabled

70.5.1.11 Receive Queue Control 4 (MAC_RXQ_CTRL4)

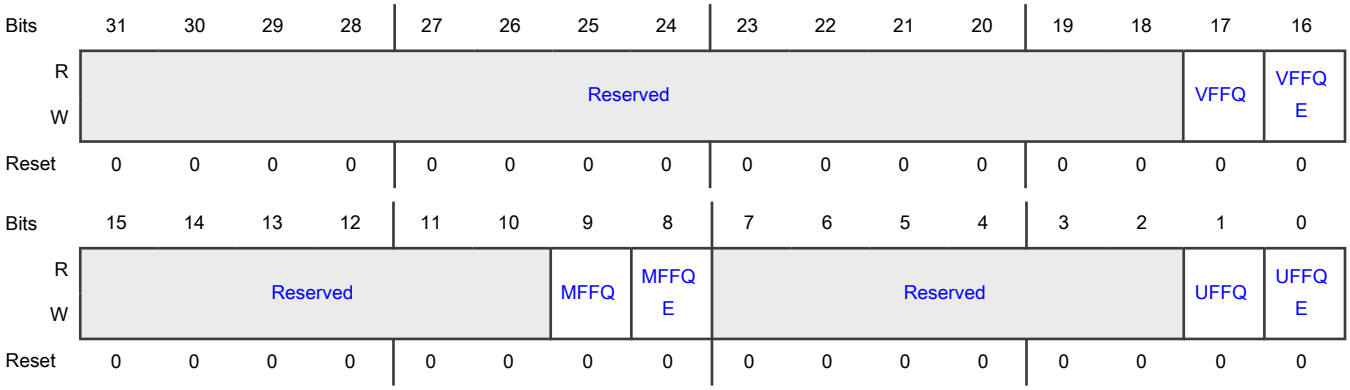
Offset

Register	Offset
MAC_RXQ_CTRL4	94h

Function

The Receive Queue Control 4 register controls the routing of unicast and multicast packets that fail the destination or source address filter to the Rx queues.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 VFFQ	VLAN Tag Filter Fail Packets Queue This field holds the Rx queue number to which the tagged packets failing the destination or source address filter (and UFFQE/MFFQE not enabled) or failing the VLAN tag filter must be routed to. This field is valid only when the VFFQE bit is set.
16 VFFQE	VLAN Tag Filter Fail Packets Queuing Enable When this bit is set, the tagged packets which fail the destination or source address filter or fail the VLAN tag filter, are routed to the Rx Queue Number programmed in the VFFQ. When this bit is reset, the tagged packets which fail the destination or source address filter or fail the VLAN tag filter are routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set. 0b - VLAN tag Filter Fail Packets Queuing is disabled 1b - VLAN tag Filter Fail Packets Queuing is enabled
15-10 —	Reserved
9 MFFQ	Multicast Address Filter Fail Packets Queue. This field holds the Rx queue number to which the Multicast packets failing the destination or source address filter are routed to. This field is valid only when the MFFQE bit is set.
8 MFFQE	Multicast Address Filter Fail Packets Queuing Enable. When this bit is set, the Multicast packets which fail the destination or source address filter is routed to the Rx Queue Number programmed in the MFFQ. When this bit is reset, the Multicast packets which fail the Destination or Source address filter is routed based on other routing options. This bit is valid only when the RA bit of the MAC_Packet_Filter register is set.

Field	Function
20 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0b - Multicast and Broadcast Queue is disabled 1b - Multicast and Broadcast Queue is enabled
19 —	Reserved
18-16 MCBCQ	Multicast and Broadcast Queue Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 000b - Receive Queue 0 001b - Receive Queue 1
15 —	Reserved
14-12 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 000b - Receive Queue 0 001b - Receive Queue 1
11 —	Reserved
10-8 —	Reserved
7 —	Reserved
6-4 PTPQ	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_Timestamp_Control register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - Receive Queue 0 001b - Receive Queue 1
3 —	Reserved
2-0 AVCPQ	AV Untagged Control Packets Queue AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 000b - Receive Queue 0 001b - Receive Queue 1

70.5.1.14 Receive Queue Control 2 (MAC_RXQ_CTRL2)

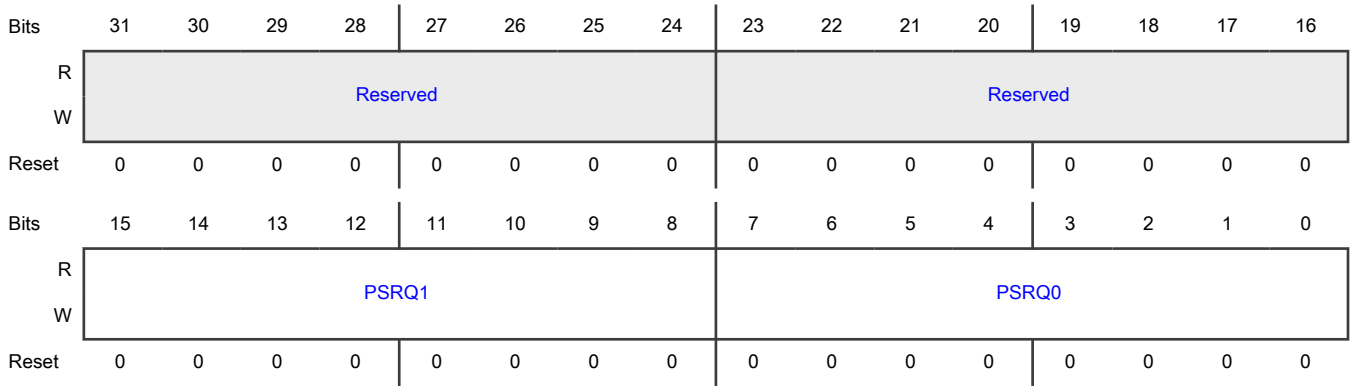
Offset

Register	Offset
MAC_RXQ_CTRL2	A8h

Function

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 —	Reserved
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues.

70.5.1.15 Interrupt Status (MAC_INTERRUPT_STATUS)

Offset

70.5.1.17 Receive Transmit Status (MAC_RX_TX_STATUS)

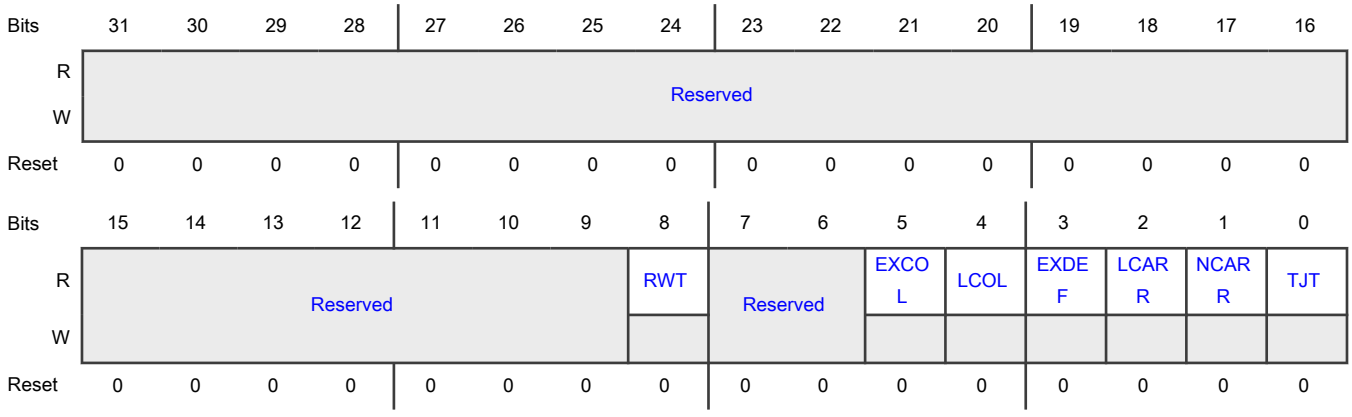
Offset

Register	Offset
MAC_RX_TX_STATUS	B8h

Function

The Receive Transmit Status register contains the Receive and Transmit Error status.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_Configuration register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No receive watchdog timeout 1b - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No collision 1b - Excessive collision is sensed
4 LCOL	Late Collision When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including Preamble in MII mode; 512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No collision 1b - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the MAC_Configuration register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No Excessive deferral 1b - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Carrier is present 1b - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of the preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Carrier is present 1b - No carrier
0 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_Configuration register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_Configuration register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No Transmit Jabber Timeout 1b - Transmit Jabber Timeout occurred

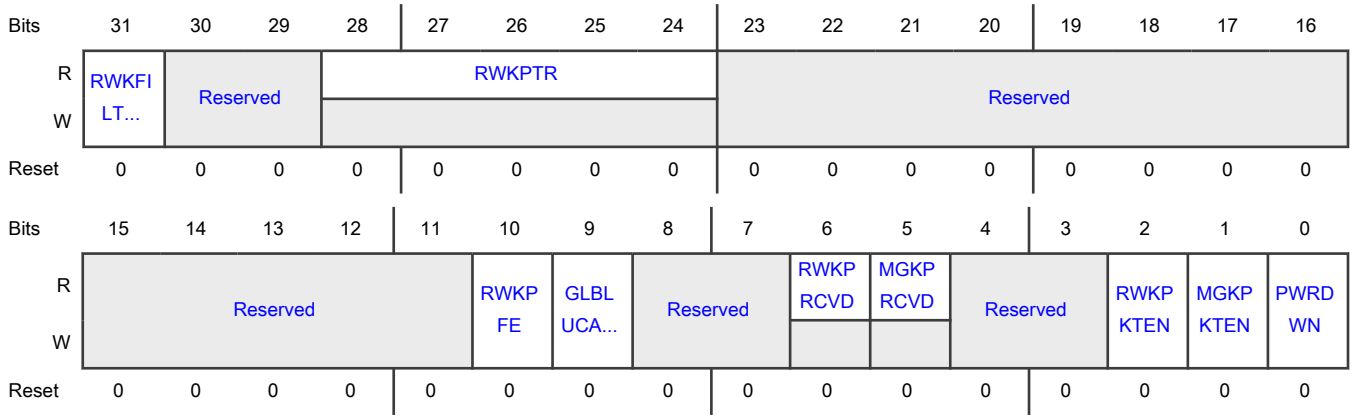
70.5.1.18 PMT Control and Status (MAC_PMT_CONTROL_STATUS)

Offset

Register	Offset
MAC_PMT_CONTROL_STATUS	C0h

Function
The PMT Control and Status Register.

Diagram



Fields

Field	Function
31 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Remote Wake-Up Packet Filter Register Pointer is not Reset 1b - Remote Wake-Up Packet Filter Register Pointer is Reset
30-29 —	Reserved
28-24 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11 —	Reserved
10 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to the application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with the setting of this bit and Magic Packet is received before wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to the application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Remote Wake-up Packet Forwarding is disabled 1b - Remote Wake-up Packet Forwarding is enabled
9 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0b - Global unicast is disabled 1b - Global unicast is enabled
8-7 —	Reserved
6 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Remote wake-up packet is received 1b - Remote wake-up packet is received
5 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - No Magic packet is received 1b - Magic packet is received
4-3 —	Reserved
2 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0b - Remote wake-up packet is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Remote wake-up packet is enabled
1 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0b - Magic Packet is disabled 1b - Magic Packet is enabled
0 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Power down is disabled 1b - Power down is enabled

70.5.1.19 Remote Wakeup Filter (MAC_RWK_PACKET_FILTER)

Offset

Register	Offset
MAC_RWK_PACKET_FILTER	C4h

Function

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_Packet_Filter register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen, or thirty-two register values in MAC_RWK_Packet_Filter register for wkuppktfilter_reg0, wkuppktfilter_reg1, ..., wkuppktfilter_reg31 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in the RWKPTR field of the MAC_PMT_Control_Status register.

The Remote Wakeup Filters are arranged in blocks of 4 filters each, and each such block has eight 32-bit wide registers, that is, wkuppktfilter_reg0-7, wkuppktfilter_reg8-15, wkuppktfilter_reg16-23 and wkuppktfilter_reg24-31. The fields of Remote Wakeup Filter are described as follows:

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

The MSB (31st bit) must be zero.

Bit j[30:0] is the byte mask.

If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".

Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are,

- The And_Previous bit setting is applicable within a set of 4 filters.

- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

- If filters chained by And_Previous bit setting have complementary programming, then a frame might never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

The minimum allowed offset is 12, which refers to the 13th byte of the packet.

The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.

- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

70.5.1.20 LPI Control and Status (MAC_LPI_CONTROL_STATUS)

Offset

Register	Offset
MAC_LPI_CONTROL_STATUS	D0h

Function

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status.

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved										LPITCSE	LPIATE	LPITXA	Reserved	PLS	LPIEN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved						RLPIST	TLPIST	Reserved				RLPIEX	RLPIEN	TLPIEX	TLPIEN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-22 —	Reserved
21 LPITCSE	LPI Tx Clock Stop Enable When this bit is set, the MAC asserts sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode to indicate that the Tx clock to MAC can be stopped. When this bit is reset, the MAC does not assert sbd_tx_clk_gating_ctrl_o signal high after it enters Tx LPI mode. If RGMII Interface is selected, the Tx clock is required for transmitting the LPI pattern. The Tx Clock cannot be gated and so the LPITCSE bit cannot be programmed. 0b - LPI Tx Clock Stop is disabled 1b - LPI Tx Clock Stop is enabled
20 LPIATE	LPI Timer Enable This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state. When LPIATE, LPITXA and LPIEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the MAC_LPI_Entry_Timer register. After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPIEN bit. This enables the re-entry into LPI state when it is IDLE again. When LPIATE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPIEN bit descriptions. 0b - LPI Timer is disabled 1b - LPI Timer is enabled
19 LPITXA	LPI Tx Automate This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side. This bit is not functional in the EQOS-CORE configurations in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the IP) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of MTL_TxQ0_Operation_Mode register, when the MAC is in the LPI mode, it exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. 0b - LPI Tx Automate is disabled 1b - LPI Tx Automate is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 —	Reserved
17 PLS	PHY Link Status This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER. When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down. 0b - link is down 1b - link is okay (UP)
16 LPIEN	LPI Enable When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. 0b - LPI state is disabled 1b - LPI state is enabled
15-10 —	Reserved
9 RLPIST	Receive LPI State When this bit is set, it indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. 0b - Receive LPI state not detected 1b - Receive LPI state detected
8 TLPIST	Transmit LPI State When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. 0b - Transmit LPI state not detected 1b - Transmit LPI state detected
7-4 —	Reserved
3 RLPIEX	Receive LPI Exit When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Note: This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0b - Receive LPI exit not detected 1b - Receive LPI exit detected
2 RLPIEN	Receive LPI Entry When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Note: This bit might not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock. 0b - Receive LPI entry not detected 1b - Receive LPI entry detected
1 TLPIEX	Transmit LPI Exit When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0b - Transmit LPI exit not detected 1b - Transmit LPI exit detected
0 TLPIEN	Transmit LPI Entry When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). 0b - Transmit LPI entry not detected 1b - Transmit LPI entry detected

70.5.1.21 LPI Timers Control (MAC_LPI_TIMERS_CONTROL)

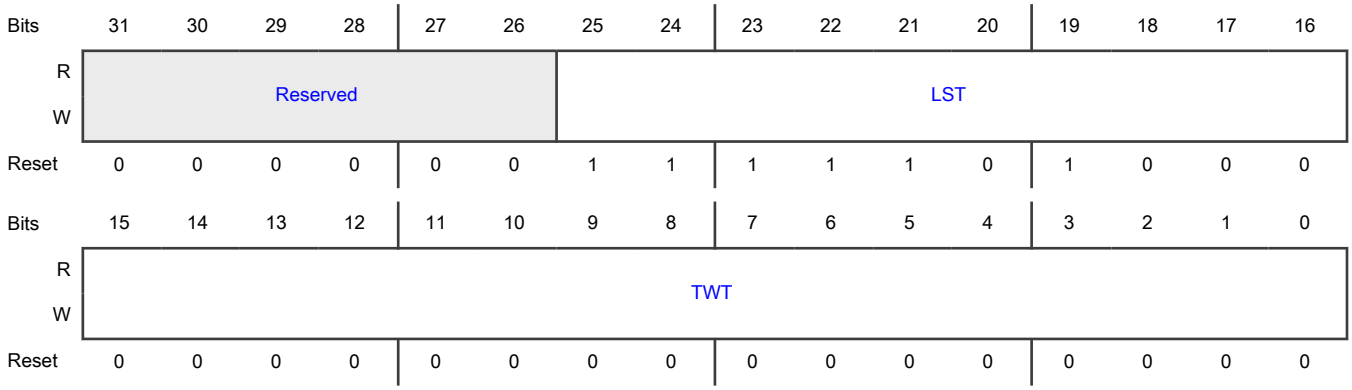
Offset

Register	Offset
MAC_LPI_TIMERS_CONTROL	D4h

Function

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 LST	LPI LS Timer This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.
15-0 TWT	LPI TW Timer This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.

70.5.1.22 Tx LPI Entry Timer Control (MAC_LPI_ENTRY_TIMER)

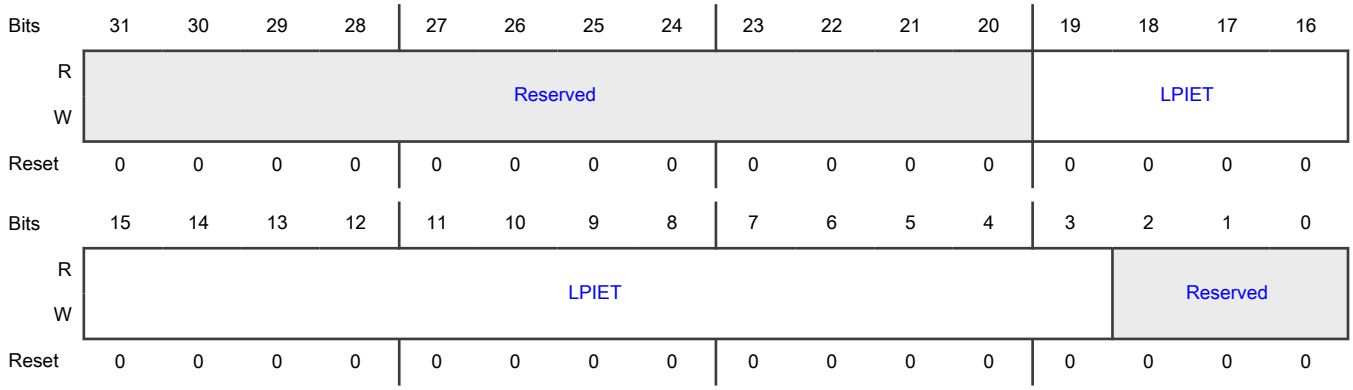
Offset

Register	Offset
MAC_LPI_ENTRY_TIMER	D8h

Function

This register controls the Tx LPI entry timer. This counter is enabled only when bit[20](LPITE) bit of MAC_LPI_Control_Status is set to 1.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-3 LPIET	LPI Entry Timer This field specifies the time in microseconds the MAC waits to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1. Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.
2-0 —	Reserved

70.5.1.23 One-microsecond Reference Timer (MAC_ONEUS_TIC_COUNTER)

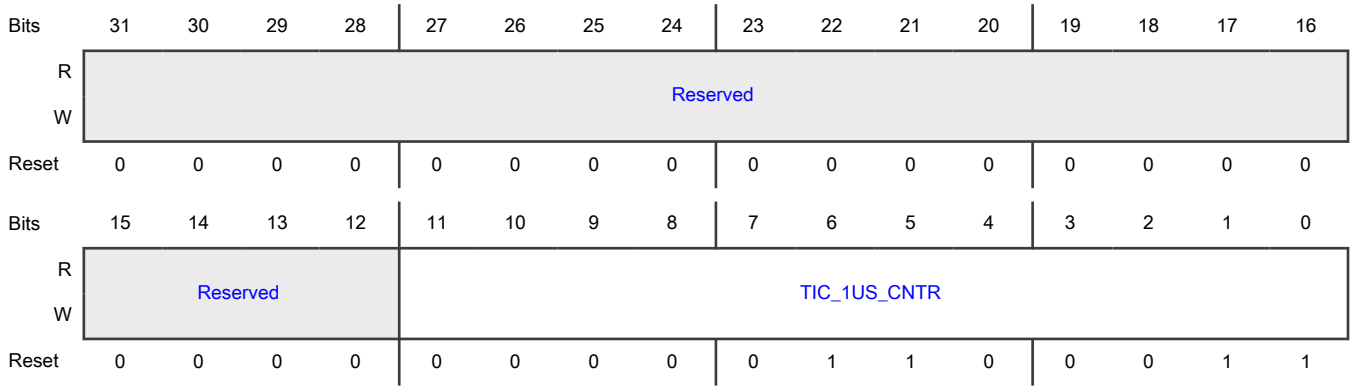
Offset

Register	Offset
MAC_ONEUS_TIC_COUNTER	DCh

Function

This register controls the generation of the Reference time (1 microsecond tic) for all the LPI timers. This timer has to be programmed by the software initially.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 TIC_1US_CNTR	1US TIC Counter The application must program this counter so that the number of clock cycles of CSR clock is 1us. (Subtract 1 from the value before programming). For example if the CSR clock is 100 MHz then this field needs to be programmed to value 100 - 1 = 99 (which is 0x63). This is required to generate the 1US events that are used to update some of the EEE related counters.

70.5.1.24 MAC Version (MAC_VERSION)

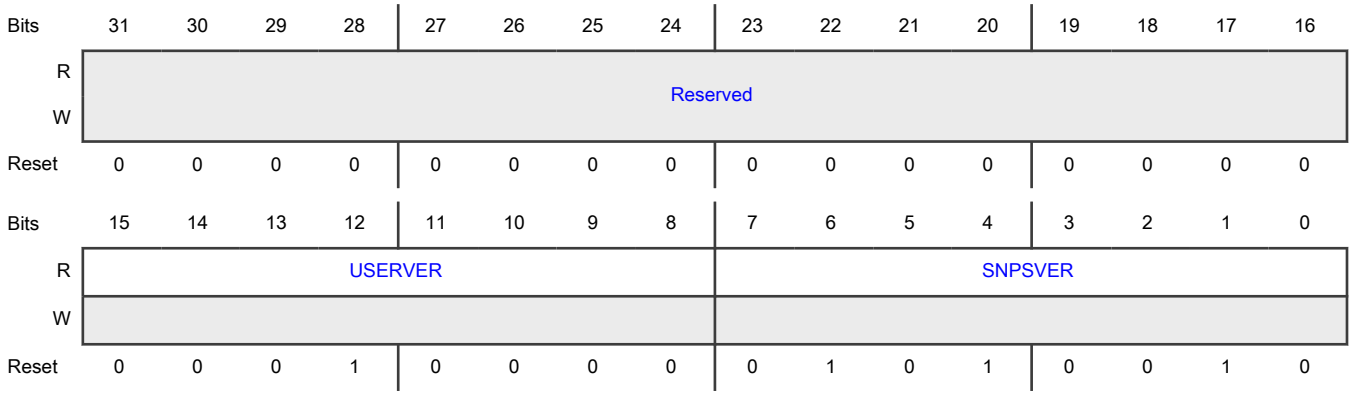
Offset

Register	Offset
MAC_VERSION	110h

Function

The version register identifies the version of the enet. This register contains two bytes: one that Synopsys uses to identify the IP release number, and the other that you set while configuring the IP.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 USERVER	User-defined Version
7-0 SNPSVER	Synopsys-defined Version

70.5.1.25 MAC Debug (MAC_DEBUG)

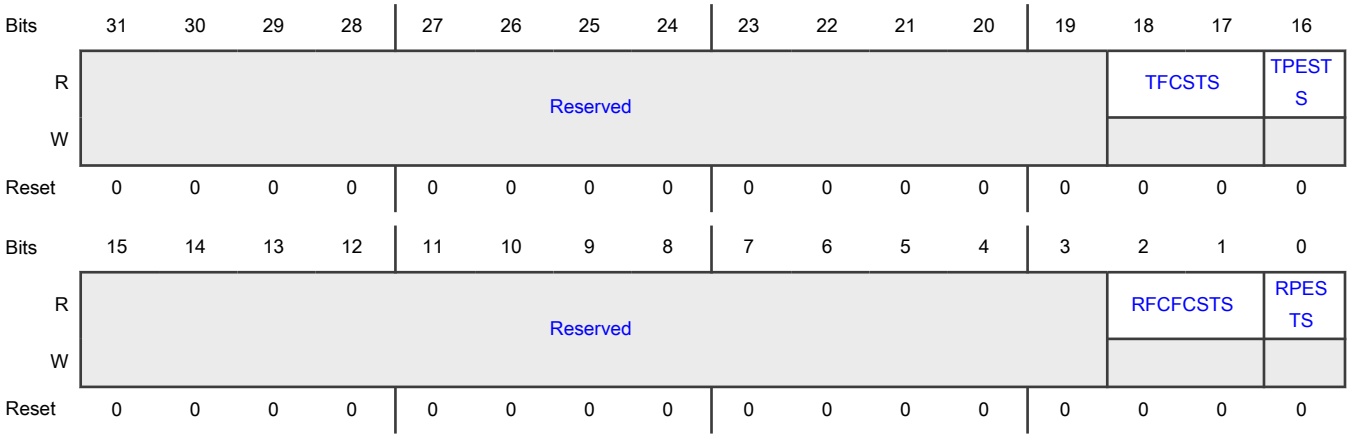
Offset

Register	Offset
MAC_DEBUG	114h

Function

The Debug register provides the debug status of various MAC blocks.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-17 TFCSTS	MAC Transmit Packet Controller Status This field indicates the state of the MAC Transmit Packet Controller module. 00b - Idle state 01b - Waiting for one of the following: Status of the previous packet OR IPG or back off period to be over 10b - Generating and transmitting a Pause control packet (in full-duplex mode) 11b - Transferring input packet for transmission
16 TPESTS	MAC GMII or MII Transmit Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII transmit protocol engine is actively transmitting data, and it is not in the Idle state. 0b - MAC GMII or MII Transmit Protocol Engine Status not detected 1b - MAC GMII or MII Transmit Protocol Engine Status detected
15-3 —	Reserved
2-1 RFCFCSTS	MAC Receive Packet Controller FIFO Status When this bit is set, this field indicates the active state of the small FIFO Read and Write controllers of the MAC Receive Packet Controller module.
0 RPESTS	MAC GMII or MII Receive Protocol Engine Status When this bit is set, it indicates that the MAC GMII or MII receive protocol engine is actively receiving data, and it is not in the Idle state.

Table continues on the next page...

	0b - MAC GMII or MII Receive Protocol Engine Status not detected 1b - MAC GMII or MII Receive Protocol Engine Status detected

70.5.1.26 Hardware Features 0 (MAC_HW_FEATURE0)

Offset

Register	Offset
MAC_HW_FEATURE0	11Ch

Function

This register indicates the presence of the first set of the optional features or functions of the enet. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

R W	Reserved	NTC			CR				Reserved			SKAP	GOC_1	GOC_0	C45E	GB
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 PSE	Preamble Suppression Enable Preamble Suppression Enable When this bit is set, the SMA suppresses the 32-bit preamble and transmits MDIO frames with only 1 preamble bit. When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications. 0b - Preamble Suppression disabled 1b - Preamble Suppression enabled
26 BTB	Back to Back transactions When this bit is set and the NTC has value greater than 0, then the MAC informs the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which is executed immediately irrespective of the number trailing clocks generated for the previous frame. When this bit is reset, then the read/write command completion (GB is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame. This bit must not be set when NTC=0. 0b - Back to Back transactions disabled 1b - Back to Back transactions enabled
25-21 PA	Physical Layer Address This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing. This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.
20-16 RDA	Register/Device Address These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.
15 —	Reserved
14-12 NTC	NTC Number of Trailing Clocks This field controls the number of trailing clock cycles generated on gmii_mdc_o (MDC) after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 CR	CR CSR Clock Range The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design: 0000: CSR clock = 60-100 MHz; MDC clock = CSR clock/42 0001: CSR clock = 100-150 MHz; MDC clock = CSR clock/62 0010: CSR clock = 20-35 MHz; MDC clock = CSR clock/16 0011: CSR clock = 35-60 MHz; MDC clock = CSR clock/26 0100: CSR clock = 150-250 MHz; MDC clock = CSR clock/102 0101: CSR clock = 250-300 MHz; MDC clock = CSR clock/124 0110: CSR clock = 300-500 MHz; MDC clock = CSR clock/204 0111: CSR clock = 500-800 MHz; MDC clock = CSR clock/324 The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is beyond the range specified in IEEE 802.3. Program the following values only if the interfacing chips support faster MDC clocks: 1000: CSR clock/4 1001: CSR clock/6 1010: CSR clock/8 1011: CSR clock/10 1100: CSR clock/12 1101: CSR clock/14 1110: CSR clock/16 1111: CSR clock/18 These bits are not used for accessing RevMII. These bits are read-only if the RevMII interface is selected as single PHY interface.
7-5 —	Reserved
4 SKAP	Skip Address Packet Skip Address Packet When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Skip Address Packet is disabled 1b - Skip Address Packet is enabled
3 GOC_1	GMII Operation Command 1 This bit is higher bit of the operation command to the PHY or RevMII, GOC_1 and GOC_O is encoded as follows: 00: Reserved 01: Write 10: Post Read Increment Address for Clause 45 PHY 11: Read When Clause 22 PHY or RevMII is enabled, only Write and Read commands are valid. 0b - GMII Operation Command 1 is disabled 1b - GMII Operation Command 1 is enabled
2 GOC_0	GMII Operation Command 0 GMII Operation Command 0 This is the lower bit of the operation command to the PHY or RevMII. When in SMA mode (MDIO master) this bit along with GOC_1 determines the operation to be performed to the PHY. When only RevMII is selected in configuration this bit is read-only and tied to 1. 0b - GMII Operation Command 0 is disabled 1b - GMII Operation Command 0 is enabled
1 C45E	Clause 45 PHY Enable Clause 45 PHY Enable When this bit is set, Clause 45 capable PHY is connected to MDIO. When this bit is reset, Clause 22 capable PHY is connected to MDIO. 0b - Clause 45 PHY is disabled 1b - Clause 45 PHY is enabled
0 GB	GMII Busy GMII Busy The application sets this bit to instruct the SMA to initiate a Read or Write access to the MDIO slave. The MAC clears this bit after the MDIO frame transfer is completed. Hence the software must not write or change any of the fields in MAC_MDIO_Address and MAC_MDIO_Data registers as long as this bit is set. For write transfers, the application must first write 16-bit data in the GDI field (and also RA field when C45E is set) in MAC_MDIO_Data register before

Table continues on the next page...

Table continued from the previous page...

Field	Function
	setting this bit. When C45E is set, it should also write into the RA field of MAC_MDIO_Data register before initiating a read transfer. When a read transfer is completed (GB=0), the data read from the PHY register is valid in the GD field of the MAC_MDIO_Data register. Note: Even if the addressed PHY is not present, there is no change in the functionality of this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - GMII Busy is disabled 1b - GMII Busy is enabled

70.5.1.31 MAC MDIO Data (MAC_MDIO_DATA)

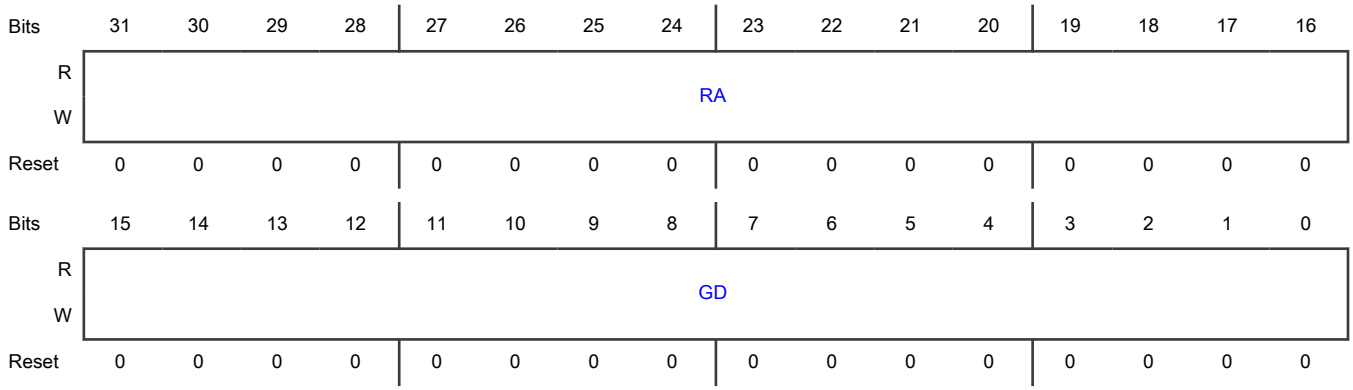
Offset

Register	Offset
MAC_MDIO_DATA	204h

Function

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in MAC_MDIO_Address. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

Diagram



Fields

When this bit is reset, the access mode of these register fields remain as Clear on Read. 0b - Register Clear on Write 1 is disabled 1b - Register Clear on Write 1 is enabled

70.5.1.33 MAC Address0 High (MAC_ADDRESS0_HIGH)

Offset

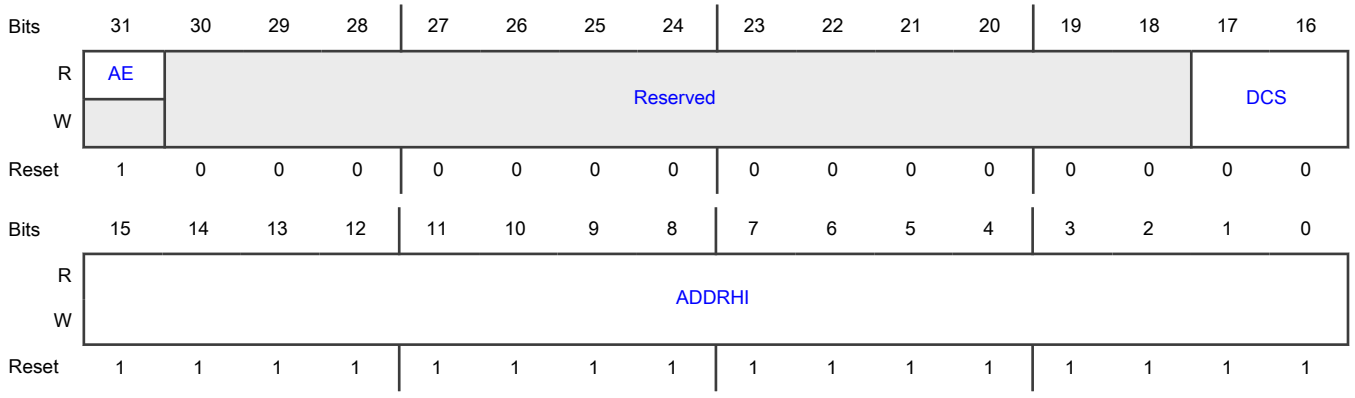
Register	Offset
MAC_ADDRESS0_HIGH	300h

Function

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Diagram



Fields

Field	Function
31 AE	Address Enable This bit is always set to 1. 0b - INVALID : This bit must be always set to 1 1b - This bit is always set to 1
30-18 —	Reserved
17-16 DCS	DMA Channel Select If the PDC bit of MAC_Ext_Configuration register is not set: This field contains the binary representation of the DMA Channel number to which an Rx packet whose DA matches the MAC Address0 content is routed. If the PDC bit of MAC_Ext_Configuration register is set: This field contains the one-hot representation of one or more DMA Channel numbers to which an Rx packet whose DA matches the MAC Address0 content is routed.
15-0 ADDRHI	MAC Address0[47:32] This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

70.5.1.34 MAC Address0 Low (MAC_ADDRESS0_LOW)

Offset

Register	Offset
MAC_ADDRESS0_LOW	304h

Function

The MAC Address0 Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

Diagram

Fields

Field	Function
31-0 ADDRLO	MAC Address0[31:0] This field contains the lower 32 bits of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.

70.5.1.35 Indirect Access Control (INDIR_ACCESS_CTRL)

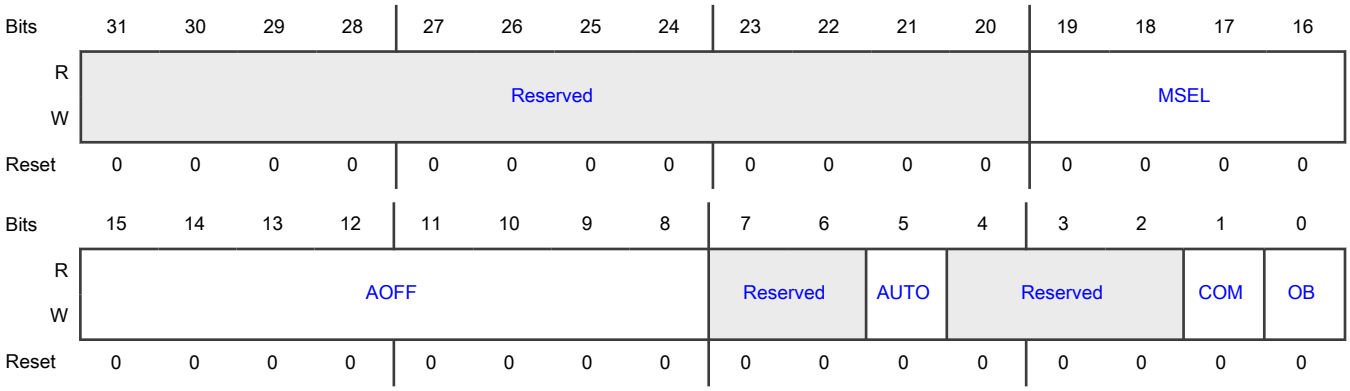
Offset

Register	Offset
INDIR_ACCESS_CTRL	A70h

Function

This register provides the Indirect Access control and status for MAC registers.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 MSEL	Mode Select This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 0000:Typ_RXQ_ (Type based RXQ mapping) 0001-1111: Reserved for future use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 AOFF	Address Offset Address Offset This field is used in indirect access of MAC_<MSEL>_<AOFF>. This field must be set along with initiation of read/write to MAC_<MSEL>_<AOFF> and should not be changed until the OB is reset. Values: 00000000: IndReg0(Indirect register 0) 00000001: IndReg1(Indirect register 1) ... 00000111: IndReg7(Indirect register 7) 00001000-11111111: Reserved for future use.
7-6 —	Reserved
5 AUTO	Auto increment 1: AOFF is incremented by 1. Software should ensure not to cause a wrap condition. Byte wise read/write is not supported when auto increment is enabled. 0: AOFF is not incremented automatically. Software should program the correct Address Offset for each access.
4-2 —	Reserved
1 COM	Command type This bit indicates the register access type. 1: Indicates a read operation. 0: Indicates a write operation. 0b - Write operation 1b - Read operation
0 OB	Operation Busy. This bit is set along with a read or write command for initiating the indirect access to MAC_<MSEL>_<AOFF> register. This bit is reset when the read or write command to MAC_<MSEL>_<AOFF> register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into MAC_<MSEL>_<AOFF> register. During a read operation, the data should be read from MAC_Indir_Access_Data register only after this bit is reset.

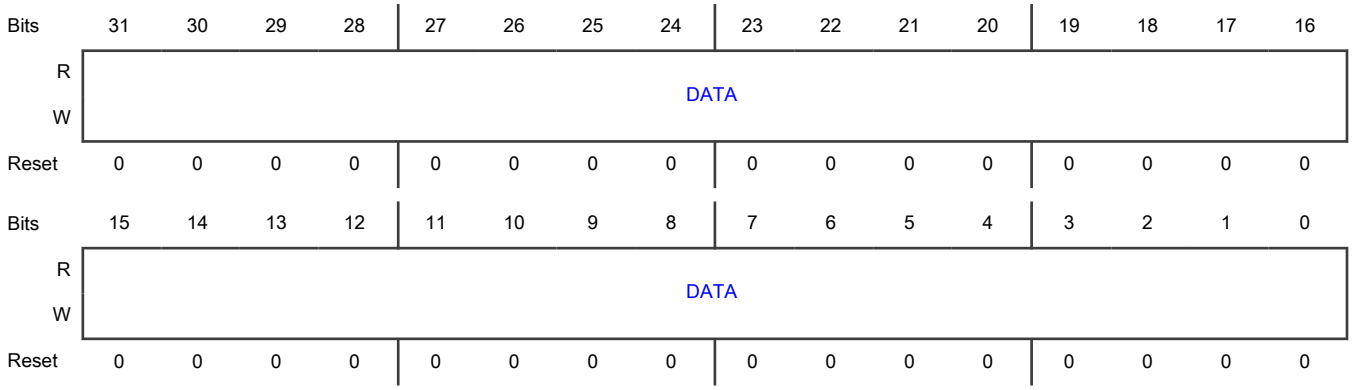
70.5.1.36 Indirect Access Data (INDIR_ACCESS_DATA)

Offset

Register	Offset
INDIR_ACCESS_DATA	A74h

Function
This register holds the read/write data for Indirect Access of MAC registers.

Diagram



Fields

Field	Function
31-0 DATA	This field contains data to read/write for Indirect address access associated with MAC_Indir_Access_Ctrl

70.5.1.37 Timestamp Control (MAC_TIMESTAMP_CONTROL)

Offset

Register	Offset
MAC_TIMESTAMP_CONTROL	B00h

Function
This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.

Diagram

01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC,Pdelay_Req,
11	x	x	Pdelay_Resp Delay_Req

15 TSMSTRENA	Enable Snapshot for Messages Relevant to Master When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. 0b - Snapshot for Messages Relevant to Master is disabled 1b - Snapshot for Messages Relevant to Master is enabled
14 TSEVNTENA	Enable Timestamp Snapshot for Event Messages When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table. 0b - Timestamp Snapshot for Event Messages is disabled 1b - Timestamp Snapshot for Event Messages is enabled
13 TSIPV4ENA	Enable Processing of PTP Packets Sent over IPv4-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default. 0b - Processing of PTP Packets Sent over IPv4-UDP is disabled 1b - Processing of PTP Packets Sent over IPv4-UDP is enabled
12 TSIPV6ENA	Enable Processing of PTP Packets Sent over IPv6-UDP When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets. 0b - Processing of PTP Packets Sent over IPv6-UDP is disabled 1b - Processing of PTP Packets Sent over IPv6-UDP is enabled
11 TSIPENA	Enable Processing of PTP over Ethernet Packets When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets. 0b - Processing of PTP over Ethernet Packets is disabled 1b - Processing of PTP over Ethernet Packets is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 TSVER2ENA	Enable PTP Packet Processing for Version 2 Format Enable PTP Packet Processing for Version 2 Format When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets. When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets. The IEEE 1588 formats are described in 'PTP Processing and Control'. 0b - PTP Packet Processing for Version 2 Format is disabled 1b - PTP Packet Processing for Version 2 Format is enabled
9 TSCTRLSSR	Timestamp Digital or Binary Rollover Control When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit. 0b - Timestamp Digital Rollover Control is disabled and Binary Rollover Control is enabled 1b - Timestamp Digital Rollover Control is enabled and Binary Rollover Control is disabled
8 TSENALL	Enable Timestamp for All Packets When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC. 0b - Timestamp for All Packets disabled 1b - Timestamp for All Packets enabled
7 —	Reserved
6 —	Reserved
5 TSADDREG	Update Addend Register When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Addend Register is not updated 1b - Addend Register is updated
4 TSTRIG	Enable Timestamp Interrupt Trigger When this bit is set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the Timestamp Trigger Interrupt is generated. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp Interrupt Trigger is not enabled 1b - Timestamp Interrupt Trigger is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 TSUPDT	Update Timestamp When this bit is set, the system time is updated (added or subtracted) with the value specified in MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled while configuring the IP) is not updated. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not updated 1b - Timestamp is updated
2 TSINIT	Initialize Timestamp When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC_System_Time_Seconds_Update and MAC_System_Time_Nanoseconds_Update registers. This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled while configuration the IP) can only be initialized. When Media Clock Generation and Recovery is configured (DWC_EQOS_FLEXI_PPS_OUT_EN) and enabled MAC_Presn_Time_Updt should also be updated before setting this field. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Timestamp is not initialized 1b - Timestamp is initialized
1 TSCFUPDT	Fine or Coarse Timestamp Update When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp. 0b - Coarse method is used to update system timestamp 1b - Fine method is used to update system timestamp
0 TSENA	Enable Timestamp When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the Receive side, the MAC processes the 1588 packets only if this bit is set. 0b - Timestamp is disabled 1b - Timestamp is enabled

70.5.1.38 Subsecond Increment (MAC_SUB_SECOND_INCREMENT)

Offset

Register	Offset
MAC_SUB_SECOND_INCREMENT	B04h

Function

This register specifies the value to be added to the internal system time register every cycle of clk_ptp_ref_i clock.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								SNSINC

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-16 SNSINC	Sub-nanosecond Increment Value Sub-second Increment Value The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in MAC_Timestamp_Control]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.
15-8 —	Reserved
7-0 —	Reserved

70.5.1.39 System Time Seconds (MAC_SYSTEM_TIME_SECONDS)

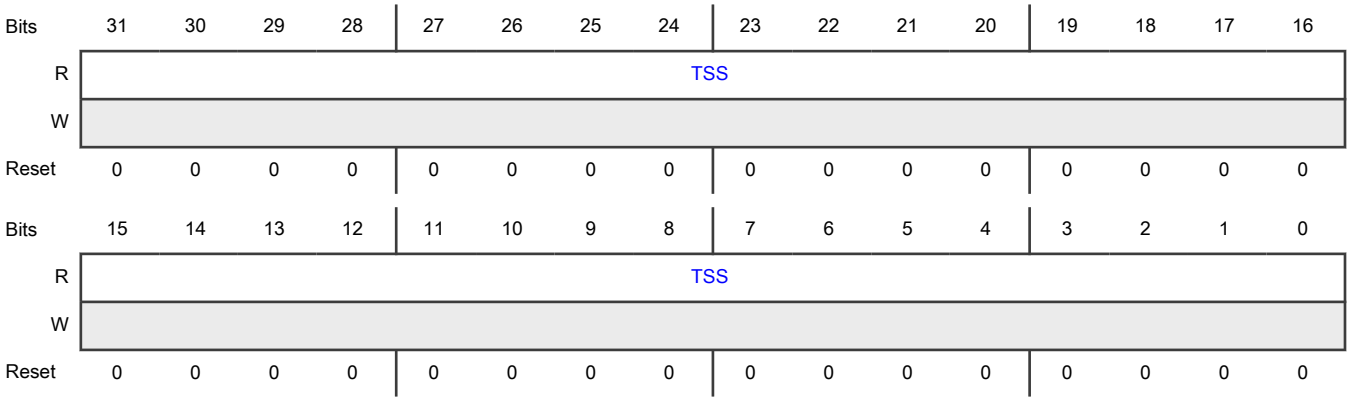
Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS	B08h

Function

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to CSR clock).

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

70.5.1.40 System Time Nanoseconds (MAC_SYSTEM_TIME_NANOSECONDS)

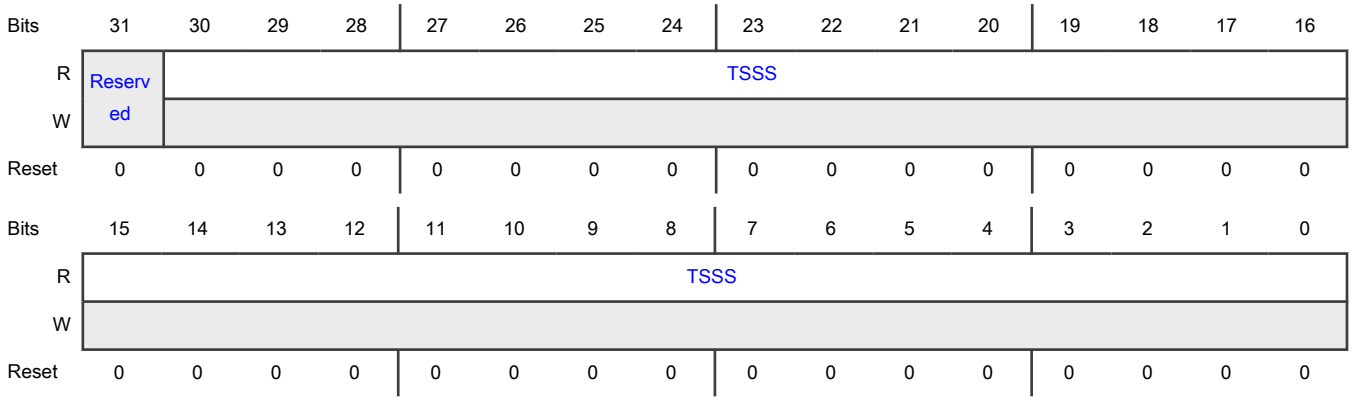
Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS	B0Ch

Function

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

Diagram



Fields

Field	Function
31 —	Reserved
30-0 TSSS	Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0. Timestamp Sub Seconds The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in MAC_Timestamp_Control, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.

70.5.1.41 System Time Seconds Update (MAC_SYSTEM_TIME_SECONDS_UPDATE)

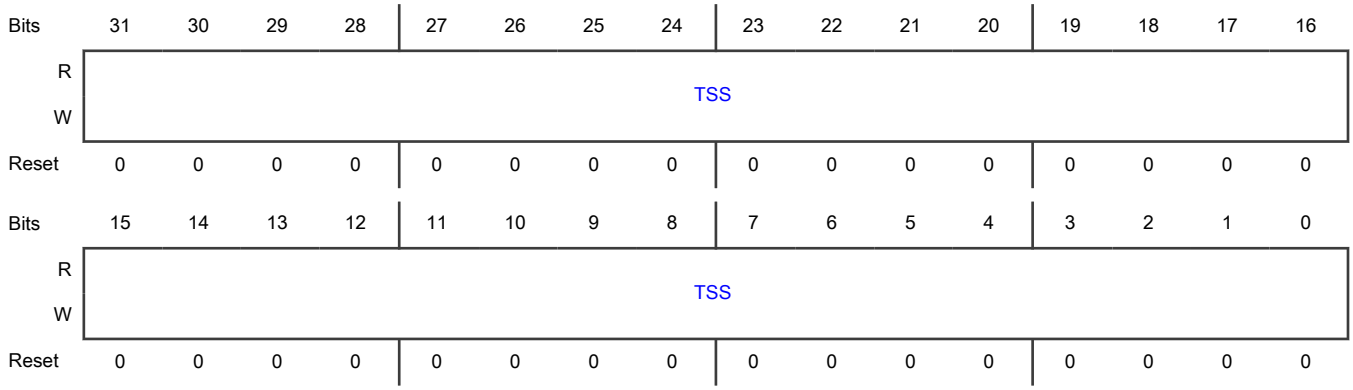
Offset

Register	Offset
MAC_SYSTEM_TIME_SECONDS_UPDATE	B10h

Function

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in DWC_eqos_top_map/EQOS_MAC/MAC_TIMESTAMP_CONTROL.

Diagram



Fields

Field	Function
31-0 TSS	Timestamp Seconds The value in this field is the seconds part of the update. Timestamp Seconds The value in this field is the seconds part of the update. When ADDSUB is reset, this field must be programmed with the seconds part of the update value. When ADDSUB is set, this field must be programmed with the complement of the seconds part of the update value. For example, to subtract 2.000000001 seconds from the system time, the TSS field in the MAC_Timestamp_Seconds_Update register must be 0xFFFF_FFFE (that is, 2^32 - 2).

70.5.1.42 System Time Nanoseconds Update (MAC_SYSTEM_TIME_NANOSECONDS_UPDATE)

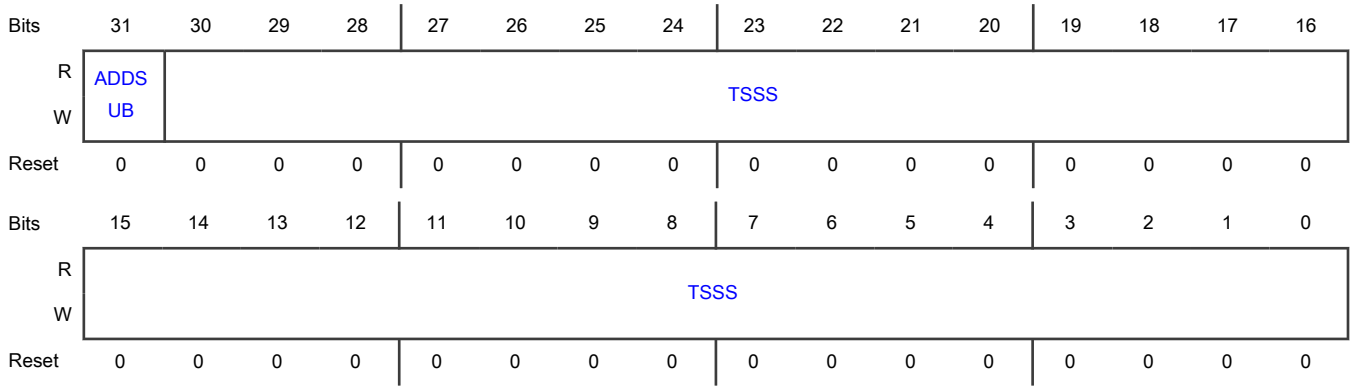
Offset

Register	Offset
MAC_SYSTEM_TIME_NANOSECONDS_UPDATE	B14h

Function

System Time Nanoseconds Update.

Diagram



Fields

Field	Function
31 ADDSUB	Add or Subtract Time Add or Subtract Time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. 0b - Add time 1b - Subtract time
30-0 TSSS	Timestamp Sub Seconds Timestamp Sub Seconds The value in this field is the sub-seconds part of the update. ADDSUB is 1: This field must be programmed with the complement of the sub-seconds part of the update value as described. ADDSUB is 0: This field must be programmed with the sub-seconds part of the update value, with an accuracy based on the TSCTRLSSR bit of the MAC_Timestamp_Control register. TSCTRLSSR field in the MAC_Timestamp_Control register is 1: - The programmed value must be 10^9 - <sub-second value>. - Each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF. TSCTRLSSR field in the MAC_Timestamp_Control register is 0: - The programmed value must be 2^31 - <sub-second_value>. - Each bit represents an accuracy of 0.46 ns. For example, to subtract 2.000000001 seconds from the system time, then the TSSS field in the MAC_Timestamp_Nanoseconds_Update register must be 0x7FFF_FFFF (that is, 2^31 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is reset and 0x3B9A_C9FF (that is, 10^9 - 1), when TSCTRLSSR bit in MAC_Timestamp_Control is set.

70.5.1.43 Timestamp Addend (MAC_TIMESTAMP_ADDEND)

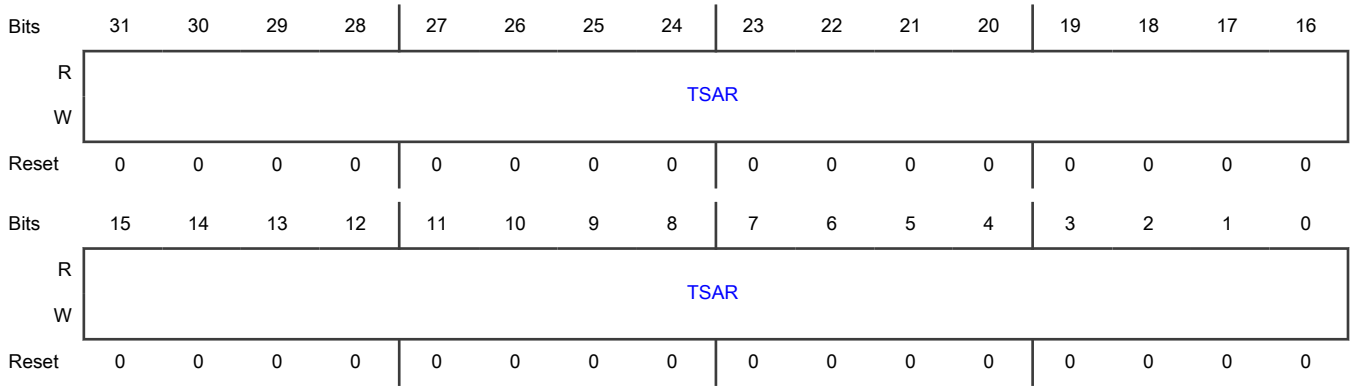
Offset

Register	Offset
MAC_TIMESTAMP_ADDEND	B18h

Function

Timestamp Addend register. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the MAC_Timestamp_Control register). The content of this register is added to a 32-bit accumulator in every clock cycle (of clk_ptp_ref_i) and the system time is updated when the accumulator overflows.

Diagram



Fields

Field	Function
31-0 TSAR	Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

70.5.1.44 Timestamp Status (MAC_TIMESTAMP_STATUS)

Offset

Register	Offset
MAC_TIMESTAMP_STATUS	B20h

Function

Timestamp Status register. All bits except Bits[27:25] gets cleared when the application reads this register.

Field	Function
TSSOVF	When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF. Access restriction applies. Clears on read (or this bit is written to 1 when RCWE bit in MAC_CSR_SW_Ctrl register is set). Self-set to 1 on internal event. 0b - Timestamp Seconds Overflow status not detected 1b - Timestamp Seconds Overflow status detected

70.5.1.45 Transmit Timestamp Status Nanoseconds (MAC_TX_TIMESTAMP_STATUS_NANOSECONDS)

Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_NANOSECONDS	B30h

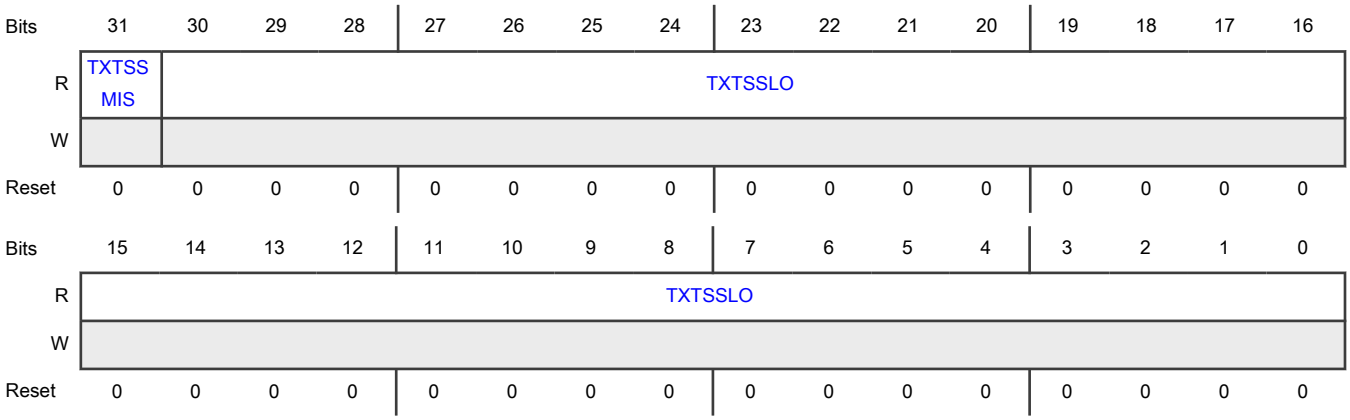
Function

This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

The MAC_Tx_Timestamp_Status_Nanoseconds register, along with MAC_Tx_Timestamp_Status_Seconds, gives the 64-bit timestamp captured for the PTP packet successfully transmitted by the MAC. This value is considered to be read by the application when the last byte of MAC_Tx_Timestamp_Status_Nanoseconds is read. In the little-endian mode, this means when bits[31:24] are read; in big-endian mode, bits[7:0] are read.

If the application does not read these registers and timestamp of another packet is captured, then either the current timestamp is lost (overwritten) or the new timestamp is lost (dropped), depending on the setting of the TXTSSTSM bit of the MAC_Timestamp_Control register. The status bit TXTSSIS bit [15] in MAC_Timestamp_Status register is set when the MAC transmitter captures the timestamp.

Diagram



Fields

Field	Function
31 TXTSSMIS	TXTSSMIS Transmit Timestamp Status Missed When this bit is set, it indicates one of the following: The timestamp of the current packet is ignored if TXTSSTSM bit of the MAC_Timestamp_Control register is reset The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the MAC_Timestamp_Control register is set. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Transmit Timestamp Status Missed status not detected 1b - Transmit Timestamp Status Missed status detected
30-0 TXTSSLO	Transmit Timestamp Status Low This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

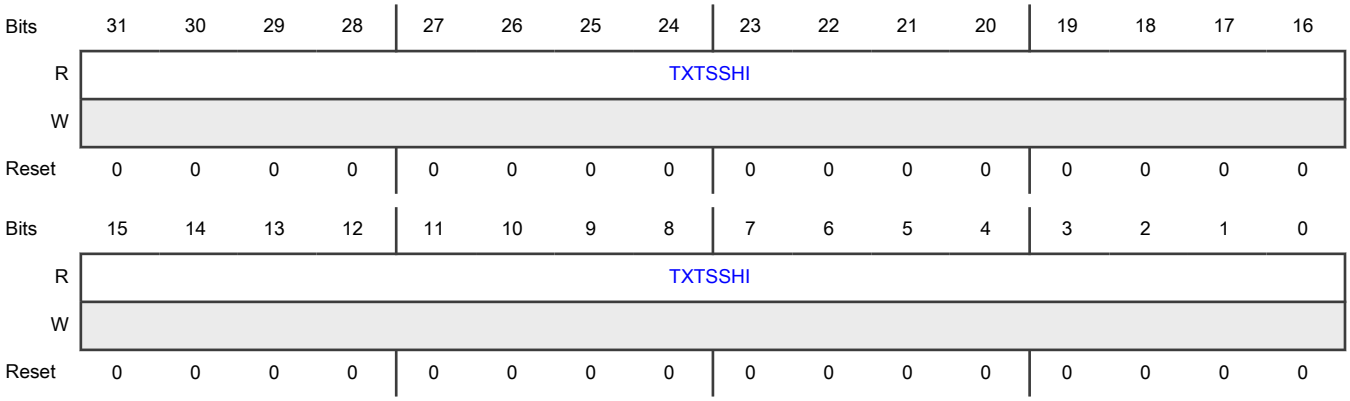
70.5.1.46 Transmit Timestamp Status Seconds (MAC_TX_TIMESTAMP_STATUS_SECONDS)

Offset

Register	Offset
MAC_TX_TIMESTAMP_STATUS_SECONDS	B34h

Function
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Diagram



Fields

Field	Function
31-0 TXTSSHI	Transmit Timestamp Status High This field contains the lower 32 bits of the Seconds field of Transmit packet's captured timestamp.

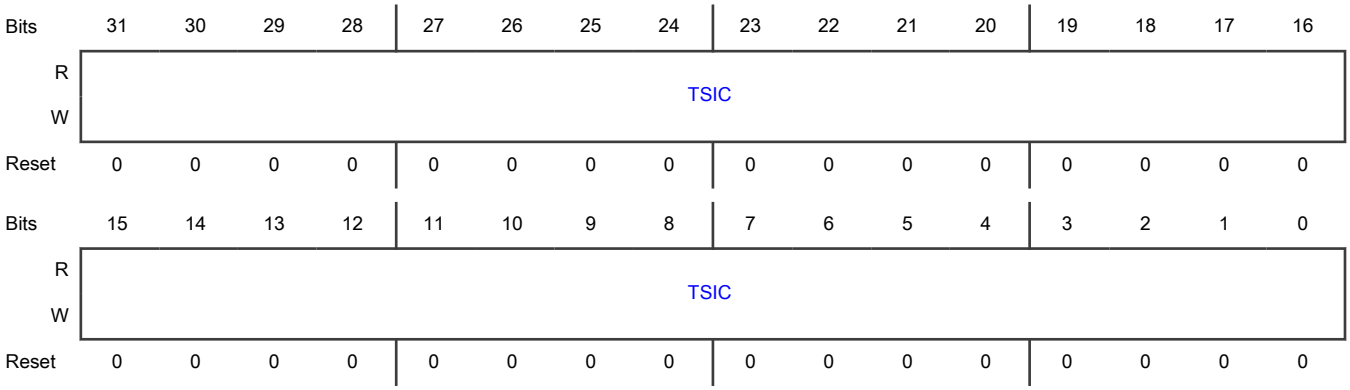
70.5.1.47 Timestamp Ingress Correction Nanosecond (MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND)

Offset

Register	Offset
MAC_TIMESTAMP_INGRESS_CORR_NANOSECOND	B58h

Function
This register contains the correction value in nanoseconds to be used with the captured timestamp value in the ingress path.

Diagram



Fields

Field	Function
31-0 TSIC	Timestamp Ingress Correction This field contains the ingress path correction value as defined by the Ingress Correction expression.

70.5.1.48 Timestamp Egress Correction Nanosecond (MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND)

Offset

Register	Offset
MAC_TIMESTAMP_EGRESS_CORR_NANOSECOND	B5Ch

Function
This register contains the correction value in nanoseconds to be used with the captured timestamp value in the egress path.

3-0 PPSCTRL_PPSCMD	PPS Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: 0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. 0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. 0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. 0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. .. 1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high) When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This behavior is because of the non-linear toggling of bits in the digital rollover mode in the MAC_System_Time_Nanoseconds register. or Flexible PPS Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are 'all-zero'. The following list describes the values of PPSCMD0: 0000: No Command 0001: START Single Pulse This command generates single pulse rising at the start point defined in MAC_PPS0_Target_Time_Seconds and MAC_PPS0_Target_Time_Nanoseconds register and of a duration defined in the PPS0 Width Register. 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by the 'Stop Pulse train at time' or 'Stop Pulse Train immediately' commands. 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. 0100: STOP Pulse train at time This command stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train command (PPSCMD = 0010). 110: Cancel STOP Pulse train This command cancels the STOP pulse train at time command if the programmed stop time has not elapsed. The PPS pulse train becomes free-running on the successful execution of this command. 0111-1111: Reserved

70.5.1.52 PPS0 Target Time Seconds (PPS0_TARGET_TIME_SECONDS)

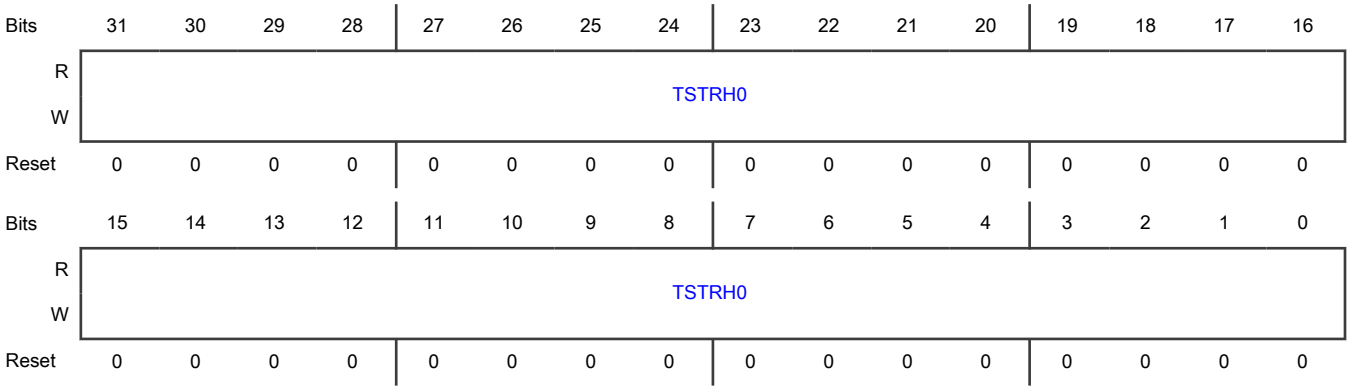
Offset

Register	Offset
PPS0_TARGET_TIME_SECONDS	B80h

Function

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of MAC_Timestamp_Status] when the system time exceeds the value programmed in these registers.

Diagram



Fields

Field	Function
31-0 TSTRH0	PPS Target Time Seconds Register PPS Target Time Seconds Register This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the MAC_PPS_Control register. If DWC_EQOS_FLEXI_PPS_OUT_EN is enabled in the configuration and PTGE field of MAC_Timestamp_Control Register is set with Presentation time control set in recovery mode, then these bits indicate the TPT being programmed by the application and in generation mode it indicates the CPT generated at the sampled trigger.

70.5.1.53 PPS0 Target Time Nanoseconds (PPS0_TARGET_TIME_NANOSECONDS)

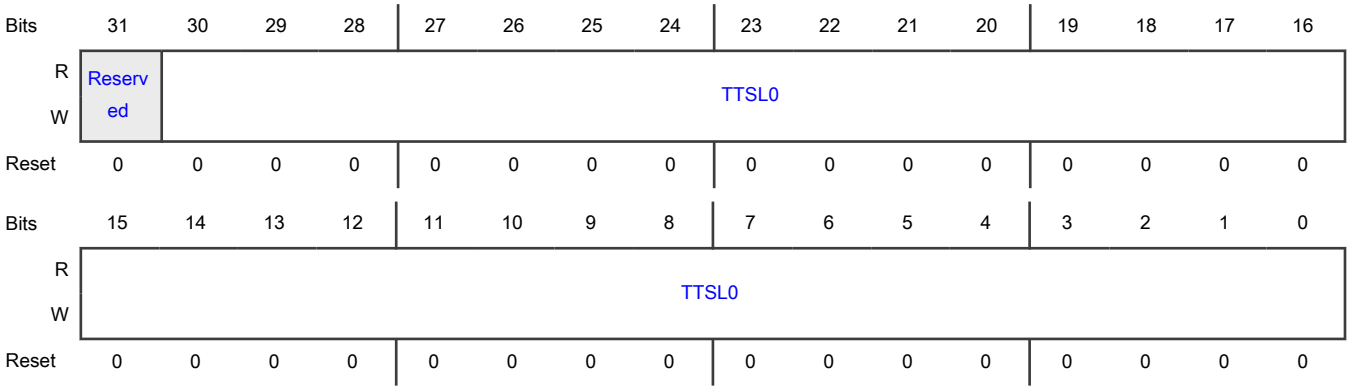
Offset

Register	Offset
PPS0_TARGET_TIME_NANOSECONDS	B84h

Function

PPS0 Target Time Nanoseconds.

Diagram



Fields

Field	Function
31 —	Reserved
30-0 TTSL0	Target Time Low for PPS Register Target Time Low for PPS Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in MAC_PPS_Control. When the TSCTRLSSR bit is reset in the MAC_Timestamp_Control register, this value should be (time in ns / 0.465). The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. When the TSCTRLSSR bit is set in the MAC_Timestamp_Control register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output might have an error margin up to one unit of sub-second increment value. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

70.5.1.54 MTL Operation Mode (MTL_OPERATION_MODE)

Offset

Register	Offset
MTL_OPERATION_MODE	C00h

Function

The Operation Mode register establishes the Transmit and Receive operating modes and commands.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When set, this bit indicates that the packets received in Queue 1 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 1 are routed to the DMA Channel programmed in the Q1MDMACH field (Bits[10:8]). 0b - Queue 1 disabled for DA-based DMA Channel Selection 1b - Queue 1 enabled for DA-based DMA Channel Selection
11-9 —	Reserved
8 Q1MDMACH	Queue 1 Mapped to DMA Channel This field controls the routing of the received packet in Queue 1 to the DMA channel: 0: DMA Channel 0 1: DMA Channel 1 This field is valid when Q1DDMACH field is reset.
7-5 —	Reserved
4 Q0DDMACH	Queue 0 Enabled for DA-based DMA Channel Selection When set, this bit indicates that the packets received in Queue 0 are routed to a particular DMA channel as decided in the MAC Receiver based on the DMA channel number programmed in the L3-L4 filter registers, or the Ethernet DA address. When reset, this bit indicates that the packets received in Queue 0 are routed to the DMA Channel programmed in the Q0MDMACH field. 0b - Queue 0 disabled for DA-based DMA Channel Selection 1b - Queue 0 enabled for DA-based DMA Channel Selection
3-1 —	Reserved
0 Q0MDMACH	Queue 0 Mapped to DMA Channel This field controls the routing of the packet received in Queue 0 to the DMA channel: 0: DMA Channel 0 1: DMA Channel 1 This field is valid when Q0DDMACH field is reset.

70.5.1.57 Queue 0 Transmit Operation Mode (MTL_TXQ0_OPERATION_MODE)

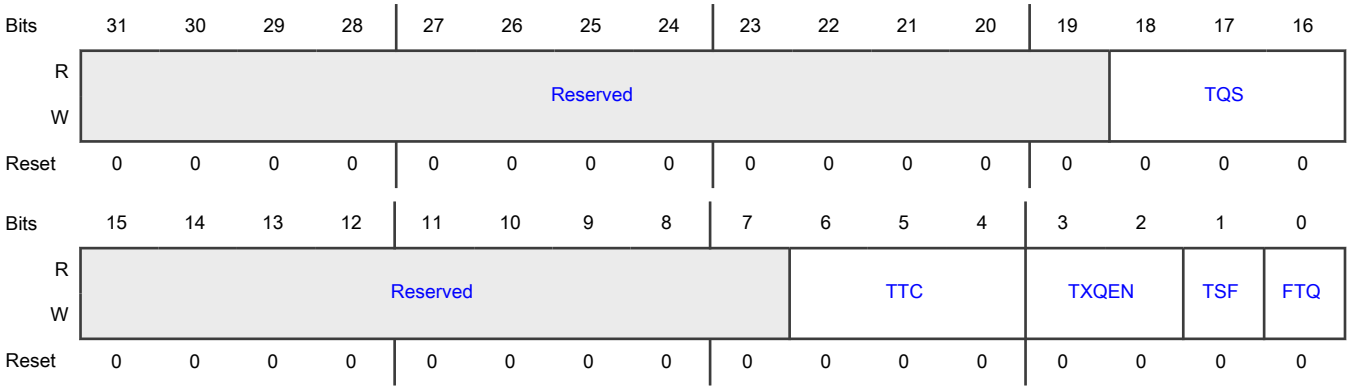
Offset

Register	Offset
MTL_TXQ0_OPERATION_MODE	D00h

Function

The Queue 0 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS+1)*256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4	Transmit Threshold Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
TTC	These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 2'b00: Not enabled 2'b01: Reserved 2'b10: Enabled 2'b11: Reserved This field is Read Only in Single Queue configurations and Read Write in Multiple Queue configurations. Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted

Table continues on the next page...

Table continued from the previous page...

Field	Function
	by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission. Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

70.5.1.58 Queue 0 Underflow Counter (MTL_TXQ0_UNDERFLOW)

Offset

Register	Offset
MTL_TXQ0_UNDERFLOW	D04h

Function

The Queue 0 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 —	Reserved
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state 01b - Read state (transferring data to the MAC transmitter)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected 1b - Transmit Queue in Pause status is detected

70.5.1.60 Queue 0 ETS Status (MTL_TXQ0_ETS_STATUS)

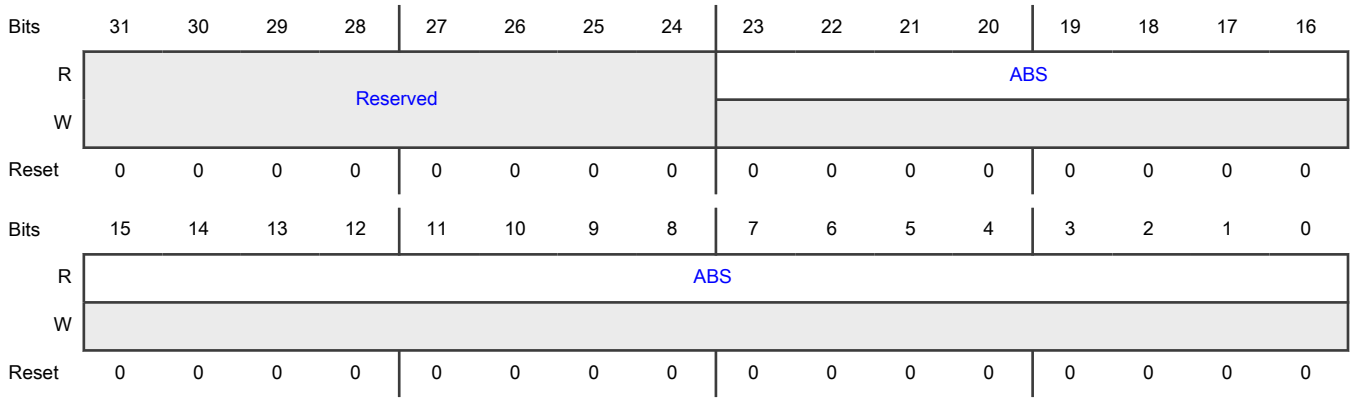
Offset

Register	Offset
MTL_TXQ0_ETS_STATUS	D14h

Function

The Queue 0 ETS Status register provides the average traffic transmitted in Queue 0.

Diagram



Fields

Field	Function
31-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. When the DCB operation is enabled for Queue 0, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

70.5.1.61 Queue 0 Quantum or Weights (MTL_TXQ0_QUANTUM_WEIGHT)

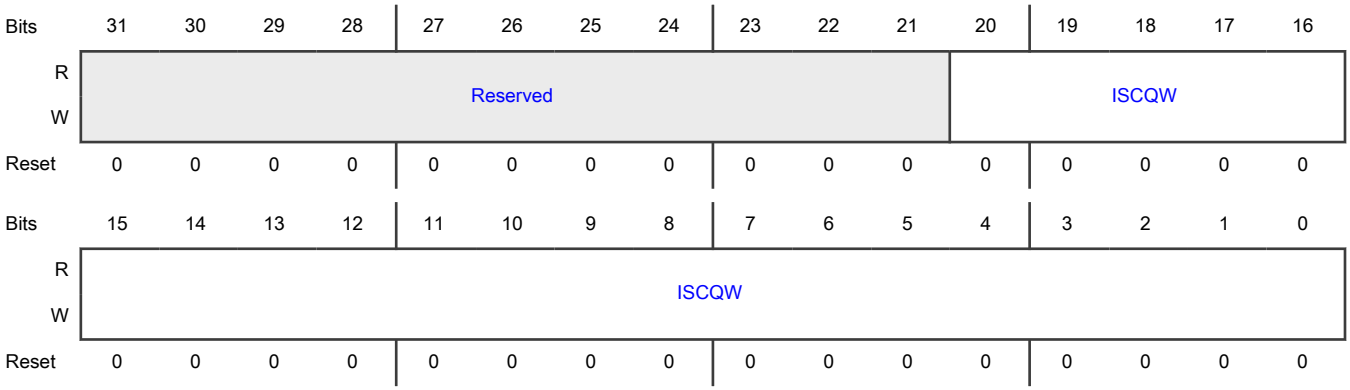
Offset

Register	Offset
MTL_TXQ0_QUANTUM_WEIGHT	D18h

Function

The Queue 0 Quantum or Weights register contains the quantum value for Deficit Weighted Round Robin (DWRR), weights for the Weighted Round Robin (WRR), and Weighted Fair Queuing (WFQ) for Queue 0.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	Quantum or Weights

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the DCB operation is enabled with DWRR algorithm for Queue 0 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. When DCB operation is enabled with WFQ algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. The higher the programmed weights lesser the bandwidth allocated for the particular Transmit Queue. This is because the weights are used to compute the packet finish time (weights * packet_size). Lesser the finish time, higher the probability of the packet getting scheduled first and using more bandwidth. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 0 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero.

70.5.1.62 Queue 0 Interrupt Control Status (MTL_Q0_INTERRUPT_CONTROL_STATUS)

Offset

Register	Offset
MTL_Q0_INTERRUPT_CONTROL_STATUS	D2Ch

Function

This register contains the interrupt enable and status bits for the queue 0 interrupts.

Diagram

24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 —	Reserved
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 —	Reserved
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated. When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 —	Reserved
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

70.5.1.63 Queue 0 Receive Operation Mode (MTL_RXQ0_OPERATION_MODE)

Offset

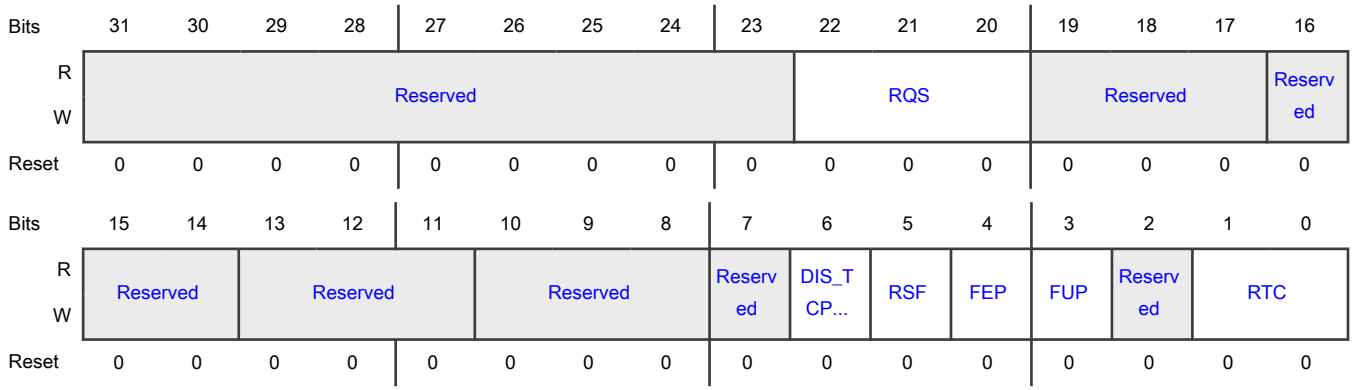
Register	Offset
MTL_RXQ0_OPERATION_MODE	D30h

Function

The Queue 0 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 RQS	Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-17 —	Reserved
16-14 —	Reserved
13-11 —	Reserved
10-8 —	Reserved
7 —	Reserved
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the enet reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes): The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

70.5.1.64 Queue 0 Missed Packet and Overflow Counter (MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT)

Offset

Register	Offset
MTL_RXQ0_MISSED_PACKET_OVERFLOW_CNT	D34h

Function

The Queue 0 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Diagram

Fields

Field	Function
31-28 —	Reserved
27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Missed Packet Counter overflow not detected 1b - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the enet because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow Counter overflow not detected 1b - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the enet because of Receive queue overflow. This counter is incremented each time the enet discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

70.5.1.65 Queue 0 Receive Debug (MTL_RXQ0_DEBUG)

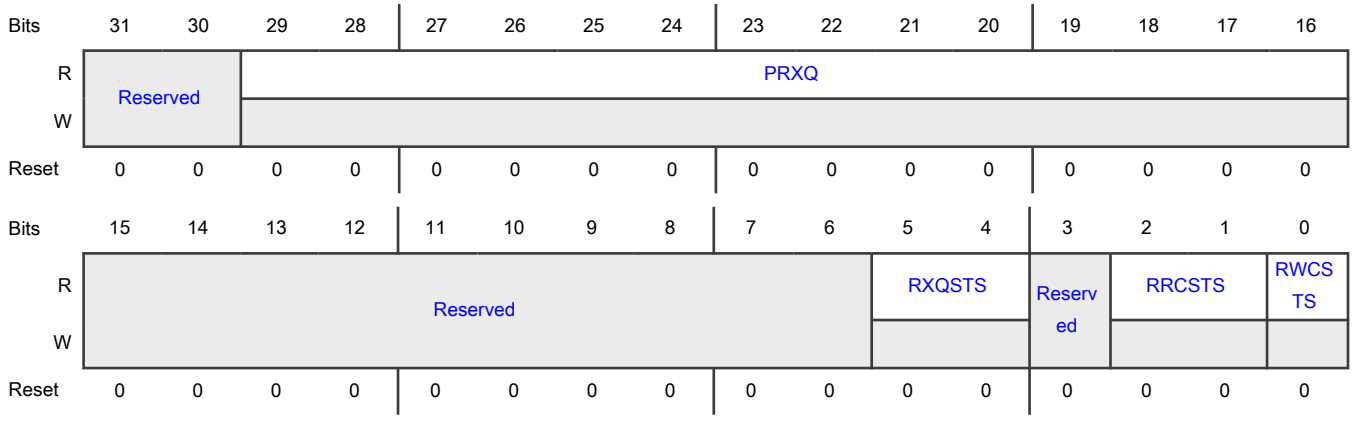
Offset

Register	Offset
MTL_RXQ0_DEBUG	D38h

Function

The Queue 0 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0b - MTL Rx Queue Write Controller Active Status not detected 1b - MTL Rx Queue Write Controller Active Status detected

70.5.1.66 Queue 0 Receive Control (MTL_RXQ0_CONTROL)

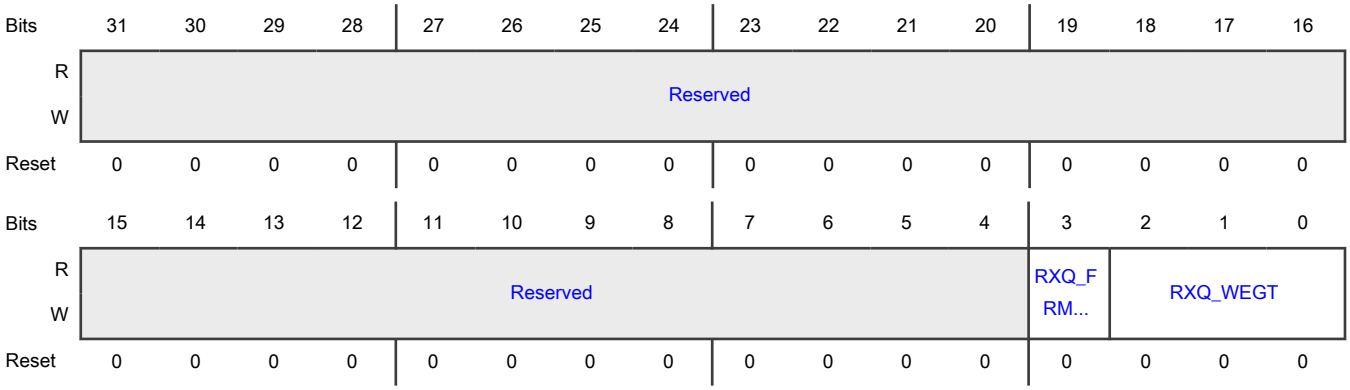
Offset

Register	Offset
MTL_RXQ0_CONTROL	D3Ch

Function

The Queue 0 Receive Control register controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the enet drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the enet drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue: PBL amount of data (indicated by ari_qN_pbl_i[]) or Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the enet drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQn_Control registers must be programmed before the MTL_Operation_Mode register.

70.5.1.67 Queue 1 Transmit Operation Mode (MTL_TXQ1_OPERATION_MODE)

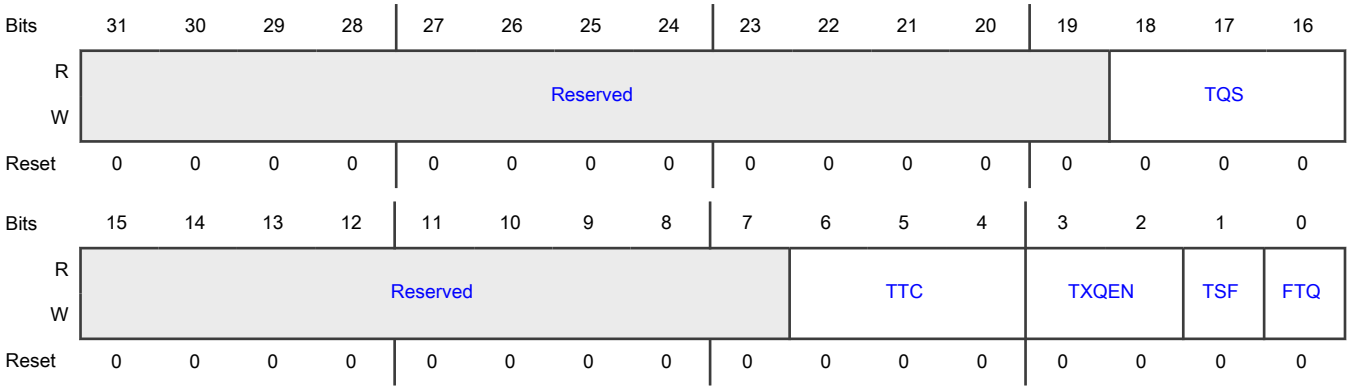
Offset

Register	Offset
MTL_TXQ1_OPERATION_MODE	D40h

Function

The Queue 1 Transmit Operation Mode register establishes the Transmit queue operating modes and commands.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 TQS	Transmit Queue Size This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The TQS field is read-write only if the number of Tx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program TQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (TQS+1)*256 bytes. When the number of Tx Queues is one, the field is read-only and the configured TX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
15-7 —	Reserved
6-4	Transmit Threshold Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
TTC	These bits control the threshold level of the MTL Tx Queue. The transmission starts when the packet size within the MTL Tx Queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset. 000b - 32 001b - 64 010b - 96 011b - 128 100b - 192 101b - 256 110b - 384 111b - 512
3-2 TXQEN	Transmit Queue Enable This field is used to enable/disable the transmit queue 0. 2'b00: Not enabled 2'b01: Enable in AV mode 2'b10: Enabled 2'b11: Reserved Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field. 00b - Not enabled 01b - Enable in AV mode (Reserved in non-AV) 10b - Enabled 11b - Reserved
1 TSF	Transmit Store and Forward When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped. 0b - Transmit Store and Forward is disabled 1b - Transmit Store and Forward is enabled
0 FTQ	Flush Transmit Queue When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the MTL_TxQ1_Operation_Mode register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (clk_tx_i) should be active. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Flush Transmit Queue is disabled 1b - Flush Transmit Queue is enabled

70.5.1.68 Queue 1 Underflow Counter (MTL_TXQ1_UNDERFLOW)

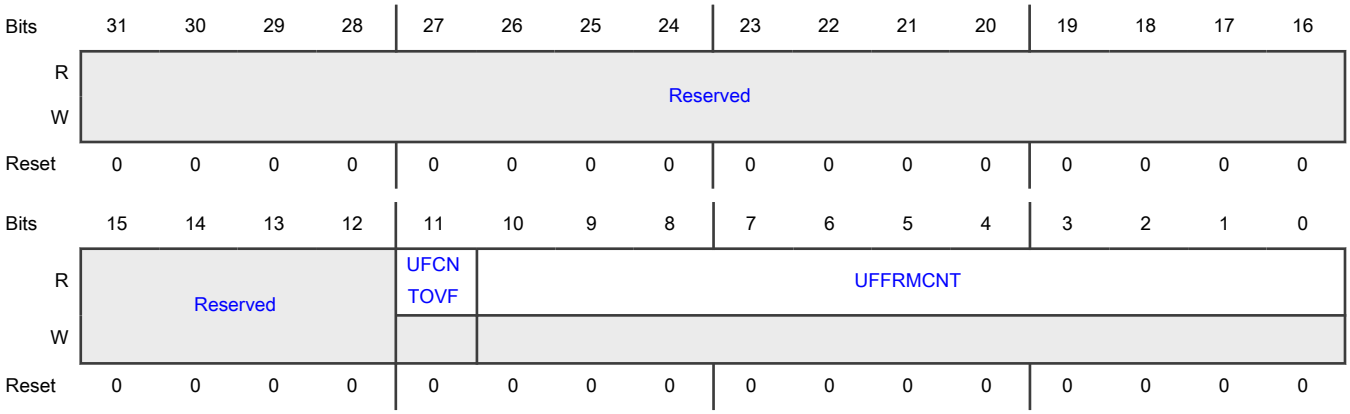
Offset

Register	Offset
MTL_TXQ1_UNDERFLOW	D44h

Function

The Queue 1 Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush

Diagram



Fields

Field	Function
31-12 —	Reserved
11	Overflow Bit for Underflow Packet Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
UFCNTOVF	This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow not detected for Underflow Packet Counter 1b - Overflow detected for Underflow Packet Counter
10-0 UFFRMCNT	Underflow Packet Counter This field indicates the number of packets aborted by the controller because of Tx Queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

70.5.1.69 Queue 1 Transmit Debug (MTL_TXQ1_DEBUG)

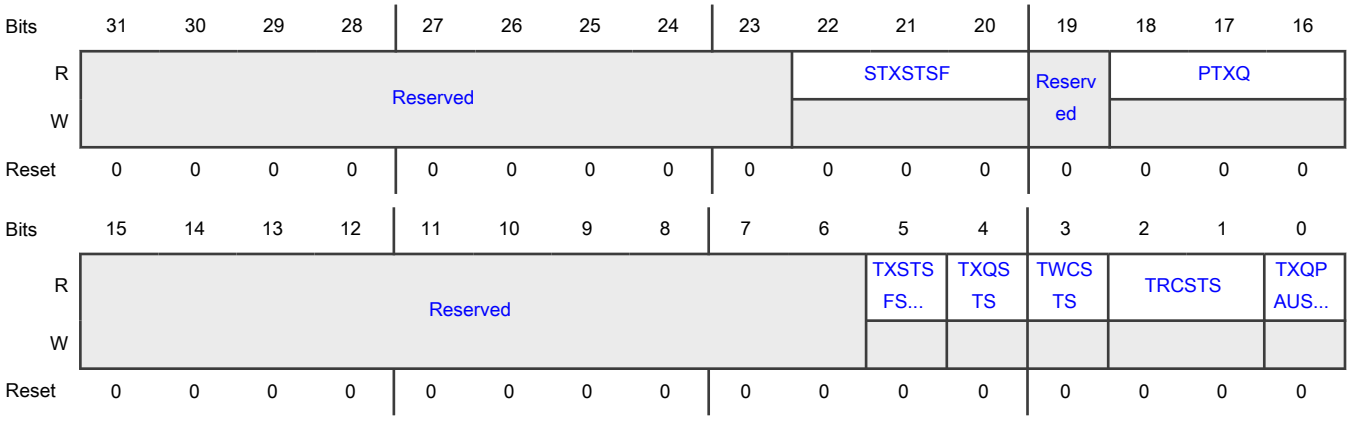
Offset

Register	Offset
MTL_TXQ1_DEBUG	D48h

Function

The Queue 1 Transmit Debug register gives the debug status of various blocks related to the Transmit queue.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 STXSTSF	Number of Status Words in Tx Status FIFO of Queue This field indicates the current number of status in the Tx Status FIFO of this queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.
19 —	Reserved
18-16 PTXQ	Number of Packets in the Transmit Queue This field indicates the current number of packets in the Tx Queue. When the DTXSTS bit of MTL_Operation_Mode register is set to 1, this field does not reflect the number of packets in the Transmit queue.
15-6 —	Reserved
5 TXSTSFSTS	MTL Tx Status FIFO Full Status MTL Tx Status FIFO Full Status When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission. 0b - MTL Tx Status FIFO Full status is not detected 1b - MTL Tx Status FIFO Full status is detected
4 TXQSTS	MTL Tx Queue Not Empty Status When this bit is high, it indicates that the MTL Tx Queue is not empty and some data is left for transmission. 0b - MTL Tx Queue Not Empty status is not detected 1b - MTL Tx Queue Not Empty status is detected
3 TWCSTS	MTL Tx Queue Write Controller Status When high, this bit indicates that the MTL Tx Queue Write Controller is active, and it is transferring the data to the Tx Queue. 0b - MTL Tx Queue Write Controller status is not detected 1b - MTL Tx Queue Write Controller status is detected
2-1 TRCSTS	MTL Tx Queue Read Controller Status This field indicates the state of the Tx Queue Read Controller: 00b - Idle state

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Read state (transferring data to the MAC transmitter) 10b - Waiting for pending Tx Status from the MAC transmitter 11b - Flushing the Tx queue because of the Packet Abort request from the MAC
0 TXQPAUSED	Transmit Queue in Pause When this bit is high and the Rx flow control is enabled, it indicates that the Tx Queue is in the Pause condition (in the full-duplex only mode) because of the following: Reception of the PFC packet for the priorities assigned to the Tx Queue when PFC is enabled Reception of 802.3x Pause packet when PFC is disabled 0b - Transmit Queue in Pause status is not detected 1b - Transmit Queue in Pause status is detected

70.5.1.70 Queue 1 ETS Control (MTL_TXQ1_ETS_CONTROL)

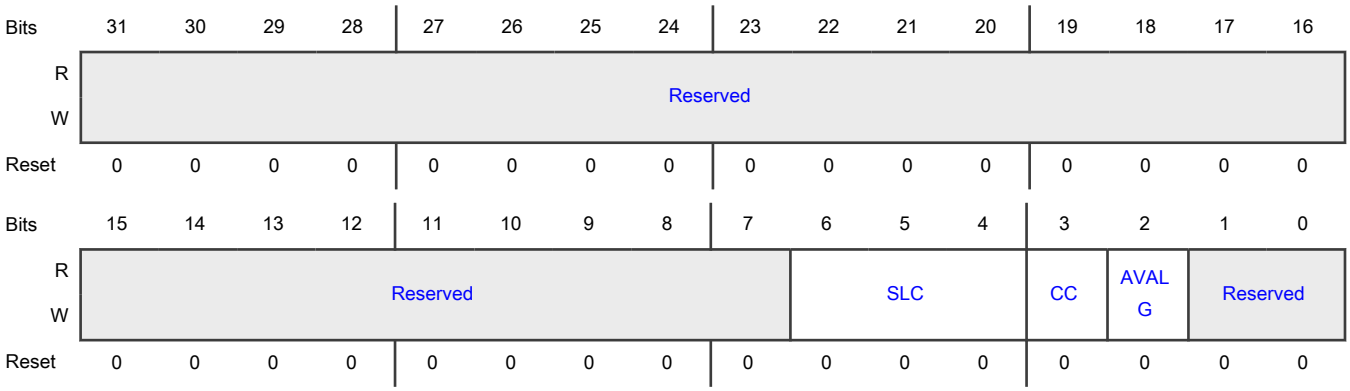
Offset

Register	Offset
MTL_TXQ1_ETS_CONTROL	D50h

Function

The Queue 1 ETS Control register controls the enhanced transmission selection operation.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-4 SLC	Slot Count If the credit-based shaper algorithm is enabled, the software can program the number of slots (of duration programmed in DMA_CH(#i)_Slot_Interval register) over which the average transmitted bits per slot, provided in the MTL_TxQ(#i)_ETS_Status register, need to be computed for Queue. The encoding is as follows: 000b - 1 slot 001b - 2 slots 010b - 4 slots 011b - 8 slots 100b - 16 slots 101b - Reserved
3 CC	Credit Control When this bit is set, the accumulated credit parameter in the credit-based shaper algorithm logic is not reset to zero when there is positive credit and no packet to transmit in Channel 1. The credit accumulates even when there is no packet waiting in Channel 1 and another channel is transmitting. When this bit is reset, the accumulated credit parameter in the credit-based shaper algorithm logic is set to zero when there is positive credit and no packet to transmit in Channel 1. When there is no packet waiting in Channel 1 and other channel is transmitting, no credit is accumulated. 0b - Credit Control is disabled 1b - Credit Control is enabled
2 AVALG	AV Algorithm When Queue 1 is programmed for AV, this field configures the scheduling algorithm for this queue: This bit when set, indicates credit based shaper algorithm (CBS) is selected for Queue 1 traffic. When reset, strict priority is selected. 0b - CBS Algorithm is disabled 1b - CBS Algorithm is enabled
1-0 —	Reserved

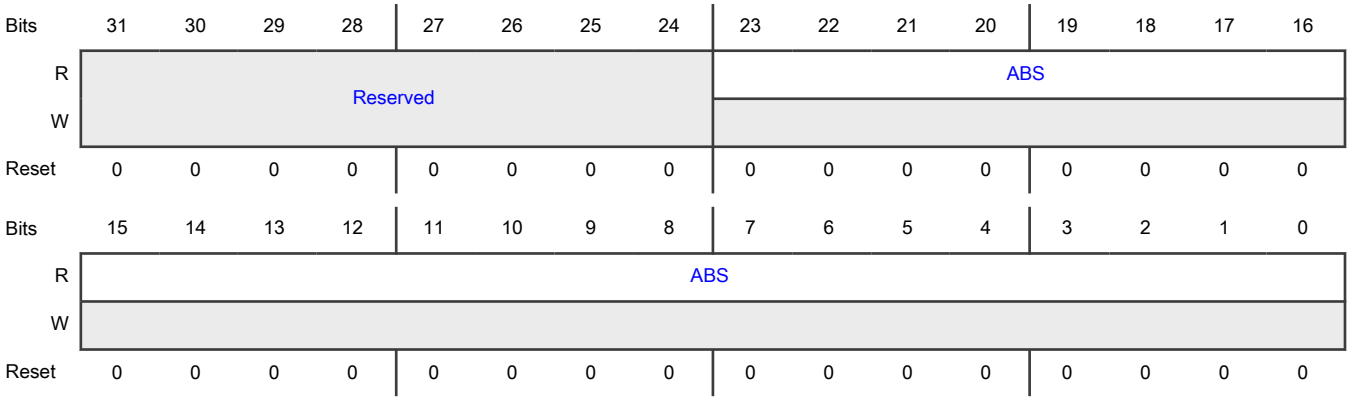
70.5.1.71 Queue 1 ETS Status (MTL_TXQ1_ETS_STATUS)

Offset

Register	Offset
MTL_TXQ1_ETS_STATUS	D54h

Function
The Queue 1 ETS Status register provides the average traffic transmitted in Queue 1.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 ABS	Average Bits per Slot This field contains the average transmitted bits per slot. If AV operation is enabled, this field is computed over number of slots, programmed in the SLC field of MTL_TxQ(#i)_ETS_CONTROL register. The maximum value of this field is 0x6_4000 in 100 Mbps, 0x3E_8000 in 1000 Mbps and 9C_4000 in 2500 Mbps mode respectively. When the DCB operation is enabled for Queue, this field is computed over every 10 million bit times slot (4 ms in 2500 Mbps; 10 ms in 1000 Mbps; 100 ms in 100 Mbps). The maximum value is 0x989680.

70.5.1.72 Queue 1 idleSlopeCredit, Quantum or Weights (MTL_TXQ1_QUANTUM_WEIGHT)

Offset

Register	Offset
MTL_TXQ1_QUANTUM_WEIGHT	D58h

Function

The Queue 1 idleSlopeCredit, Quantum or Weights register provides the average traffic transmitted in Queue 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-21 —	Reserved
20-0 ISCQW	idleSlopeCredit, Quantum or Weights When AV feature is enabled, this field contains the idleSlopeCredit value required for the credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns for 100 Mbps; 8 ns for 1000 Mbps; 3.2 ns for 2500 Mbps) when the credit is increasing. The software should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. Bits[20:14] must be written to zero. Quantum When the DCB operation is enabled with DWRR algorithm for Queue 1 traffic, this field contains the quantum value in bytes to be added to credit during every queue scanning cycle. The maximum value is 0x1312D0 bytes. Weights When DCB operation is enabled with WFQ algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x3FFF where weight of 0 indicates 100% bandwidth. Bits[20:14] must be written to zero. When DCB operation or generic queuing operation is enabled with WRR algorithm for Queue 1 traffic, this field contains the weight for this queue. The maximum value is 0x64. Bits [20:7] must be written to zero. Note 1: In multiple Queue configuration this field in respective per queue register must be programmed to some non-zero value when multiple queues are enabled or single queue other than Q0 is enabled. This field need not be programmed when only Q0 is enabled. In general, when WRR algorithm is selected a non-zero value must be programmed on both Receive and Transmit. In Receive, the register is MTL_Operation_Mode register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Note 2: For WFQ algorithm, higher the programmed weights lesser the bandwidth allocated for that Transmit Queue. The finish time is not a function of particular packet alone but it is as per the formula: (previous_finish_time of particular Transmit Queue + (weights*packet_size)) Note 3: The weights programmed do not correspond to the number of packets but the fraction of bandwidth or time allocated for particular queue w.r.t. total BW or time.

70.5.1.73 Queue 1 sendSlopeCredit (MTL_TXQ1_SENDSLOPECREDIT)

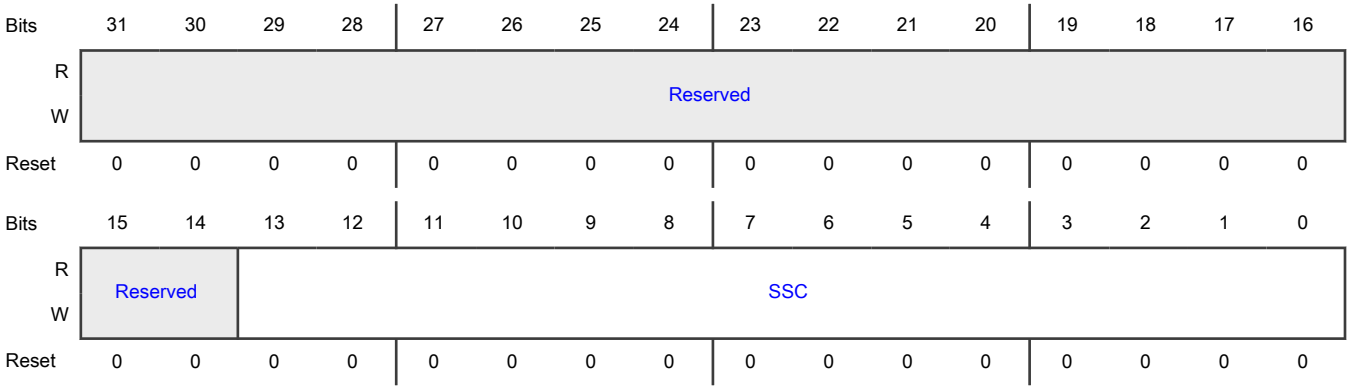
Offset

Register	Offset
MTL_TXQ1_SENDSLOPECREDIT	D5Ch

Function

The sendSlopeCredit register contains the sendSlope credit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 SSC	sendSlopeCredit Value When AV operation is enabled, this field contains the sendSlopeCredit value required for credit-based shaper algorithm for Queue 1. This is the rate of change of credit in bits per cycle (40 ns, 8 ns and 3.2 ns for 100 Mbps, 1000 Mbps and 2500 Mbps respectively) when the credit is decreasing. The software

Table continues on the next page...

Table continued from the previous page...

Field	Function
	should program this field with computed credit in bits per cycle scaled by 1,024. The maximum value is portTransmitRate, that is, 0x2000 in 1000/2500 Mbps mode and 0x1000 in 100 Mbps mode. This field should be programmed with absolute sendSlopeCredit value. The credit-based shaper logic subtracts it from the accumulated credit when Channel 1 is selected for transmission.

70.5.1.74 Queue 1 hiCredit (MTL_TXQ1_HICREDIT)

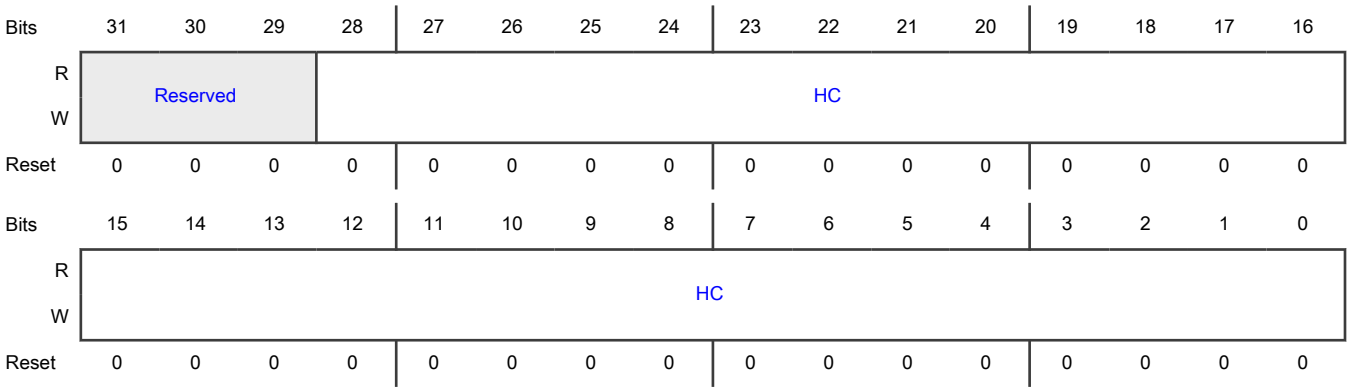
Offset

Register	Offset
MTL_TXQ1_HICREDIT	D60h

Function

The hiCredit register contains the hiCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-0 HC	hiCredit Value When the AV feature is enabled, this field contains the hiCredit value required for the credit-based shaper algorithm. This is the maximum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value is maxInterferenceSize, that is, best-effort maximum packet size (16,384 bytes or 131,072 bits). The value to be specified is 131,072 * 1,024 = 134,217,728 or 0x0800_0000.

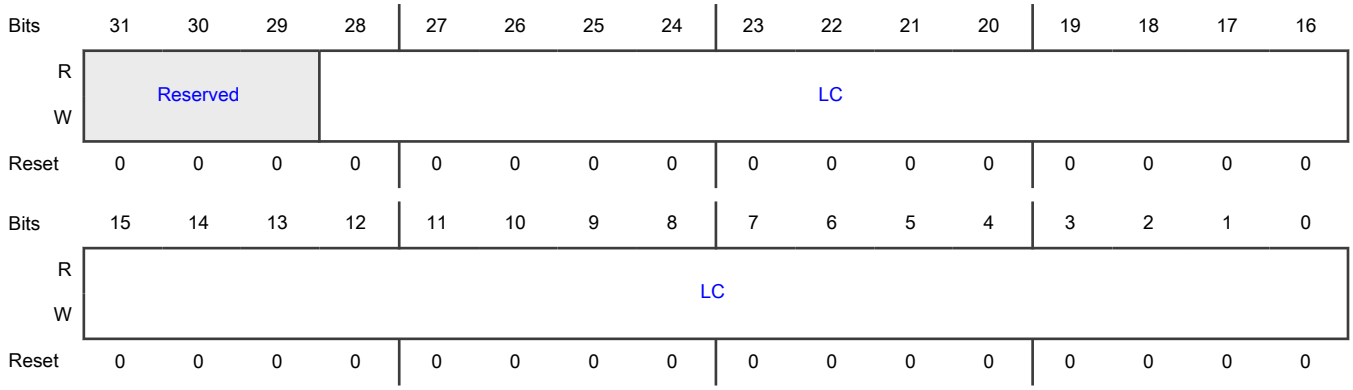
70.5.1.75 Queue 1 loCredit (MTL_TXQ1_LOCREDIT)

Offset

Register	Offset
MTL_TXQ1_LOCREDIT	D64h

Function
The loCredit register contains the loCredit value required for the credit-based shaper algorithm for the Queue.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-0 LC	loCredit Value When AV operation is enabled, this field contains the loCredit value required for the credit-based shaper algorithm. This is the minimum value that can be accumulated in the credit parameter. This is specified in bits scaled by 1,024. The maximum value to be programmed is corresponds to twice the maxFrameSize transmitted from this queue. If the maxFrameSize is 8192 bytes, then (8192*2) * 8 * 1024 = 134,217,728 or 0x0800_0000. Because it is a negative value, the programmed value is 2's complement of the value, that is, 0x1800_0000.

70.5.1.76 Queue 1 Interrupt Control Status (MTL_Q1_INTERRUPT_CONTROL_STATUS)

Offset

Register	Offset
MTL_Q1_INTERRUPT_CONTROL_STATUS	D6Ch

Function

This register contains the interrupt enable and status bits for the queue 1 interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-25 —	Reserved
24 RXOIE	Receive Queue Overflow Interrupt Enable When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled. 0b - Receive Queue Overflow Interrupt is disabled 1b - Receive Queue Overflow Interrupt is enabled
23-17 —	Reserved
16 RXOVFIS	Receive Queue Overflow Interrupt Status This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Queue Overflow Interrupt Status not detected 1b - Receive Queue Overflow Interrupt Status detected
15-10 —	Reserved
9 ABPSIE	Average Bits Per Slot Interrupt Enable When this bit is set, the MAC asserts the sbd_intr_o or mci_intr_o interrupt when the average bits per slot status is updated.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this bit is cleared, the interrupt is not asserted for such an event. 0b - Average Bits Per Slot Interrupt is disabled 1b - Average Bits Per Slot Interrupt is enabled
8 TXUIE	Transmit Queue Underflow Interrupt Enable When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled. 0b - Transmit Queue Underflow Interrupt Status is disabled 1b - Transmit Queue Underflow Interrupt Status is enabled
7-2 —	Reserved
1 ABPSIS	Average Bits Per Slot Interrupt Status When set, this bit indicates that the MAC has updated the ABS value. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Average Bits Per Slot Interrupt Status not detected 1b - Average Bits Per Slot Interrupt Status detected
0 TXUNFIS	Transmit Queue Underflow Interrupt Status This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Queue Underflow Interrupt Status not detected 1b - Transmit Queue Underflow Interrupt Status detected

70.5.1.77 Queue 1 Receive Operation Mode (MTL_RXQ1_OPERATION_MODE)

Offset

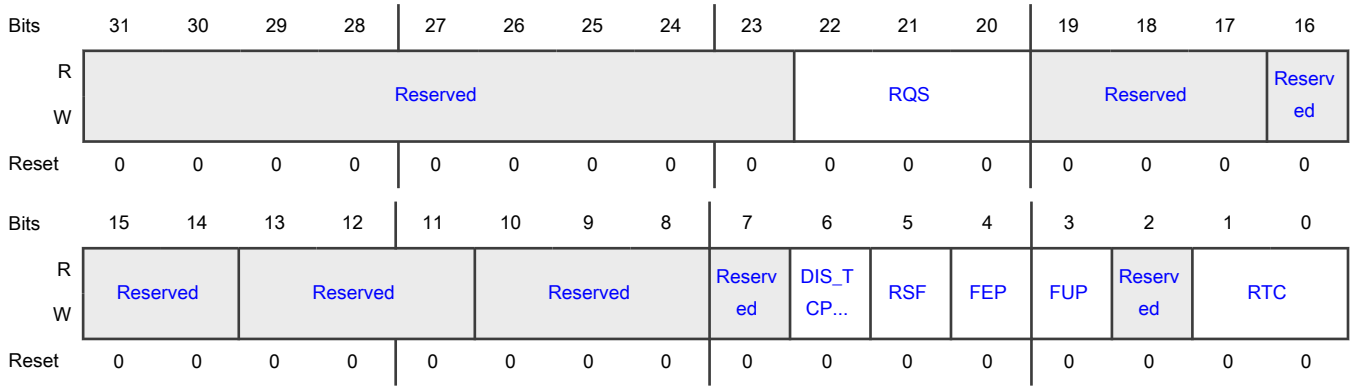
Register	Offset
MTL_RXQ1_OPERATION_MODE	D70h

Function

The Queue 1 Receive Operation Mode register establishes the Receive queue operating modes and command.

The RFA and RFD fields are not backward compatible with the RFA and RFD fields of 4.00a release

Diagram



Fields

Field	Function
31-23 —	Reserved
22-20 RQS	Receive Queue Size Receive Queue Size This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx Queues more than one, the reset value is 0x0 and indicates size of 256 bytes. This means that value of 0x0 = 256 bytes, 0x1 = 512 bytes and so on. So, program RQS [5:0] = 6'b001111 to allocate queue size of 4096 (4K) bytes. In general, the size of the Queue = (RQS+1)*256 bytes. When the number of Rx Queues is one, the field is read-only and the configured RX FIFO size in blocks of 256 bytes is reflected in the reset value. The width of this field depends on the Rx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits: LOG2(2048/256) = LOG2(8) = 3 bits
19-17 —	Reserved
16-14 —	Reserved
13-11 —	Reserved
10-8 —	Reserved
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 DIS_TCP_EF	Disable Dropping of TCP/IP Checksum Error Packets When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset. 0b - Dropping of TCP/IP Checksum Error Packets is enabled 1b - Dropping of TCP/IP Checksum Error Packets is disabled
5 RSF	Receive Queue Store and Forward When this bit is set, the enet reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register. 0b - Receive Queue Store and Forward is disabled 1b - Receive Queue Store and Forward is enabled
4 FEP	Forward Error Packets When this bit is reset, the Rx queue drops packets with error status (CRC error, GMII_ER, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet might be forwarded to the application or DMA. 0b - Forward Error Packets is disabled 1b - Forward Error Packets is enabled
3 FUP	Forward Undersized Good Packets When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01. 0b - Forward Undersized Good Packets is disabled 1b - Forward Undersized Good Packets is enabled
2 —	Reserved
1-0 RTC	Receive Queue Threshold Control These bits control the threshold level of the MTL Rx queue (in bytes):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1. 00b - 64 01b - 32 10b - 96 11b - 128

70.5.1.78 Queue 1 Missed Packet and Overflow Counter (MTL_RXQ1_MISSED_PACKET_OVERFLOW_CNT)

Offset

Register	Offset
MTL_RXQ1_MISSED_PACKET_OVERFLOW_CNT	D74h

Function

The Queue 1 Missed Packet and Overflow Counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Diagram

27 MISCNTOVF	Missed Packet Counter Overflow Bit When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Missed Packet Counter overflow not detected 1b - Missed Packet Counter overflow detected
26-16 MISPKTCNT	Missed Packet Counter This field indicates the number of packets missed by the enet because the application asserted ari_pkt_flush_i[] for this queue. This counter is reset when this register is read with mci_be_i[0] at 1b1. This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability. Access restriction applies. Clears on read. Self-set to 1 on internal event.
15-12 —	Reserved
11 OVFCNTOVF	Overflow Counter Overflow Bit When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Overflow Counter overflow not detected 1b - Overflow Counter overflow detected
10-0 OVFPKTCNT	Overflow Packet Counter This field indicates the number of packets discarded by the enet because of Receive queue overflow. This counter is incremented each time the enet discards an incoming packet because of overflow. This counter is reset when this register is read with mci_be_i[0] at 1'b1. Access restriction applies. Clears on read. Self-set to 1 on internal event.

70.5.1.79 Queue 1 Receive Debug (MTL_RXQ1_DEBUG)

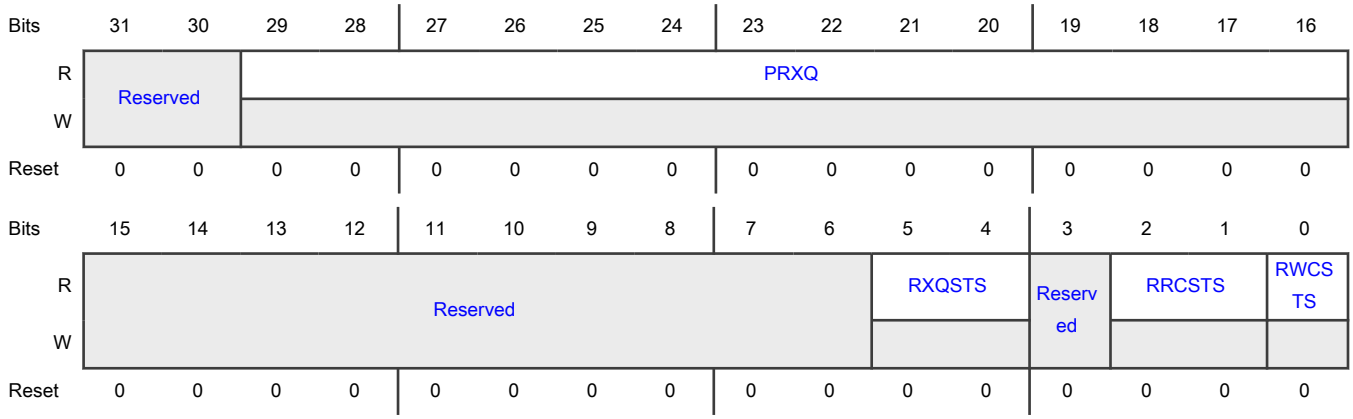
Offset

Register	Offset
MTL_RXQ1_DEBUG	D78h

Function

The Queue 1 Receive Debug register gives the debug status of various blocks related to the Receive queue.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-16 PRXQ	Number of Packets in Receive Queue This field indicates the current number of packets in the Rx Queue. The theoretical maximum value for this field is 256KB/16B = 16K Packets, that is, Max_Queue_Size/Min_Packet_Size.
15-6 —	Reserved
5-4 RXQSTS	MTL Rx Queue Fill-Level Status This field gives the status of the fill-level of the Rx Queue: 00b - Rx Queue empty 01b - Rx Queue fill-level below flow-control deactivate threshold 10b - Rx Queue fill-level above flow-control activate threshold 11b - Rx Queue full
3 —	Reserved
2-1 RRCSTS	MTL Rx Queue Read Controller State This field gives the state of the Rx queue Read controller: 00b - Idle state 01b - Reading packet data 10b - Reading packet status (or timestamp) 11b - Flushing the packet data and status

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 RWCSTS	MTL Rx Queue Write Controller Active Status When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx Queue. 0b - MTL Rx Queue Write Controller Active Status not detected 1b - MTL Rx Queue Write Controller Active Status detected

70.5.1.80 Queue 1 Receive Control (MTL_RXQ1_CONTROL)

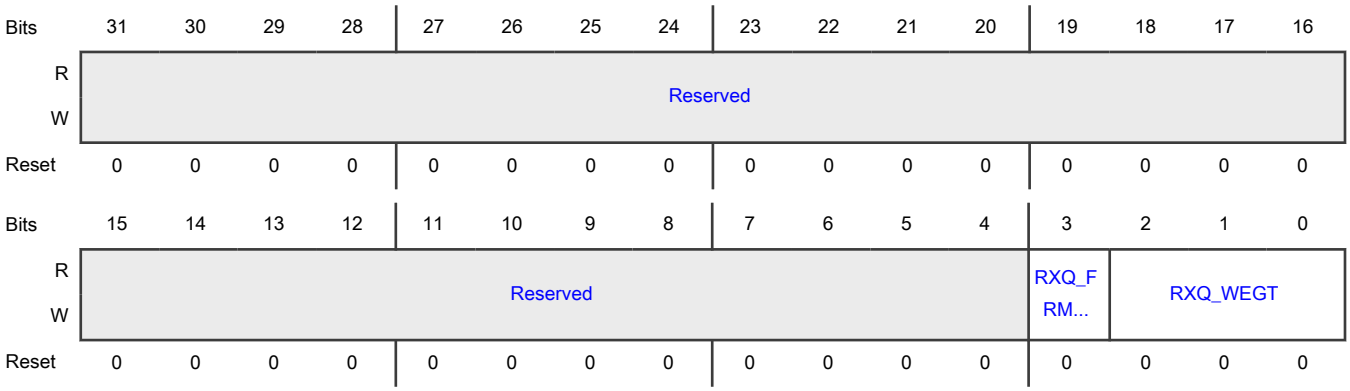
Offset

Register	Offset
MTL_RXQ1_CONTROL	D7Ch

Function

The Queue 1 Receive Control register controls the receive arbitration and passing of received packets to the application.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 RXQ_FRM_ARBIT	Receive Queue Packet Arbitration When this bit is set, the enet drives the packet data to the ARI interface such that the entire packet data of currently-selected queue is transmitted before switching to other queue. When this bit is reset, the enet drives the packet data to the ARI interface such that the following amount of data of currently-selected queue is transmitted before switching to other queue:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	PBL amount of data (indicated by ari_qN_pbl_i[]) or Complete data of a packet The status and the timestamp are not a part of the PBL data. Therefore, the enet drives the complete status (including timestamp status) during first PBL request for the packet (in store-and-forward mode) or the last PBL request for the packet (in Threshold mode). 0b - Receive Queue Packet Arbitration is disabled 1b - Receive Queue Packet Arbitration is enabled
2-0 RXQ_WEGT	Receive Queue Weight This field indicates the weight assigned to the Rx Queue 0. This field needs to be programmed with one value less than the required weight, that is, reset value of 0 indicates weight of 1, value of 1 indicates weight of 2, and so on. The weight is used as the number of continuous PBL or packets requests (depending on the RXQ_FRM_ARBIT) allocated to the queue in one arbitration cycle. Note: The change in value of RXQ_WEGT takes effect only after the completion of current service round or when there is change from RAA=SP to RAA=WSP algorithm. This approach is taken so that there is smooth transition. For the RXQ_WEGT value to take effect at the start, the MTL_RxQn_Control registers must be programmed before the MTL_Operation_Mode register.

70.5.1.81 DMA Bus Mode (DMA_MODE)

Offset

Register	Offset
DMA_MODE	1000h

Function

The Bus Mode register establishes the bus operating modes for the DMA.

8 —	Reserved
7-5 —	Reserved
4-2 TAA	Transmit Arbitration Algorithm This field is used to select the arbitration algorithm for the Transmit side when multiple Tx DMAs are selected. 000b - Fixed priority. (Channel 0 has the lowest priority and the last channel has the highest priority) 001b - Weighted Strict Priority (WSP) 010b - Weighted Round-Robin (WRR) 011b - Reserved (for 3'b011 to 3'b111)
1 DA	DMA Tx or Rx Arbitration Scheme This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels: 0: Weighted Round-Robin with Rx:Tx or Tx:Rx The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit. 1: Fixed Priority The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path. 0b - Weighted Round-Robin with Rx:Tx or Tx:Rx 1b - Fixed Priority
0 SWR	Software Reset When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all enet clock domains. Before reprogramming any enet register, a value of zero should be read in this bit. This bit must be read at least 4 CSR clock cycles after it is written to 1. Note: The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present

Table continues on the next page...

Table continued from the previous page...

Field	Function
	for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0b - Software Reset is disabled 1b - Software Reset is enabled

70.5.1.82 DMA System Bus Mode (DMA_SYSBUS_MODE)

Offset

Register	Offset
DMA_SYSBUS_MODE	1004h

Function

The System Bus mode register controls the behavior of the AHB or AXI master. It mainly controls burst splitting and number of outstanding requests.

Diagram

Field	Function
0 AXWHSTS	AHB Master Status When high, this bit indicates that the AHB master FSMs are in the non-idle state. 0b - AXI Master Write Channel or AHB Master Status not detected 1b - AXI Master Write Channel or AHB Master Status detected

70.5.1.85 DMA Channel 0 Control (DMA_CH0_CONTROL)

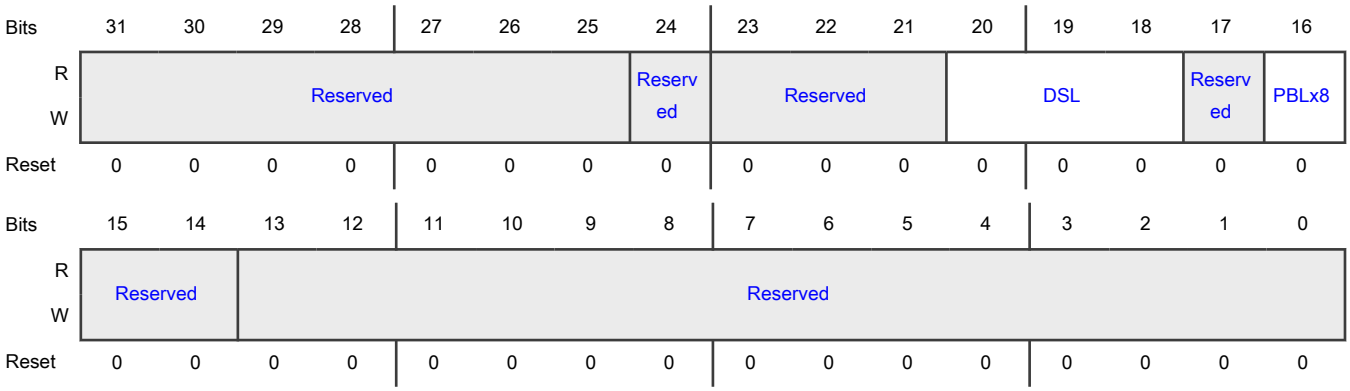
Offset

Register	Offset
DMA_CH0_CONTROL	1100h

Function

The DMA Channel 0 Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-18 DSL	Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 —	Reserved
16 PBLx8	8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in DMA_CH(#i)_Tx_Control and Bits[21:16] in DMA_CH(#i)_Rx_Control is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled
15-14 —	Reserved
13-0 —	Reserved

70.5.1.86 DMA Channel 0 Transmit Control (DMA_CH0_TX_CONTROL)

Offset

Register	Offset
DMA_CH0_TX_CONTROL	1104h

Function
The DMA Channel 0 Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.

22 ETIC	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in DMA_CH0_Control register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	2. Set the TxPBL. **NOTE** Note: The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQ(#i)_Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-13 —	Reserved
12 —	Reserved
11-5 —	Reserved
4 OSF	Operate on Second Packet When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TxDesc_List_Address register. The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_Status register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TxDesc_List_Address register, the DMA behavior is unpredictable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TxDesc_List_Address register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

70.5.1.87 DMA Channel 0 Receive Control (DMA_CH0_RX_CONTROL)

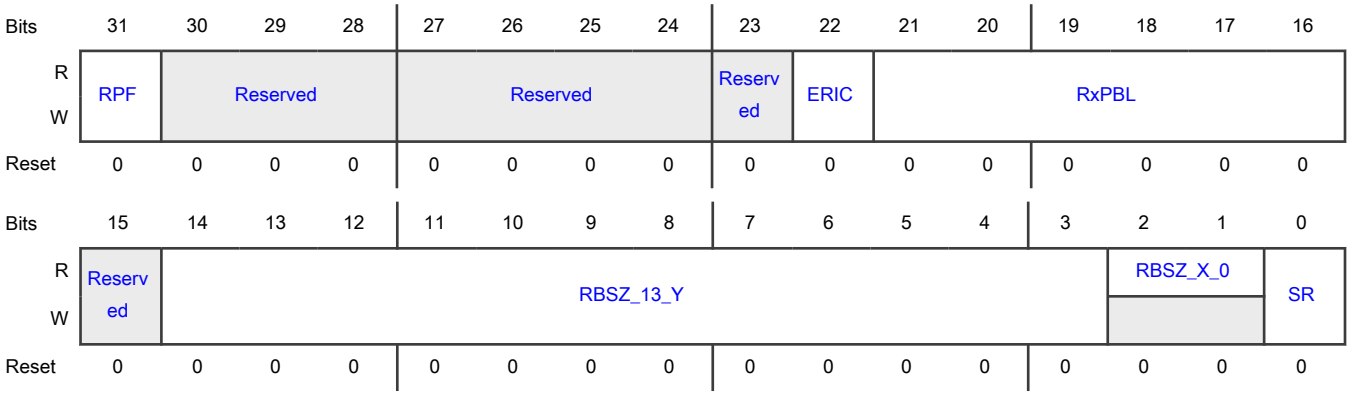
Offset

Register	Offset
DMA_CH0_RX_CONTROL	1108h

Function

The DMA Channel 0 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush. 1: enet automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are

Table continues on the next page...

Table continued from the previous page...

Field	Function
	received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing is done on the Read side of the Rx Queue. 0: enet does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue. Note: The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CH(#i)_Rx_Control register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 —	Reserved
27-24 —	Reserved
23 —	Reserved
22 ERIC	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after the completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. The PBL can be programmed with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_Control register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQn_Operation_Mode register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
14-3 RBSZ_13_Y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_Y and lower RBSZ_X_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_X_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_Y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_X_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_Y and RBSZ_X_0. The RBSZ_X_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH0_RxDesc_List_Address register. The position at which the Rx process was previously stopped If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH0_Status register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH0_RxDesc_List_Address register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

70.5.1.88 Channel 0 Tx Descriptor List Address register (DMA_CH0_TXDESC_LIST_ADDRESS)

Offset

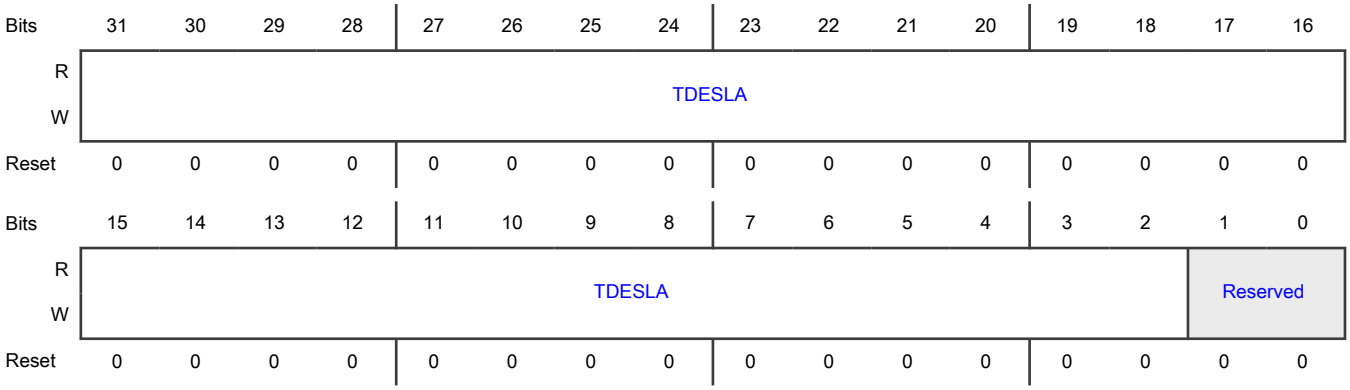
Register	Offset
DMA_CH0_TXDESC_LIST_ADDRESS	1114h

Function

The Channel 0 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-2 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved

70.5.1.89 Channel 0 Rx Descriptor List Address register (DMA_CH0_RXDESC_LIST_ADDRESS)

Offset

Register	Offset
DMA_CH0_RXDESC_LIST_ADDRESS	111Ch

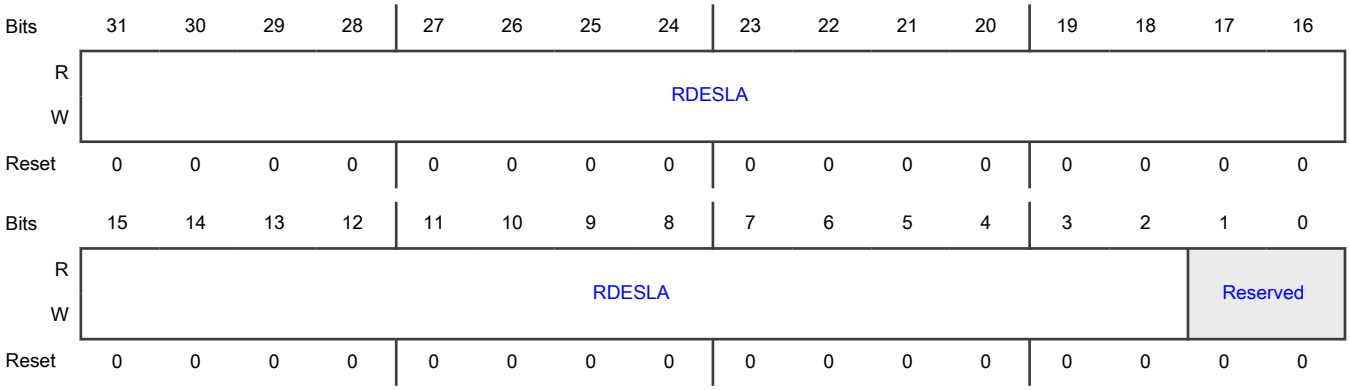
Function

The Channel 0 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-2 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration

70.5.1.92 Channel 0 Tx Descriptor Ring Length (DMA_CH0_TXDESC_RING_LENGTH)

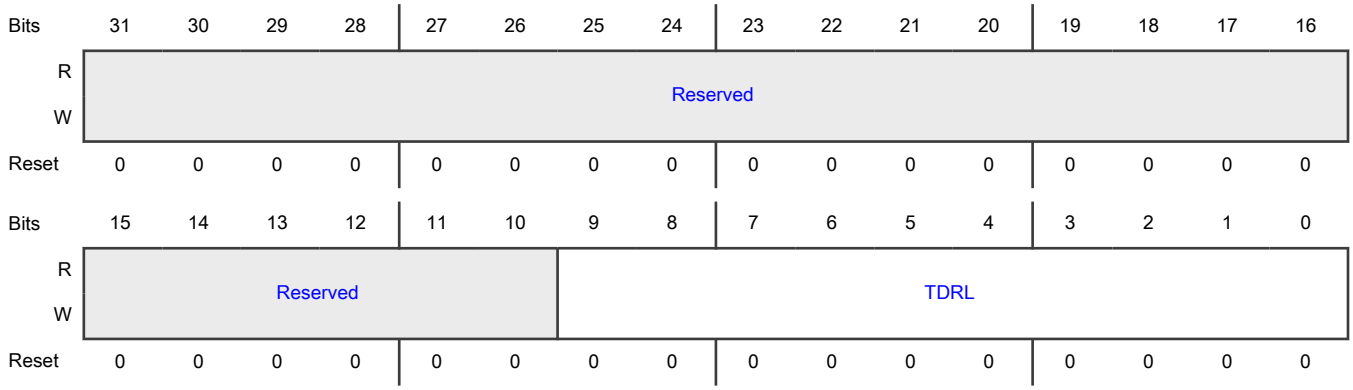
Offset

Register	Offset
DMA_CH0_TXDESC_RING_LENGTH	112Ch

Function

The Channel 0 Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 TDRL	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. We recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

70.5.1.93 Channeli Receive Control (DMA_CH0_RX_CONTROL2)

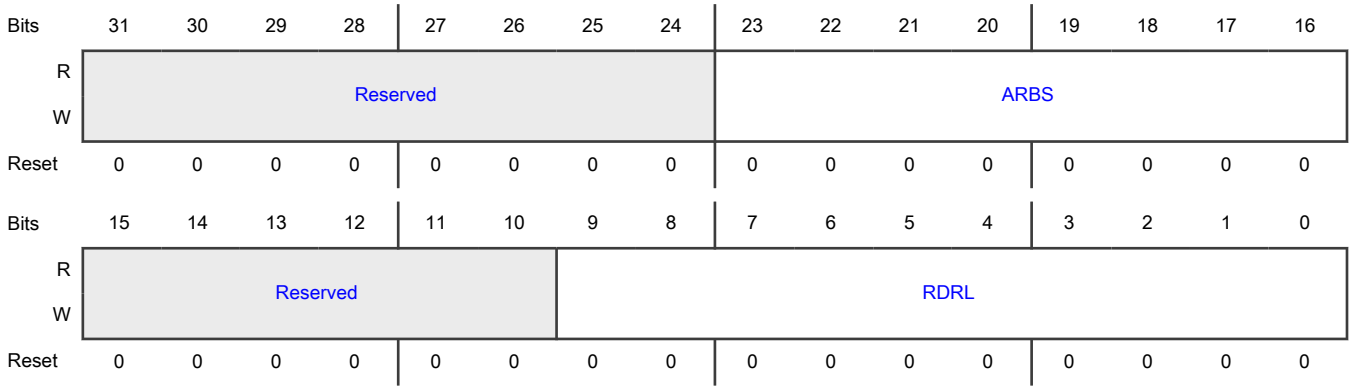
Offset

Register	Offset
DMA_CH0_RX_CONTROL2	1130h

Function

The Channeli Receive Control register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 ARBS	Alternate Receive Buffer Size Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH(#i)_Rx_Control. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively)
15-10 —	Reserved
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

70.5.1.94 Channeli Interrupt Enable (DMA_CH0_INTERRUPT_ENABLE)

Offset

Register	Offset
DMA_CH0_INTERRUPT_ENABLE	1134h

Function

Enables the interrupts reported by Status register.

70.5.1.95 Channel 0 Receive Interrupt Watchdog Timer (DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER)

Offset

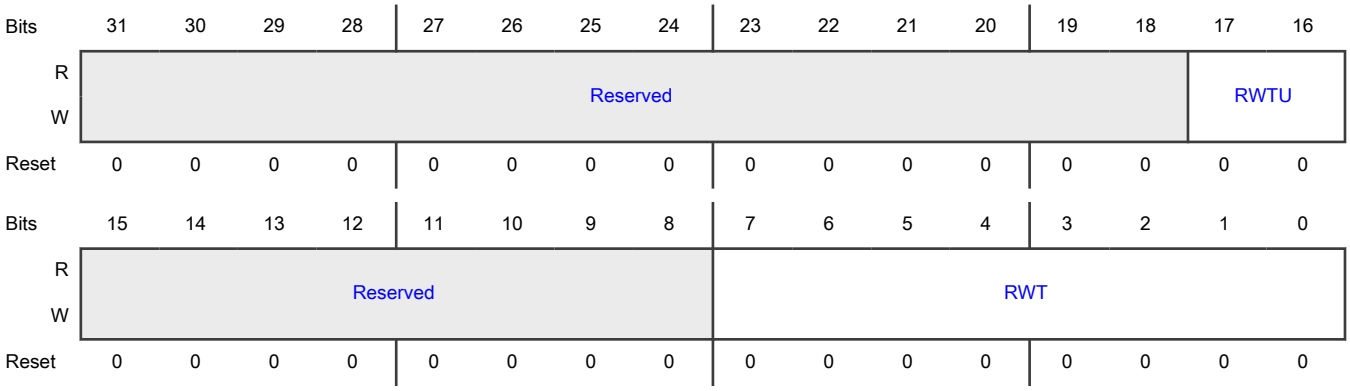
Register	Offset
DMA_CH0_RX_INTERRUPT_WATCHDOG_TIMER	1138h

Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA.

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the STATUS register.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. 2'b00: 256 2'b01: 512 2'b10: 1024 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

70.5.1.96 Channel 0 Slot Function Control and Status (DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS)

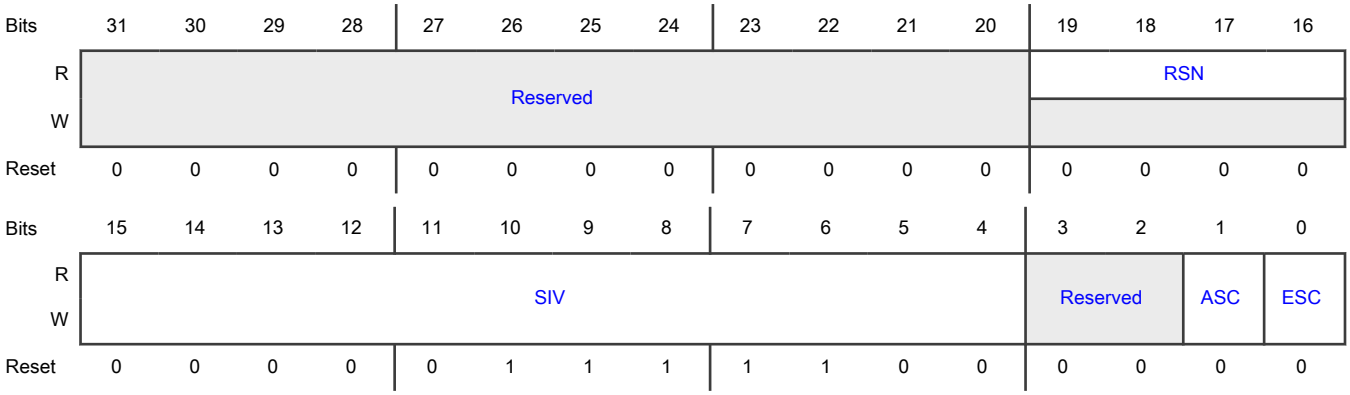
Offset

Register	Offset
DMA_CH0_SLOT_FUNCTION_CONTROL_STATUS	113Ch

Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default/reset value is 0x07C which corresponds to slot interval of 125 us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	equal to the reference slot number given in the RSN field or ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

70.5.1.97 Channel 0 Current Application Transmit Descriptor (DMA_CH0_CURRENT_APP_TXDESC)

Offset

Register	Offset
DMA_CH0_CURRENT_APP_TXDESC	1144h

70.5.1.101 DMA Channel 0 Status (DMA_CH0_STATUS)

Offset

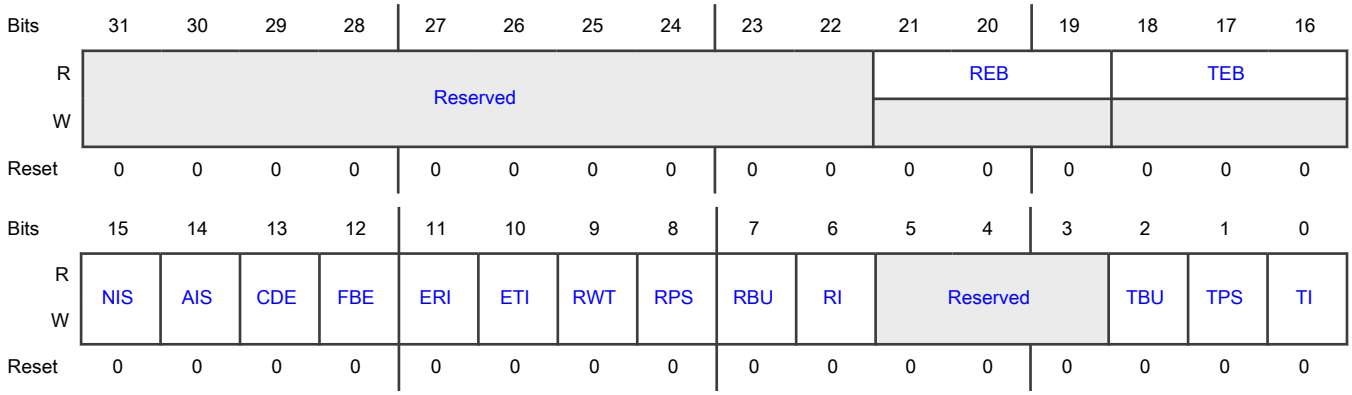
Register	Offset
DMA_CH0_STATUS	1160h

Function

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

Note: The number of STATUS register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Diagram



Fields

Field	Function
31-22 —	Reserved
21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 21 - 1'b1: Error during data transfer by Rx DMA - 1'b0: No Error during data transfer by Rx DMA Bit 20 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access Bit 19 - 1'b1: Error during read transfer - 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 18 - 1'b1: Error during data transfer by Tx DMA - 1'b0: No Error during data transfer by Tx DMA Bit 17 - 1'b1: Error during descriptor access

Table continues on the next page...

Table continued from the previous page...

Field	Function
	- 1'b0: Error during data buffer access Bit 16 - 1'b1: Error during read transfer - 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 0: Transmit Interrupt Bit 2: Transmit Buffer Unavailable Bit 6: Receive Interrupt Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_INTERRUPT_ENABLE register: Bit 1: Transmit Process Stopped Bit 7: Receive Buffer Unavailable Bit 8: Receive Process Stopped Bit 10: Early Transmit Interrupt Bit 12: Fatal Bus Error Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, ERIC = 0: This bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. ERIC = 1: This bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ERIC: ETIC = 0: This bit is set only after the Tx DMA has transferred a complete packet to MTL. ETIC = 1: This bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected 1b - Early Transmit Interrupt status detected
9	Receive Watchdog Timeout

Table continues on the next page...

Table continued from the previous page...

Field	Function
RWT	This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following: Change the ownership of the descriptor by setting Bit 31 of TDES3. Issue a Transmit Poll Demand command.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

70.5.1.102 Channel 0 Missed Frame Counter (DMA_CH0_MISS_FRAME_CNT)

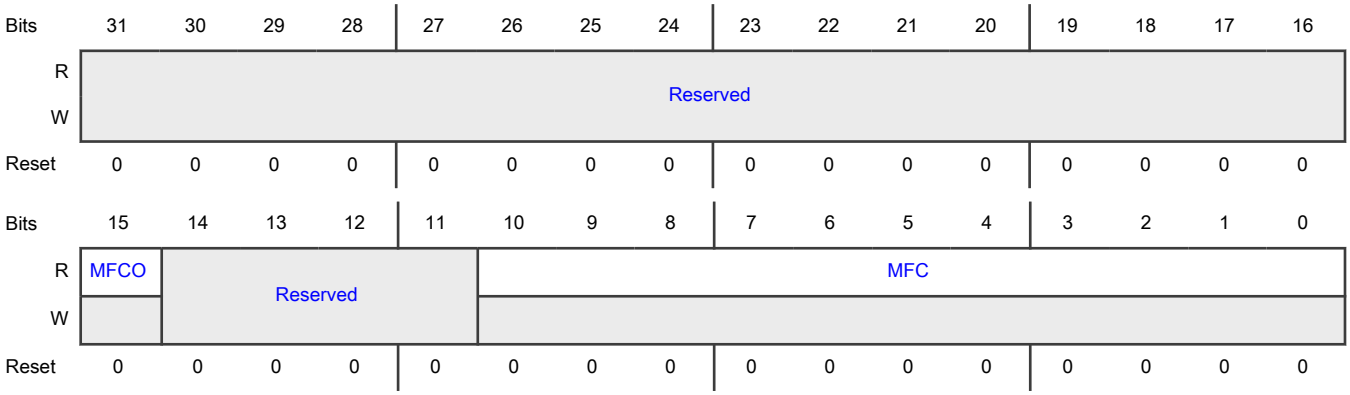
Offset

Register	Offset
DMA_CH0_MISS_FRAME_CNT	1164h

Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in RX_CONTROL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 —	Reserved
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

70.5.1.103 Channel 0 Receive ERI Counter (DMA_CH0_RX_ERI_CNT)

Offset

Register	Offset
DMA_CH0_RX_ERI_CNT	116Ch

Function

The DMA_CH0_RX_ERI_CNT register provides the count of the number of times ERI was asserted.

70.5.1.104 DMA Channel 1 Control (DMA_CH1_CONTROL)

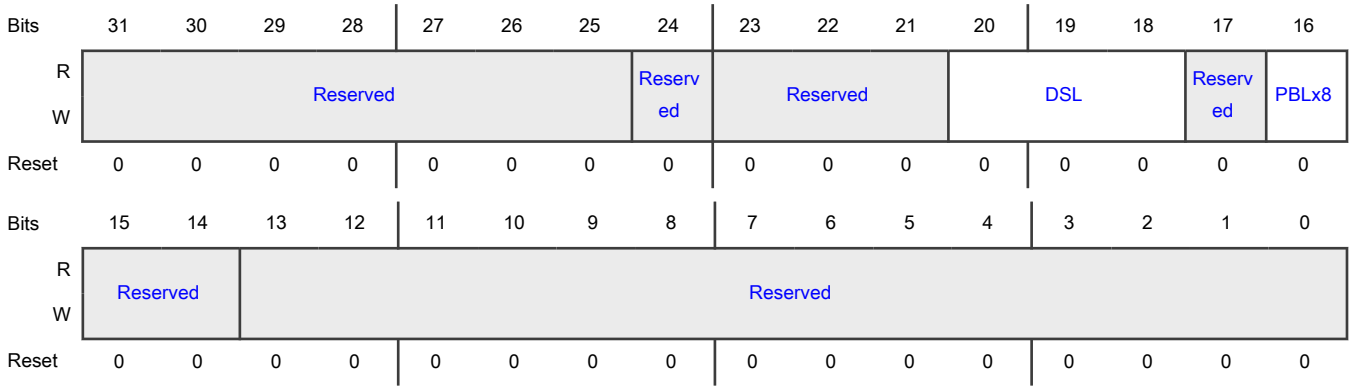
Offset

Register	Offset
DMA_CH1_CONTROL	1180h

Function

The DMA Channel 1 Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-21 —	Reserved
20-18 DSL	Descriptor Skip Length Descriptor Skip Length This bit specifies the Word, Dword, or Lword number (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of the current descriptor to the start of the next descriptor. When the DSL value is equal to zero, the DMA takes the descriptor table as contiguous.
17 —	Reserved
16 PBLx8	8xPBL mode 8xPBL mode When this bit is set, the PBL value programmed in Bits[21:16] in TX_CONTROL and Bits[21:16] in DMA_CH1_RX_CONTROL is multiplied by eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. 0b - 8xPBL mode is disabled 1b - 8xPBL mode is enabled
15-14 —	Reserved

22 ETIC	Early Transmit Interrupt Control When this bit is set, Early Transmit Interrupt (ETI) status is set after completion of transfer of data from buffers of a transmit descriptor in which IOC bit (TDES2[31]) is set. When this bit is reset, ETI is set only after a complete packet is transferred to the MTL TX FIFO memory. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
21-16 TxPBL	Transmit Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: • Set the 8xPBL mode in DMA_CH0_Control register. • Set the TxPBL. **NOTE** The maximum value of TxPBL must be less than or equal to half the Tx Queue size (TQS field of MTL_TxQn Operation_Mode register) in terms of beats. This is required so that the Tx Queue has space to store at least another Tx PBL worth of data while the MTL Tx Queue Controller is transferring data to MAC. For example, in 64-bit data width configurations the total locations in Tx Queue of size 512 bytes is 64, TxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-13 —	Reserved
12 —	Reserved

4	Operate on Second Packet

Table continues on the next page...

Table continued from the previous page...

Field	Function
OSF	When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained. 0b - Operate on Second Packet disabled 1b - Operate on Second Packet enabled
3-1 TCW	Transmit Channel Weight This field indicates the weight assigned to the corresponding Transmit channel. When reset is complete, this field is set to 0 for all channels by default, resulting in equal weights to all channels.
0 ST	Start or Stop Transmission Command When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the base address of the Transmit list set by the DMA_CH0_TXDESC_LIST_ADDRESS register. The position at which the transmission was previously stopped If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the DMA_CH0_STATUS register is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the DMA_CH0_TXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted. To change the list address, you need to program DMA_CH0_TXDESC_LIST_ADDRESS register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state. 0b - Stop Transmission Command 1b - Start Transmission Command

70.5.1.106 DMA Channel 1 Receive Control (DMA_CH1_RX_CONTROL)

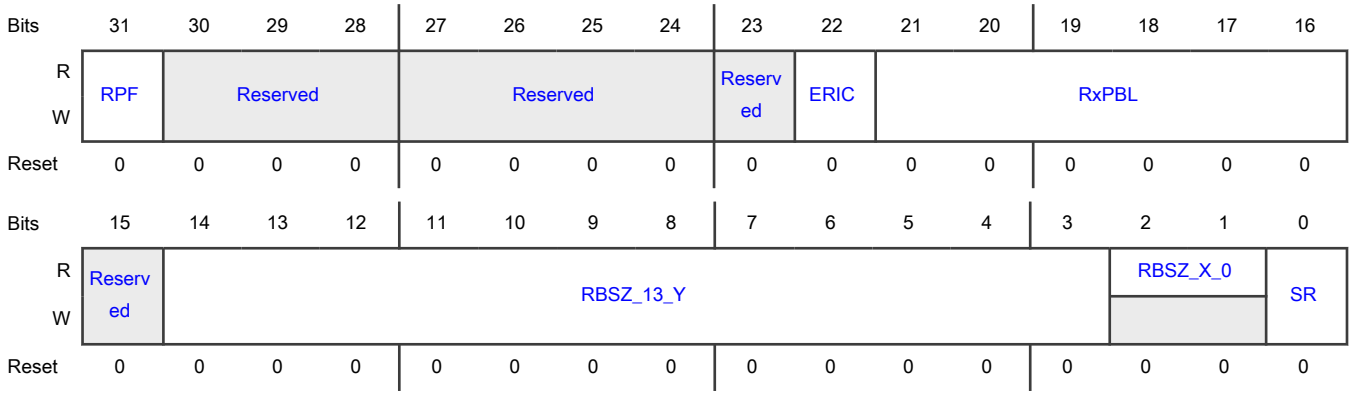
Offset

Register	Offset
DMA_CH1_RX_CONTROL	1188h

Function

The DMA Channel 1 Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

Diagram



Fields

Field	Function
31 RPF	Rx Packet Flush. When this bit is set to 1, then module automatically flushes the packet from the Rx Queues destined to this DMA Rx Channel, when it is stopped. When this bit remains set and the DMA is re-started by the software driver, the packets residing in the Rx Queues that were received when this RxDMA was stopped, are flushed out. The packets that are received by the MAC after the RxDMA is re-started are routed to the RxDMA. The flushing is done on the Read side of the Rx Queue. When this bit is set to 0, module does not flush the packet in the Rx Queue destined to this RxDMA Channel when it is in STOP state. This might cause head-of-line blocking in the corresponding RxQueue. **NOTE** The stopping of packet flow from a Rx DMA Channel to the application by setting RPF works only when there is one-to-one mapping of Rx Queue to Rx DMA channels. In Dynamic mapping mode, setting RPF bit in any DMA_CH(#i)_Rx_Control register might flush packets from unintended Rx Queues which are destined to the stopped Rx DMA Channel. 0b - Rx Packet Flush is disabled 1b - Rx Packet Flush is enabled
30-28 —	Reserved
27-24 —	Reserved
23 —	Reserved
22 ERIC	Early Receive Interrupt Control When this bit is set, Early Receive Interrupt (ERI) status is set after the completion of every burst transfer of data from the Rx DMA to the buffer. When this bit is reset, ERI is set only after a complete buffer is filled up by the RxDMA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled
21-16 RxPBL	Receive Programmable Burst Length These bits indicate the maximum number of beats to be transferred in one DMA block data transfer. The DMA always attempts max burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior. To transfer more than 32 beats, perform the following steps: 1. Set the 8xPBL mode in the DMA_CH0_CONTROL register. 2. Set the RxPBL. Note: The maximum value of RxPBL must be less than or equal to half the Rx Queue size (RQS field of MTL_RxQn_OPERATION_MODE register) in terms of beats. This is required so that the Rx Queue has space to store at least another Rx PBL worth of data while the Rx DMA is transferring a block of data. For example, in 64-bit data width configurations the total locations in Rx Queue of size 512 bytes is 64, so RxPBL and 8xPBL needs to be programmed to less than or equal to 32.
15 —	Reserved
14-3 RBSZ_13_Y	Receive Buffer size High RBSZ[13:0] is split into two fields higher RBSZ_13_Y and lower RBSZ_X_0. The RBSZ[13:0] field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16K bytes. The buffer size is applicable to payload buffers when split headers are enabled. Note: The buffer size must be a multiple of 4, 8, or 16 depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). This is required even if the value of buffer address pointer is not aligned to data bus width. Hence the lower RBSZ_X_0 bits are read-only and the value is considered as all-zero. Thus the RBSZ_13_Y indicates the buffer size in terms of locations (with the width same as bus-width).
2-1 RBSZ_X_0	Receive Buffer size Low RBSZ[13:0] is split into two fields RBSZ_13_Y and RBSZ_X_0. The RBSZ_X_0 is the lower field whose width is based on data bus width of the configuration. This field is of width 2, 3, or 4 bits for 32-bit, 64-bit, or 128-bit data bus width respectively. This field is read-only (RO).
0 SR	Start or Stop Receive When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets. The DMA tries to acquire descriptor from either of the following positions: The current position in the list This is the address set by the DMA_CH1_RXDESC_LIST_ADDRESS register. The position at which the Rx process was previously stopped

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the DMA_CH1_STATUS register is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the DMA_CH1_RXDESC_LIST_ADDRESS register, the DMA behavior is unpredictable. When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state. 0b - Stop Receive 1b - Start Receive

70.5.1.107 Channel 1 Tx Descriptor List Address (DMA_CH1_TXDESC_LIST_ADDRESS)

Offset

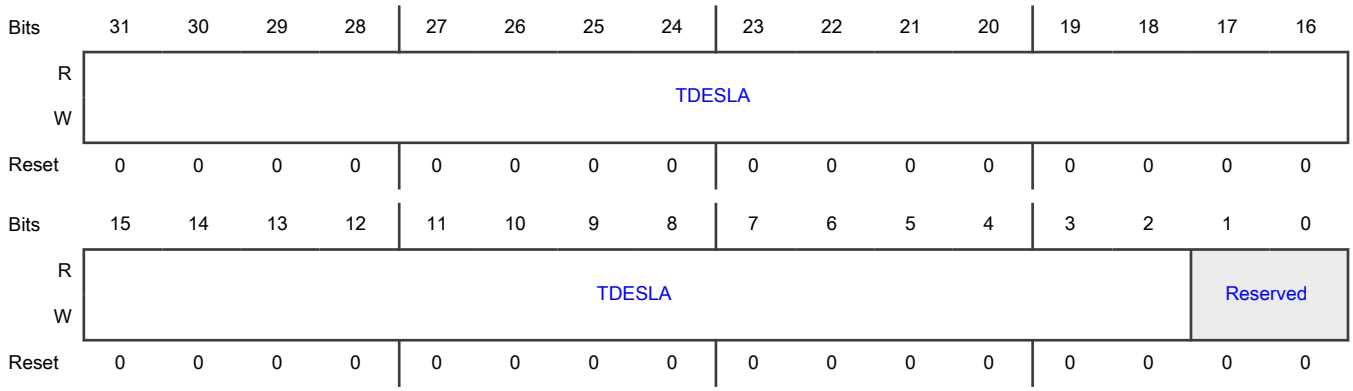
Register	Offset
DMA_CH1_TXDESC_LIST_ADDRESS	1194h

Function

The Channel 1 Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in DMA_CH1_TX_CONTROL register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

Diagram



Fields

Field	Function
31-2 TDESLA	Start of Transmit List This field contains the base address of the first descriptor in the Transmit descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). The width of this field depends on the configuration: 31:2 for 32-bit configuration 31:3 for 64-bit configuration 31:4 for 128-bit configuration
1-0 —	Reserved

70.5.1.108 Channel 1 Rx Descriptor List Address (DMA_CH1_RXDESC_LIST_ADDRESS)

Offset

Register	Offset
DMA_CH1_RXDESC_LIST_ADDRESS	119Ch

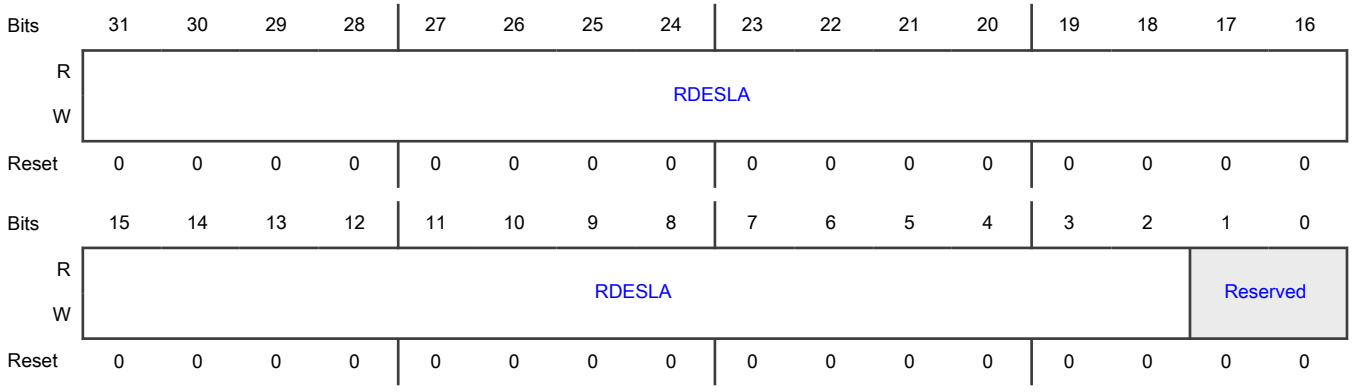
Function

The Channel 1 Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in DMA_CH1_RX_CONTROL register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Diagram



Fields

Field	Function
31-2 RDESLA	Start of Receive List This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO). Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9-0 TDRL	Transmit Descriptor Ring Length This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. We recommends a minimum ring descriptor length of 4. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

70.5.1.112 DMA Channel 1 Receive Control (DMA_CH1_RX_CONTROL2)

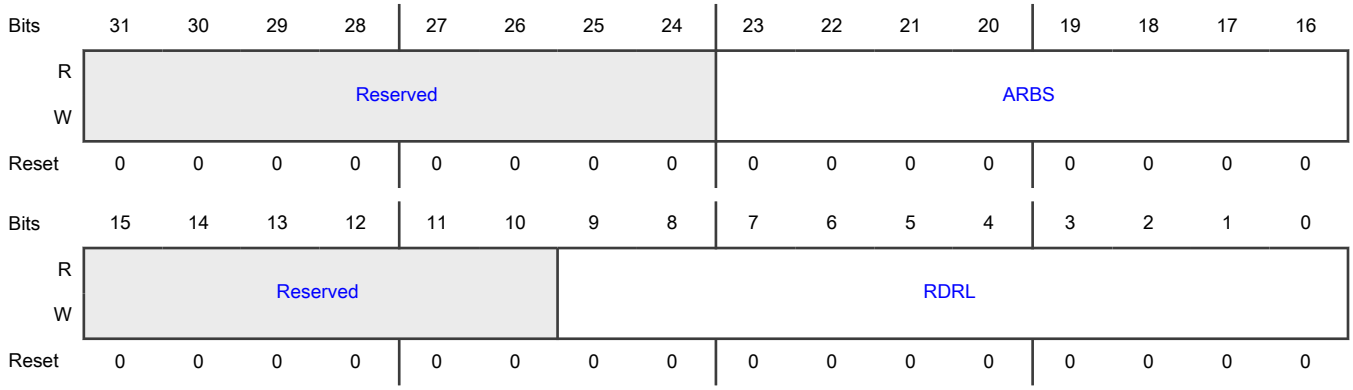
Offset

Register	Offset
DMA_CH1_RX_CONTROL2	11B0h

Function

The Channel 1 Receive Control register controls the Rx features such as Rx Descriptor Ring Length and Alternate Rx Buffer Size.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 ARBS	Alternate Receive Buffer Size

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates size in bytes for Buffer 1 when ARBS is programmed to a non-zero value (when split header feature is not enabled). When split header feature is enabled, ARBS indicates the buffer size for header data. The maximum alternate buffer is limited to 1020, 1016 or 1008-bytes depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively). When ARBS=0, Rx Buffer1 and Rx Buffer2 sizes are based on RBSZ field of DMA_CH(#i)_Rx_Control. Width of ARBS field is 8, 7 or 6-bits depending on the data bus widths (32-bit, 64-bit, or 128-bit respectively)
15-10 —	Reserved
9-0 RDRL	Receive Descriptor Ring Length This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. For example, You can program any value up to 0x3FF in this field. This field is 10 bits wide, if you program 0x3FF, you can have 1024 descriptors. If you want to have 10 descriptors, program it to a value of 0x9.

70.5.1.113 Channel 1 Interrupt Enable (DMA_CH1_INTERRUPT_ENABLE)

Offset

Register	Offset
DMA_CH1_INTERRUPT_ENABLE	11B4h

Function

The Channel 1 Interrupt Enable register enables the interrupts reported by the Status register.

15 NIE	Normal Interrupt Summary Enable When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: Bit 0: Transmit Interrupt Bit 2: Transmit Buffer Unavailable Bit 6: Receive Interrupt Bit 11: Early Receive Interrupt When this bit is reset, the normal interrupt summary is disabled. 0b - Normal Interrupt Summary is disabled 1b - Normal Interrupt Summary is enabled
14 AIE	Abnormal Interrupt Summary Enable When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the DMA_CH0_Status register: Bit 1: Transmit Process Stopped Bit 7: Rx Buffer Unavailable Bit 8: Receive Process Stopped Bit 9: Receive Watchdog Timeout Bit 10: Early Transmit Interrupt Bit 12: Fatal Bus Error Bit 13: Context Descriptor Error When this bit is reset, the abnormal interrupt summary is disabled. 0b - Abnormal Interrupt Summary is disabled 1b - Abnormal Interrupt Summary is enabled
13 CDEE	Context Descriptor Error Enable When this bit is set along with the AIE bit, the Descriptor error interrupt is enabled. When this bit is reset, the Descriptor error interrupt is disabled. 0b - Context Descriptor Error is disabled 1b - Context Descriptor Error is enabled
12 FBEE	Fatal Bus Error Enable When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Fatal Bus Error is disabled 1b - Fatal Bus Error is enabled
11 ERIE	Early Receive Interrupt Enable When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled. 0b - Early Receive Interrupt is disabled 1b - Early Receive Interrupt is enabled
10 ETIE	Early Transmit Interrupt Enable When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled. 0b - Early Transmit Interrupt is disabled 1b - Early Transmit Interrupt is enabled
9 RWTE	Receive Watchdog Timeout Enable When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled. 0b - Receive Watchdog Timeout is disabled 1b - Receive Watchdog Timeout is enabled
8 RSE	Receive Stopped Enable When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled. 0b - Receive Stopped is disabled 1b - Receive Stopped is enabled
7 RBUE	Receive Buffer Unavailable Enable When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled. 0b - Receive Buffer Unavailable is disabled 1b - Receive Buffer Unavailable is enabled
6 RIE	Receive Interrupt Enable When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled. 0b - Receive Interrupt is disabled 1b - Receive Interrupt is enabled
5-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 TBUE	Transmit Buffer Unavailable Enable When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled. 0b - Transmit Buffer Unavailable is disabled 1b - Transmit Buffer Unavailable is enabled
1 TXSE	Transmit Stopped Enable When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled. 0b - Transmit Stopped is disabled 1b - Transmit Stopped is enabled
0 TIE	Transmit Interrupt Enable When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. 0b - Transmit Interrupt is disabled 1b - Transmit Interrupt is enabled

70.5.1.114 Channel 1 Receive Interrupt Watchdog Timer (DMA_CH1_RX_INTERRUPT_WATCHDOG_TIMER)

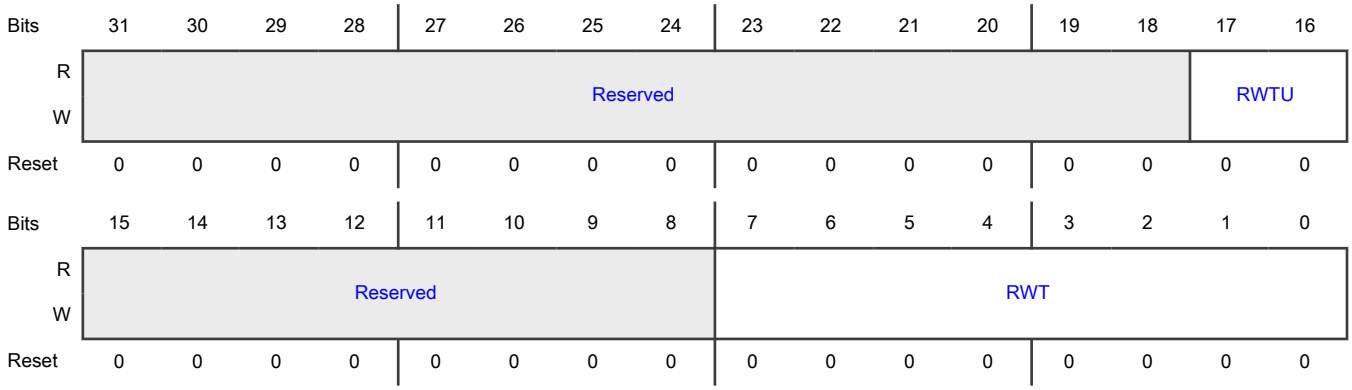
Offset

Register	Offset
DMA_CH1_RX_INTERRUPT_WATCHDOG_TIMER	11B8h

Function

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the STATUS register.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 RWTU	Receive Interrupt Watchdog Timer Count Units This fields indicates the number of system clock cycles corresponding to one unit in RWT field. 2'b00: 256 2'b01: 512 2'b10: 1024 2'b11: 2048 For example, when RWT=2 and RWTU=1, the watchdog timer is set for 2*512=1024 system clock cycles.
15-8 —	Reserved
7-0 RWT	Receive Interrupt Watchdog Timer Count This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set. The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the DMA_CH(#i)_Status register, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

70.5.1.115 Channel 1 Slot Function Control and Status (DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS)

Offset

Register	Offset
DMA_CH1_SLOT_FUNCTION_CONTROL_STATUS	11BCh

Function

The Slot Function Control and Status register contains the control bits for slot function and the status for Transmit path.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved												RSN			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	SIV												Reserved		ASC	ESC
W																
Reset	0	0	0	0	0	1	1	1	1	1	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16 RSN	Reference Slot Number This field gives the current value of the reference slot number in the DMA. It is used for slot comparison.
15-4 SIV	Slot Interval Value This field controls the period of the slot interval in which the TxDMA fetches the scheduled packets. A value of 0 specifies the slot interval of 1 us while the maximum value 4095 specifies the slot interval of 4096 us. The default/reset value is 0x07C which corresponds to slot interval of 125 us
3-2 —	Reserved
1 ASC	Advance Slot Check When set, this bit enables the DMA to fetch the data from the buffer when the slot number (SLOTNUM) programmed in the Tx descriptor is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	equal to the reference slot number given in the RSN field or ahead of the reference slot number by up to two slots This bit is applicable only when the ESC bit is set. 0b - Advance Slot Check is disabled 1b - Advance Slot Check is enabled
0 ESC	Enable Slot Comparison When set, this bit enables the checking of the slot numbers programmed in the Tx descriptor with the current reference given in the RSN field. The DMA fetches the data from the corresponding buffer only when the slot number is equal to the reference slot number or ahead of the reference slot number by one slot When reset, this bit disables the checking of the slot numbers. The DMA fetches the data immediately after the descriptor is processed. **NOTE** The UFO (UDP Fragmentation over IPv4)/TSO/USO should not be enabled along with TBS/AVB Slot number check. The UFO/TSO/USO involves multiple packets/segments/ fragments transmission for single packet received from application and the slot number check are applicable for fetching of only first segment/fragment. As a result it might be difficult for software to specify slot number for subsequent packets. 0b - Slot Comparison is disabled 1b - Slot Comparison is enabled

70.5.1.116 Channel 1 Current Application Transmit Descriptor (DMA_CH1_CURRENT_APP_TXDESC)

Offset

Register	Offset
DMA_CH1_CURRENT_APP_TXDESC	11C4h

Function

The Channel 1 Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.

70.5.1.120 DMA Channel 1 Status (DMA_CH1_STATUS)

Offset

Register	Offset
DMA_CH1_STATUS	11E0h

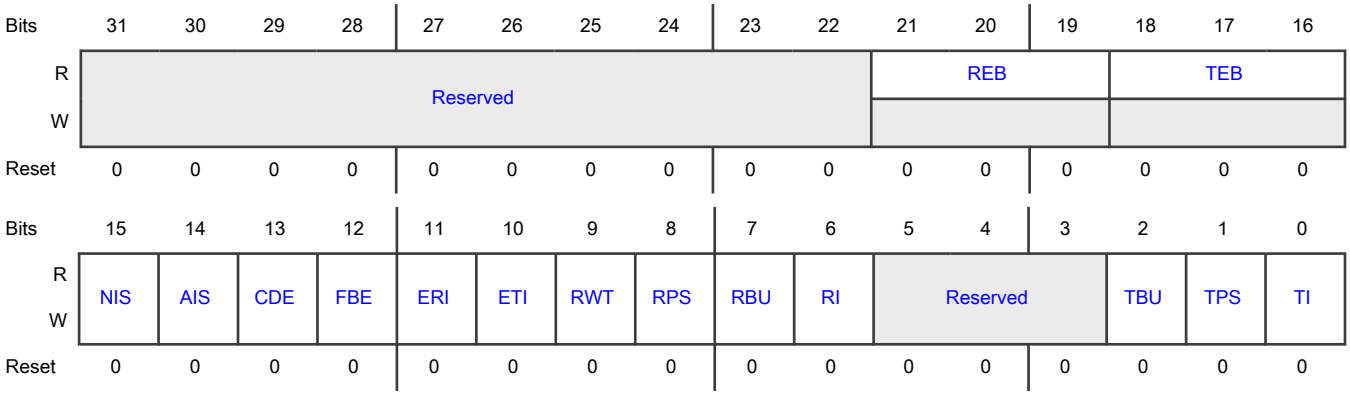
Function
The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.

NOTE

The number of STATUS register in the configuration is the higher of number of Rx DMA Channels and Tx DMA Channels.

Diagram



Fields

Field	Function
31-22 —	Reserved
21-19 REB	Rx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 21 1'b1: Error during data transfer by Rx DMA 1'b0: No Error during data transfer by Rx DMA Bit 20 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 19 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
18-16 TEB	Tx DMA Error Bits This field indicates the type of error that caused a Bus Error. For example, error response on the AHB or AXI interface. Bit 18 1'b1: Error during data transfer by Tx DMA

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1'b0: No Error during data transfer by Tx DMA Bit 17 1'b1: Error during descriptor access 1'b0: Error during data buffer access Bit 16 1'b1: Error during read transfer 1'b0: Error during write transfer This field is valid only when the FBE bit is set. This field does not generate an interrupt.
15 NIS	Normal Interrupt Summary Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 0: Transmit Interrupt Bit 2: Transmit Buffer Unavailable Bit 6: Receive Interrupt Bit 11: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in DMA_CH0_Interrupt_Enable register) affect the Normal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Normal Interrupt Summary status not detected 1b - Normal Interrupt Summary status detected
14 AIS	Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the DMA_CH0_Interrupt_Enable register: Bit 1: Transmit Process Stopped Bit 7: Receive Buffer Unavailable Bit 8: Receive Process Stopped Bit 10: Early Transmit Interrupt Bit 12: Fatal Bus Error Bit 13: Context Descriptor Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Abnormal Interrupt Summary status not detected 1b - Abnormal Interrupt Summary status detected
13 CDE	Context Descriptor Error This bit indicates that the DMA Tx/Rx engine received a descriptor error, which indicates invalid context in the middle of packet flow (intermediate descriptor) or all one's descriptor in Tx case and on Rx side it indicates DMA has read a descriptor with either of the buffer address as ones which is considered to be invalid. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Context Descriptor Error status not detected 1b - Context Descriptor Error status detected
12 FBE	Fatal Bus Error This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Fatal Bus Error status not detected 1b - Fatal Bus Error status detected
11 ERI	Early Receive Interrupt This bit when set indicates that the RxDMA has completed the transfer of packet data to the memory. In configurations supporting ERIC, ERIC = 0: This bit is set only after the Rx DMA has completely filled up a receive buffer with packet data. ERIC = 1: This bit is set after every burst transfer of data from the Rx DMA to the buffer. The setting of RI bit automatically clears this bit. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Receive Interrupt status not detected 1b - Early Receive Interrupt status detected
10 ETI	Early Transmit Interrupt This bit when set indicates that the TxDMA has completed the transfer of packet data to the MTL TXFIFO memory. In configurations supporting ERIC: ETIC = 0: This bit is set only after the Tx DMA has transferred a complete packet to MTL. ETIC = 1: This bit is set after completion of (partial) packet data transfer from buffers in the Transmit descriptor in which IOC = 1. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Early Transmit Interrupt status not detected

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Early Transmit Interrupt status detected
9 RWT	Receive Watchdog Timeout This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received. 0b - Receive Watchdog Timeout status not detected 1b - Receive Watchdog Timeout status detected
8 RPS	Receive Process Stopped This bit is asserted when the Rx process enters the Stopped state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Process Stopped status not detected 1b - Receive Process Stopped status detected
7 RBU	Receive Buffer Unavailable This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Buffer Unavailable status not detected 1b - Receive Buffer Unavailable status detected
6 RI	Receive Interrupt This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. The reception remains in the Running state. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Receive Interrupt status not detected 1b - Receive Interrupt status detected
5-3 —	Reserved
2 TBU	Transmit Buffer Unavailable This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	To resume processing the Transmit descriptors, the application should do the following: Change the ownership of the descriptor by setting Bit 31 of TDES3. Issue a Transmit Poll Demand command. For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Buffer Unavailable status not detected 1b - Transmit Buffer Unavailable status detected
1 TPS	Transmit Process Stopped This bit is set when the transmission is stopped. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Process Stopped status not detected 1b - Transmit Process Stopped status detected
0 TI	Transmit Interrupt This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor. Access restriction applies. Self-set to 1 on internal event. Setting 1 clears. Setting 0 has no effect. 0b - Transmit Interrupt status not detected 1b - Transmit Interrupt status detected

70.5.1.121 Channel 1 Missed Frame Counter (DMA_CH1_MISS_FRAME_CNT)

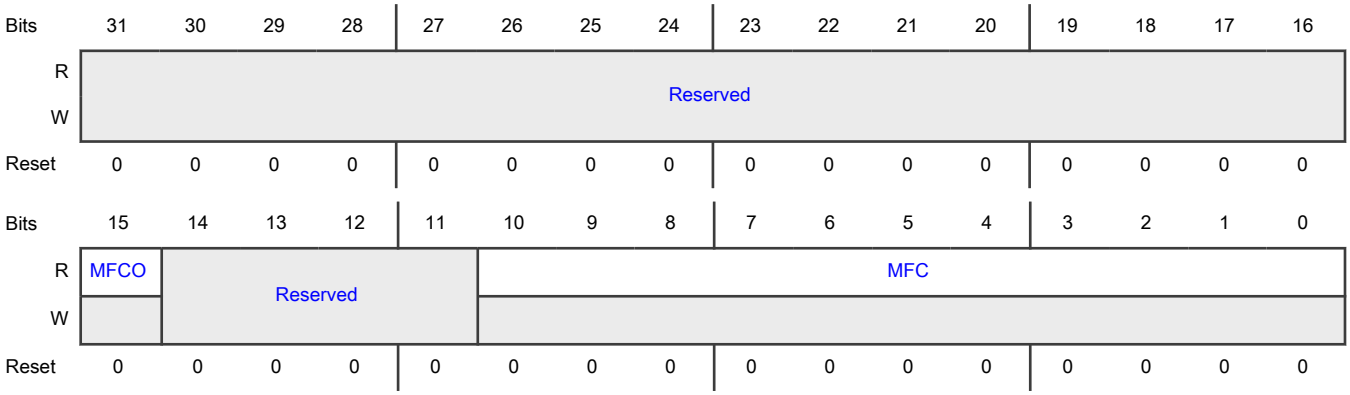
Offset

Register	Offset
DMA_CH1_MISS_FRAME_CNT	11E4h

Function

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programming RPF field in RX_CONTROL register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 MFCO	Overflow status of the MFC Counter When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event. 0b - Miss Frame Counter overflow not occurred 1b - Miss Frame Counter overflow occurred
14-11 —	Reserved
10-0 MFC	Dropped Packet Counters This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in DMA_CH${i}_Rx_Control register. The counter gets cleared when this register is read. Access restriction applies. Clears on read. Self-set to 1 on internal event.

70.5.1.122 Channel 1 Receive ERI Counter (DMA_CH1_RX_ERI_CNT)

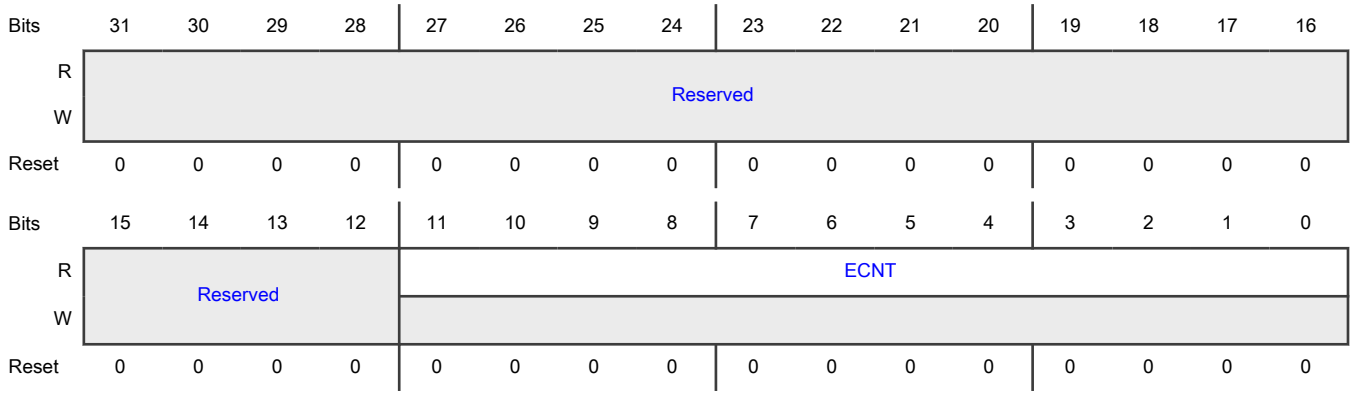
Offset

Register	Offset
DMA_CH1_RX_ERI_CNT	11ECh

Function

The Channel 1 Receive ERI Counter register provides the count of the number of times ERI was asserted.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 ECNT	ERI Counter When ERIC bit of RX_CONTROL register is set, this counter increments for burst transfer completed by the Rx DMA from the start of packet transfer. This counter will get reset at the start of new packet.

71.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.
- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

71.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

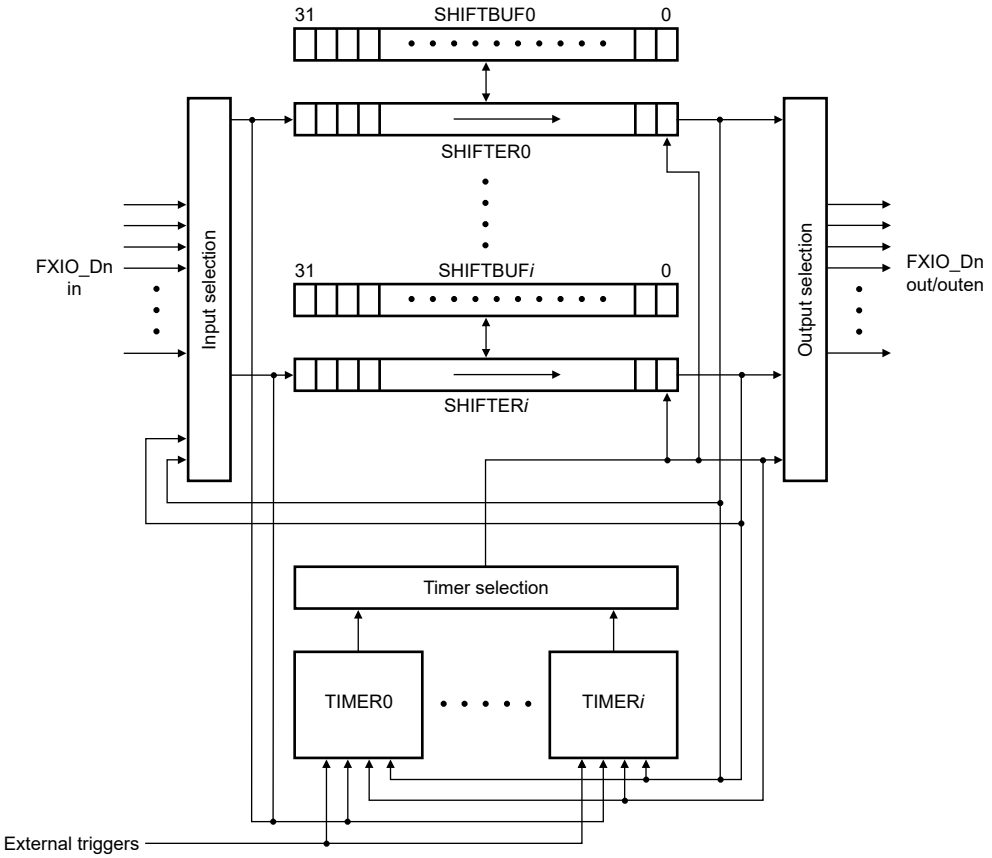

Figure 430. Block diagram

71.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:
  - Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during Stop mode
  - Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs
  - Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  - UART

— I2C

— SPI

— I2S

— Camera IF

— Motorola 68K or Intel 8080 bus

— PWM or waveform generation

— Input-capture (pulse-edge interval measurement), such as SENT

71.3 Functional description

71.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

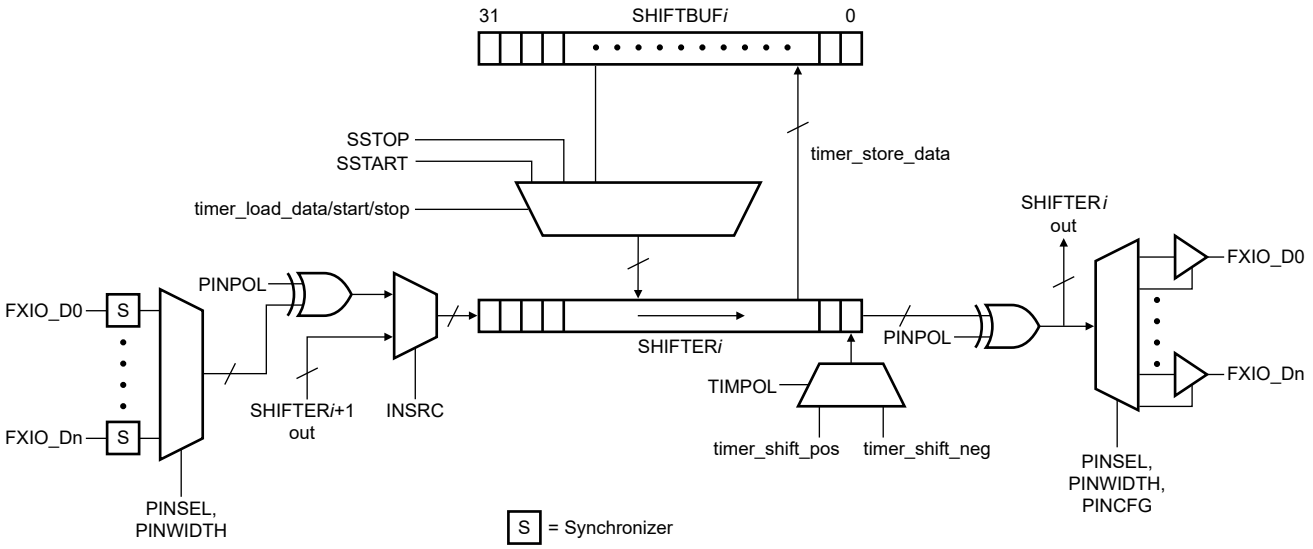

Figure 431. Shifter microarchitecture

71.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

71.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

71.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

71.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

71.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which can remain in a low-power mode.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

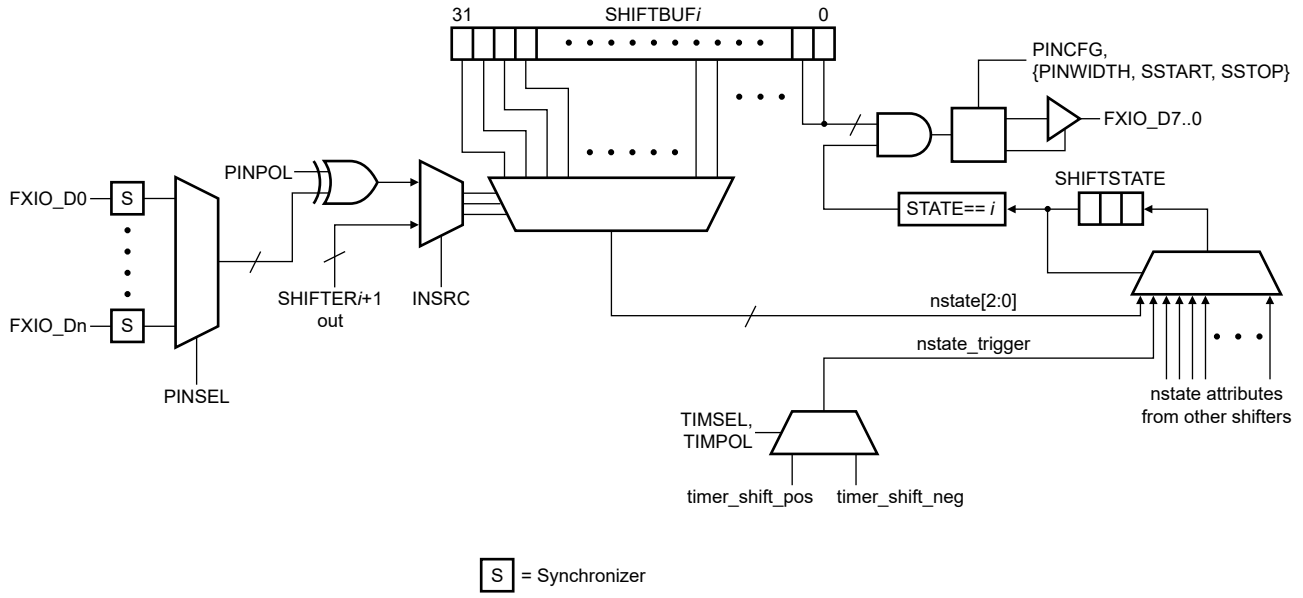

Figure 432. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 672. Next state computation for SHIFTSTATE[STATE] = *n*

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
0	0	0	SHIFTBUF*n*[2:0]
0	0	1	SHIFTBUF*n*[5:3]
0	1	0	SHIFTBUF*n*[8:6]
0	1	1	SHIFTBUF*n*[11:9]
...	...	...	...
1	1	1	SHIFTBUF*n*[23:21]

NOTE

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

71.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

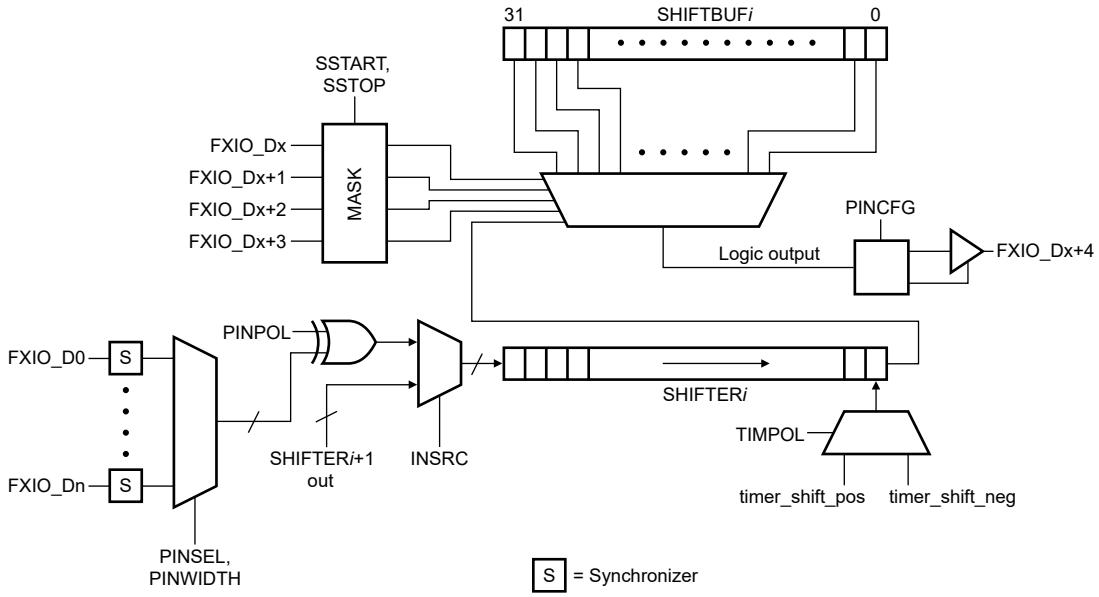

Figure 433. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 673. Logic lookup table for shifter *n*

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]

Table continues on the next page...

Table 673. Logic lookup table for shifter *n* (continued)

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

71.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

71.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

71.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

71.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

71.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

71.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

71.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare

register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

71.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

71.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

71.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

71.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

71.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

71.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

71.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

71.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

71.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if CTRL[DOZEN] is 0 and the FLEXIO functional clock remains enabled.

The exception to this is in PD mode. In this case, CTRL[DOZEN] is ignored and FLEXIO waits for all timers to complete any pending operation before acknowledging PD mode entry.

71.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

71.3.6 Clocking

Table 674. FLEXIO clocks

Clock	Description
Functional clock	Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses.
Bus clock	Is used only for bus accesses to the control and configuration registers.

71.3.7 Reset

Table 675. FLEXIO reset types

Reset	Description
Chip reset	Resets the FLEXIO logic and registers to their default states on chip reset.
Software reset	Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register.

71.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 676. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low-power wake-up
SHIFTSTAT[SSF]	Shifter status flag	Y	Y	Y
SHIFTERR[SEF]	Shifter error flag	Y	N	Y
TIMSTAT[TSF]	Timer status flag	Y	Y	Y
PINSTAT[PSF]	Pin status flag	Y	N	Y
TRGSTAT[ETSF]	External trigger status flag	Y	N	Y

71.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

71.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

71.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

71.4 External signals

Table 677. External signals

Signal	Description	Direction
FXIO_D*n* (*n* = 0...31)	Bidirectional FLEXIO shifter and timer pin	Input or output

71.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).
3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

71.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

71.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 678. UART transmit configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields.

Table continues on the next page...

Table 678. UART transmit configuration (continued)

Register	Value	Configuration
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h.
TIMCTL*n*	01C0_0001h	Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 679. UART transmit configuration for slow baud rate

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTL*n*	0740_0003h	Configure the 16-bit counter using the timer 1 output as an internal trigger source.
TIMCMP(*n* + 1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock, and configure

Table continues on the next page...

Table 679. UART transmit configuration for slow baud rate (continued)

Register	Value	Configuration
		TIMCMP[15:0] as (baud rate divider ÷ 2) - 1.
TIMCFG(*n* + 1)	0000_1200h	Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS.
TIMCTL(*n* + 1)	01C0_0003h	Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

71.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 680. UART receiver configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin positive edge and disable on

Table continues on the next page...

Table 680. UART receiver configuration (continued)

Register	Value	Configuration
		compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	0000_0081h	Configure the dual 8-bit counter using the inverted pin 0 input.
SHIFTBUF*n*	Data to receive	You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 681. UART receiver with RTS configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0030_6100h	Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n* + 1)	0143_0003h	Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag.

Table continues on the next page...

Table 681. UART receiver with RTS configuration (continued)

Register	Value	Configuration
SHIFTBUF*n*	Data to receive	You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

71.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

NOTE

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 682. SPI controller (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the negative edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the positive edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.

Table continues on the next page...

Table 682. SPI controller (CPHA = 0) configuration (continued)

Register	Value	Configuration
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using the inverted pin 3 output as target select.
SHIFTBUF*n*	Data to transmit	You can write transmit data to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

Table 683. SPI controller (CPHA = 1) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0021h	Start bit loads data on first shift.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the negative edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits x 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using pin 2 output (shift clock), with the shifter 0 flag as the inverted trigger. Write 1 to the

Register	Value	Configuration
		PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using inverted pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

71.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 684. SPI target (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the falling edge of shift clock with output data on pin 0.

Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

71.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for

the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

NOTE

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

Table 686. I2C controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0.
SHIFTCFG(*n* + 1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n* + 1)	0180_0001h	Configure receive using timer 1 on the falling edge of clock with input data on pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger.
TIMCMP(*n* + 1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1.
TIMCFG(*n* + 1)	0020_1112h	Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input.
TIMCTL(*n* + 1)	01C0_0183h	Configure 16-bit counter using inverted pin 1 input (SCL).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the shifter

		status flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

71.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 687. I2S controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.

SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the falling edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted pin 2 output (bit clock), with shifter 0 flag as the inverted trigger.

Table continues on the next page...

Table 687. I2S controller configuration (continued)

Register	Value	Configuration
		Write 0 to the PINPOL field to invert the polarity of the output shift clock.
TIMCMP(*n* + 1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1.
TIMCFG(*n* + 1)	0000_0100h	Enable when timer 0 is enabled and never disable.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.

71.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 688. I2S target configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0180_0101h	Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger.
TIMCMP(*n* + 1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG(*n* + 1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(*n* + 1)	0340_0283h	Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger.
TIMCMP(*n* + 2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n* + 2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(*n* + 2)	04C0_0383h	Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written

Table continues on the next page...

Table 688. I2S target configuration (continued)

Register	Value	Configuration
		using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer.

71.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 689. SENT receiver configuration

Register	Value	Configuration
TIMCMP*n*	—	Stores counter value at the falling edge of the pin.
TIMCFG*n*	0000_6000h	Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTL*n*	0040_0007h	Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger.

71.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 690. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Configuration
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using timer 0 on the negative edge of clock.
TIMCMP*n*	0000_001Fh	Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

1. *n* = 0 or 4

71.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 691. Motorola 68K and Intel 8080 write configuration

Register	Value	Configuration
SHIFTCFG0...0	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...0	0000_0002h	Configure transmit using timer 0 on the positive edge of clock.
TIMCMP0	0000_0101h (1 beat)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO

Table continues on the next page...

Table 691. Motorola 68K and Intel 8080 write configuration (continued)

Register	Value	Configuration
	0000_1F01h (16 beats)	clock. Set TIMCMP[15:8] as (number of beats × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2200h	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	01C3_1001h (Motorola 68K, 1 beat) 1DC3_1001h (Motorola 68K, 16 beats) 01C3_1081h (Intel 8080, 1 beat) 1DC3_1081h (Intel 8080, 16 beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with shifter 0 (1-beat) or shifter 0 (16 beats) flag as the inverted trigger.
SHIFTBUF0...0	Data to transmit	Transmit data can be written to SHIFTBUF0 (1 beat) or SHIFTBUF0...0(16-beats) to initiate a transfer; use the shifter status flag to indicate when data can be written using interrupt or DMA request.

Table 692. Motorola 68K and Intel 8080 read configuration

Register	Value	Configuration
SHIFTCFG0...3	000F_0100h	Configure 16-bit parallel shift in from the adjacent shifter.
SHIFTCFG0	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...0	0080_0001h	Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with shifter 0 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger.
SHIFTBUF0...0	Data received	Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...0

Table continues on the next page...

Table 692. Motorola 68K and Intel 8080 read configuration (continued)

Register	Value	Configuration
		(16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

71.6.11 Low-power state machine

Table 693 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Throughout this operation, the CPU can be kept in a stop or VLPS mode by writing 0 to CTRL[DOZEN] and ensuring that FLEXIO_CLK is enabled. Figure 434 shows the states and transitions implemented by this example.

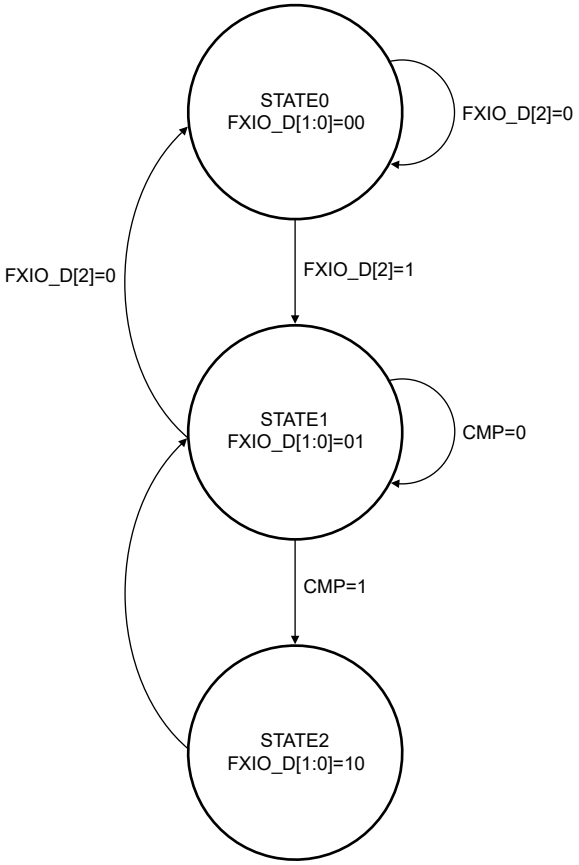

Figure 434. State diagram

Table 693. State machine configuration

Register	Value	Configuration
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1).

Table continues on the next page...

Table 693. State machine configuration (continued)

Register	Value	Configuration
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low.
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

71.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 694. Keypad interface configuration

Register	Value	Configuration
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern; each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In Logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure Logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care).
TIMCMP0	0000_00ffh	Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using the shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure four shifts at half the frequency of the timer 1 trigger.

Table continues on the next page...

Table 694. Keypad interface configuration (continued)

Register	Value	Configuration
TIMCFG2	0110_2100h	Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset.
TIMCTL2	0740_0001h	Configure dual 8-bit counter using timer 1 output as the trigger.
SHIFTBUF3	Keypad scan result	Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request.

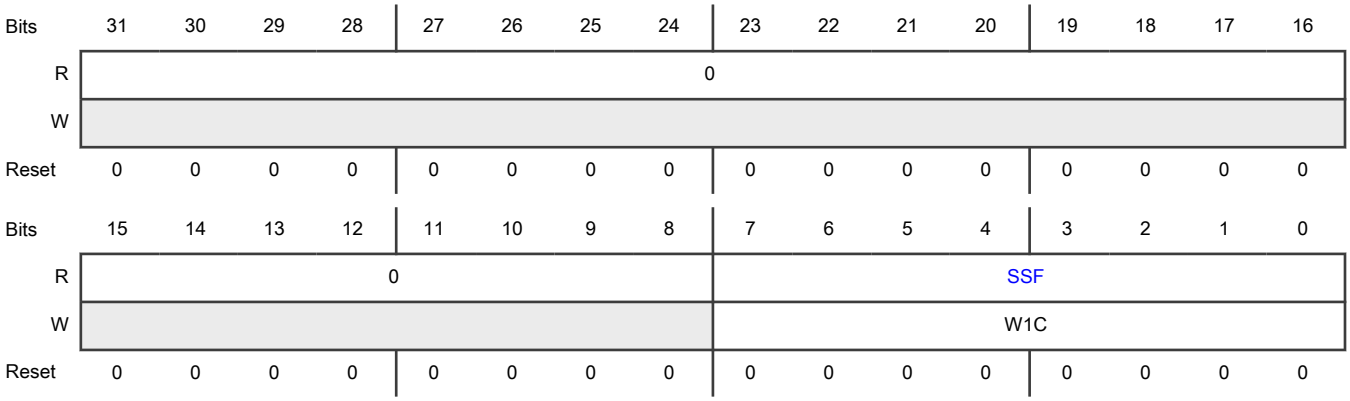
71.7.1.6 Shifter Status (SHIFTSTAT)

Offset

Register	Offset
SHIFTSTAT	10h

Function
Contains shifter status flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag Indicates the shifter status. This flag is updated in one of the following cases: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), the status flag is set when SHIFTBUF is loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), the status flag is set when SHIFTBUF data is transferred to the shifter (SHIFTBUF is empty) or when SHIFTCTL*n*[SMOD] is initially configured as 010b (Transmit mode). The status flag is cleared when you write to the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), the status flag is set when a match occurs between SHIFTBUF and the shifter. The status flag is cleared when you read the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the status flag returns the current match result between SHIFTBUF and the shifter. You cannot clear the status flag by reading the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 110b (State mode), the status flag for a shifter sets when it is selected by the current state pointer. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the status flag returns the current value of the programmable logic block output. You can clear this status flag by writing a logic one to the flag for all modes except Match Continuous mode, State mode, and Logic mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

71.7.1.7 Shifter Error (SHIFTERR)

Offset

31-8 —	Reserved
7-0 SEF	Shifter Error Flag Indicates shifter error flag status. This flag is set when one of the following events occurs: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), it indicates that either the shifter is ready to store new data into SHIFTBUF before the previous data is read from SHIFTBUF (SHIFTBUF overrun), or the received start or stop bit does not match the expected value. • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), it indicates that the shifter is ready to load new data from SHIFTBUF before new data is written into SHIFTBUF (SHIFTBUF underrun). • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), it indicates the occurrence of a match event before the previous match data is read from SHIFTBUF (SHIFTBUF overrun). • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the error flag is set when a match occurs between SHIFTBUF and the shifter. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the error flag is set when the output of the programmable logic block is asserted. For SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the flag can also be cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

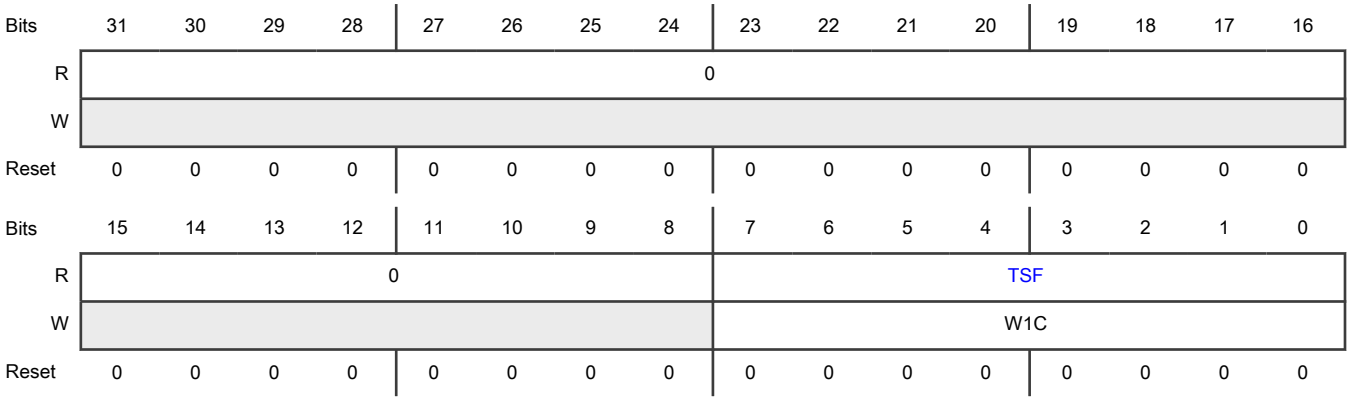
71.7.1.8 Timer Status Flag (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function
Reports timer status.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flag Indicates timer status. This flag is set depending on Timer mode: • In 8-bit baud counter mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 8-bit high PWM mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 16-bit counter mode, this flag is set when the 16-bit counter equals zero and decrements. • In 16-bit counter disable mode, TSF is set when a timer disable event is detected. • In 8-bit word counter mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 8-bit low PWM mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 16-bit input capture mode, TSF is set when a timer disable event is detected and the flag is clear. In this mode, you must read Timer Control (TIMCTL0 - TIMCTL7) only when TSF is set. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

71.7.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

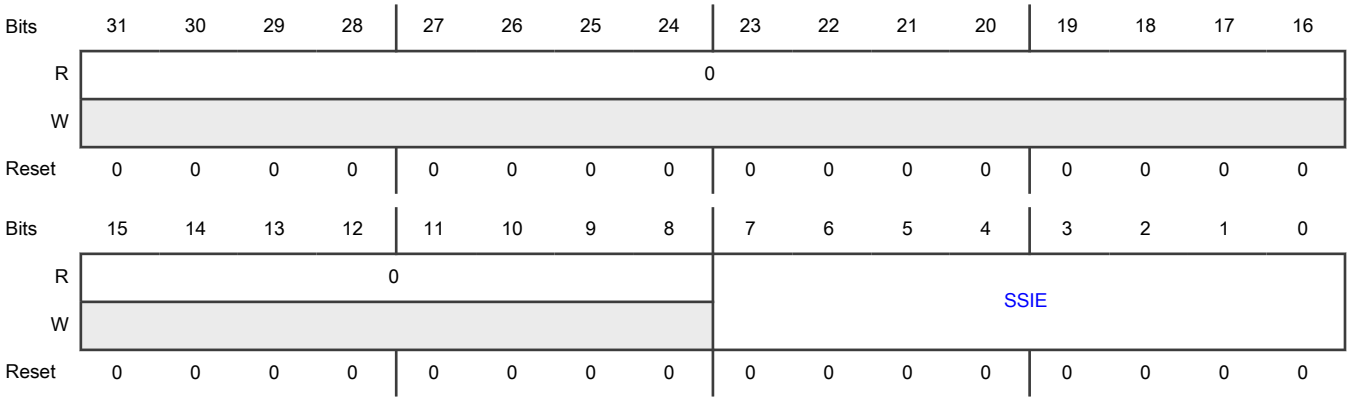
Offset

Register	Offset
SHIFTSIEN	20h

Function

Enables shifter status interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSIE	Shifter Status Interrupt Enable Enables interrupt generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable

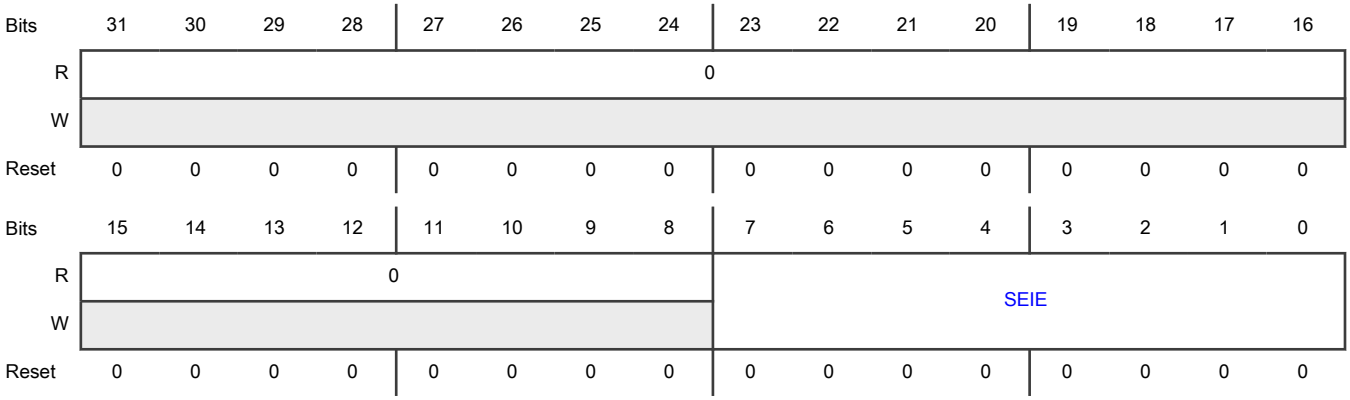
71.7.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

Offset

Register	Offset
SHIFTEIEN	24h

Function
Enables shifter error interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when the corresponding SHIFTERR[SEF] flag is set. If you write 0 to this field, SHIFTERR[SEF] is disabled; and if you write 1 to this field, SHIFTERR[SEF] is enabled. 0b - Disable 1b - Enable

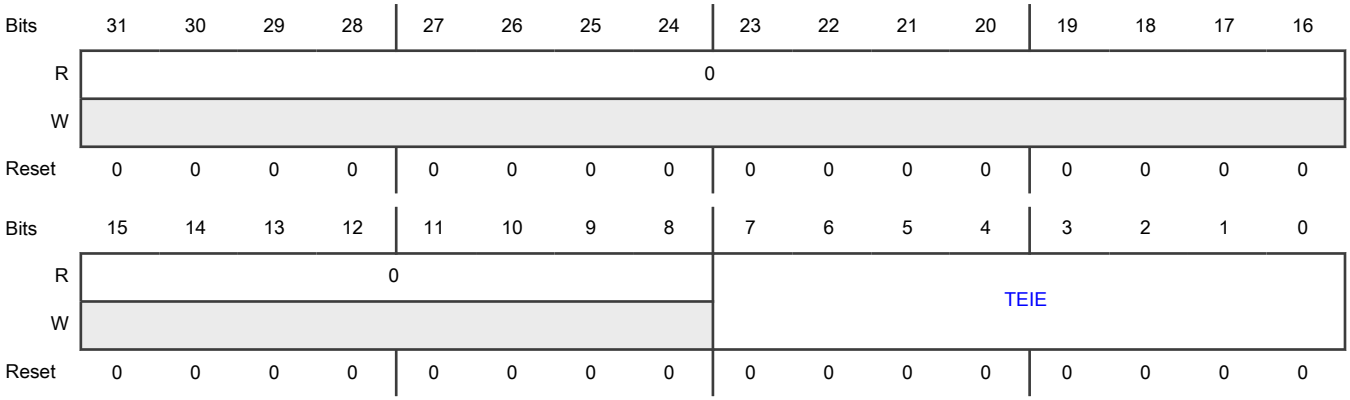
71.7.1.11 Timer Interrupt Enable (TIMIEN)

Offset

Register	Offset
TIMIEN	28h

Function
Enables timer status interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when the corresponding TIMSTAT[TSF] flag is set. If you write 0 to this field, TIMSTAT[TSF] is disabled; and if you write 1 to this field, TIMSTAT[TSF] is enabled. 0b - Disable 1b - Enable

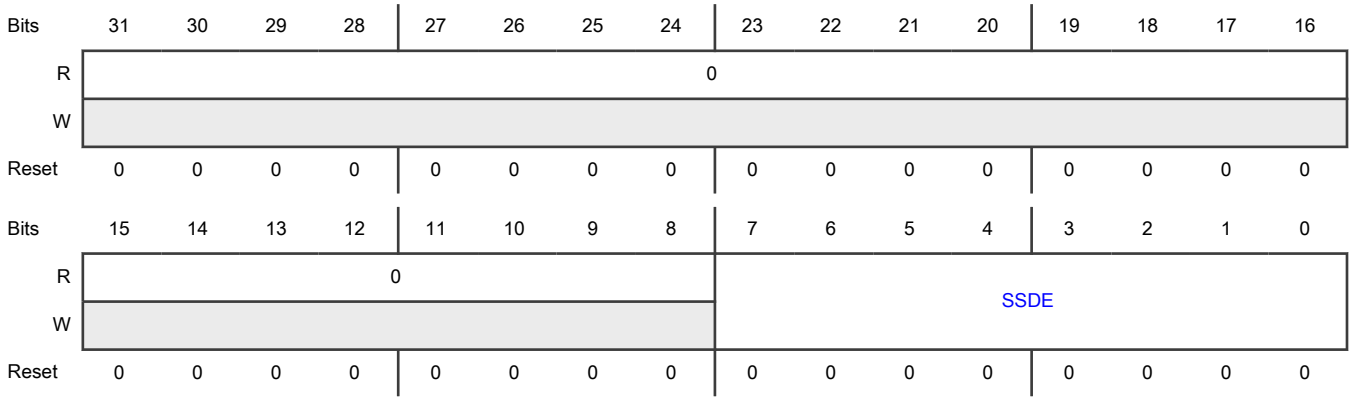
71.7.1.12 Shifter Status DMA Enable (SHIFTSDEN)

Offset

Register	Offset
SHIFTSDEN	30h

Function
Enables shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled. 0b - Disable 1b - Enable

71.7.1.13 Timer Status DMA Enable (TIMERSDEN)

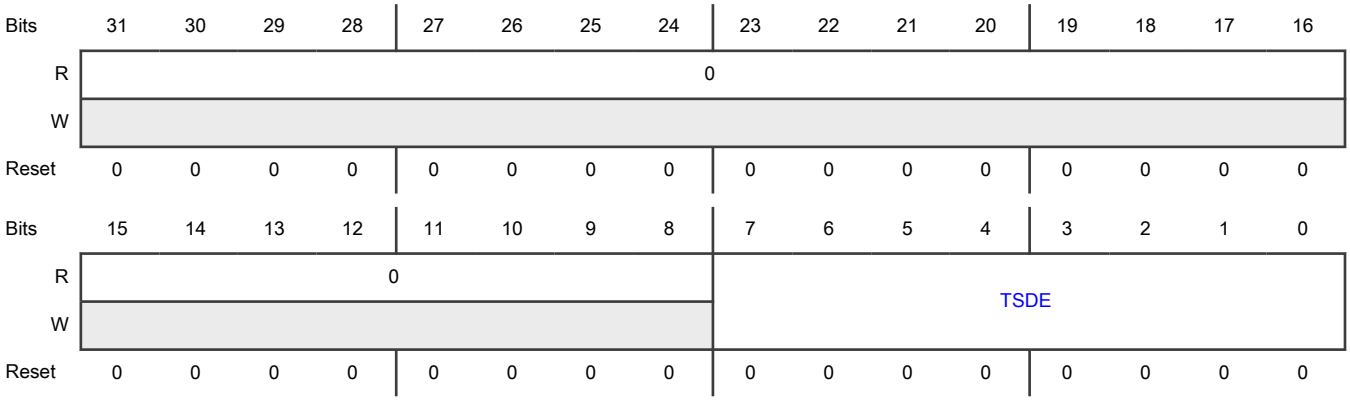
Offset

Register	Offset
TIMERSDEN	38h

Function

Enables DMA requests when the timer status flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when the corresponding TIMSTAT[TSF] flag is set. When the timer status DMA request is enabled, reading or writing to a timer compare register clears the corresponding timer status register. The DMA must therefore read or write to the timer compare register as part of the DMA transfer; otherwise, the DMA request remains asserted. 0b - Disable 1b - Enable

71.7.1.14 Shifter State (SHIFTSTATE)

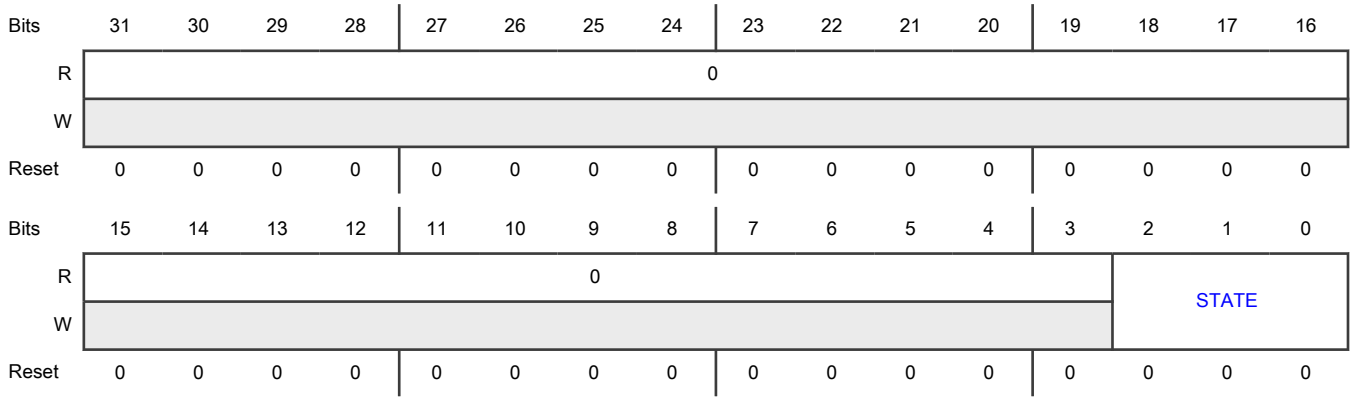
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains a pointer to track the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer Maintains a pointer to track the current shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the return of an incorrect state. The value that you write to this field overrides the current state.

71.7.1.15 Trigger Status (TRGSTAT)

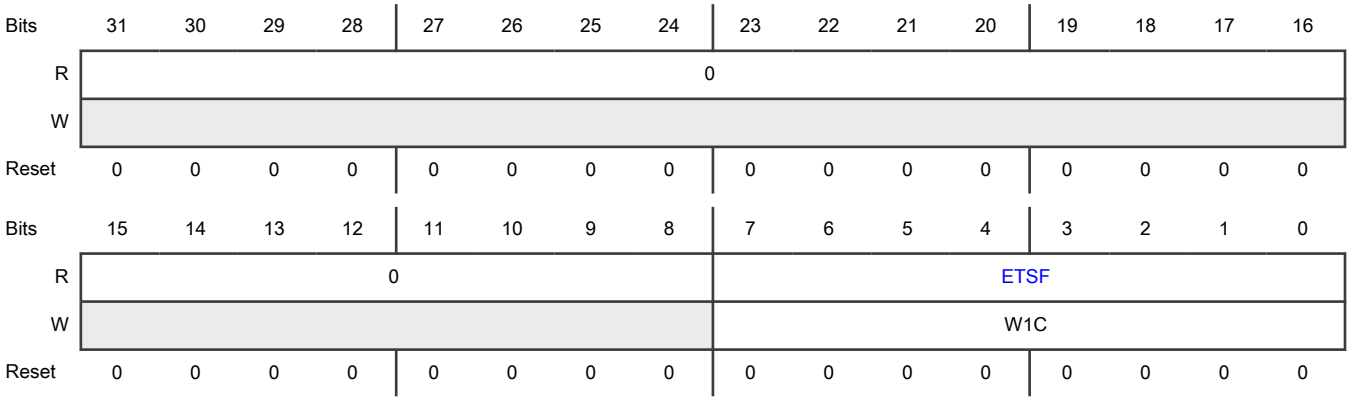
Offset

Register	Offset
TRGSTAT	48h

Function

Contains external trigger status flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 ETSF	External Trigger Status Flag Specifies whether the external trigger status flag is set when a rising edge is detected on the corresponding external trigger input. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

71.7.1.16 External Trigger Interrupt Enable (TRIGIEN)

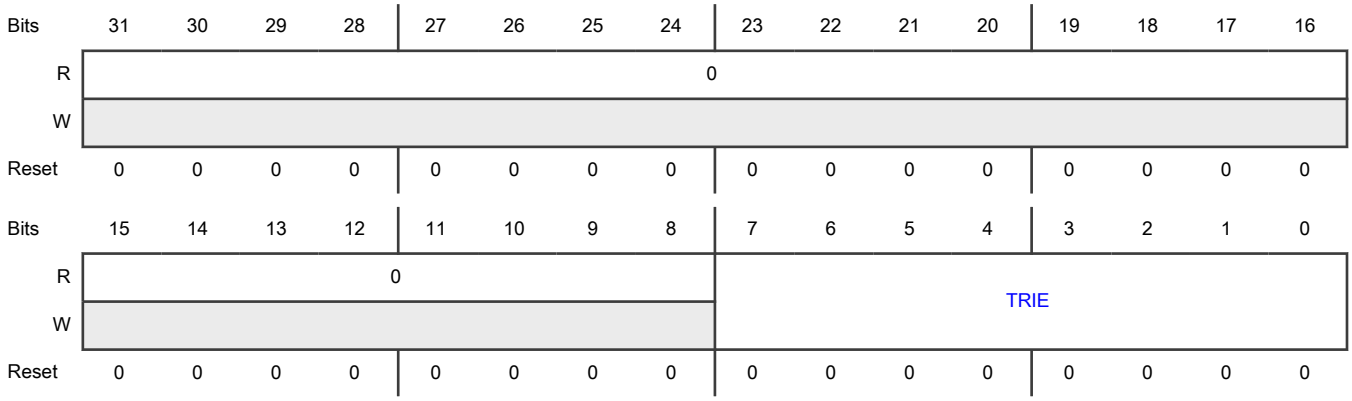
Offset

Register	Offset
TRIGIEN	4Ch

Function

Enables external trigger interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TRIE	External Trigger Interrupt Enable Enables interrupt generation when the corresponding TRGSTAT[ETSF] flag is set. If you write 0 to this field, TRGSTAT[ETSF] is disabled, and if you write 1 to this field, TRGSTAT[ETSF] is enabled. 0b - Disable 1b - Enable

71.7.1.17 Pin Status (PINSTAT)

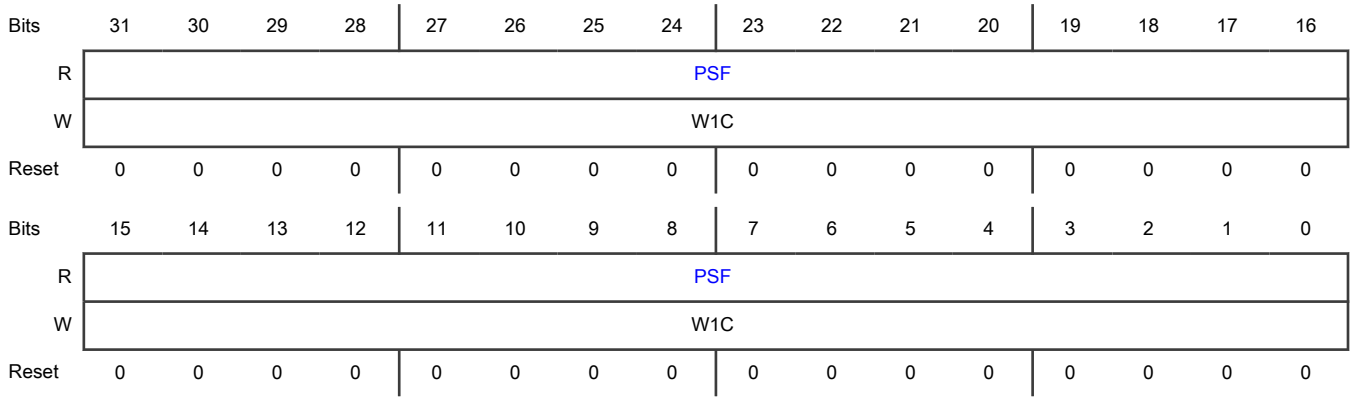
Offset

Register	Offset
PINSTAT	50h

Function

Contains pin status flags.

Diagram



Fields

Field	Function
31-0 PSF	Pin Status Flag Indicates whether the pin status flag is set when a rising edge or falling edge (if configured) is detected on the corresponding pin, as configured by the pin. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000_0000_0000_0000_0000b - Clear 0000_0000_0000_0000_0000_0000_0000_0001b - Set When writing 0000_0000_0000_0000_0000_0000_0000_0000b - No effect 0000_0000_0000_0000_0000_0000_0000_0001b - Clear the flag

71.7.1.18 Pin Interrupt Enable (PINIEN)

Offset

Register	Offset
PINIEN	54h

Function

Enables pin status interrupts.

Diagram

Fields

Field	Function
31-0 PRE	Pin Rising Edge Specifies whether the pin status flag is set whenever a rising edge is detected on the pin. 0b - Not set 1b - Set

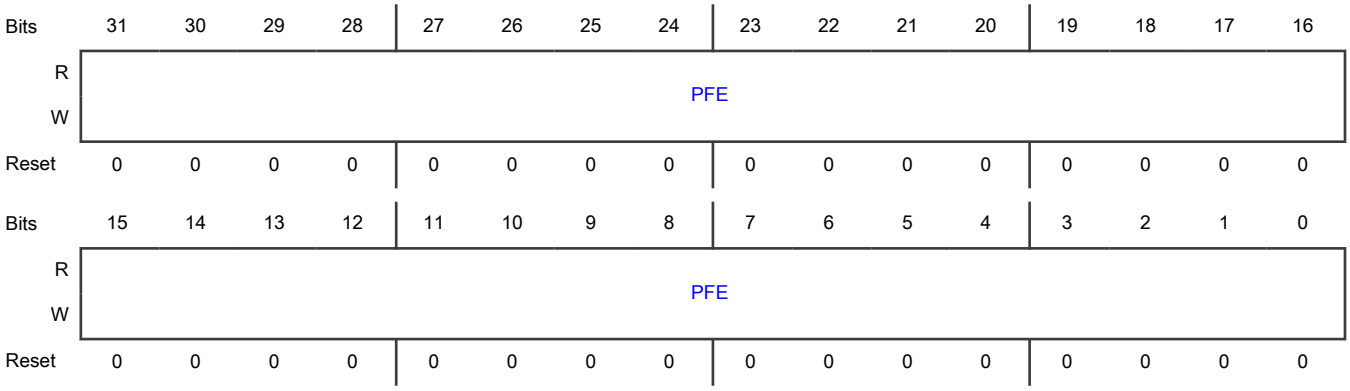
71.7.1.20 Pin Falling Edge Enable (PINFEN)

Offset

Register	Offset
PINFEN	5Ch

Function
Enables the pin status flag on a falling edge.

Diagram



Fields

Field	Function
31-0 PFE	Pin Falling Edge Specifies whether the pin status flag is set whenever a falling edge is detected on the pin. 0b - Not set 1b - Set

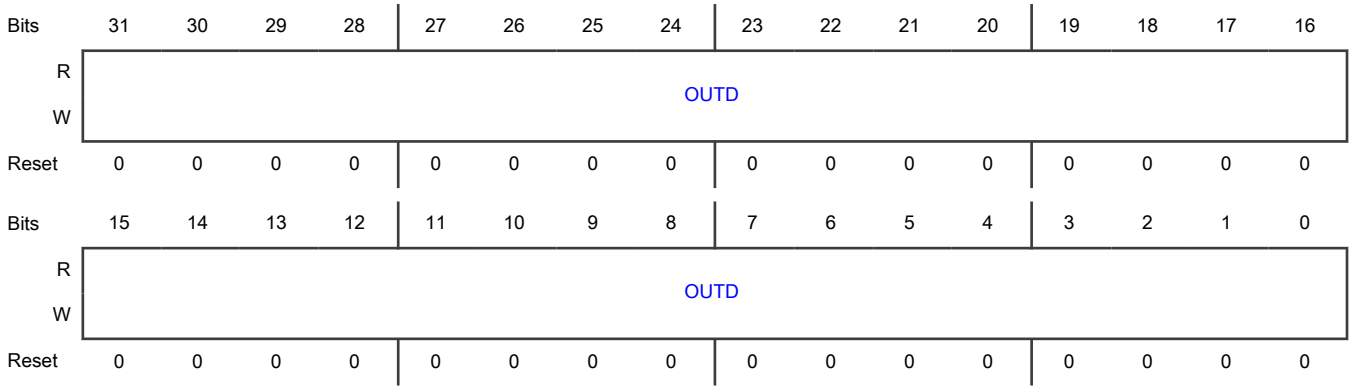
71.7.1.21 Pin Output Data (PINOUTD)

Offset

Register	Offset
PINOUTD	60h

Function
Contains data output when direct pin output is enabled.

Diagram



Fields

Field	Function
31-0 OUTD	Output Data Configures the value driven on the corresponding pin when direct pin output is enabled. 0b - Logic zero 1b - Logic one

71.7.1.22 Pin Output Enable (PINOUTE)

Offset

Register	Offset
PINOUTE	64h

Function
Enables pin output.

Diagram

R	0															
W	OUTTOG															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures the corresponding pins to toggle. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) is inverted and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD is inverted; corresponding field in PINOUTE becomes 1

71.7.1.27 Shifter Control (SHIFTCTL0 - SHIFTCTL7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Function

Provides shifter controls.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				TIMSEL				TIMPOL	0			PINCFG			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			PINSEL					PINPOL	0			SMOD			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL = i selects TIMERi.
23 TIMPOL	Timer Polarity Determines whether the shift occurs on the positive edge or negative edge of the shift clock. 0b - Positive edge 1b - Negative edge
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration Specifies shifter pin configuration. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When initially configuring PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b and then perform a subsequent write to update the rest of the Control register with the value of PINCFG as 00b. 00b - Shifter pin output disabled 01b - Shifter pin open-drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects the pin that is used by the shifter input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Shifter Pin Polarity Specifies the shifter pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active high 1b - Active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter. 000b - Disable 001b - Receive mode; capture the current shifter content into SHIFTBUF on expiration of the timer 010b - Transmit mode; load SHIFTBUF contents into the shifter on expiration of the timer 011b - Reserved 100b - Match Store mode; shifter data is compared to SHIFTBUF content on expiration of the timer 101b - Match Continuous mode; shifter data is continuously compared to SHIFTBUF contents 110b - State mode; SHIFTBUF contents store programmable state attributes 111b - Logic mode; SHIFTBUF contents implement programmable logic lookup table

71.7.1.28 Shifter Configuration (SHIFTCFG0 - SHIFTCFG7)

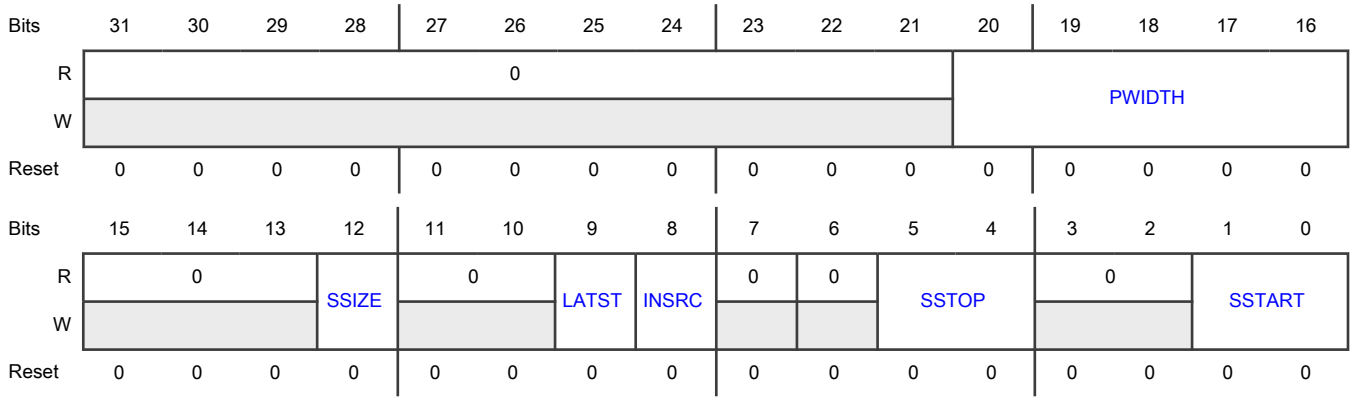
Offset

For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Function
Provides fields for shifter configuration.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 PWIDTH	Parallel Width Configures the number of bits to be shifted on each shift clock for all shifters: • 1-bit shift for PWIDTH = 0 • 2-bit shift for PWIDTH = 1 • 4-bit shift for PWIDTH = 2...3 • 8-bit shift for PWIDTH = 4...7 • 16-bit shift for PWIDTH = 8...15 • 32-bit shift for PWIDTH = 16...31 For shifters that support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with PINSEL, also selects the pins to be driven or sampled on each shift clock: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Shifters that do not support parallel transmit or parallel receive only support parallel shift when SHIFTCFG*n*[INSRC] = 1. If SHIFTCTL*n*[SMOD] = 110b (State mode), use this field to disable state outputs (see State mode).
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift registers. A 24-bit Shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations. When the Shift register is configured for a 24-bit shift, configuring PWIDTH as 8..15 performs a 12-bit shift and PWIDTH as 16..31 performs a 24-bit shift.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - 32-bit 1b - 24-bit
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match Shift register is configured to both shift and store on the same cycle. 0b - Store the pre-shift register state 1b - Store the post-shift register state
8 INSRC	Input Source Selects the input source for the shifter. Configuring this field as 1 is not supported for the last shifter. 0b - Pin 1b - Shifter n+1 output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop Allows automatic stop bit insertion, if the selected timer has also enabled a stop bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] is 1b or 100b (Receive mode or Match Store mode), this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] is 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Stop bit disabled for Transmitter, Receiver, and Match Store modes 01b - Stop bit disabled for Transmitter, Receiver, and Match Store modes; when timer is in stop condition, Receiver and Match Store modes store receive data on the configured shift edge 10b - Transmitter mode outputs stop bit value 0 in Match Store mode; if stop bit is not 0, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge) 11b - Transmitter mode outputs stop bit value 1 in Match Store mode; if stop bit is not 1, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 SSTART	Shifter Start Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable 01b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift 10b - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag 11b - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag

71.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Function

Contains shift buffer data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SHIFTBUF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]: • If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins. • If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). • If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode). • If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode).

71.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SHIFTBUFBYS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

71.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

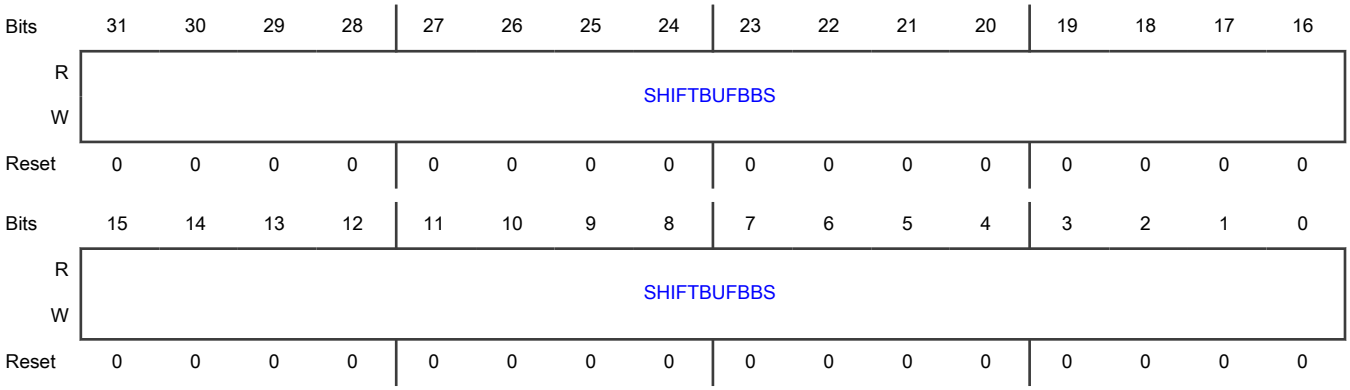
For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Function

Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), except that reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

71.7.1.33 Timer Control (TIMCTL0 - TIMCTL7)

Offset

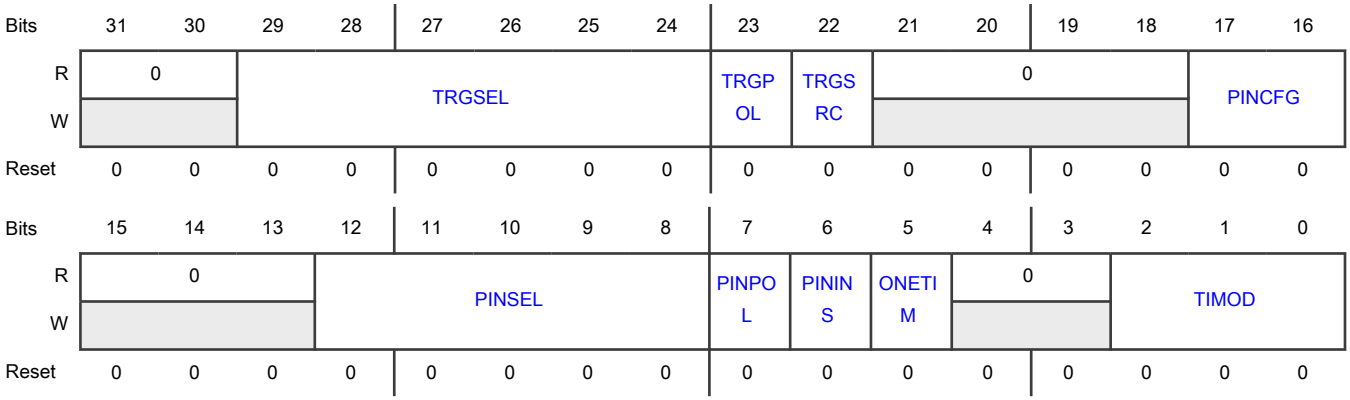
For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Function

Controls various settings for timer *n*.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select Selects the trigger. The valid values for TRGSEL depend on the configuration of Parameter (PARAM): • If TRGSRC = 1, the valid values for *n* depend on the settings of PARAM[PIN], PARAM[TIMER], and PARAM[SHIFTER]. • If TRGSRC = 0, the valid values for *n* depend on PARAM[TRIGGER]. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, *n* = 0 to 31, for a shifter, *n* = 0 to 7, and for a timer, *n* = 0 to 7. If TRGSRC = 0, configure the trigger selection as *n* = external trigger *n* input. If TRGSRC = 1, you can configure the internal trigger to select an input pin as 2×*n* = pin *n* input. If TRGSRC = 1, you can configure the internal trigger to select a shifter or timer signal as: • 4×*n* + 1 = shifter *n* status flag • 4×*n* + 3 = timer *n* trigger output Following are the values for expanded internal trigger selection (TRGSRC = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000 = Pin 0 • 0001 = Shifter 0 flag • 0010 = Pin 1 • 0011 = Timer 0 trigger • 0100 = Pin 2 • 0101 = Shifter 1 flag • 0110 = Pin 3 • 0111 = Timer 1 trigger • ... • This continues up to pin 31, shifter 7, and timer 7.
23 TRGPOL	Trigger Polarity Specifies whether the trigger is active high or active low. 0b - Active high 1b - Active low
22 TRGSRC	Trigger Source Specifies whether the selected trigger source is external or internal. 0b - External 1b - Internal
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When you initially configure PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set the value of PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b, and then perform a subsequent write to update the rest of the Control register with PINCFG as 00b. 00b - Timer pin output disabled 01b - Timer pin open-drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects the pin that is used by the timer input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Timer Pin Polarity Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. 0b - Active high 1b - Active low
6 PININS	Timer Pin Input Select Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered. 0b - PINSEL selects timer pin input and output 1b - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL
5 ONETIM	Timer One Time Operation Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again. 0b - Generate the timer enable event as normal 1b - Block the timer enable event unless the timer status flag is clear
4-3 —	Reserved
2-0 TIMOD	Timer Mode Specifies the timer mode: • In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. • In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. • In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. • In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. • In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh. 000b - Timer disabled 001b - Dual 8-bit counters baud mode 010b - Dual 8-bit counters PWM high mode 011b - Single 16-bit counter mode 100b - Single 16-bit counter disable mode 101b - Dual 8-bit counters word mode 110b - Dual 8-bit counters PWM low mode 111b - Single 16-bit input capture mode

71.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Function

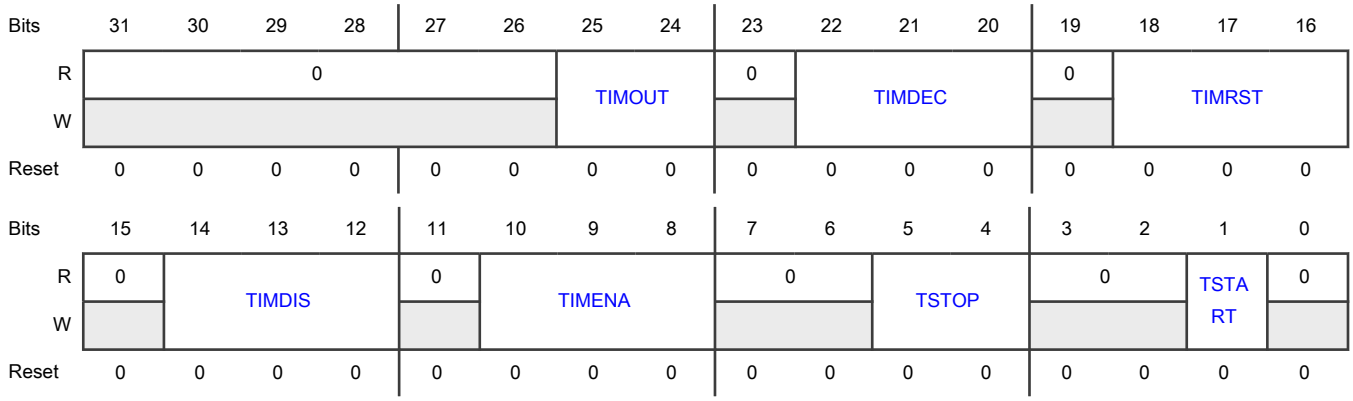
Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

NOTE

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00b - Logic one when enabled; not affected by timer reset 01b - Logic zero when enabled; not affected by timer reset 10b - Logic one when enabled and on timer reset 11b - Logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the timer decrement and that of the shift clock. 000b - Decrement counter on FLEXIO clock; shift clock equals timer output 001b - Decrement counter on trigger input (both edges); shift clock equals timer output 010b - Decrement counter on pin input (both edges); shift clock equals pin input 011b - Decrement counter on trigger input (both edges); shift clock equals trigger input 100b - Decrement counter on FLEXIO clock divided by 16; shift clock equals timer output 101b - Decrement counter on FLEXIO clock divided by 256; shift clock equals timer output 110b - Decrement counter on pin input (rising edge); shift clock equals pin input 111b - Decrement counter on trigger input (rising edge); shift clock equals trigger input
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8 bits that configure the baud rate. In all other modes, the timer reset resets full 16 bits of the counter. 000b - Never reset timer 001b - Timer reset on timer output high. 010b - Timer reset on timer pin equal to timer output 011b - Timer reset on timer trigger equal to timer output 100b - Timer reset on timer pin rising edge 101b - Reserved 110b - Timer reset on trigger rising edge 111b - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on timer n-1 disable 010b - Timer disabled on timer compare (upper 8 bits match and decrement) 011b - Timer disabled on timer compare (upper 8 bits match and decrement) and trigger low 100b - Timer disabled on pin rising or falling edge 101b - Timer disabled on pin rising or falling edge provided trigger is high 110b - Timer disabled on trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on timer n-1 enable 010b - Timer enabled on trigger high 011b - Timer enabled on trigger high and pin high

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Timer enabled on pin rising edge 101b - Timer enabled on pin rising edge and trigger high 110b - Timer enabled on trigger rising edge 111b - Timer enabled on trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Specifies whether the stop bit is enabled. The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Disabled 01b - Enabled on timer compare 10b - Enabled on timer disable 11b - Enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Specifies whether the start bit is enabled. If it is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Disabled 1b - Enabled
0 —	Reserved

71.7.1.35 Timer Compare (TIMCMP0 - TIMCMP7)

Offset

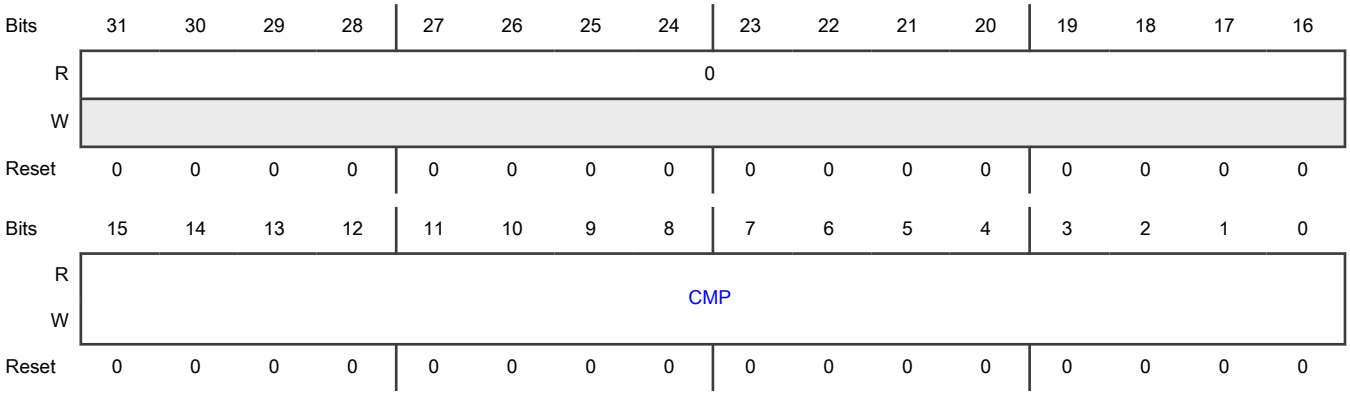
For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value Loads into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider as (CMP[7:0] + 1) × 2. The upper 8 bits configure the number of bits in each word as (CMP[15:8] + 1) ÷ 2. In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word as (CMP[7:0] + 1) ÷ 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) ÷ 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. You must read this register only when the timer status flag is set.

71.7.1.36 Shifter Buffer Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

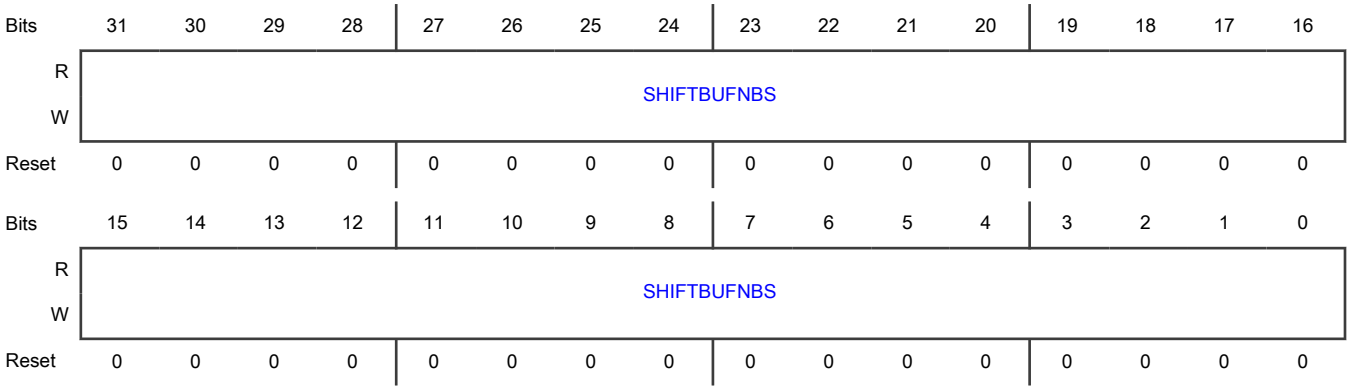
For n = 0 to 7:

Register	Offset
SHIFTBUFNBSn	680h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is nibble-swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFNBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are nibble-swapped within each byte. Reads return {SHIFTBUF[27:24], SHIFTBUF[31:28], SHIFTBUF[19:16], SHIFTBUF[23:20], SHIFTBUF[11:8], SHIFTBUF[15:12], SHIFTBUF[3:0], SHIFTBUF[7:4]}.

71.7.1.37 Shifter Buffer Halfword Swapped (SHIFTBUFHWS0 - SHIFTBUFHWS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFHWSn	700h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is halfword-swapped.

72.1.1 Module instances

This device has two instances of the I3C module, I3C0 and I3C1.

72.1.2 High-Keeper methods

This device supports all High-Keeper methods.

72.2 Overview

I3C is a communications processor that improves upon the use and power of I2C, and provides an alternative to SPI for mid-speed applications.

The I3C bus protocol supports:

- In-band interrupts (IBI): these interrupts move from target to controller without extra wires, and the controller knows which target sent the interrupt
- Common command codes (CCC)
- Dynamic addressing
- Multi-controller and multi-drop
- Hot-Join (HJ)
- I2C compatibility

I3C supports all required and many optional features of the MIPI Alliance Specification for I3C, v1.0, except for ternary data rates (HDR-TSP and HDR-TSL). See Features for more information.

72.2.1 Block diagram

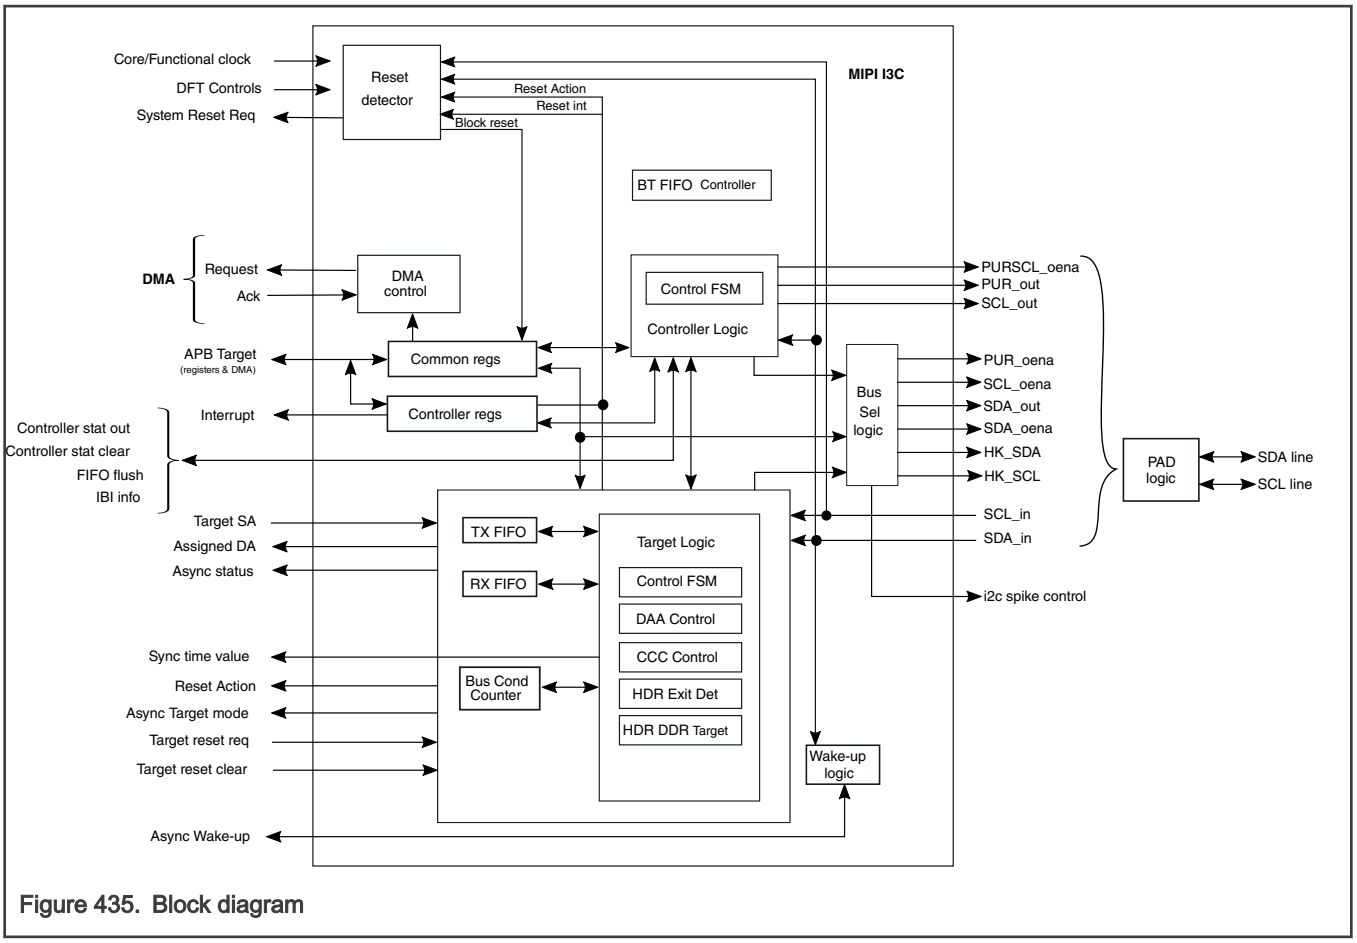

Figure 435. Block diagram

72.2.2 Features

- Two-wire multidrop bus that is capable of 12.5 MHz clock speeds with up to 11 devices:
  - Uses standard pads with 4 mA drive.
  - Dynamically assigns target addresses, and targets do not require static addresses (SAs). However, targets can have an I2C static address assigned at startup, so the target can operate on an I2C bus. By default, I3C supports 7-bit I2C-style addresses.
  - Allows targets to use the inbound SCL clock as the peripheral clock (instead of the clock from the controller) so that devices can have slow or inaccurate clocks internally.
  - Allows simple targets, such as temperature sensors, to have no internal clock.
  - I3C controller supports handoff from Open-Drain to Push-Pull mode for ACK to data transfer.
  - Generally, the controller terminates the read, but for I3C, the target can also end the read.
- IBIs that allow targets to send notifications to a controller:
  - Can be equivalent to a separate GPIO, but can also be directly data-bearing.
  - Can be prioritized. When multiple targets send interrupts to a controller at the same time, the order is resolved. Dynamic addresses (DAs) establish the priority of the targets, so the controller controls the priority of the targets.

    Targets with lower-value DAs are higher-priority level IBIs.

  - Can start interrupts even when the controller is not active on the bus. A free-running clock is not required, but starting an interrupt requires a Bus Available condition.
  - Can resolve an initial event via a time-stamping option, not requiring an interrupt.
- Built-in commands for applications created in software or firmware by using the register interface maintained in a separate space. These commands do not collide with normal controller-to-target messages and:
  - Control bus behavior, modes and states, low-power state, inquiries, and more.
  - Have an extra room for new built-in commands for other groups.
- Organized forms of multicontroller modes that are secondary controllers using clean handoffs between different controllers.
- Hot-Join onto I3C bus allows devices to connect to the bus later than when the bus starts. This:
  - Enables a device or module to access the I3C bus after power up or when physically inserted onto the I3C bus.
  - Provides a clean method for notification when new devices or modules access the I3C bus.
- I3C can use both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus.
  - I3C target devices can operate on I2C buses.
  - I3C supports bridging to I2C, SPI, UART, and other buses.
  - Special mode for old-style I2C buses (no targets) with clock stretching.
- Higher data rate modes are available:
  - I3C has a high data rate: double data rate (HDR-DDR) mode, which is double the data rate of SDR .
  - Only the controller and the specific target must support the higher data rate (the other targets can ignore it).

I3C supports most of the I3C features (see Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2)), except for the ternary data rates (HDR-TSP and HDR-TSL) and peer-to-peer messaging.

72.3 Functional description

72.3.1 Operating modes

This section describes all functional operation modes of the I3C module.

72.3.1.1 Target and controller roles for I3C

The I3C protocol defines these roles for devices on the I3C bus:

- Main controller: initially configures the I3C bus and serves as the first active controller
- Secondary controller: accepts the controller role from any active controller to become the new active controller (the secondary controller may then pass the controller role along: either back to the previous active controller, or on to any other controller-capable device)
- Target: responds to commands from any I3C controller
- I2C target: responds to commands from any controller

The I3C peripheral contains both controller and target components and can be configured to be either controller or target, or as target with secondary controller capability. However, if I3C is chosen to be a controller, then the I3C peripheral supports Target mode to facilitate handoffs to multiple controllers.

In general, any I3C controller can be a controller or a target because a controller becomes a target when giving over control to another controller. The only exceptions to this rule occur when using point-to-point communication or when using a controller that never shares controllership.

72.3.1.1.1 Controller requirements

Controller mode uses software that supports the requirements of the controller (including as a secondary controller):

- Managing the enter dynamic address assignment (ENTDAA) assigning dynamic addresses (DAs) to each target. The I3C peripheral supports this process but requires you to make choices.
- Driving the serial data (SDA) signal in both Open-Drain and Push-Pull modes. After START command, SDA is in Open-Drain mode and after Repeated START command, it is in Push-Pull mode:
  - SDA is subject to arbitration because both controller and target can drive the SDA line (arbitration is also useful for handoff from controller to target).
  - The ninth bit of SDA controller write data is an odd parity bit.
- Building a table of targets and their capabilities to control which actions and commands may be sent to the targets.
- Managing requests such as IBI and controller requests (handoff).
- Adjusting clock speed or write-to-read timing to match the limitations of the target. This adjustment can be done in hardware using dividers and uneven duty cycles, but you must decide how.
- Adjusting the maximum data length.
- Being a target after the controller role handoff to another controller-capable device.

The controller needs an accurate clock capable of running at a frequency that is the multiple of a frequency between 11 MHz and 12.5 MHz. Following are the possible clock frequencies:

- 24 MHz (multiple of 12 MHz)
- 48 MHz (multiple of 12 MHz)
- 133 MHz
- 160 MHz

If required to use a lower I3C SCL value, for example as small as 5 MHz (although the lower value does not support a mixed bus system):

- The controller clock can be a multiplier of that value.
- A lower SCL can also be achieved using a higher PPBAUD value.

72.3.1.1.2 I3C target acts like I2C target on I3C buses

If the target is assigned an I2C static address, the I3C target acts like an I2C device when it first powers on. If the I3C target is placed on an I2C bus with an I2C controller, then the I3C target stays in I2C mode and operates normally. The software is aware that the I3C target is in I2C mode because:

- There has not been an interrupt (see SSTATUS[DACHG]) indicating that a dynamic address was assigned.

For full I2C support of Fast mode (Fm) and Fast-mode Plus (Fm+), the pads must support a 50-ns spike filter. This filter must be turned off when the I3C 7Eh broadcast address is received (indicating an I3C controller). You can turn off the spike filters via hardware using the raw net indicating that the address was received, or via software. I3C does not need a 50-ns spike filter to operate on an I2C bus. Therefore, the spike filter is not a requirement for the I3C peripheral.

Depending on the configuration, the module supports most I2C features. Supported features include an extended 10-bit address, DeviceID, and software reset. See Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2) for more information.

72.3.1.1.3 How a target rejoins the I3C bus

When a target tries to rejoin the I3C bus following a power-up or hard reset, the target needs a new dynamic address (DA). The target can rejoin the I3C bus in these ways:

- If the DA is lost, Hot-Join is used.

- If the DA is retained in the peripheral (for example, with state retention flip-flops), SCONFIG[OFFLINE] is used.

When SCONFIG[SLVENA] is 1, SCONFIG[OFFLINE] may become 1. This setting causes the peripheral to rejoin the bus safely. It does so by ensuring that the I3C bus is not in HDR mode, using the same approach as TE0 or TE1 exit. The peripheral waits for the HDR exit pattern from the controller, or for 60 µs of SCL and SDA lines not changing, whichever occurs first.

After using SCONFIG[OFFLINE], the I3C peripheral cannot safely use IBI until SSTATUS[STOP] becomes 1. This status ensures that the next START is safe to use for IBI.

If the application has to perform an IBI, it must wait for SSTATUS[STOP] to become 1, or for SCL and SDA lines to remain high for 200 µs. You can perform this process using the SSTATUS and SINTSET controls:

- If Target Status (SSTATUS) indicates that the bus is not busy and the peripheral interrupts on START or STOP, use a timer to measure 200 µs. If the timer finishes with no START or STOP, it is safe to use IBI.
- If a START causes an interrupt, then the timer must be turned off and the application must wait for a STOP.
- If a STOP causes an interrupt, it is safe to use IBI.

72.3.1.2 Using the I3C controller for I2C and I3C

The I3C controller operates with the following set of built-in capabilities with the application flow:

- Built-in enter dynamic address assignment (ENTDAA) mechanism to simplify the assignment of dynamic addresses to targets. This feature is used when set dynamic address from static address (SETDASA) is not available.

  NOTE

  When SETDASA CCC is available, use SETDASA CCC before using ENTDAA CCC; all targets without assigned dynamic addresses respond to ENTDAA CCC.

- Request for START + address with IBI support, including both I2C and I3C modes.
- SDR write flow via FIFO, with automatic parity in I3C and ACK or NACK detection in I2C.
- SDR read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C.
- Request for Repeated START + address or STOP when finished with the previous request, including both I2C and I3C.
- Auto-IBI mode, which responds immediately to a target-initiated IBI and can be used when in Sleep or Deep Sleep mode.
- Special message mode for SDR and DDR to simplify DMA use.
- Automated SCL, SDA, pullup, and High-Keeper controls.
- I2C and I3C frequency and duty cycle configurations from functional clock.

  NOTE

  You must configure Controller Configuration (MCONFIG) and Controller In-band Interrupt Registry and Rules (MIBIRULES) before using the controller.

72.3.1.3 Protocol modes and states

The following modes are activated in I3C:

- I2C mode is the default mode on startup:
  - If no I2C static address is used, this mode has no effect other than to track frames looking for I3C transitional frames.
  - If an I2C static address is used, the device can interact with the I2C bus controller using the address.
- When in I2C mode, I3C Transitory Frame mode occurs whenever the I3C broadcast address is received (7Eh). In particular:
  - This mode occurs when 7Eh is broadcast followed by SETDASA from the controller. If there is a static address match or 01h, the target is assigned a dynamic address and it enters I3C SDR mode.

— This mode occurs when 7Eh is broadcast followed by ENTDAA from the controller. If the target can send a 48-bit provisioned ID (48b ID), a dynamic address is assigned, and the target enters I3C SDR mode.

— If a Hot-Join arbitrated event occurs (sending 02h when the controller generates another address such as 7Eh), there is a conceptual Hot-Join mode. ENTDAA or SETDASA sets a dynamic address to resolve the event, and the target enters I3C SDR mode.

NOTE

An I3C target can operate as a normal I2C target only when it has a static address. Otherwise, it matches nothing in I2C and waits for the aforementioned events.

- I3C SDR mode is the standard mode after I3C activates, which is defined by a dynamic address being assigned. This mode is the resting mode of I3C, and all devices are normally in SDR mode:
  — RSTDAA CCC causes an exit from SDR mode and a return to I2C mode. This transition is not normally used.

    RSTDAA can be issued to ensure all I3C targets participate in an upcoming dynamic address assignment process, before the I3C controller starts assigning the target address.

  — SETNEWDA does not affect the SDR mode; it only changes the dynamic address of an I3C device that already had a dynamic address assigned.

  — When in SDR mode, the device ignores messages to or from its original I2C static address.
- The I3C CCC command submode of type Direct or Broadcast. Following are the options to exit the CCC:
  — Exit the Broadcast CCC submode by a Repeated START or by a STOP.

  — Exit the Direct CCC submode by a 7Eh broadcast address after a Repeated START or by a STOP.

  — I3C dynamic address assignment (DAA) CCC command enters DAA mode. This mode is a special mode for dynamic addressing. Use STOP to exit. If a target has a dynamic address, the command is ignored.
- I3C SETDASA CCC command enters Static Address Match submode, which allows matching the static address of the device (if any). The command is ignored when a target has a dynamic address, or when the target in I2C mode has no static address.

NOTE

The special point-to-point address is also matched.

- I3C HDR modes are activated by ENTHDR*n* CCC commands, where *n* represents the type of HDR (0 to 7). This mode is valid until an HDR exit pattern is detected, irrespective of whether HDR mode for a target is supported.

  Exit-pattern detection must always be on to prevent errors. Alternatively, you could set it to be activated only on ENTHDR.
- Internal states such as IBI or no-IBI and Low-Power mode are flagged internally (see SSTATUS[EVDET] for more information). These states are exported to the application and affect the engine to restrain it from performing a prohibited operation.

72.3.1.4 Address match

For an address match to occur, the target matches the I3C broadcast address and either the I2C-style static address or I3C dynamic address (see Table 696).

The address match is inactive (just listening) for all Repeated START commands and also for the START command, unless an IBI, CR, or Hot-Join has been activated. If inactive, it simply tries to match. If not matched, it waits for a Repeated START or STOP command. If an IBI, CR, or Hot-Join has been activated, the arbitration mechanism is used for START (but never for a Repeated START).

When matching the 7Eh broadcast address, it looks for a CCC until the next Repeated START or STOP command.

Table 696. Address match conditions

For	Match condition occurs when	Notes
I3C broadcast address	The address is 111 1110b (written as 7Eh)	
I2C-style static address	• The device has a static address. • The device is not in I3C mode.	When in I3C mode, the address matches only until the ENTDAA, SETDASA, or SETAASA command has a dynamic address assigned. **NOTE** SETDASA matches the static address or the special one-controller-to-one-target point-to-point address.
I3C dynamic address	It is assigned by ENTDAA or SETDASA or modified by SETNEWDA	

72.3.2 Operations

This section describes the operations of the module.

72.3.2.1 Reading and writing I2C messages using the normal method

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to read out data.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to supply data.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure the following fields in Controller Control (MCTRL) simultaneously:
   a. Write 1 to REQUEST (EmitStartAddr).
   b. Write 1 to TYPE (I2C).
   c. Configure IBIRESP to respond to IBIs in your chosen manner.
   d. Write 1 to DIR for read, or write 0 for write.
   e. Write the static address of the I2C target to ADDR.
   f. Configure RDTERM to the maximum length for read operations, to auto-terminate, or set it to STOP as the data is read out. For example, write 1 (with MCTRL[REQUEST] = 0) to stop after the next character.
3. Write or read the data.

- For write operations, write to Controller Write Data Byte (MWDATAB) for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte:
  - — You can perform or start this operation before setting up interrupts.
  - — If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.
- For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB). DMA may also be used.

4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may end with a STOP, or a new message may start with a Repeated START:
   a. Write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion. (When sending STOP in I2C mode, MCONFIG[ODSTOP] and MCTRL[TYPE] must be 1.)
   b. Write 1 to MCTRL[REQUEST] (EmitStartAddr to restart). IBI is not possible in this case.

NOTE

I2C Fm and I2C Fm+ modes are supported for legacy I2C devices as per the I3C standard specifications. See I2C configuration to meet timing requirements for Fm and Fm+ modes for more information.

72.3.2.2 Reading and writing I3C messages using the normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as the method for I2C with a few differences:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the I3C module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to read out bytes.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to supply bytes.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Set up Controller Control (MCTRL).
   - Option 1: Configure the following fields of Controller Control (MCTRL) simultaneously in this way:
     a. Write 1 to REQUEST (EmitStartAddr).
     b. Write 0 to TYPE for I3C SDR mode or write 2 for DDR mode.
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 1 to DIR for read, or write 0 for write.
     e. Write the dynamic address of the I3C target to ADDR.
     f. For read operations, you can configure RDTERM to the maximum length to terminate automatically.
     g. For write operations, prewriting the data (MWDATAB or MWDATAH) is preferred to ensure that there are no time delays waiting for the data.

        For DMA with MCTRL, use Controller Write Byte Data 1 (to Bus) (MWDATAB1).

NOTE

HDR-DDR mode requires writing an 8-bit command value for read or write. This value must be written into the TX FIFO via Controller Write Data Byte (MWDATAB). The END field is not used for this byte.

- Option 2: This option is preferred when stopped (bus free condition) in SDR mode, and not in HDR-DDR mode. It allows any target to issue an IBI and avoids collisions with an IBI address. Also, it is faster (when the MSB of the dynamic address is always 0).

  Configure the following fields of Controller Control (MCTRL) in this way:

  a. Write 1 to REQUEST (EmitStartAddr). No prewritten transmit data can be in the FIFO.
  b. Write 0 to TYPE (I3C).
  c. Configure IBIRESP to respond to IBIs in your chosen manner.
  d. Write 0 to DIR.
  e. Write 7Eh to ADDR.
  f. Wait for MCTRLDONE (via interrupt, for example), then proceed as in option 1. The option 2 method has advantages for IBIs when 7Eh is sent on START (but not on Repeated START conditions).

3. Write or read the data.
   - For write operations, write to MWDATAB for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte. For HDR-DDR, the byte with END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs:
     — You can perform or start this operation before step 1 (REQUEST = 1) of the option 1 method, but not before the option 2 method.
     — If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.
   - For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB) or Controller Read Data Halfword (MRDATAH). DMA may also be used. When using DMA, read using the same registers.
4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may be ended with STOP (or EXIT in HDR mode). Alternatively, a new message may be started with a Repeated START (or HDR-Restart in HDR mode):
   - In SDR mode, write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion.
   - For HDR mode, write 6 to MCTRL[REQUEST] (ForceExit) to end HDR mode. Then wait for the MCTRLDONE status to be asserted for its completion. When sending the HDR exit pattern, MCONFIG[ODSTOP] must be 0.
   - Write 1 to MCTRL[REQUEST] (EmitStartAddr to start another message). IBI is not possible in this case.

72.3.2.3 Determining bus types

As shown in the following tables, the meaning of MCTRL[TYPE] changes according to the value of MCTRL[REQUEST].

Table 697. Determining bus types

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
0	I3C: SDR mode of I3C	I3C: SDR mode of I3C	Exit pattern
1	I2C: standard I2C protocol	I2C: standard I2C protocol	Reserved
2	DDR: HDR-DDR mode of I3C. The bus enters Double Data Rate (DDR) mode (7E and then ENTHDR0), if the module is not in DDR mode already. The first byte	Reserved	Target reset

Table continues on the next page...

Table 697. Determining bus types (continued)

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
	written to the transmit FIFO must be a command and already in the FIFO. To end DDR mode, use ForceExit.		
3	BT: HDR-BT mode of I3C. If not already in HDR-BT, the bus automatically enters BT mode (7E and then ENTHDR3). You must also configure the MHDRBTCFG register for multilane and CMD rules.	Reserved	Reserved

72.3.2.4 Sending a CCC to I3C targets

The normal common command code (CCC) method uses an I3C write operation with an address of 7Eh (the CCC is the first byte):

- For broadcast type, any remaining bytes are sent with the CCC. This operation ends with a STOP or a Repeated START and 7Eh.
- For direct type, only the CCC byte is sent (or by a CCC and a defining byte, if required by the CCC).

  These bytes are followed by a Repeated START and the address of the I3C target (for SETDASA, this address is its I2C static address). This sequence may be repeated with more Repeated START conditions and addresses until done. It may end in STOP or a Repeated START and 7Eh. After the Repeated START and target address, the values are read or written depending on the CCC.
- I3C provides interrupts (by hardware) for unhandled and handled CCC when received by the target. Its state is reflected in Target Status (SSTATUS).

I3C controllers require to emit a single START, 7E/W sequence with both SCL high and SCL low half periods at full open-drain timing (for example, 200 ns). This sequence allows I3C targets acting as I2C legacy devices to turn off their I2C 50-ns spike filters, if they have them.

NOTE

START, 7E/W is a notation indicating a START command, followed by the 7Eh broadcast address and then by a write command.

After that sequence, addresses following START may be sent with Open-Drain Low (for example, 200 ns) but high of Push-Pull timing (for example, 40 ns). The I3C controller must emit this START, 7E/W sequence with MCONFIG[ODHPP] = 0. ODHPP is Open-Drain High period at Push-Pull speeds, and MCONFIG[ODHPP] is usually 1.

NOTE

- MCONFIG[ODHPP] is ignored when sending a message to an I2C legacy device on an I3C bus.
- Each Repeated START is a new EmitStart request. This request can be chained by an interrupt or pushed by a message model using DMA.

72.3.2.5 IBI handling

An IBI occurs when a target sends its address after a START, and that address is numerically the lowest. That is, it is lower than the address sent by the controller and addresses sent by any other targets. When the controller sends 7Eh, the controller always loses the arbitration.

The IBI can occur unexpectedly when any new START (not a Repeated START) is sent. The IBI can also occur in response to a target pulling SDA low. This condition can occur in one of these ways:

- The controller has set the request to AutoIBI mode, so the IBI occurs automatically. The controller sends 7Eh to allow the target to win the arbitration.
- The application receives the SLVSTART (target START request) interrupt, so it sends 7Eh.

The IBI response is configured by MCTRL[IBIRESP], which can be set to:

- NACK (always reject the IBI).
- ACK (always accept the IBI):
  - You must configure Controller In-band Interrupt Registry and Rules (MIBIRULES) so that the engine knows whether IBI bytes follow.
  - If IBI bytes follow (also known as IBI mandatory byte), then the COMPLETE field does not become 1 when IBIWON becomes 1. RXPEND becomes 1 for one or more bytes in the receive FIFO. When the last byte is received, then the COMPLETE field becomes 1. The controller automatically stops IBI data after 9 bytes (including the mandatory data byte). MCTRL[RDTERM] can be used with MCTRL[REQUEST] = 0 to end the process of receiving data sooner. I3C supports address ACK to mandatory byte transition during IBI from Open_Drain (controller acknowledges the target address) to Push Pull (target sends SDR data).
  - I3C target supports up to 7 bytes (maximum limit is defined by IBIEXT1[MAX]) of extended IBI data following a mandatory data byte. Extended data to send, if any, is present in Extended IBI Data 1 (IBIEXT1) and Extended IBI Data 2 (IBIEXT2).
- Manual (allow the decision to be made by the application on a case-by-case basis):
  - The application rewrites it when stopped, pending an IBI.
  - The application can ACK or NACK the IBI based on the IBI address defined in MSTATUS.
  - This mode selects whether there is an IBI byte when accepting the IBI request from targets.

Accurate timestamping of I3C target data is supported in I3C though Async mode 0. In I3C Asynchronous Timing Control mode, a target device timestamp event occurs within that target. The target notifies the controller about the event by generating an IBI.

72.3.2.6 Assigning dynamic addresses to I3C devices

If dynamic addresses (DAs) are all assigned below 40h (7-bit values from 3Fh down to 03h, except where not allowed), then MIBIRULES[MSB0] can be 1. This setting optimizes the START timing. When dynamic addresses are assigned, you must program Controller In-band Interrupt Registry and Rules (MIBIRULES) based on which I3C target uses IBI bytes (present in SIDEXT[BCR]).

Any SETDASA assignments can be performed via the normal CCC model. These assignments cannot be performed when using the static address for the directed part.

There is a built-in mechanism to process DAA mode:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when a target has sent its ID and BCR or DCR, and a new DA is needed.
   - COMPLETE: Indicates when DAA is done (NACKed by all targets).
   - RXPEND: Indicates the reading of the IDs of the targets. You can also use this field to allow DMA to read out bytes.
   - IBIWON: Indicates when an IBI has occurred (normally there are no IBI conditions when assigning dynamic addresses to the I3C device).
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure Controller Control (MCTRL):
   a. Write 4 to MCTRL[REQUEST] (ProcessDAA).
   b. Set MCTRL[IBIRESP] to IBI response, if possible. If not possible, set to the first target assignment.

3. Wait for the MCTRLDONE interrupt when reading ID using the RXPEND interrupt. If MSTATUS[STATE] = 5 (DAA mode) and MSTATUS[BETWEEN] = 1, it is waiting to write a dynamic address:
    a. Write the dynamic address into Controller Write Data Byte (MWDATAB) using bits 6:0, such as 14h for DA = 7'h14.
    b. Write 4 to MSTATUS[STATE] (ProcessDAA again). This option writes the DA, then moves to the next DA.
    c. If MSTATUS[COMPLETE] = 1 and MSTATUS[STATE] = 0, then all targets are assigned.
    d. If MSTATUS indicates NACK after writing a new DA, the DA is not accepted by the target. The next step is to write 2 to MCTRL[REQUEST] (EmitStop) and start over. It is also acceptable to write 4 to MCTRL[REQUEST] (ProcessDAA again).

72.3.2.7 Using Controller Message mode

Controller Message mode is intended for use with DMA although Message mode can also be used by the processor. In Message mode, all writes are to the same location, including control and data. Reads occur from an associated location.

NOTE

The data writes for Message mode work in the same way as the halfword access registers, Controller Write Data Halfword (MWDATAH) and Controller Read Data Halfword (MRDATAH).

To send a message via Single Data Rate (SDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL). This request includes the following items:
    - The address.
    - I2C or I3C.
    - Read or write.
    - The count of bytes to process.
    - How to end (on STOP or ready for Repeated START).
2. Process the data:
    - For write operations, write the rest of the data to Controller Write Message Data in SDR mode (MWMSG_SDR_DATA). Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when it has already consumed the number of bytes configured in the LEN field.
    - For read operations, a DMA trigger (or interrupt) indicates when the RX FIFO is ready to be read out via Controller Read Message in SDR mode (MRMSG_SDR).
3. Select the in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
4. Use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using Controller Control (MCTRL). To exit Message mode with the original message, use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using the MCTRL register.

To send a message via Double Data Rate (DDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL). This request includes:
    - The count of byte pairs.
    - How to end the message (through HRD exit or to wait for HDR restart).
2. Write the second control data to MWMSG_DDR_CONTROL. This second write includes:
    - The address.
    - Read or write.

- The 7-bit command value.

3. Process the data:
   - For write operations, write the rest of the data to MWMSG_DDR_DATA. Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when the program count MWMSG_DDR_CONTROL register reaches 0.
   - For read operations, a DMA trigger (or interrupt) indicates when the receive FIFO is ready to be read out.
4. Select in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
5. Use END type exit (MCTRL[REQUEST] = 6) with a zero-length message or by using the MCTRL register to exit DDR Message mode with the original message.

72.3.2.8 Handing off controllership to another target and getting it back

To hand off controllership, the controller can perform either of the following actions:

- Wait for a controller request (CR) (that is, MSTATUS[IBIWON] = 1 interrupt), indicating that the CR is using MSTATUS[IBITYPE].
- Push the request manually.

In either case, the controller sends a GETACCMST request, which is a directed GET informing the target that it is being assigned controllership. If the target accepts this request, it returns its dynamic address in bits 7:1 and the negative parity of its dynamic address in bit 0. A STOP must be issued, and MCONFIG[MSTENA] must be set to 2 (switching to Target mode).

To gain controllership, the target sends a CR using Target Control (SCTRL):

- If MCONFIG[MSTENA] is 2, the GETACCCR CCC is ACKed.
- If MCONFIG[MSTENA] is not 2, the GETACCCR CCC is NACKed.

After controllership is granted, MSTATUS[NOWMASTER] becomes 1. The application must enable MINTSET[NOWMASTER], so the application is interrupted when a controllership transfer occurs.

72.3.2.9 Controller engine flow diagram

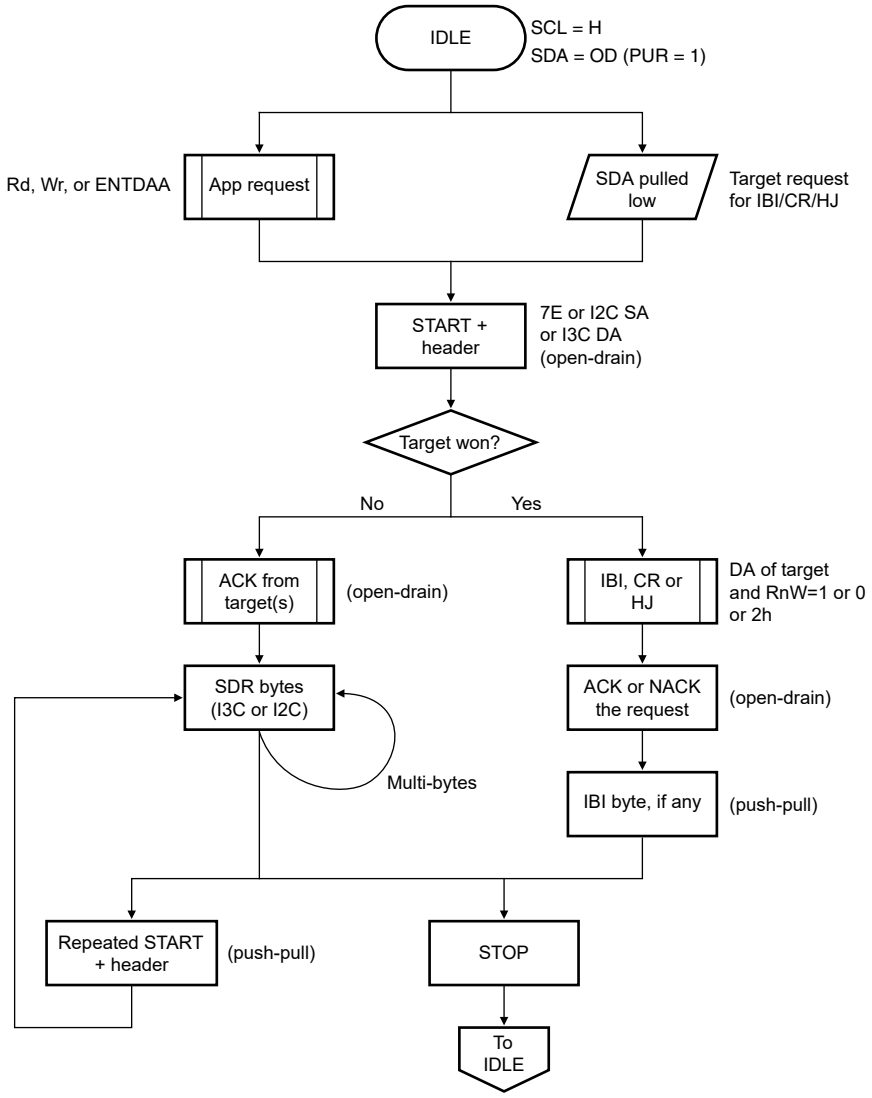

Figure 436. Controller engine flow diagram for SDR (HDR flow progresses from SDR bytes)

72.3.2.10 Target data write from controller

When the address match is valid for the target dynamic address and the type is W (write from controller), the target ACKs the address. It does so unless some condition prevents it, such as a full buffer. On ACK, the Write state is entered. Once ACKed, it waits for each complete data byte. This process occurs in two steps:

1. Eight bits are clocked in and stored in the next buffer location when in the Write state.
2. On the ninth bit:
   - In I3C mode, the W9TH state (in I3C, the ninth data bit written by the controller is the parity of the preceding eight data bits) is used and the parity is checked. The buffer is marked as complete with or without a parity error.
   - In I2C mode, the W9TH state (in I2C, the ninth data bit written by the controller is an ACK by the target) is used and the data is ACKed and stored.

When the address match is valid for the 7Eh broadcast address, the target acknowledges it. After first data completion, it sets the in_ccc broadcast or direct flag (based on bit 7 of the command). If recognized, it parses the command, setting that bit as well. The

recognized commands are for dynamic address work and modes. The CCC and DAA blocks handle the workload afterward. If not supported, then the commands are passed up to the system.

72.3.2.11 Target data write to controller

When the address match is valid for the target dynamic address, and the type is R (read by controller), the target ACKs the address. The target does so unless there is no data waiting for the read. On ACK, the Read state is entered.

After being ACKed, it emits the data byte at a time, with the ninth bit using the R9TH state. In I2C, the ninth data bit from target to controller is an ACK by the controller. In I3C, this bit allows the target to end a read, and allows the controller to abort a read:

- In I3C mode, the T bit is emitted to allow the device to indicate whether this byte is the last. If it is not the last byte, the controller may terminate the read via the T bit.
- In I2C mode, the ninth bit allows the controller to terminate via NACK, or else it allows the read to continue via ACK. On completion of each byte read, the "done" signal is pulsed to get the next byte.

If the read is terminated by the controller unexpectedly (abort in I3C, NACK before END marked), the application is notified.

72.3.3 Clocking

The controller works on the following primary clocks:

- The system clock, which controls access to the memory-mapped registers.
- A functional clock (FCLK), which is used to generate the SCL clock rate on the I2C or I3C bus.

I3C supports adjusting clock frequency and accuracy via Target Time Control Clock (STCCLOCK).

CLK_SLOW is used to check conditions such as bus availability, bus free for IBI, or HJ. The slow clock helps to save power:

- To determine the Bus Available condition for IBI, the target needs a clock to generate the ~1 µs timing. To support this requirement, a slow clock (CLK_SLOW) is provided to save on power.
- I3C supports a counter field, SCONFIG[BAMATCH], to calculate the Bus Available condition. BAMATCH provides the count of the slow clock. This field counts 1 µs or more to allow an IBI to drive SDA low when the controller is free. The I3C module controls the maximum width and maximum values.

I3C supports a timeout when stalled for too long in a frame. This timeout occurs when:

- The transmit FIFO or receive FIFO is not handled and the bus is stuck in the middle of a message.
- No STOP is issued and the bus is between messages.
- IBI manual is used and no decision is made.

72.3.4 Reset

- Global or system reset fed into the module: Everything is reset by this global or system reset. Release is assumed to be synchronized with the system clock. It is not synchronized with SCL or SDA. These signals must not be active when the reset is released; otherwise, I3C enters Hot-Join mode and remains inactive.
- Software reset

72.3.5 Interrupts

This section describes all the interrupts (IRQs) that this module generates. All status interrupts are updated in Controller Status (MSTATUS) and Target Status (SSTATUS).

Supported interrupts occur:

- For pending IBI, CR, or Hot-Join that have been sent by a target.
- When a CCC is received and is handled by the module (SSTATUS[CHANDLED]).

- When an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR, or CRC error.

72.4 External signals

Table 698. External signals

Signal	Description	Direction
SCL	Serial clock	Input or output
SDA	Serial data	Input or output
PUR	Pull up resistance. There is an internal pull-up resistance on SDA, which is controlled by the I3C controller. If the internal pullup is not enough, PUR can be used to control an external pull-up resistance on SDA actively.	Output

72.5 Initialization

72.5.1 Controller configuration

Certain configuration is performed when initializing this module. Controller Configuration (MCONFIG) controls the frequencies, duty cycle, optimizations for performance, and other parameters.

Table 699. Configuration for module initialization

Configuration parameter		Description
MSTENA	Controller enable	Determines whether the peripheral starts in Controller mode (main controller in I3C terms) or starts in Target mode (and switches to Controller mode later).
HKEEP	High-Keeper	Determines how the high-keeper (weak pullup) is implemented, depending on the device capabilities.
PPBAUD	Push-Pull baud	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This frequency sets the SCL half-clock period baseline (used at least for the high time of SCL). The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is 0, then SCL high = SCL low (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) Examples: • If FCLK = 24 MHz, then PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then PPBAUD = 1 yields 12.5 MHz (20 + 20 = 40 ns per half period)
PPLOW	Push-Pull low	Changes the duty cycle for Push-Pull. It indicates how many more FCLK cycles to use for low. The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is a nonzero value, then: • SCL high (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) • SCL low (in ns) = (1 + PPBAUD + PPLOW) × 1000 ÷ FCLK (in MHz) For example, when FCLK is 50 MHz, PPBAUD is 1, and PPLOW is 1, then the periods are:

Table continues on the next page...

Table 699. Configuration for module initialization (continued)

Configuration parameter		Description
		• (1 + 1) × 1000 ÷ 50 = 20 + 20 = 40 ns high • (1 + 1 + 1) × 1000 ÷ 50 = 20 + 20 + 20 = 60 ns low This timing is equivalent to 10 MHz SCL, but this timing maintains the 40 ns high needed; therefore, I2C devices do not see the high periods. **NOTE** The PPLOW value does not have any impact on Open-Drain mode and I2C mode SCL rate calculations.
ODBAUD	Open-Drain baud	Determines the number of PPBAUD periods to make up one I3C Open-Drain half-clock baseline. If ODHPP is 0, the ODBAUD half-clock time period = (ODBAUD + 1) × PPBAUD high period. If ODHPP is 0, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (2 + 2 × PPBAUD) × (ODBAUD + 1) Target to get open-drain half-clock period is 200 ns. For example: • If PPBAUD yields 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 can be used to get 200 ns. See ODHPP for details on short high and long low. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (2 + 2 × 1) × 5 = 2.5 MHz.
ODHPP	Open-Drain High Push-Pull	Optional field that allows the I3C open drain to be long low and short high. The high period of SCL is the PPBAUD period. This period leaves enough time for the pull-up resistor to pull the SDA high when SCL is low. It is also quick when SCL is high and there are no changes happening. ODBAUD low half-clock time period = (ODBAUD + 1) × PPBAUD high period. ODBAUD high half-clock time period = PPBAUD high period If ODHPP is 1, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (1 + PPBAUD) × (ODBAUD + 1) + (1 + PBAUD) For example: • If PPBAUD produces 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 and ODHPP = 1. These settings provide a high period of 40 ns and a low period of 200 ns. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (1 + 1) × 5 + (1 + 1) = 4.16 MHz.
I2CBAUD	I2C baud	Indicates the number of ODBAUD periods that are required to communicate with I2C devices (MCTRL[TYPE] = 2 or MWMSG_SDR_CONTROL[I2C] = 1). For example, if ODBAUD gives 200 ns, and the goal is Fm+ (Fast Mode, 1 MHz), then the sum must be 1 µs. I2CBAUD acts differently for odd and even values. For example:

Table continues on the next page...

Table 699. Configuration for module initialization (continued)

Configuration parameter		Description
		• If I2CBAUD = 3, it gives three ODBAUD periods low and two ODBAUD periods high. • If I2CBAUD = 4, it gives four ODBAUD periods for low and four ODBAUD periods for high. • Also, if I2CBAUD = 3, this yields 200 × 3 = 600 ns and 200 × 2 = 400 ns, with the sum 600 + 400 = 1000 ns = 1 µs.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and return. This time is normally 2 ns to 5 ns (or sometimes more). If the skew is too fast, then add more delay. The skew allows specifying the number of FCLKs to insert.

Additional optimizations:

- Use MIBIRULES[MSB0] to obtain faster start header times. If the controller application assigns all I3C dynamic addresses to be less than 40h (it does not have MSB set), you can write 1 to MIBIRULES[MSB0]. When the controller emits 7Eh (broadcast) and a target does not drive the first bit low, the rest of the header can be at push-pull speeds. This speed is two times faster or more, depending on optimizations.
- Auto-emit 7Eh speeds up the frame when used with MIBIRULES[MSB0]. It allows the processor to sleep when the frame starts automatically (in response to a target).

72.5.2 Interrupt service flow

Set up interrupts for Controller Status (MSTATUS) in Controller Interrupt Set (MINTSET).

Set up interrupts for Target Status (SSTATUS) in Target Interrupt Set (SINTSET).

72.6 Application information

72.6.1 I2C configuration to meet timing requirements for Fm and Fm+ modes

I2C Fm and I2C Fm+ modes are supported according to the I3C standard specifications.

Table 700 shows the configuration for Fm mode, where frequency is close to 400 kHz but timing requirement is not met (T_{SU_STA} is not met) because the actual value is 600 ns. Rest of the requirements are met as per the I2C data sheet.

Table 701 shows the configuration for Fm mode, where all timing requirements are met.

Table 700. Configuration for Fm mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	11	370 kHz	T_{SU_STA} - 353 ns
48 MHz	1	4	11	370 kHz	T_{SU_STA} - 353 ns
133/134 MHz	5	4	11/12	412 kHz / 382 kHz	T_{SU_STA} - 267 ns and T_{SU_STO} - 529 ns
160 MHz	6	4	10	380 kHz	T_{SU_STA} - 312 ns

Table 701. Configuration for Fm mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	1	2	9	363 kHz	All requirements met as per the I2C data sheet
48 MHz	3	2	9	363 kHz	All requirements met as per the I2C data sheet
133/134 MHz	11	2	9/8	338 kHz / 372 kHz	All requirements met as per the I2C data sheet
160 MHz	13	2	9/8	345 kHz / 422 kHz	All requirements met as per the I2C data sheet

Table 702 shows the configuration for Fm+ mode, where the frequency is close to 1 MHz. In this case, the T_{SU_STA} timing requirement is not met because the actual value is 260 ns. Rest of the requirements are met as per the I2C data sheet.

Table 703 shows the configuration for Fm+ mode, where all timing requirements are met. To meet all the timing specifications, frequency may differ from 1 MHz. Use the configurations listed in Table 703.

Table 702. Configuration for Fm+ mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	3	960 kHz	T_{SU_STA} - 228 ns
48 MHz	1	4	3	960 kHz	T_{SU_STA} - 228 ns
133/134 MHz	4	4	3	1.087 MHz	T_{SU_STA} - 156 ns
160 MHz	6	4	3	912 kHz	T_{SU_STA} - 181 ns

Table 703. Configuration for Fm+ mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	3	6	749 kHz	All requirements met as per the I2C data sheet
48 MHz	1	3	6	749 kHz	All requirements met as per the I2C data sheet
133/134 MHz	4	3	6	839 kHz	All requirements met as per the I2C data sheet
160 MHz	6	3	6	713 kHz	All requirements met as per the I2C data sheet

NOTE

The controller module provides an option to slow down the clock for standard speed mode to support legacy I2C standard targets as well (although this option may not necessarily meet the exact timing requirement of the standard mode according to the standard I2C timing specification).

For the timing requirements under consideration, see the "I3C timing requirements when communicating with I2C legacy devices" table in the MIPI I3C v1.1.1 specification available on www.mipi.org.

72.7 I3C register descriptions

Writing to a read-only (RO) register, except to Controller Interrupt Mask (MINTMASKED), causes bus errors. This module does not verify whether programmed values in the registers are correct. You must ensure that valid programmed values are written.

However, the peripheral ignores writes to RO registers and returns 0 for reads from WO or nonexistent registers. It requires all 32-bit registers to be read and written as 32-bit and aligned to 32 bits. The peripheral uses the advanced peripheral bus (APB: AMBA 3 APB Protocol Specification v1.0); therefore, the peripheral does not know whether partial read or write operations (less than 32 bits) are used.

Fields

Field	Function
31-28 I2CBAUD	I2C Baud Rate Specifies the I2C low and high times in ODBAUD counts: • I2CBAUD >> 1 is the main count load, and it is count - 1. So, I2CBAUD >> 1: I2CBAUD = 0 for one ODBAUD beat and I2CBAUD = 1 for two ODBAUD beats.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If I2CBAUD[28] is 1, then the low time has one extra ODBAUD beat. The I2CBAUD field is normally 3, where ODBAUD gives 200 ns. For I2CBAUD >> 1, I2CBAUD = 1, which means two ODBAUD beats. To meet the requirements for Fast-mode Plus (Fm+), (2 + 1) × 200 = 600 ns low, with 2 × 200 = 400 ns high for 1 µs period. For Fast mode (Fm), I2CBAUD is normally 11 (giving 2.6 µs) or 6 (giving 2.4 µs).
27-25 SKEW	Skew Specifies the number of FCLK counts for an SDA change after SCL for I3C push-pull. This skew is in addition to the roundtrip of the SCL line from the pad back to the module (6 ns or more): • SKEW is normally not needed, so assign SKEW = 0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules. Use the following values: • In I2C Controller mode (MCONFIG[MSTENA] = 11b) — SKEW > 0 when clock stretching feature is not required. — SKEW = 0 when clock stretching feature is required. • In I3C Controller mode, use SKEW = 0.
24 ODHPP	Open Drain High Push-Pull Enables ODHPP. If you write 0 to this field, open-drain SCL high half-clock period is the same as the open-drain low SCL half period. If you write 1 to this field, open-drain high SCL half-lock period is one PPBAUD count for I3C messages. This setting is faster and works for I3C devices. Any legacy I2C devices on the bus do not see the SCL high level at all (less than the spike filter period). For open-drain timing, check upon the first 7Eh broadcast allowing I3C peripherals acting as I2C legacy devices to turn off their I2C 50-ns spike filters. See Sending a CCC to I3C targets for more information. 0b - Disable 1b - Enable
23-16 ODBAUD	Open Drain Baud Rate Specifies the open drain baud rate. ODBAUD is configured in terms of number of PPBAUD counts - 1. This field must not be 0; this setting is not the same as push-pull. See Controller configuration for more information. The open-drain baud rate is usually 200 ns (see I2CBAUD for I2C counts). When used with MCONFIG[ODHPP], this setting produces 250 ns per clock in I3C. In this case, if MCONFIG[PPBAUD] provides 12 MHz, then one PPBAUD count is half of 12 MHz, or 41.67 ns. To obtain a rate around 200 ns, use a value of 5 - 1 = 4 for ODBAUD.
15-12 PPLOW	Push-Pull Low Acts as an adder for push-pull low to create a duty cycle with a longer low period, with up to 15 more FCLK cycles low than high. PPLOW = 0 produces a 50/50 duty cycle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 PPBAUD	Push-Pull Baud Rate Specifies the push-pull baud rate. The number of FCLK counts makes each push-pull low and normally high period. PPBAUD = 0 when run at 1/2 input FCLK speed. For example, a 24 MHz FCLK produces a 12 MHz SCL because each FCLK is SCL low or SCL high. MCONFIG[PPLOW] has an effect on the duty cycle. For example, 24 MHz with 50/50 duty cycle is 12 MHz. However, when PPLOW adds three more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz or 5 beats).
7 —	Reserved
6 ODSTOP	Open Drain Stop Enables open-drain stop. If you write 0 to this field, open-drain stop is disabled. ODSTOP must be disabled when sending an HDR exit pattern. If you write 1 to this field, open-drain stop is enabled. STOP condition is emitted at open-drain speeds even for I3C messages. In legacy devices, this feature can ensure that the legacy devices see the STOP condition. 0b - Disable 1b - Enable
5-4 HKEEP	High-Keeper Indicates how High-Keeper is supported. If this field is 0b, use pull-up resistor (PUR). No separate pin_HK_SDA or pin_HK_SCL is used. Only pin_PUR_oena is used for SDA. The pin_SCL_oena pin is held high in this mode, SCL clock is push-pull, and pin_SCL_out toggles, which is the actual clock. If this field is 1b, High-Keeper controls are in place; pin_HK_SDA or pin_HK_SCL (High-Keeper) controls are used. SCL may use an HK or that signal (pin_HK_SCL) may only OR into pin_SCL_oena. The pin_HK_SDA pin is used as well for SDA high keeper, along with pin_PUR_oena. If this field is 10b, the functionality is passive on SDA, can Hi-Z (high-impedance) for bus free (Idle) and hold. The pins, pin_HK_SDA and pin_HK_SCL, are not used; only a combination of SDA_oena and pin_PUR_oena are used. If this field is 11b, the functionality is passive on SDA and SCL, can Hi-Z (high-impedance) both for bus free (Idle), and can Hi-Z SDA for hold. This is for I2C Clock Stretching mode, where both SCL and SDA are open drain. Use HKEEP = 2/3 for I2C modes. Use HKEEP = 0/1 for I3C modes. **NOTE** Your chip may not support any or all High-Keeper methods. You must check the availability of High-Keeper methods. 00b - None

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - WIRED_IN 10b - PASSIVE_SDA 11b - PASSIVE_ON_SDA_SCL
3 DISTO	Disable Timeout Disables the timeout that produces application errors. If the controller is left in a state other than Stopped for more than 100 µs (because 10 kHz is the slowest allowed I3C speed), the timeout sends a MERRWARN interrupt. To prevent the MERRWARN interrupt during development or testing, write 1 to DISTO to disable the timeout. In systems that support timeouts, timeout is disabled automatically during debug. 0b - Enabled 1b - Disabled, if configured
2 —	Reserved
1-0 MSTENA	Controller Enable Indicates whether the controller is enabled and the states it can use. If this field is 0b, the controller is disabled. The module can only use Target mode. If this field is 1b, the controller is enabled. When used upon start-up, this module is the main controller by default. I3C controls the bus unless the controller is handed off. When this happens, MSTENA must become 2 so that it has the capability to become the controller again. Performing the handoff means emitting the GETACCMST CCC command. If the command is accepted, I3C emits a STOP condition and sets this field to 2 (or 0). If this field is 10b, I3C is controller-capable, but is operating as a target now. When used from the start, I3C starts as a target, but is prepared to switch to Controller mode. To switch to this mode, the target emits a controller request (CR) or receives a GETACCMST CCC command and accepts it (to switch on the STOP condition). Legacy I2C—if this field is 11b, I2C Controller mode uses an open-drain clock (to allow clock stretching) and relies on passive pull-up resistors (PURs) on both SCL and SDA. This mode uses only I2CBAUD. START requests can only be made for I2C type, and I3C requests are not accepted. If there are only I2C targets on the bus and no clock stretching, use type 1 instead. Type 1 has a push-pull SCL clock, which is faster and uses less power. 00b - CONTROLLER_OFF 01b - CONTROLLER_ON 10b - CONTROLLER_CAPABLE 11b - I2C_CONTROLLER_MODE

72.7.3 Target Configuration (SCONFIG)

Offset

Register	Offset
SCONFIG	4h

Function

Contains fields that must be configured before the module is activated.

Field	Function
31-25 SADDR	Static Address Sets the I2C 7-bit static address, which otherwise must be 0.
24 —	Reserved
23-16 BAMATCH	Bus Available Match Specifies the bus available condition match value for the current slow clock. BAMATCH provides the count of the slow clock to count out 1 µs (or more) to allow an IBI to drive SDA low when the controller is not doing so. I3C controls the maximum width and maximum values.
15-12 —	Reserved
11-10 —	Reserved
9	Offline

Table continues on the next page...

Table continued from the previous page...

Field	Function
OFFLINE	Enables wait to ensure that the bus is not in HDR mode. If this field is 1 when SCONFIG[SLVENA] is 1, then I3C waits for either 60 µs of bus quiet or an HDR exit pattern. This waiting ensures that the bus is not in HDR mode, and so can safely monitor the next activity in Single Data Rate (SDR) mode. 0b - Disable 1b - Enable
8 IDRAND	ID random Specifies whether SIDPARTNO[PARTNO] is a random value. 0b - Part number and an instance 1b - Random value
7 —	Reserved
6-5 —	Reserved
4 DDROK	Double Data Rate OK Allows HDR-DDR messaging. If DDROK = 1, write 1 to the corresponding SIDEXT[BCR] field to indicate that high data rate (HDR) is available, and configure the corresponding HDRCAP HDR-DDR field to allow using DDR mode. **NOTE** DDROK must be 1 before the target can connect to the I3C bus. The target peripheral indicates to the controller whether the target can support the feature during dynamic address assignment. 0b - Do not allow HDR-DDR messaging 1b - Allow HDR-DDR messaging
3 S0IGNORE	Ignore TE0 or TE1 Errors Ignores TE0 or TE1 errors. If you write 1 to this field, the target does not detect TE0 or TE1 errors, so it does not lock up waiting on an exit pattern. You must not use this setting when the bus does not use HDR mode. 0b - Do not ignore TE0 or TE1 errors 1b - Ignore TE0 or TE1 errors
2 MATCHSS	Match Start or Stop Enables match START or STOP condition. If you write 1 to this field, SINTSET[START] and SINTSET[STOP] become 1 only when SSTATUS[MATCHED] is 1. This setting allows the START and STOP fields to be used to detect the end of a message to or from this target.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
1 NACK	Not Acknowledge Controls the ACK or NACK capability. If you write 1 to this field, the target rejects all requests, except for a CCC broadcast. NACK = 1 must be used with caution because the controller may decide that the target is missing, if NACK is overused. 0b - Always disable NACK mode 1b - Always enable NACK mode (works normally)
0 SLVENA	Target Enable Enables the target. If you write 0 to this field, the target ignores the I2C or I3C bus. If you write 1 to this field, the target can operate on the I2C or I3C bus. You must not write 1 to this field before registers such as Target Configuration (SCONFIG), Target ID Part Number (SIDPARTNO), Target ID Extension (SIDEXT), and others are configured because these registers affect the data to and from the controller. Target enable is configured just once before the bus comes up. If target enable is used at other times, SCAPABILITIES[IBI_MR_HJ] must be 1 before writing 1 to SLVENA so that the device does not see a START or STOP condition incorrectly. 0b - Disable 1b - Enable

72.7.4 Target Status (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Indicates the sticky status for interrupts, states, and modes related to the I3C bus. Not all fields of the register are used if the module only acts as a target. The fields are divided into current activity, interrupt maskable actions, and then states and modes on the bus.

Diagram

Fields

Field	Function
31-30 TIMECTRL	Time Control Indicates whether time control is enabled, and in which mode. 00b - NO_TIME_CONTROL (no time control is enabled) 01b - SYNC_MODE (Synchronous mode is enabled) 10b - ASYNC_MODE (Asynchronous standard mode (0 or 1) is enabled) 11b - BOTHSYNCASYNC (both Synchronous and Asynchronous modes are enabled)
29-28 ACTSTATE	Activity State from Common Command Codes (CCC) Indicates the activity state from CCC. 00b - NO_LATENCY (normal bus operations) 01b - LATENCY_1MS (1 ms of latency) 10b - LATENCY_100MS (100 ms of latency) 11b - LATENCY_10S (10 seconds of latency)
27 HJDIS	Hot-Join Disabled Indicates whether hot-join is disabled. When hot-join is disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
26 —	Reserved
25 MRDIS	Controller Requests Disable Indicates whether controller requests are disabled. When controller requests are disabled, CTRL requests are not responded to.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
24 IBIDIS	In-Band Interrupts Disable Indicates whether in-band interrupts are disabled. When in-band interrupts are disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
23-22 —	Reserved
21-20 EVDET	Event Details Indicates current details of the last (EVENT = 1) or pending event. 00b - NONE (no event or no pending event) 01b - NO_REQUEST (request is not sent yet; either there is no START condition yet, or is waiting for Bus-Available or Bus-Idle (HJ)) 10b - NACKed (not acknowledged, request sent and rejected); I3C tries again 11b - ACKed (acknowledged; request sent and accepted), so done (unless the time control data is still being sent)
19 —	Reserved
18 EVENT	Event Indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. See the upper status register fields for details. This field becomes 1 only when acknowledged by a controller. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No event occurred 1b - IBI, CR, or HJ occurred When writing 0b - No effect 1b - Clear the flag
17 CHANDLED	Common Command Code Handled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether an HDRMATCH CCC is being handled by I3C. This field is for notification only, but it may result in updates to this register. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC handling not in progress 1b - CCC handling in progress When writing 0b - No effect 1b - Clear the flag
16 HDRMATCH	High Data Rate Command Match Indicates whether the HDR command matched the I3C dynamic address of this device. The HDR command is available as the first byte, with RXPEND = 1. The MSB of the command byte indicates whether it is a read or a write command. If the HDR command is a read, and there are to-bus bytes waiting, then the command is ACKed and the data is sent back. Otherwise, the HDR command is NACKed. **NOTE** When this field is 1, you must check SSTATUS[ERRWARN] because the HPAR error may occur after signaling this HDR command. The parity occurs after the destination address and command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not match 1b - Matched the I3C dynamic address When writing 0b - No effect 1b - Clear the flag
15 ERRWARN	Error Warning Indicates that an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition (see Target Errors and Warnings (SERRWARN) for more information).
14 CCC	Common Command Code Indicates whether a CCC has been received, and is not handled by I3C. There are two types of common command codes: • Broadcast CCC, which corresponds with RXPEND, and the first byte is the CCC (command).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Direct CCC, which may never be directed to this device. If the direct CCC is directed to this device, then TXSEND or RXPEND are triggered, and RXPEND contains the command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC not received 1b - CCC received When writing 0b - No effect 1b - Clear the flag
13 DACHG	Dynamic Address Change Indicates an occurrence of dynamic address (DA) change. Actual DA can be seen in the DYNADDR register. If this field is 1, DA change is detected. The target DA has been assigned, reassigned, or reset (lost) and is now in the state of being valid or none. This field is also used when the MAP auto feature is configured, changing one or more MAP items. See DYNADDR and MAPCTRL*n* for more information. DYNAADDR for the main DA (0) indicates whether the last change was because of Auto-MAP. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No DA change detected 1b - DA change detected When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	Transmit Buffer Not Full Indicates that the transmit buffer is not full. If DMA is enabled for transmitting, then it is also signaled to provide more data. To-bus buffer or FIFO can accept more data to be transmitted. For all but external FIFOs, this process uses SDATACTRL[TXTRIG], which defaults to "not full". 0b - Transmit buffer full 1b - Transmit buffer not full
11 RX_PEND	Received Message Pending Indicates whether a received message is pending. The field indicates when a message from the controller that is not being handled by I3C (not a CCC message) is received. I3C processes such messages internally. For all but external FIFOs, this process uses SDATACTRL[RXTRIG], which

Table continues on the next page...

Table continued from the previous page...

Field	Function
	defaults to "not empty". If DMA is enabled for receiving, then DMA is signaled as well. This field automatically becomes 0 if data is read (from FIFO and non-FIFO sources). 0b - No received message pending 1b - Received message pending
10 STOP	Stop Indicates whether the Stopped state is detected. The STNOTSTOP state also indicates when the module is in Stop mode. A fast STOP and START combination may not trigger the Stop status. In that case, the Start status is always set. If this field is 1, it indicates that the Stop state was present on the bus since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stopped state detected 1b - Stopped state detected When writing 0b - No effect 1b - Clear the flag
9 MATCHED	Matched Indicates whether an incoming header matched the I3C dynamic or I2C static address (if any) of this device since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Header not matched 1b - Header matched When writing 0b - No effect 1b - Clear the flag
8 START	Start Indicates whether a START or Repeated START was detected after this flag was last cleared. This flag is not usually needed, but can be used for wake events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 STHDR	Status High Data Rate Indicates whether the I3C bus is in HDR-DDR mode, regardless of whether HDR mode is supported by this module, and regardless of whether the message is intended for this module or some other module. 0b - I3C bus not in HDR-DDR mode 1b - I3C bus in HDR-DDR mode
5 STDAA	Status Dynamic Address Assignment Indicates whether the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus target has a dynamic address. 0b - Not in ENTDAA mode 1b - In ENTDAA mode
4 STREQWR	Status Request Write Indicates whether the REQ in process is SDR write data from the controller to this bus target (or all targets), but not in ENTDAA mode. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR write 1b - SDR write data from the controller, but not in ENTDAA mode
3 STREQRD	Status Request Read Indicates whether the REQ in process is an SDR read from this target. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR read 1b - SDR read from this target or an IBI is being pushed out
2	Status Common Command Code Handler

Table continues on the next page...

Table continued from the previous page...

Field	Function
STCCCH	Indicates whether a CCC message is being handled automatically. 0b - No CCC message handled 1b - Handled automatically
1 STMSG	Status Message Indicates whether the bus target is busy (listening to the bus traffic or responding). If STNOSTOP = 1, STMSG is 0 when a nonmatching address is seen, until the next Repeated START or STOP condition occurs. 0b - Idle 1b - Busy
0 STNOTSTOP	Status not Stop Indicates the status of the bus. If this field is 0, I3C is in a STOP condition. If this field is 1, the bus is busy (has activity). Other fields of this register may also be set when busy. STNOTSTOP can also become 1 after a TE0 or TE1 error, when I3C is waiting for an exit pattern. 0b - In STOP condition 1b - Busy

72.7.5 Target Control (SCTRL)

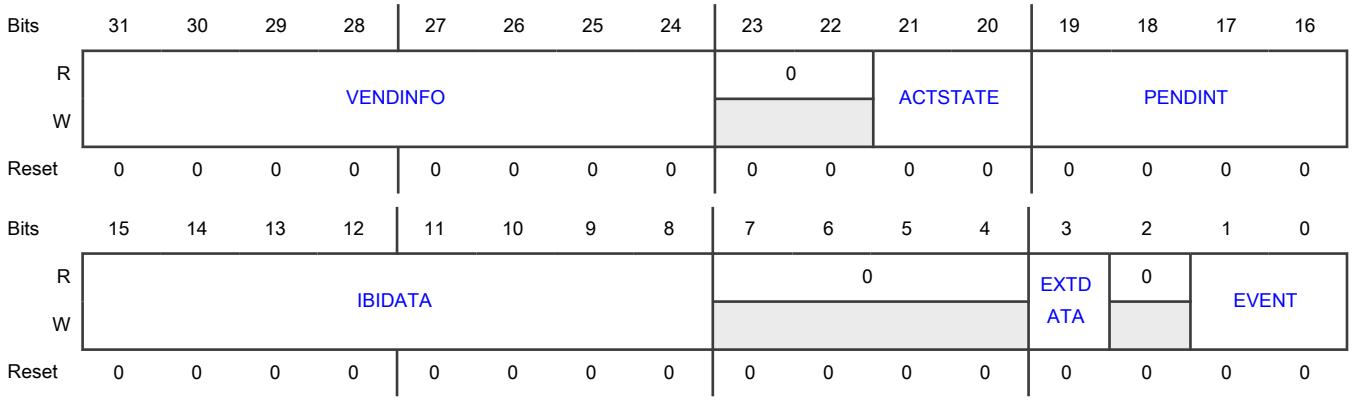
Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus (for example, event generation such as interrupts to the controller). Only if I3C is configured to support various special operations for the target, this register is used to activate those operations. These events include IBI and GETSTATUS fields (except the protocol error, which is automatically set).

Diagram



Fields

Field	Function
31-24 VENDINFO	Vendor Information Controls vendor information that the GETSTATUS CCC returns. You must set this field to the Vendor Reserved field that the GETSTATUS CCC returns. The application must maintain the vendor information because the controller reads this field. If this field is not configured, then the GETSTATUS field always returns 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity State of Target Controls the activity state of the target. You must set this field to the activity state of the target that the GETSTATUS CCC command returns as activity mode. The application must maintain the activity state because the controller reads this field. If you do not configure the activity state, then the GETSTATUS command always returns 0.
19-16 PENDINT	Pending Interrupt Specifies whether an IBI interrupt is pending. You must set this field to the pending interrupt that the GETSTATUS CCC command returns. The application must maintain the pending interrupt because the controller reads this field. If PENDINT = 0: • The GETSTATUS command returns 1 if an IBI interrupt is pending. • The GETSTATUS field returns 0 if an IBI interrupt is not pending.
15-8 IBIDATA	In-Band Interrupt Data Controls the data byte accompanying the IBI, if the module is enabled for IBI. If SCTRL[IBIDATA] is enabled, then IBI is required.
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 EXTDATA	Extended Data Enables extended data. After IBIDATA is emitted, extended data is acquired from IBIEXT1 and IBIEXT2, if configured. If extended data is used with time control, the data follows the time information. See IBIEXT1[MAX] for more information. 0b - Disable 1b - Enable
2 —	Reserved
1-0 EVENT	Event Requests an event. If this field is 0b, it indicates Normal mode, in which if this field becomes 0 from a nonzero value and event processing has not yet started, the event processing is canceled. However, event processing is not canceled if it has already started. If this field is 1b, an IBI is pushed onto the I3C bus. If there is data associated with the IBI, the data is read from SCTRL[IBIDATA]. If time control is enabled, this data includes any time-control-related bytes. Additionally, SCTRL[IBIDATA][7] becomes 1 automatically (as is required for time control). The IBI interrupt occurs after the first (mandatory) IBIDATA, if any. If this field is 10b, a controller request is started; the meaning depends on SIDEXT[BCR] configured in I3C. If this field is 11b, a hot-join (HJ) request is started, which is used when the device is powered on after the I3C bus is already powered up. It is also used when the device is connected using hot-insertion methods (the device is powered up when it is physically inserted in the powered-up I3C bus). The HJ waits for Bus Idle, and SCTRL[EVENT] = HOT_JOIN_REQUEST must be set before the target enable (SCONFIG[SLVENA]). If this field is a nonzero value, it requests an event. After the request, SSTATUS[EVENT] and SSTATUS[EVDET] show the status as it progresses. After completion, this field automatically returns to 0. After this field becomes a nonzero value, you can write only 0 it (to cancel) until the event processing is finished. 00b - NORMAL_MODE 01b - IBI 10b - CONTROLLER_REQUEST 11b - HOT_JOIN_REQUEST

72.7.6 Target Interrupt Set (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

Sets interrupt enables for select Target Status (SSTATUS) fields. Reading this register (SINTSET) returns the status of the interrupt enable:

- To activate an interrupt enable, write 1 to its corresponding field in this register (SINTSET).
- To disable an interrupt, write 1 to its corresponding field in Target Interrupt Clear (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow the masking of interrupt sources. They also allow the checking of which interrupts are activated. The normal method is to enable an interrupt, and then after the interrupt occurs, clear the interrupt either by writing to Target Status (SSTATUS) or by performing an action on the corresponding data register. The interrupt is level-held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races; if a new event occurs, that new event is not lost:

- SINTSET sets interrupt enables for Target Status (SSTATUS) fields. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for the SSTATUS fields.
- SINTMASKED returns the value of the SSTATUS fields ANDed with their interrupt enables.

Diagram

Fields

Field	Function
31-20 —	Reserved
19 —	Reserved
18 EVENT	Event Interrupt Enable Enables event interrupts. This field indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. The field is configured to support events. See SSTATUS[EVDET] for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
17 CHANDLED	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field specifies whether CCC is being handled by I3C. Target Status (SSTATUS) shows new results. You can use this field to track when activity states and masks on events (for example, IBIs) occur. The field is used for CCCs that are enabled. 0b - Disable 1b - Enable
16 DDRMATCHED	Double Data Rate Interrupt Enable Enables DDR match for read or write command. This field indicates when DDR matches for read or write command, and the field is used only if HDR is enabled. 0b - Disable 1b - Enable
15 ERRWARN	Error or Warning Interrupt Enable Enables error or warning interrupts. This field indicates whether an error or warning has occurred, such as data underrun, data overrun, parity error, or HDR-DDR CRC error, or any other error or warning condition. See Target Errors and Warnings (SERRWARN) for cause of error. Only available for errors related to configured features. 0b - Disable 1b - Enable
14 CCC	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field indicates whether a CCC has been received, and is not handled by I3C. For CCCs that the block does not handle, RXPEND also interrupts, and SSTATUS[STREQRD] indicates that it is a CCC sending a read request. 0b - Disable 1b - Enable
13 DACHG	Dynamic Address Change Interrupt Enable Enables dynamic address change interrupts: interrupt on dynamic address defined (SETDASA or ENTDAA) or lost (RSTDAA). See Controller Dynamic Address (MDYNADDR) for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 TXSEND	Transmit Interrupt Enable Enables transmit interrupts. This field indicates whether to-bus buffer or FIFO can accept more data to be transmitted. The corresponding interrupt occurs when the controller requests data to read from this target. This interrupt occurs on the first request (header) as well as when ready for more data. The corresponding interrupt occurs when the controller requests data to be read from this target. If this interrupt is for a FIFO, it triggers on the transmit emptiness trigger. If this interrupt is for DMA, then it indicates message end (DMA end or termination). 0b - Disable 1b - Enable
11 RXPEND	Receive Interrupt Enable Enables receive interrupts. This field specifies when a message from the controller that is not being handled by the module is received. For example, where data is consumed by hardware directly when it goes into the FIFO (excludes CCCs being handled automatically). If this interrupt is for a FIFO, it indicates a receive fullness trigger. If this interrupt is for DMA, then it indicates message end. 0b - Disable 1b - Enable
10 STOP	Stop Interrupt Enable Enables stop interrupts. This field detects the Stopped state present on the bus since the bus was last cleared. Use SINTSET[START] as the preferred interrupt when needed. This interrupt may not trigger for a quick STOP and START combination because it relates to the state of being stopped. 0b - Disable 1b - Enable
9 MATCHED	Match Interrupt Enable Enables match interrupts. Incoming header matched the I3C dynamic or I2C static address of this device since the bus was last cleared. If configured and if no dynamic address is set, this interrupt is also for matching a header on an I2C static address. See Controller Dynamic Address (MDYNADDR) for related information. 0b - Disable 1b - Enable
8	Start Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
START	Enables start interrupts. A START or Repeated START (such as wakeup) is seen after this field last became 0. See SINTSET[STOP] for related information. 0b - Disable 1b - Enable
7-0 —	Reserved

72.7.7 Target Interrupt Clear (SINTCLR)

Offset

Register	Offset
SINTCLR	14h

Function

Clears interrupt enables for select Target Status (SSTATUS) fields. To clear an interrupt enable, write 1 to the corresponding field in this register (SINTCLR). Writing 0 has no effect.

Diagram

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20-18 —	Reserved
17 OWRITE	Over-Write Error Indicates that Target Write Data Byte (SWDATAB) or Target Write Data Byte End (SWDATABE) was written to when full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overwrite error 1b - Overwrite error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Over-Read Error Indicates that Target Read Data Byte (SRDATAB) was read for more bytes than were available, by the application. This field also indicates over-read errors for Target Read Data Halfword (SRDATAH), if it is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No over-read error 1b - Over-read error When writing 0b - No effect 1b - Clear the flag
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 S0S1	TE0 or TE1 Error Indicates whether a TE0 or TE1 error occurred and the target is locked and waiting for an HDR exit pattern. Writing 1 to S0S1 causes I3C to release the lock, but this method must be used with great care. S0S1 becomes 0 automatically when an exit pattern is detected, so writing 1 to S0S1 must be used under controlled circumstances to avoid problems. Before starting to operate normally after this error, I3C waits for a START (or Repeated START) or STOP state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No TE0 or TE1 error occurred 1b - TE0 or TE1 error occurred When writing 0b - No effect 1b - Clear the flag
10 HCRC	HDR-DDR CRC Error Indicates whether an HDR-DDR CRC error occurred on a message from the controller. Error reasons include an HDR restart and an exit being issued before an HDR-DDR message from the controller has finished. This error calls into question the data from the entire DDR command frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No HDR-DDR CRC error occurred 1b - HDR-DDR CRC error occurred When writing 0b - No effect 1b - Clear the flag
9 HPAR	HDR Parity Error Indicates when an HDR parity error or framing error on a message from the controller occurs. The corresponding command or data that has the error is usually in the RX buffer, which can be read using Target Read Data Byte (SRDATAB). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No HDR parity error 1b - HDR parity error When writing 0b - No effect 1b - Clear the flag
8 SPAR	SDR Parity Error Indicates when an SDR parity error on a message from the controller occurs. This error also sets the GETSTATUS protocol error field (which becomes 0 after a GETSTATUS read). For read operations, this field becomes 1 when a read abort (timeout) occurs because of the controller not driving clock for more than 100 µs during an SDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No SDR parity error 1b - SDR parity error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 INVSTART	Invalid Start Error Indicates an invalid condition with SCL falling before SDA falls, so there is no start. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No invalid start error 1b - Invalid start error When writing 0b - No effect 1b - Clear the flag
3 TERM	Terminated Error Indicates when the controller terminates a read from a target, if an END is not set by the target (on the same read or the previous read). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No terminated error 1b - Terminated error When writing 0b - No effect 1b - Clear the flag
2 URUNNACK	Underrun and Not Acknowledged (NACKed) Error Indicates when the internal to-bus buffer or FIFO is underrun in the read header and so the module NACKed the header. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun; not acknowledged error 1b - Underrun; not acknowledged error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Indicates when the internal to-bus buffer or FIFO is underrun during data read (the application is not providing the data fast enough). The END field or register must be used if the read was the last one. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun error 1b - Underrun error When writing 0b - No effect 1b - Clear the flag
0 ORUN	Overrun Error Indicates when the internal from-bus buffer or FIFO has overrun (arrival of too many characters that you cannot process fast enough). Cutting off the RX_FIFO too close to the boundary when DUT is a target for SDR write or HDR-DDR write can cause an ORUN error when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun error 1b - Overrun error When writing 0b - No effect 1b - Clear the flag

72.7.10 Target DMA Control (SDMACTRL)

Offset

Register	Offset
SDMACTRL	20h

Function

Allows DMA to be used for inbound and outbound messages. This register is limited in value for target use because the target must be reactive. These are the two common use case models:

- To avoid an overrun in from-bus collection: if SCONFIG[MATCHSS] becomes 1, then the processor enables the interrupts for START and STOP and enables the DMA to collect the data. The START or STOP interrupt only occurs after a message is directed to the target (MATCHED is 1). The DMA copied data can then be examined.

  NOTE

  Do not enable DMA after a transaction starts. To avoid an RX FIFO overrun, DMA must be enabled only when enabling the target and interrupts.

- To perform larger reads from the to-bus: I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the target). Because of this process, the DMA can be used to push through the data:
  - For I3C, the processor must manage the last value, unless the DMA moves wider words and is able to write 1 to the END field. These values are 16-bit values when in Byte mode or 32-bit values when in Halfword mode.
  - For I2C, the controller determines the last value, so the DMA may end early or run out when the controller expects more values.

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	Width of DMA Operations Indicates the width of DMA operations, if configured to allow halfword data accesses. 00b,01b - Byte 10b - Halfword (16 bits) (this value ensures that two bytes are available in the FIFO) 11b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-2 DMATB	DMA Write (To-Bus) Trigger Enables DMA writes. If this field is enabled, it starts a request DMA on a transmit trigger (see Target Data Control (SDATACTRL)). DMATB requests until full, unless the DMA is set up as a trigger. DMATB becomes 0 when MSTATUS[ERRWARN] becomes 1. If you write 1b to this field, DMA is enabled for one frame (ended by DMA or terminated). DMATB automatically becomes 0 after a STOP or START. See SCONFIG[MATCHSS] for more information. If you write 10b to this field, DMA is enabled until turned off. The value must only be used with Controller Message mode. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off 11b - Reserved
1-0 DMAFB	DMA Read (From-Bus) Trigger Enables DMA reads. If this field is enabled, DMAFB requests DMA on receive trigger (see SDATACTRL). It requests until empty, unless the DMA is set up as a trigger. This field becomes 0 when SSTATUS[ERRWARN] becomes 1. If this field is 1b (DMA is enabled for one frame), it automatically becomes 0 on STOP or Repeated START. See SCONFIG[MATCHSS] for more information. **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the target and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off 11b - Reserved

72.7.11 Target Data Control (SDATACTRL)

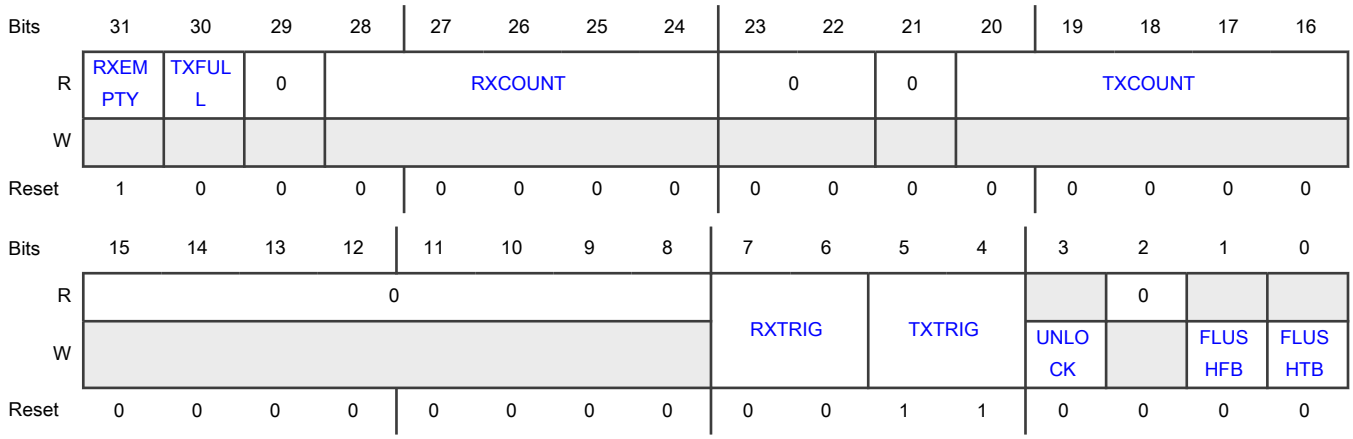
Offset

Register	Offset
SDATACTRL	2Ch

Function

Assists in data control when no FIFO is used. Also assists in data control of FIFO when the FIFO is available (regardless of size) allowing some control over the FIFO behavior. This register controls when to interrupt based on fullness or emptiness of a buffer or FIFO. It also controls behavior related to width, when the buffer or FIFO is not 1 byte wide.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Count of Bytes in Receive
23-22 —	Reserved
21 —	Reserved
20-16 TXCOUNT	Count of Bytes in Transmit
15-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. The field affects the RXPEND interrupt. 00b - Trigger when not empty 01b - Trigger when 1/4 or more full 10b - Trigger when 1/2 or more full 11b - Trigger when 3/4 or more full
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. The field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Default (trigger when 1 less than full or less)
3 UNLOCK	Unlock Indicates whether the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 in the same cycle while writing to TXTRIG or RXTRIG. 0b - Cannot be changed 1b - Can be changed
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Not normally used.
0 FLUSHTB	Flush To-Bus Buffer or FIFO Indicates when the controller terminates a to-bus (read) message prematurely.

72.7.12 Target Write Data Byte (SWDATAB)

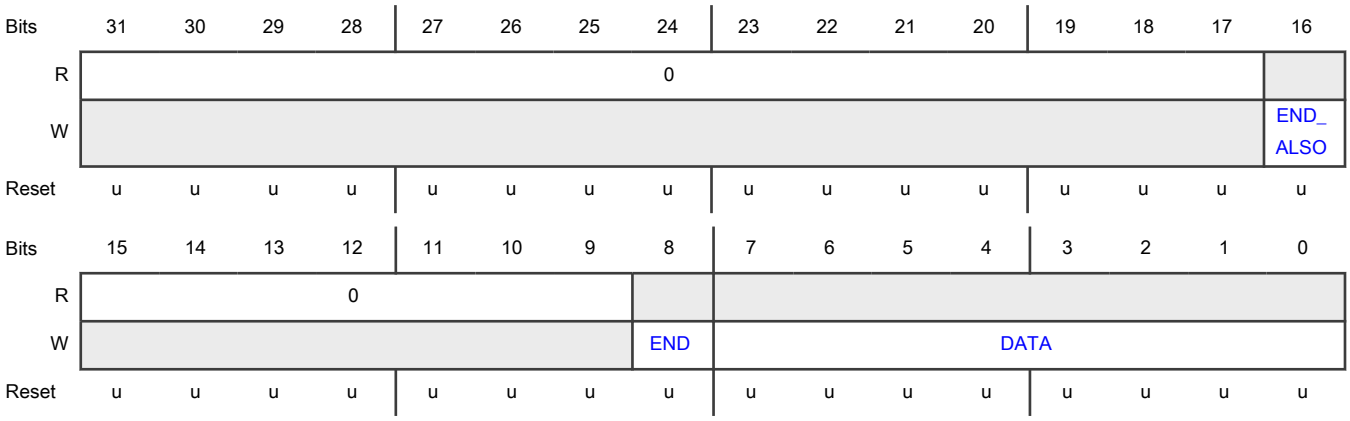
Offset

Register	Offset
SWDATAB	30h

Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used. Writing a byte requires a byte plus an end-of-data (last) marker bit. A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End Also Marks the last byte of the message. This field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End Marks the last byte of the message. If this field is 0, it indicates that there are more bytes in the message. This field is required for I3C, but is optional for I2C. For HDR-DDR, the byte with END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
7-0 DATA	Data Indicates the data byte to be sent to the controller.

72.7.13 Target Write Data Byte End (SWDATABE)

Offset

Register	Offset
SWDATABE	34h

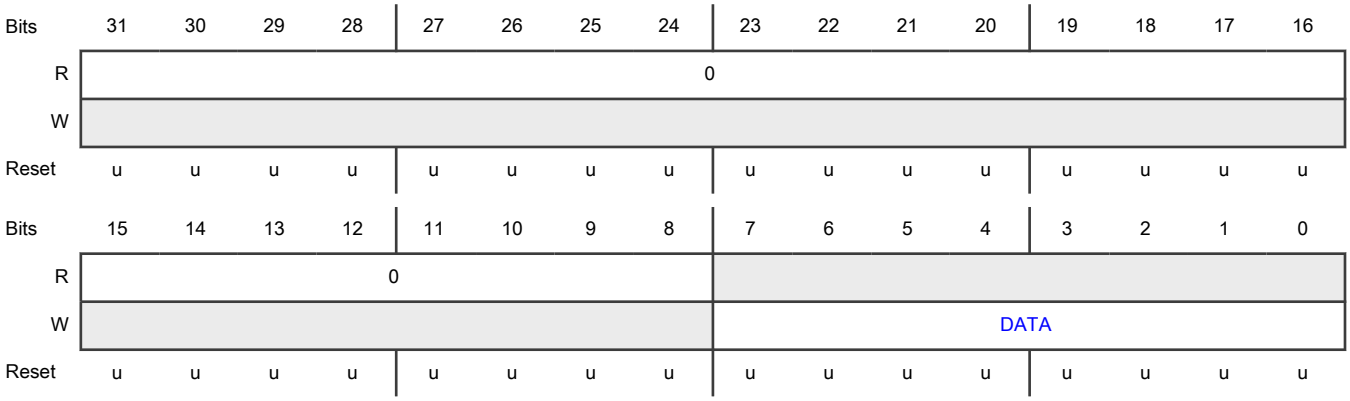
Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used.

Unlike Target Write Data Byte (SWDATAB), writing a byte only requires the byte itself, and is marked as end-of-data (last byte). A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the data byte to be sent to the controller.

72.7.14 Target Write Data Halfword (SWDATAH)

Offset

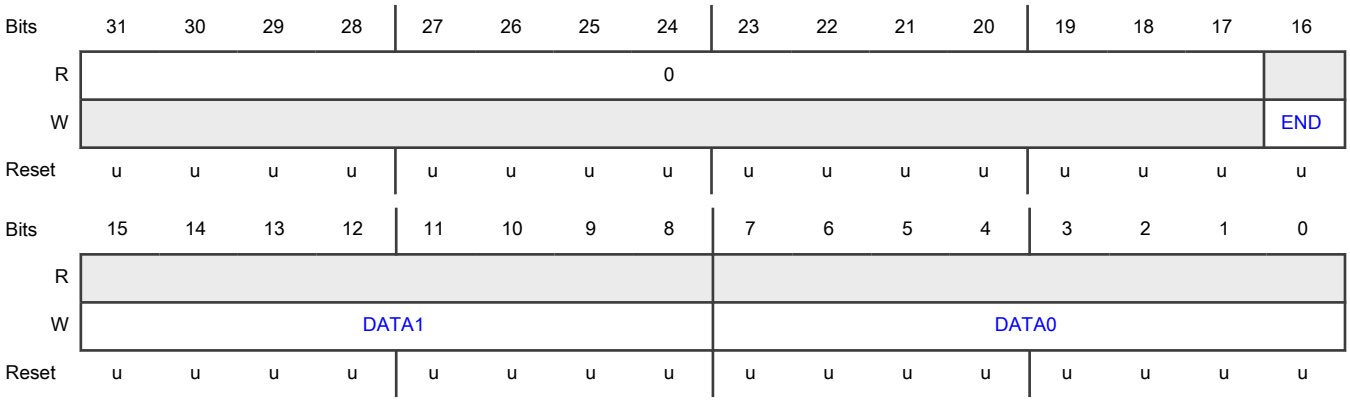
Register	Offset
SWDATAH	38h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used. The low byte is followed by the high byte. The 16th bit marks the end; that is, the last byte of the halfword is the end.

An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Marks the last byte of the message. This field always marks DATA1 as the end. The field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

72.7.15 Target Write Data Halfword End (SWDATAHE)

Offset

Register	Offset
SWDATAHE	3Ch

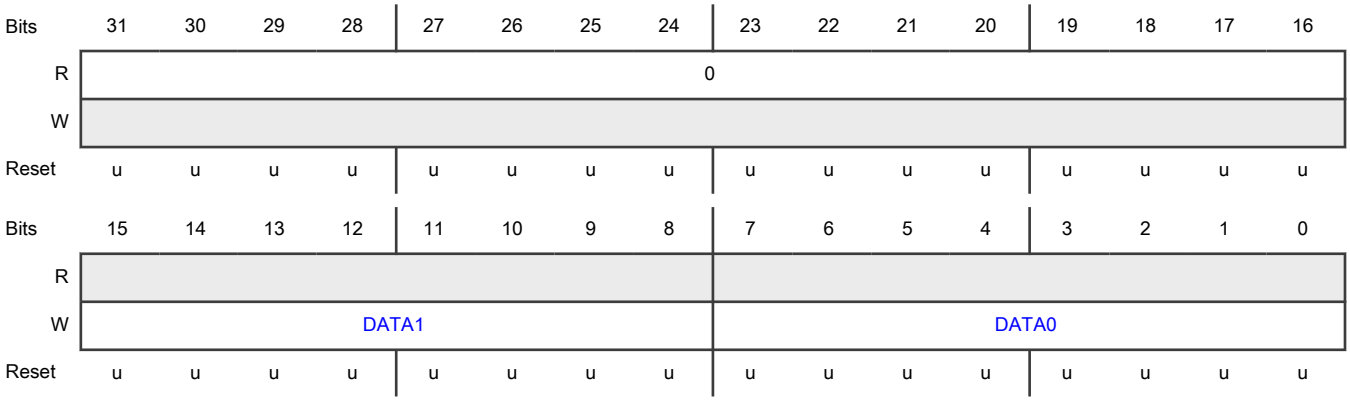
Function

Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way it writes to Target Write Data Halfword (SWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

72.7.16 Target Read Data Byte (SRDATAB)

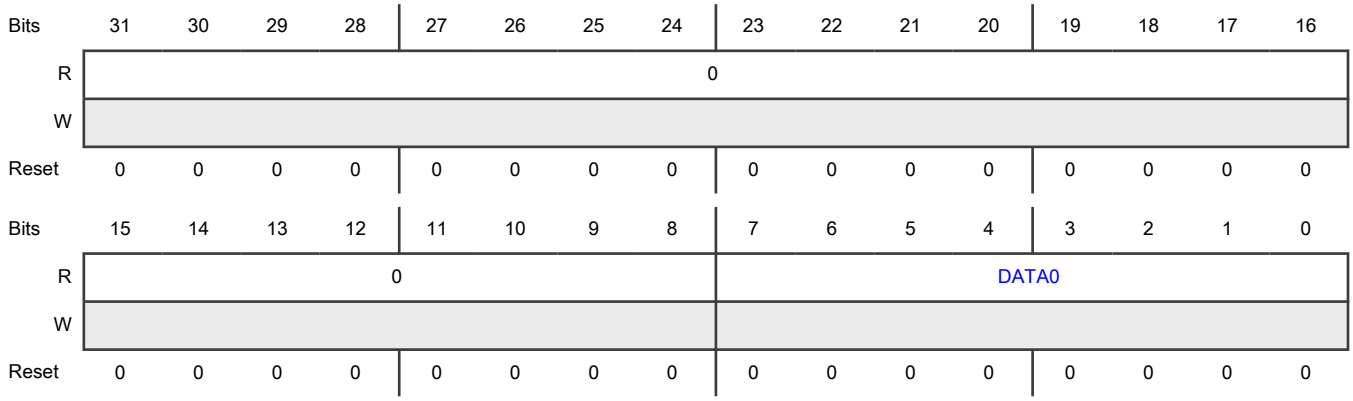
Offset

Register	Offset
SRDATAB	40h

Function

Allows reading a byte from the bus (controller). A byte must not be read unless there is data waiting, as indicated by SSTATUS[RX_PEND] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Data 0 Indicates the byte read from the controller.

72.7.17 Target Read Data Halfword (SRDATAH)

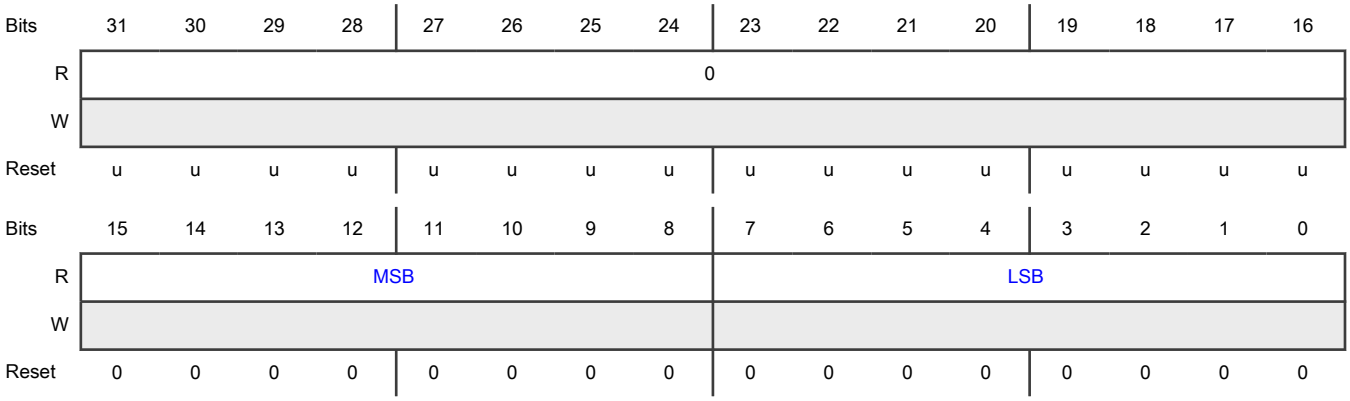
Offset

Register	Offset
SRDATAH	48h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the use of receive FIFO level trigger or SDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Indicates the second byte read from the target.
7-0 LSB	Low Byte Indicates the first byte read from the target.

72.7.18 Target Write Data Byte (SWDATAB1)

Offset

Register	Offset
SWDATAB1	54h

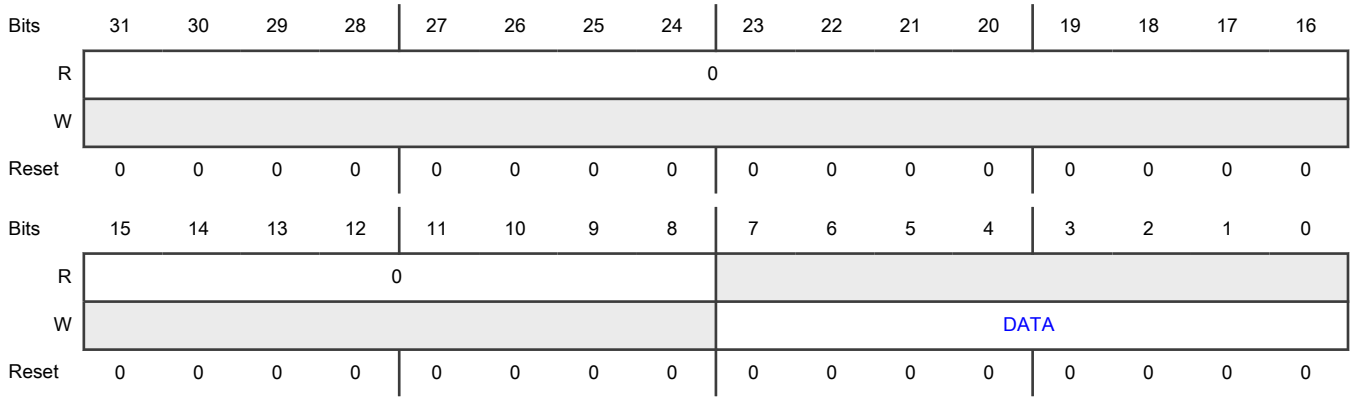
Function

Allows writing a single byte to the bus (to the controller) in a way that only bits 7:0 are used.

This register is intended to be used by DMAs (the upper bytes of the APB word are ignored).

A byte must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the byte to be sent to the controller.

72.7.19 Target Capabilities 2 (SCAPABILITIES2)

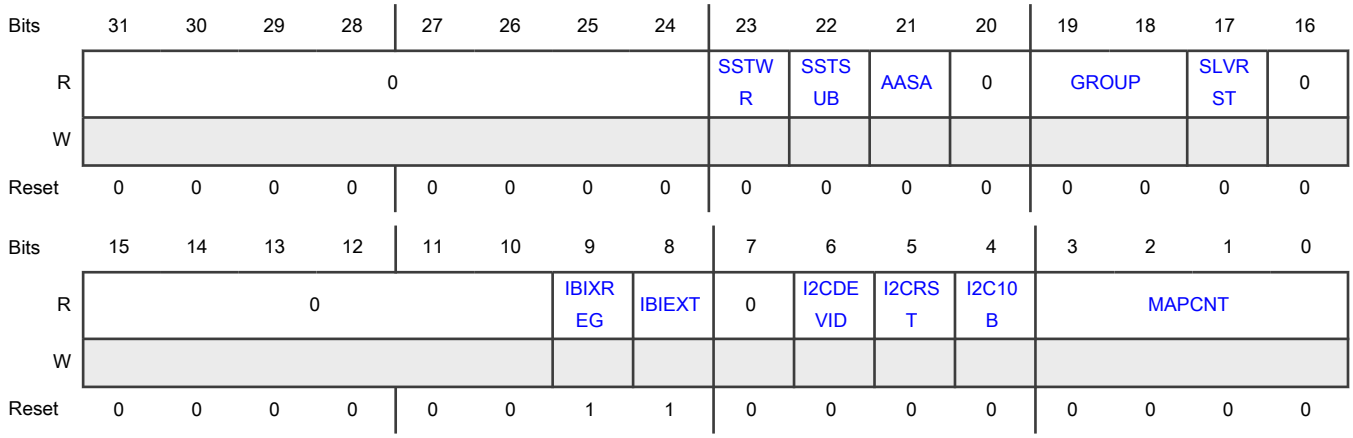
Offset

Register	Offset
SCAPABILITIES2	5Ch

Function

Indicates which features are available and supported in this module, including controller and target capabilities, HDR modes, and others.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SSTWR	Target-Target(s)-Tunnel Write Capable Indicates whether target-target(s)-tunnel is write capable. 0b - Not write capable 1b - Write capable
22 SSTSUB	Target-Target(s)-Tunnel Subscriber Capable Indicates whether target-target(s)-tunnel is subscriber capable. 0b - Not subscriber capable 1b - Subscriber capable
21 AASA	SETAASA Supports the set static address as dynamic address CCC (SETAASA) feature. 0b - SETAASA not supported 1b - SETAASA supported
20 —	Reserved
19-18 GROUP	Group Indicates whether v1.1 group addressing is supported. Groups use mapping, so MAPCNT must be the same or greater than GROUP. 00b - v1.1 group addressing not supported 01b - One group supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Two groups supported 11b - Three groups supported
17 SLVRST	Target Reset Indicates whether v1.1 target reset is supported. 0b - Not supported 1b - Supported
16 —	Reserved
15-10 —	Reserved
9 IBIXREG	In-Band Interrupt Extended Register Supports extended registers for IBIs. This field indicates whether Extended IBI Data 1 (IBIEXT1) is available. Extended IBI Data 2 (IBIEXT2) is available if IBIEXT1[MAX] > 3. 0b - Not supported 1b - Supported
8 IBIEXT	In-Band Interrupt EXTDATA Supports SCTRL[EXTDATA] to allow data beyond the mandatory data byte (MDB) for IBIs. 0b - Not supported 1b - Supported
7 —	Reserved
6 I2CDEVID	I2C Device ID Indicates whether I2C device ID is supported. 0b - Not supported 1b - Supported
5 I2CRST	I2C Software Reset Supports I2C software reset. 0b - Not supported 1b - Supported
4	I2C 10-bit Address

Table continues on the next page...

Table continued from the previous page...

Field	Function
I2C10B	Supports 10-bit I2C address in MAP 1. If this field is 1, MAPCNT must be 1 or greater. 0b - Not supported 1b - Supported
3-0 MAPCNT	Map Count Indicates the number of maps that are allowed. If there is no mapping, this field is 0.

72.7.20 Target Capabilities (SCAPABILITIES)

Offset

Register	Offset
SCAPABILITIES	60h

Function

Indicates which features are available and supported in this module, including controller and/or target capabilities, HDR modes, and others.

31 DMA	Direct Memory Access Indicates whether DMA is supported. 0b - Not supported 1b - Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 INT	Interrupts Indicates whether interrupts are supported. 0b - Not supported 1b - Supported
29-28 FIFORX	FIFO Receive Indicates the size of receive (from-bus) FIFO. **NOTE** Controller and target use the same receive FIFO, so size is the same for the controller receive FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two or three 01b - Four 10b - Eight 11b - 16 or larger
27-26 FIFOTX	FIFO Transmit Indicates the size of transmit (to-bus) FIFO. **NOTE** Controller and target use the same transmit FIFO, so size is the same for the controller transmit FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two 01b - Four 10b - Eight 11b - 16 or larger
25-23 EXTFIFO	External FIFO Indicates whether external FIFOs are enabled. If they are not enabled, then check FIFOTX and FIFORX for the internal FIFO. 000b - No external FIFO available 001b - Standard available or free external FIFO 010b - Request track external FIFO All other values are reserved.
22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 TIMECTRL	Time Control Specifies whether any time-control type is supported. 0b - No time control supported 1b - At least one time-control type supported
20-16 IBI_MR_HJ	In-Band Interrupts, Controller Requests, Hot-Join Events Indicates which events (IBI, CR, and HJ) are allowed. For example, if this field is 00011b, IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. 0_0000b - Application cannot generate IBI, CR, or HJ 1_xxxxb - Application can use SCONFIG[BAMATCH] for bus-available timing x_1xxxb - Application can generate a Hot-Join event x_x1xxb - Application can generate a controller request for a secondary controller x_xx1xb - When bit 0 = 1, the IBI has data from the SCTRL register x_xxx1b - Application can generate an IBI
15-12 CCCHANDLE	Common Command Codes Handling Indicates what manages CCC between I3C and the application. 0000b - All handling features disabled 1xxxb - GETSTATUS CCC returns the value of SCTRL[VENDINFO] x1xxb - GETSTATUS CCC returns the values of SCTRL[PENDINT] and SCTRL[ACTSTATE] xx1xb - The I3C module manages maximum read and write lengths, and max data speed xxx1b - The I3C module manages events, activities, status, HDR, and if enabled for it, ID and static-address-related items
11-10 SADDR	Static Address Indicates how the static address is managed. 00b - No static address 01b - Static address is fixed in hardware 10b - Hardware controls the static address dynamically (for example, from the pin strap) 11b - SCONFIG register supplies the static address
9 MASTER	Controller Specifies whether controller capability is supported. 0b - Not supported 1b - Supported
8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 HDRSUPP	High Data Rate Support Indicates which HDR modes are supported. 00b - No HDR modes supported 01b - DDR mode supported All other values are reserved.
5-2 IDREG	ID Register Indicates which ID features are available in the configurable registers. 0000b - All ID register features disabled 1xxxb - A Bus Characteristics Register (BCR) is available x1xxb - A Device Characteristic Register (DCR) is available xx1xb - An ID Random field is available xxx1b - ID Instance is a register; used if there is no PARTNO register
1-0 IDENA	ID 48b Handler Indicates what handles the 48-bit ID value. 00b - Application 01b - Hardware 10b - Hardware, but the I3C module instance handles ID 48b 11b - A part number register (PARTNO)

72.7.21 Target Dynamic Address (SDYNADDR)

Offset

Register	Offset
SDYNADDR	64h

Function

Fills with the assigned address after the controller has assigned it via SETDASA or ENTDAA CCC commands. It clears if the RESETDAA CCC is used. The current validity state is also indicated through SSTATUS[DAVALID], which can be used to interrupt the processor. The DCAUSE field can be used to determine the changes, if enabled.

NOTE

If mapped addresses are enabled, they are accessed through the SMAPCTRL*n* registers.

The first dynamic address (DA[0]) may be written irrespective of whether the mapping is enabled, if configured to allow writes used to restore the DA after a power-down (an ultra-low power state that loses power to peripherals but retains the DA somewhere else). This is not required if state-retention flops are used for the DA. This mechanism only allows writes when target is disabled

(and is ignored otherwise). If the controller uses RSTDAA or SETNEWDA, then it overrides this mechanism and yields to the controller-assigned DA. When enabling the target, SCONFIG[OFFLINE] must be 1. This waits for evidence that the bus is not in I3C HDR mode and exits when an HDR exit pattern is seen or when 60 µs has expired. This makes it safe to monitor START and STOP. If the application needs to do an IBI, then the application must either wait for a STOP (see STATUS) or make sure that 200 µs have gone by with no activity (no START or STOP) before the application emits the IBI.

The MAPIDX or MAPSA model allows writing additional DAs (and SAs) into a list (the number in the list is preconfigured); any DA or SA with DAVALID = 0 are never matched. The additional DAs may be based on the bridge target CCC or done by a move (read current DA and then copy into the upper map, and then invalidate the 0 map) when matching ENTDAA over and over. Any mapped location can be invalidated by writing MAPIDX and DAVALID = 0. The mapped ones are not reset by the RSTDA CCC (see Target Message Map Address (SMSGMAPADDR)).

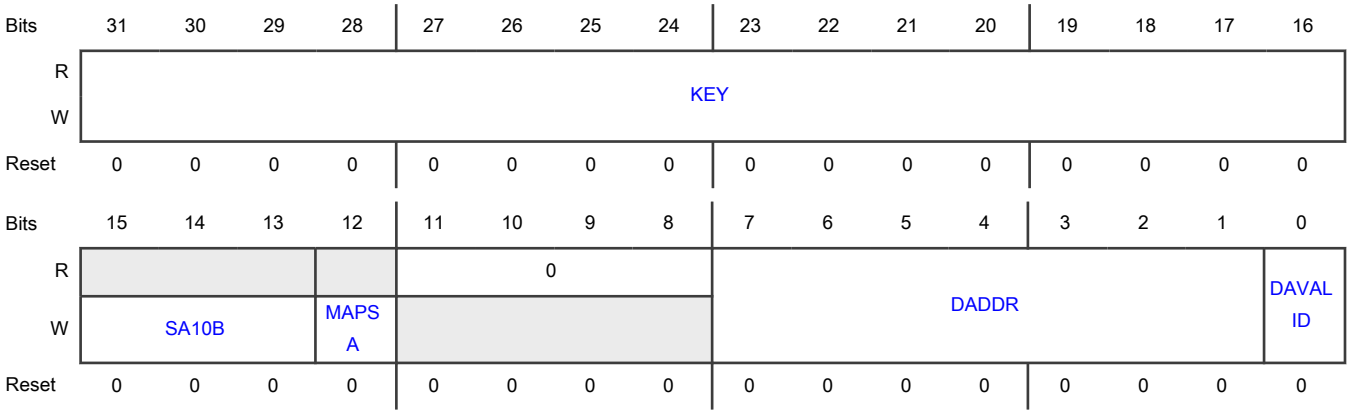
To copy the base DA to the mapped set, you must perform the configuration to allow it; otherwise it leads to distinct mechanisms:

- If used in I3C mode, a base DA is required, so the last one must not be cleared (or writing a dynamic address with DAVALID = 1 is necessary).

NACK/ACK of mapped DAs/SAs: The register also permits specific DAs (above the base) to NACK or ACK writes or reads, such as for bridges when the endpoint is busy. The NACK must not be set for too long, or the controller may consider the target in an error state. The model is to write with KEY = A731h and the MAPIDX and DAVALID to select ACK or NACK.

Mapping: If MAPIDX ≠ 0 and KEY = 0, then the next read returns details on the static or dynamic address at that location. If the read does not have MAPIDX ≠ 0, then it is not an acceptable location.

Diagram



Fields

Field	Function
31-16 KEY	Key Specifies the value of KEY. Must be set to A4D9h to write to the DADDR field (and 1 to the DAVALID field). Write only when a target is not enabled (for restoring after power-down sleep with auto-restore). The mapped locations and base may be written when a target is enabled, but do not write when there are transactions on the I3C bus. KEY reads back 1 if overwritten, else KEY is 0 if assigned by the controller including when the controller changes it. If address mapping is allowed, then writing with KEY = CB19h is used to clear the base DA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If mapping is allowed, then writing with the key of A731h means that MAPIDX indicates which mapped address to set to ACK or NACK, such that DAVALID = 1 if ACK, DAVALID = 0 if NACK. This allows having the address refuse write and read requests when NACK. When using read back from map index (write with MAPIDX ≠ 0, KEY = 0, read) bit [16] = 1 if NACK, else 0.
15-13 SA10B	10-Bit Static Address Stores a 10-bit static address composed of {SA10B,DADDR}, if not 0 when MAPSA is set. Only one static address may be stored this way, and it must be MAPIDX == 1.
12 MAPSA	Map a Static Address Sets a static address into the list if MAPSA = 1 on a write with MAPIDX ≠ 0; otherwise, a dynamic address is used.
11-8 —	Reserved
7-1 DADDR	Dynamic Address Specifies the dynamic address (DA). This is the assigned dynamic address when DAVALID is 1 and is a static address if the MAPSA field is 1.
0 DAVALID	Dynamic Address Valid Determines whether a dynamic address is assigned. This field is 1 for ACK and 0 for NACK when using the A731h KEY. 0b - DANOTASSIGNED: a dynamic address is not assigned 1b - DAASSIGNED: a dynamic address is assigned

72.7.22 Target Maximum Limits (SMAXLIMITS)

Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the controller (or the originally requested limits). The maximum limits are not enabled in the hardware design, including maximum read and write lengths. If the maximum read and write lengths are enabled, then the current setting (including the default request) shows up in this register (SMAXLIMITS).

Diagram

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum Write Length Indicates the maximum write length, which must be between 8 to 4095 (saturation). The application must not set the maximum write length to a higher value than the maximum write length set by the controller.
15-12 —	Reserved
11-0 MAXRD	Maximum Read Length Indicates the maximum read length, which must be between 16 to 4095 (saturation). The application must not set the maximum read length to a higher value than the maximum read length set by the controller.

72.7.23 Target ID Part Number (SIDPARTNO)

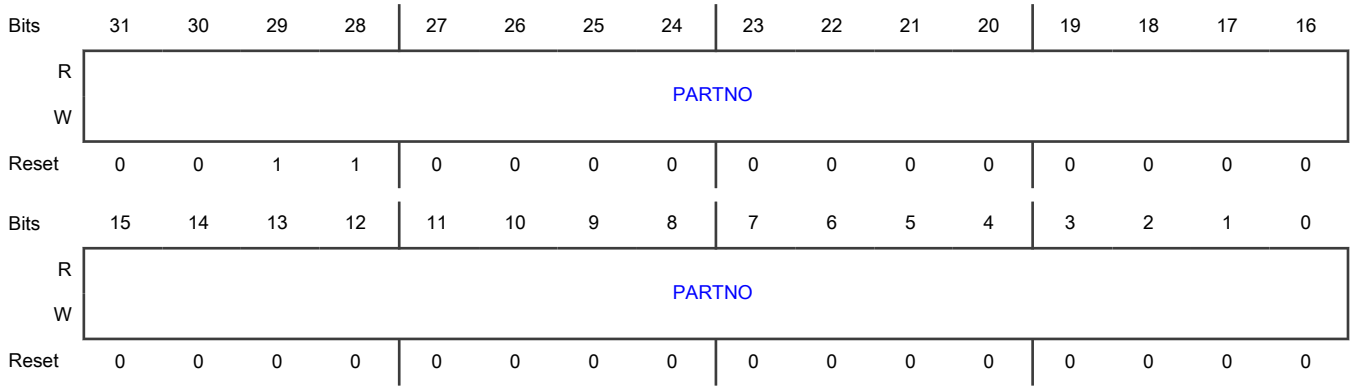
Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows you to write the ID part number. You must write a nonzero value into the PARTNO field because 0 is not valid.

Diagram



Fields

Field	Function
31-0 PARTNO	Part Number

72.7.24 Target ID Extension (SIDEXT)

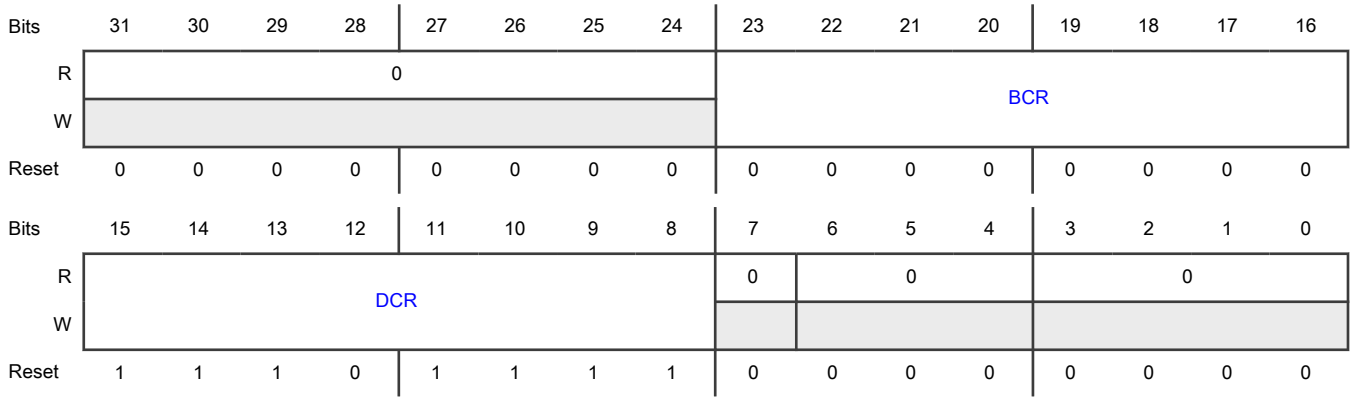
Offset

Register	Offset
SIDEXT	70h

Function

Allows you to write the ID extension of DCR and/or BCR.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Sets the value for BCR, if this field is configured. Otherwise, the default value is considered. This field controls features such as secondary controller and slow-speed requirements.
15-8 DCR	Device Characteristic Register Sets the value for DCR, if this field is configured. Otherwise, the default value is considered.
7 —	Reserved
6-4 —	Reserved
3-0 —	Reserved

72.7.25 Target Vendor ID (SVENDORID)

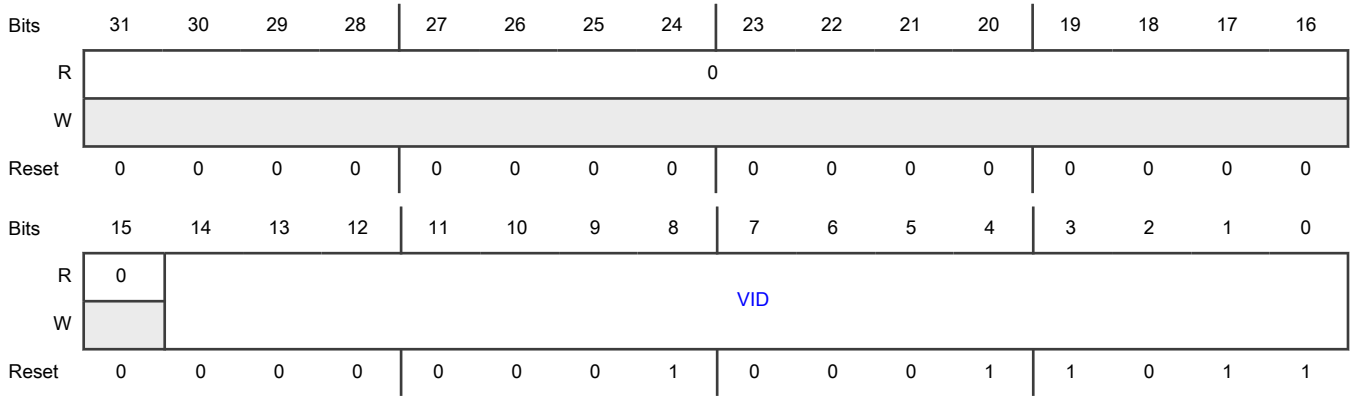
Offset

Register	Offset
SVENDORID	74h

Function

Allows you to write the vendor ID. The default value is the chip vendor ID, and is set from the constant field. When using the chip vendor ID, the part number (PARTNO) does not collide with other uses. The MIPI vendor ID is available to all companies (MIPI membership is not required). To get a vendor ID, make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID Configures the 15-bit MIPI vendor ID. If not configured, the default value is considered.

72.7.26 Target Time Control Clock (STCCLOCK)

Offset

Register	Offset
STCCLOCK	78h

Function

Allows you to dynamically set the time control clock and accuracy information. The clock frequency and accuracy are constants set by the hardware. If the clock can be adjusted (that is, divided) or if the accuracy could vary with knowable information, then the clock may be set via this register, which must be updated whenever the clock source is changed.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock Frequency Indicates the clock frequency in 0.5 MHz steps. For example, a value of 20 in this field indicates a frequency of 10 MHz. Default set by parameters if configured.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 ACCURACY	Clock Accuracy Indicates the clock accuracy in 1/10ths of %. For example, a value of 15 indicates an accuracy of 1.5%. Default set by parameters if configured.

72.7.27 Target Message Map Address (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

Allows you to determine which address is matched when STATUS[MATCHED] = 1. This register is used when the DYNADDR register builds a list of extra DAs or SAs to match. It holds the last three matches.

Diagram

19-16 MAPLASTM2	Matched Previous Index 2 Indicates index 2 of the previous matched address (0 for the base address).
15-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-8 MAPLASTM1	Matched Previous Address Index 1 Indicates index 1 of the previous matched address (0 for the base address).
7-5 —	Reserved
4 LASTSTATIC	Last Static Address Matched Indicates whether the last matched address was an I2C static address or an I3C dynamic address. 0b - I3C dynamic address 1b - I2C static address
3-0 MAPLAST	Matched Address Index Indicates the matched address index for current or last matched message (0 for the base address).

72.7.28 Controller Control (MCTRL)

Offset

Register	Offset
MCTRL	84h

Function

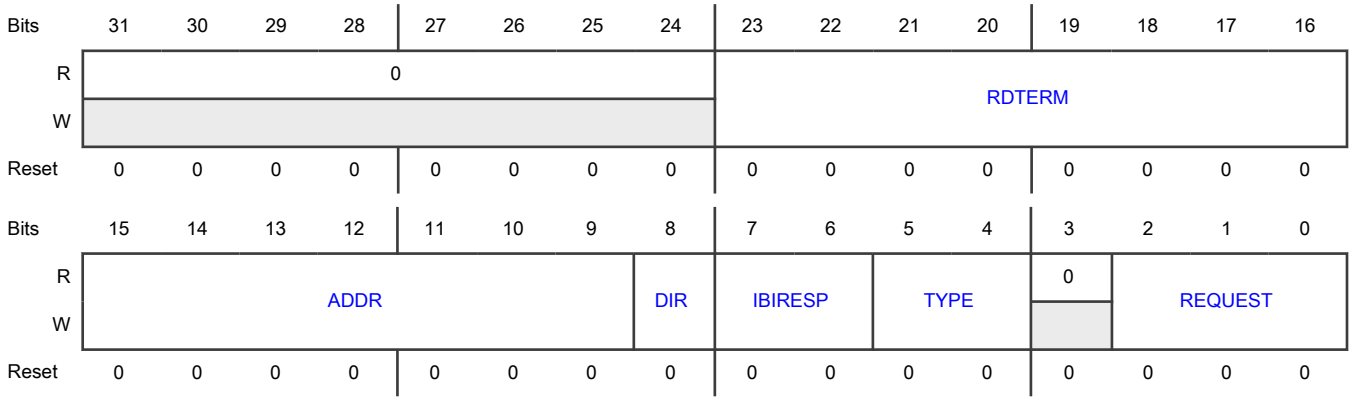
Starts activities on the I3C or I2C bus (see the MWMSG registers). A request cannot be changed when a message is in progress; the REQUEST field becomes 0 automatically.

You must write to MCTRL fields as per use case or as mentioned in Operating modes. Bit read and write checking may not work independently.

NOTE

If MCONFIG[MSTENA] is configured for I2C Controller mode (legacy I2C), only REQUEST = 1 and REQUEST = 2 are accepted. Also, fields are constrained to I2C-supported fields.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read Terminate Counter Determines when to terminate a read operation: • For I2C, this field controls when to NACK a read. • For I3C, this field can be used to terminate (end) a read: — If RDTERM is 0, it has no effect. — If RDTERM is 1, the read terminates after the next character. — If RDTERM is 2, the read terminates after the next two characters. The field supports up to 255 characters. In DDR mode, RDTERM terminates the read based on word counts (for DDR) instead of byte counts (for SDR). The field self-clears when MSTATUS[COMPLETE] becomes 1. **NOTE** You may write 1 to this field anytime, but a value greater than 1 must be written when starting EmitStartAddress.
15-9 ADDR	Address Indicates the type of address: I3C dynamic address or I2C static address. Some values are not allowed based on the bus that is used (I3C or I2C).
8 DIR	Direction Indicates the direction, write or read. 0b - Write 1b - Read
7-6	In-Band Interrupt Response

Table continues on the next page...

Table continued from the previous page...

Field	Function
IBIRESP	Indicates the response to use when you get an IBI from START, and when to force using an IBI ACK NACK request when completing a manual IBI. Completion of a manual IBI means that the target DA is known, and so the mandatory byte (or not) is specified by the application when acknowledging. This field is also used when a message is emitted in Message mode using the MWMSG_SDR or MWMSG_DDR registers. If an IBI with MDB (mandatory byte) is ACKed, the controller limits it to a maximum of eight more bytes after the MDB. RDTERM = 1 can be used with REQUEST = NONE to terminate data from a target sooner. If this field is 0b, it indicates ACK (acknowledge). When REQUEST = 1 (EmitStartAddr) or REQUEST = 7 (AutoIBI), Controller In-band Interrupt Registry and Rules (MIBIRULES) decides whether to ACK with mandatory byte. When REQUEST = 3 (IBIAckNack), ACK with no mandatory byte. If this field is 1b, it indicates NACK (reject) or no acknowledgement. If this field is 10b, it indicates acknowledge with mandatory byte. When REQUEST = 1 or REQUEST = 7, ignore Controller In-band Interrupt Registry and Rules (MIBIRULES). Do not use this setting unless only targets with a mandatory byte can cause an IBI. When REQUEST = 3, ACK with mandatory byte. If this field is 11b, it indicates manual. When REQUEST = 1 or REQUEST = 7, stop and wait for a decision using the IBI ACK NACK request. When REQUEST = 3, this field is reserved. **NOTE** A CR and HJ always cause IBIRESP to become 3 (manual) so the application must decide. 00b - ACK (acknowledge) 01b - NACK (reject) 10b - Acknowledge with mandatory byte 11b - Manual
5-4 TYPE	Bus Type with EmitStartAddr Works with REQUEST to determine the bus type. See Determining bus types for more information. The following values are valid only if REQUEST is 1. 00b - I3C 01b - I2C 10b - DDR 11b - Reserved
3 —	Reserved
2-0 REQUEST	Request Emits the requested operation when performing in pieces, instead of performing by message. You must check Controller Status (MSTATUS) because some requests can only be made in some states. For example, the system cannot enter SDR mode from DDR mode, and it cannot use an incorrect request in DAA mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0b, it indicates that no request is present (NONE). The REQUEST field returns to NONE after finishing a request. Controller Status (MSTATUS) indicates the state of the controller. See AutoIBI mode. NONE is written as 0 only in these cases: when writing 1 to MCTRL[RDTERM] (to stop a read in progress) or when configuring MCTRL[IBIRESP] for MSG use. If this field is 1b, it emits START with address and direction (EMITSTARTADDR), either from Stopped state or in the middle of a single data rate (SDR) message. If from Stopped state (Idle), then EmitStart may be prevented by an event (such as IBI, CR, HJ). In this case, an appropriate interrupt is signaled. EmitStart can be resubmitted. If this field is 10b, it emits a STOP on bus (EMITSTOP). Must be in SDR mode. In DAA mode, emitting STOP exits DAA mode. If this field is 11b, it indicates manual IBI ACK or NACK (IBIACKNACK). When MCTRL[IBIRESP] indicates a hold on an IBI to allow a manual decision, this request completes it. The field uses MCTRL[IBIRESP] to provide the information. If this field is 100b, and if currently not in DAA mode, it emits START, 7E, ENTDAA sequence, and then emits 7E/R to process the first target (PROCESSDAA). Stops just before the new dynamic address (DA) is to be emitted. The DA is written using Controller Write Data Byte (MWDATAB), then process DAA is requested again to write the new address, and then it starts the next unless marked to STOP. An MSTATUS indicating NACK means DA was not accepted (for example, parity error). If PROCESSDAA is NACKed on the 7E/R request, meaning no more targets need a DA, then a COMPLETE is signaled (along with DONE) and a STOP issued. If this field is 110b, it emits an exit pattern from any state (force exit and target reset). End DDR mode (including MSGDDR), including a STOP afterward. If this field is 111b, the target is held in a Stopped state, but autoemits a START, 7E sequence when the target holds SDA low for an IBI (AUTOIBI). Actual IBI handling is defined by MCTRL[IBIRESP]. 000b - NONE 001b - EMITSTARTADDR 010b - EMITSTOP 011b - IBIACKNACK 100b - PROCESSDAA 101b - Reserved 110b - Force Exit and Target Reset 111b - AUTOIBI

72.7.29 Controller Status (MSTATUS)

Offset

Register	Offset
MSTATUS	88h

Function

Indicates the controller status, including which events cause interrupts. The peripherals share the IRQ (called parallel-to-target status).

Because a peripheral can either be in Controller or Target mode, but not both at the same time, only one (target or controller peripheral) can cause the IRQ. If there is an IRQ and the peripheral is a controller, then this register (MSTATUS) indicates the status.

If there is an IRQ and the peripheral is a target, then Target Status (SSTATUS) indicates the status.

This register self-clears if the COMPLETE field becomes 1.

If the MCONFIG register is configured only for I2C, some states and fields never remain active (for example, DAA or IBI).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	ERRWARN	0	IBIWON	TXNOTFU...	RXPEND	COMPLETE	MCTRLDO...	SLVSTART	IBITYPE		NACKED	BETWEEN	0	STATE		
W			W1C			W1C	W1C	W1C								
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI Address Indicates the address of: • The IBI when MSTATUS[IBITYPE] = 1. • The CR, when MSTATUS[IBITYPE] = 2. • 7'h2 when HJ, when MSTATUS[IBITYPE] = 3.
23-20 —	Reserved
19 NOWMASTER	Module is now Controller Indicates whether the module is now a controller. That is, it was previously a target, and controllership acceptance was requested from the previous controller and controllership was accepted. The reverse operation (controller becomes a target) does not need an interrupt because the application grants it through the GETACCMST CCC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not a controller 1b - Controller When writing 0b - No effect 1b - Clear the flag
18-16 —	Reserved
15 ERRWARN	Error or Warning Indicates whether an error occurred, such as improper register use, overrun, or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. See Controller Errors and Warnings (MERRWARN) for more information. 0b - No error or warning 1b - Error or warning
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) Won Indicates whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. Arbitration requires manual intervention for CR and HJ, and optionally requires it for IBI if MCTRL[IBIRESP] = 3 (manual). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No IBI arbitration won 1b - IBI arbitration won When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	TX Buffer or FIFO Not Full

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the buffer, FIFOm, or message register can accept another byte or halfword. FIFO uses trigger level. If DMA is enabled for transmitting, it transfers data as long as it is not full. 0b - Receive buffer or FIFO full 1b - Receive buffer or FIFO not full
11 RXPEND	RXPEND Indicates whether a message is being received from a target and bytes are in the input buffer or FIFO: • When using a FIFO, this message is at least one FIFO trigger's worth (a minimum of one byte in the FIFO). • When DMA is enabled for receiving, the DMA is signaled. RXPEND becomes 0 when the data is read. 0b - No receive message pending 1b - Receive message pending
10 COMPLETE	Complete Indicates whether a message is complete: • With MWMSG_SDR or MWMSG_DDR, the COMPLETE condition occurs when MWMSG_SDR_CONTROL[LEN] or MWMSG_DDR_CONTROL[LEN] reaches 0. • When MCTRL[REQUEST] = 1 (EmitStartAddr), this COMPLETE condition occurs after the end of a write operation, or after a read operation has terminated or ended. • With an IBI (AutoIBI or EmitStartAddr), the COMPLETE condition occurs at the end of IBI data (if any). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 MCTRLDONE	Controller Control Done Indicates whether the module has completed an MCTRL request. MCTRLDONE automatically becomes 0 when writing a new control. If MCTRL[REQUEST] = 1 (EmitStartAddr), MCTRLDONE becomes 1 when the address goes out (and is ACKed, NACKed, or ended in an IBI). If ACKed, MSTATUS[COMPLETE] becomes 1 after the write or read data is complete.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If MCTRL[REQUEST] = 4 (ProcessDAA), MCTRLDONE becomes 1 when the module is ready to emit the dynamic address (DA) for the target, or when no more targets are ACKing. This condition can be determined by using the MSTATUS[BETWEEN] and MSTATUS[STATE] fields. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not done 1b - Done When writing 0b - No effect 1b - Clear the flag
8 SLVSTART	Target Start Indicates whether a target is or was requesting a START by holding SDA low. Handling starts automatically when MCTRL[REQUEST] = 7 (AutoIBI). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Target not requesting START 1b - Target requesting START When writing 0b - No effect 1b - Clear the flag
7-6 IBITYPE	In-Band Interrupt (IBI) Type Indicates the type of IBI of the last event that won the arbitration, whether the interrupt was ACKed, NACKed, or pending. 00b - NONE (no IBI: this status occurs when MSTATUS[IBIWON] becomes 0) 01b - IBI 10b - CR 11b - HJ
5 NACKED	Not Acknowledged Indicates whether the last start and address sequence was NACKed (was not ACKed by the addressed target). 0b - Not NACKed 1b - NACKed (not acknowledged)

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 BETWEEN	Between Indicates whether the controller is active between messages or dynamic address assignments (DAA). It is active when: • MSTATUS[STATE] is MSGSDR, DDR, or DAA, or NORMACT, and the state is between messages or DAAs. It is expecting a new message or DAA to start (or STOP or exit). • MSTATUS[STATE] is NORMACT. The module is waiting for the transmit FIFO to be not empty or the receive FIFO to be not full. 0b - Inactive (for other cases) 1b - Active
3 —	Reserved
2-0 STATE	State of the Controller Indicates the current controller state. If this field is 0b, it indicates that the controller is idle (the bus has stopped.) If this field is 1b, it indicates target request. The bus has stopped but a target is holding SDA low. When using auto-emit IBI (MCTRL[REQUEST] = 7), the controller does not remain in this state. If this field is 10b, it indicates entry into Single Data Rate Message mode, using MWMSG_SDR. If this field is 11b, it indicates entry into normal active SDR mode, using MCTRL, MWDATA*n*, and MRDATA*n* registers. The controller remains in this state until a STOP is issued. If this field is 100b, it indicates entry into Double Data Rate Message mode, using MWMSG_DDR or the normal method with DDR. The controller remains in the DDR state until the controller exits using EXIT (emitting the Exit pattern). If this field is 101b, it indicates entry into Dynamic Address Assignment (ENTDAA) mode. If this field is 110b, it indicates wait for an IBI ACK/NACK decision. If this field is 111b, it indicates receiving an IBI. This state is used after IBI, CR, or HJ has won an arbitration. The IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow. 000b - IDLE (bus has stopped) 001b - SLVREQ (target request) 010b - MSGSDR 011b - NORMACT 100b - MSGDDR 101b - DAA 110b - IBIACK 111b - IBIRCV

72.7.30 Controller In-band Interrupt Registry and Rules (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using IBI, and keeps a registry of the targets that use the IBI byte.

This register defines the IBI mandatory byte rules for the targets and determines which targets do (or do not) have a mandatory byte.

Concerning ADDR*n* fields: The address has 6 bits. Assuming that MIBIRULES[MSB0] = 1, the most significant bit of each address is 0. In this case, each address is 7 bits (usually written as A7 to A1) and A7 must be 0. If the application does not use that optimal convention, the "manual" method of IBI ACK handling must be used (see MCTRL[IBIRESP] for more information).

By default, the ADDR*n* values indicate the targets with a mandatory byte. If MIBIRULES[NOBYTE] = 1, the ADDR*n* values indicate targets that do not have a mandatory IBI byte.

NOTE

A7 = 0 is only needed for targets that use IBI. For legacy I2C devices, A7 can use any valid value because I2C devices cannot cause an IBI.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	NOBYTE	MSB0	ADDR4						ADDR3						ADDR2	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	ADDR2				ADDR1				ADDR0							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 NOBYTE	No IBI byte Specifies whether the ADDR*n* fields refer to targets with or without a mandatory IBI byte. 0b - With mandatory IBI byte 1b - Without mandatory IBI byte
30 MSB0	Most Significant Address Bit is 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies whether MSB is 0 for all I3C dynamic addresses. Assigning 1 to this field allows the START header to be optimized. 0b - MSB is not 0 1b - MSB is 0
29-24 ADDR4	ADDR4 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
23-18 ADDR3	ADDR3 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
17-12 ADDR2	ADDR2 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
11-6 ADDR1	ADDR1 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
5-0 ADDR0	ADDR0 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

72.7.31 Controller Interrupt Set (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Returns the status of the interrupt enables when read. This register sets interrupt enables for select fields in Controller Status (MSTATUS):

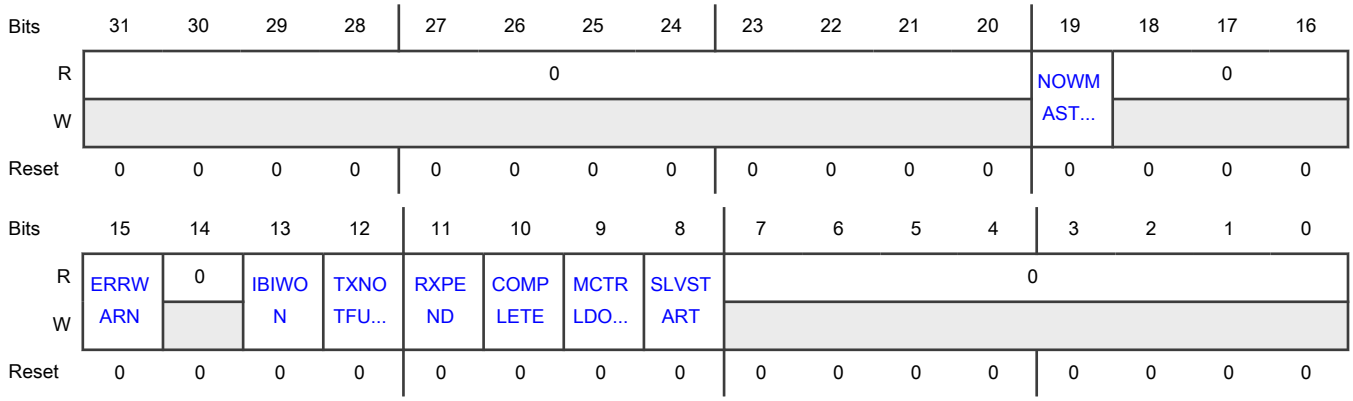
- To activate an interrupt enable, write 1 to its corresponding field.
- To disable an interrupt enable, write 1 to the appropriate field in Controller Interrupt Clear (MINTCLR). Writing 0 to the interrupt enable in MINTSET does not disable the interrupt.

The interrupt registers allow masking of interrupt sources as well as checking which interrupts are activated in Controller Status (MSTATUS). The normal method is to enable an interrupt and then after that interrupt fires, clear the interrupt either by writing to Controller Status (MSTATUS) or via an action on the corresponding data register. The interrupt is level-held, meaning that the interrupt remains 1 until the cause is cleared by some method. The module prevents races; if a new event comes in, that new event is not lost.

These interrupts are parallel to Target Interrupt Set (SINTSET) and Target Interrupt Clear (SINTCLR), and only one interrupt set is active depending on the state (controller or target operation):

- MINTSET: Sets interrupt enables for MSTATUS fields. Reading the MINTSET register returns the status of the interrupt enables.
- MINTCLR: Clears interrupt enables for MSTATUS fields.
- MINTMASKED: Returns the value of the MSTATUS fields ANDed with their interrupt enables.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 NOWMASTER	Now Controller Interrupt Enable Enables the corresponding interrupt to indicate whether the module is now a controller (now this I3C module is a controller). That is, it was previously a target; controllership acceptance was requested from the previous controller and it was accepted. 0b - Disable 1b - Enable
18-16 —	Reserved
15 ERRWARN	Error or Warning (ERRWARN) Interrupt Enable Enables the corresponding interrupt to indicate whether an error occurred, such as improper register use, overrun or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. 0b - Disable 1b - Enable
14 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IBIWON	IBI Won Interrupt Enable Enables the corresponding interrupt to indicate whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. 0b - Disable 1b - Enable
12 TXNOTFULL	Transmit Buffer/FIFO Not Full Interrupt Enable Enables the corresponding interrupt to indicate whether the buffer, FIFOm, or message register can accept another byte or halfword. 0b - Disable 1b - Enable
11 RXPEND	Receive Pending Interrupt Enable Enables the corresponding interrupt to indicate whether a message is being received from a target and bytes are in the input buffer or FIFO.
10 COMPLETE	Completed Message Interrupt Enable Enables the corresponding interrupt to indicate whether a message is complete. 0b - Disable 1b - Enable
9 MCTRLDONE	Controller Control Done Interrupt Enable Enables the corresponding interrupt to indicate whether the module has completed an MCTRL request. 0b - Disable 1b - Enable
8 SLVSTART	Target Start Interrupt Enable Enables the corresponding interrupt to indicate whether a target is or was requesting a START by holding SDA low. 0b - Disable 1b - Enable
7-0 —	Reserved

72.7.32 Controller Interrupt Clear (MINTCLR)

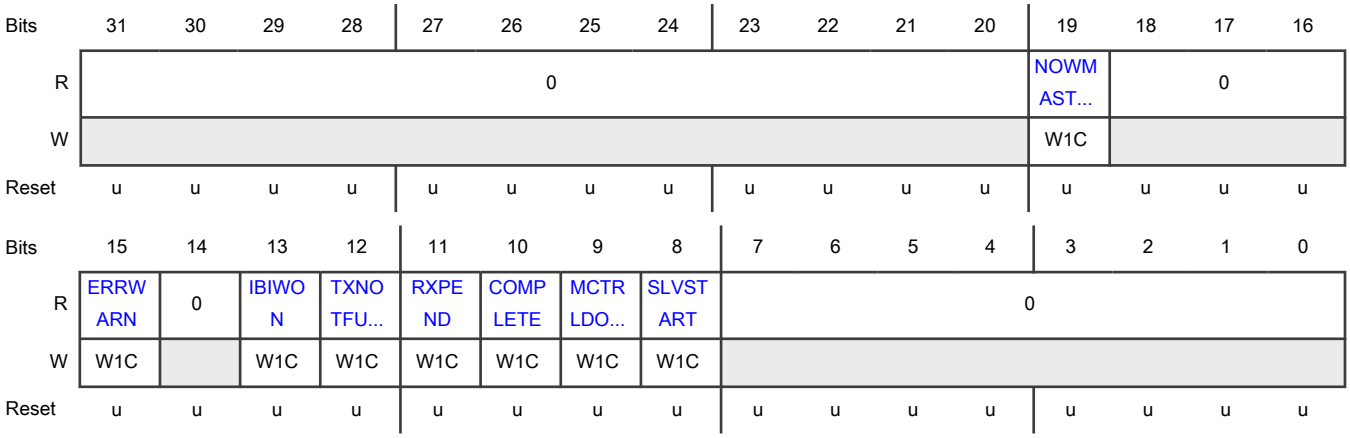
Offset

Register	Offset
MINTCLR	94h

Function

Clears interrupt enables for select fields in Controller Status (MSTATUS). Writing 1 clears the corresponding interrupt enable. Writing 0 has no effect.

Diagram



Fields

Field	Function

72.7.34 Controller Errors and Warnings (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

Contains errors and warnings. When any errors or warnings are not 0, then MSTATUS[ERRWARN] is 1.

Parallel-to-target ERRWARN:

- In Controller mode, use this register (MERRWARN).
- In Target mode, use Target Errors and Warnings (SERRWARN).

The error fields in both registers (MERRWARN and SERRWARN) are similar in meaning.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20 TIMEOUT	Timeout Error Indicates an error caused by the module stalling for too long in a frame. This stalling occurs when: • The transmit FIFO or receive FIFO is not handled, and the bus is stuck in the middle of a message. • No STOP is issued after data transfer (there is a gap between messages). • IBI manual is used and no decision has been made. The maximum stall period is 10 kHz or 100 µs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
19 INVREQ	Invalid Request Error Indicates an error caused by an invalid use of a request: • Not using IBI ACK NACK when stopped in manual hold for IBI acknowledgment. • Using a request other than ForceStop or ForceExit when in a message. Other requests are valid when the message is done. • Other mismatched uses (for example, IBI ACK NACK in normal states). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
18 MSGERR	Message Error Indicates an error caused by: • Trying to write to or read from the MWMSG_SDR register when in a DDR message. • Trying to write to or read from the MWMSG_DDR register when in an SDR message. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
17 OWRITE	Overwrite Error Indicates an error caused by trying to write to Controller Write Data Byte (MWDATAB) when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Overread Error Indicates an error caused by: • Trying to read from Controller Read Data Byte (MRDATAB) when the FIFO is empty. • Trying to read from the MRMSG_SDR register or the MRMSG_DDR register when no message has yet started. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Error When writing 0b - No effect 1b - Clear the flag
15-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 HCRC	High Data Rate CRC Error Indicates that a cyclic redundancy check (CRC) error occurred from a DDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
9 HPAR	High Data Rate Parity Indicates a parity error from a DDR read, including a bad preamble on a read. This does not stop the read because it is not safe to terminate; the read data may become misframed. Ends on a run of 1 second. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
8-5 —	Reserved
4 —	Reserved
3 WRABT	Write Abort Error Indicates an error caused by the I2C target NACKing the write data, terminating the message. For example, the controller is writing in I2C and the target NACKed the write. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
2 NACK	Not Acknowledge Error Indicates an error caused by the target or targets NACKing (not acknowledging) the last address. If 7Eh is the address, then it indicates all targets NACKed the last address. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** In HDR mode, this error occurs when an address is not accepted (as opposed to NACKed). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
1 —	Reserved

Field	Function
0 —	Reserved

72.7.35 Controller DMA Control (MDMACTRL)

Offset

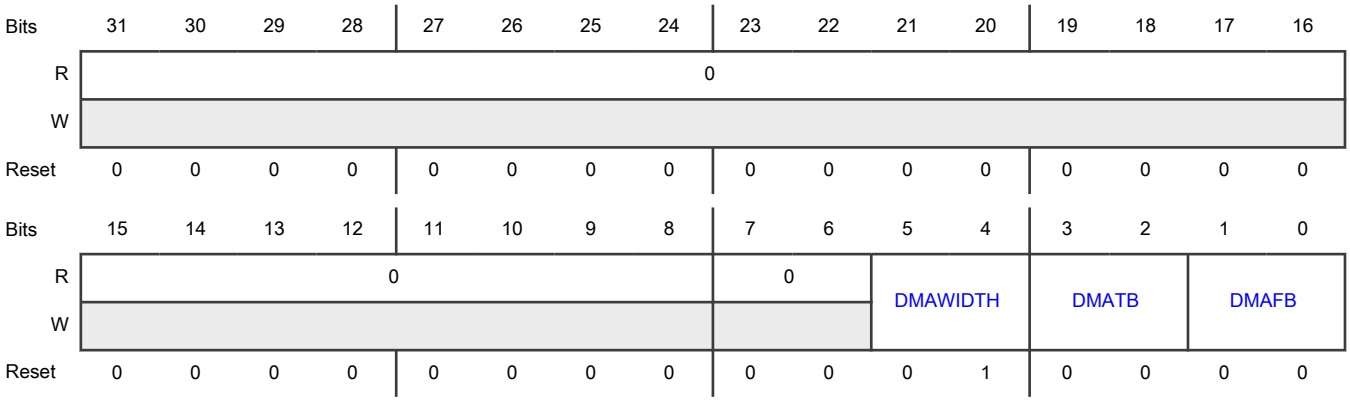
Register	Offset
MDMACTRL	A0h

Function

DMA can be used with a controller in these ways:

- Push or pull data for MCTRL[REQUEST] = 1 (EmitStartAddr) request written by the processor.
- Implementing message mode, completely controlled by DMA.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	DMA Width Specifies the data width of DMA operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The halfword (16 bits) setting ensures that two bytes are free or available in FIFO. 00b,01b - Byte 10b - Halfword (16 bits) 11b - Reserved
3-2 DMATB	DMA to Bus Represents the DMA write (to-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a transmit trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until full, unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or START causes DMATB to become 0 (see SCONFIG[MATCHSS]). Normally, DMA enable must be used only in Controller Message mode. 00b - DMA not used 01b - Enable DMA for one frame (ended by DMA or terminated) 10b - Enable DMA until DMA is turned off 11b - Reserved
1-0 DMAFB	DMA from Bus Represents the DMA read (from-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a receive trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until empty unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or Repeated START causes DMAFB to automatically become 0 (see SCONFIG[MATCHSS]). **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the controller and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - Enable DMA for one frame 10b - Enable DMA until DMA is turned off 11b - Reserved

72.7.36 Controller Data Control (MDATACTRL)

Offset

Register	Offset
MDATACTRL	ACh

Function

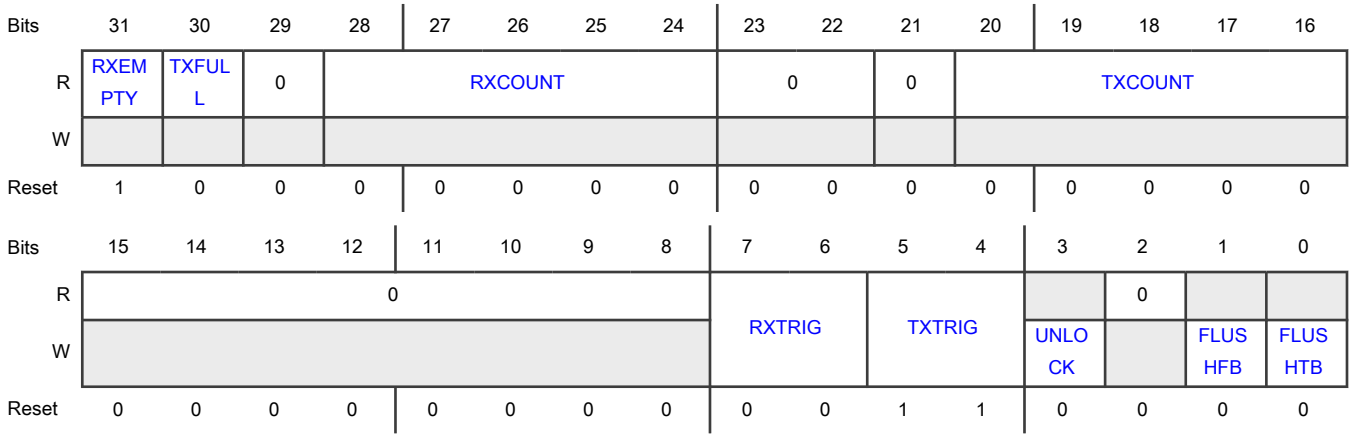
Assists in data control when there is no FIFO. This register also assists the FIFO when FIFO is available (regardless of size), and this assistance allows some control over the FIFO behavior. In particular, the register provides control over when to interrupt when a particular state of fullness or emptiness is reached. It also controls behavior related to width, when the width is not 1 byte wide.

This register acts as an alias of Target Data Control (SDATACTRL).

NOTE

When flushing a FIFO if DMA is in use, disable the DMA channel first. You must not use FIFO flush when a message (in that direction) is in flight.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Receive Byte Count Contains the count of bytes in the receive FIFO or buffer.
23-22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 —	Reserved
20-16 TXCOUNT	Transmit Byte Count Contains the count of bytes waiting in the TXFIFO. This count is the number of bytes that the application has written to the transmit FIFO that have not yet gone onto the bus.
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. This field affects the RXPEND interrupt. 00b - Trigger when not empty 01b - Trigger when 1/4 full or more 10b - Trigger when 1/2 full or more 11b - Trigger when 3/4 full or more
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. This field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Trigger when 1 less than full or less (default)
3 UNLOCK	Unlock Unlocks the functionality so that the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 (unlocked) in the same cycle when writing to TXTRIG or RXTRIG. If this field is 0 (locked), RXTRIG and TXTRIG fields cannot be changed on a write. 0b - Locked 1b - Unlocked
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Flushes from-bus buffer or FIFO. You normally do not use this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No action 1b - Flush the buffer
0 FLUSHTB	Flush To-Bus Buffer or FIFO Flushes to-bus buffer or FIFO. This field is used when the controller terminates a to-bus message (read) prematurely. 0b - No action 1b - Flush the buffer

72.7.37 Controller Write Data Byte (MWDATAB)

Offset

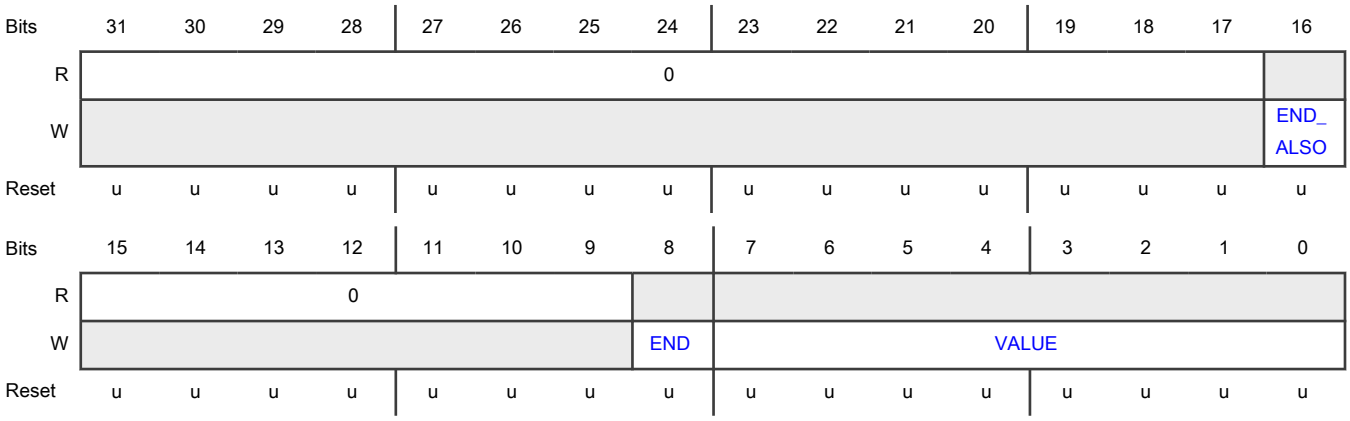
Register	Offset
MWDATAB	B0h

Function

Allows writing bytes to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte (SWDATAB).

Diagram



Fields

Field	Function
31-17	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
16 END_ALSO	End of Message ALSO Indicates end of message, used to end an outbound message normally. Every message must indicate when it is the last message to be sent. This method can be used with the MDATABE register. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End of Message Indicates the end of a message. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
7-0 VALUE	Data Byte Represents the byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

72.7.38 Controller Write Data Byte End (MWDATABE)

Offset

Register	Offset
MWDATABE	B4h

Function

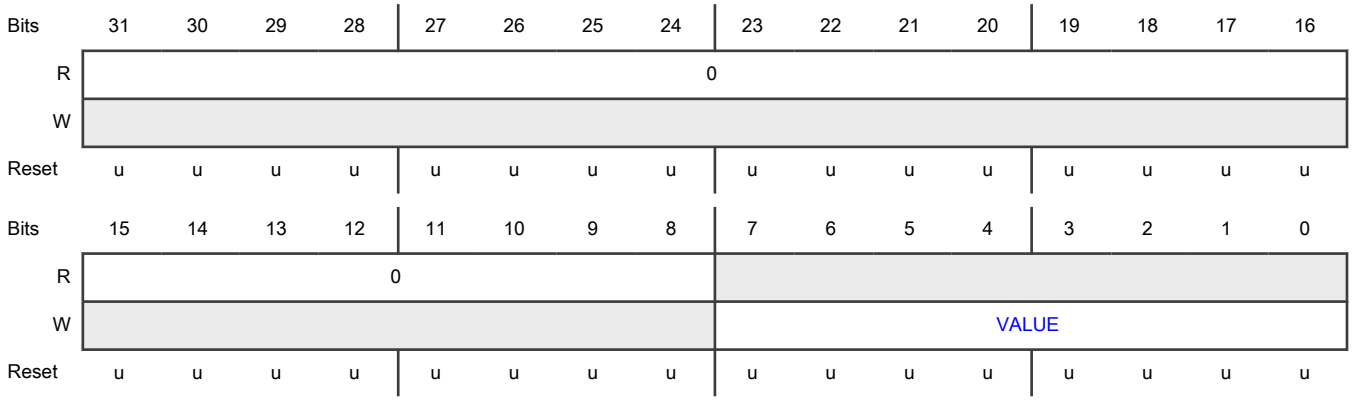
Allows writing the last byte to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte End (SWDATABE).

NOTE

MWDATABE can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data Represents the last byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

72.7.39 Controller Write Data Halfword (MWDATAH)

Offset

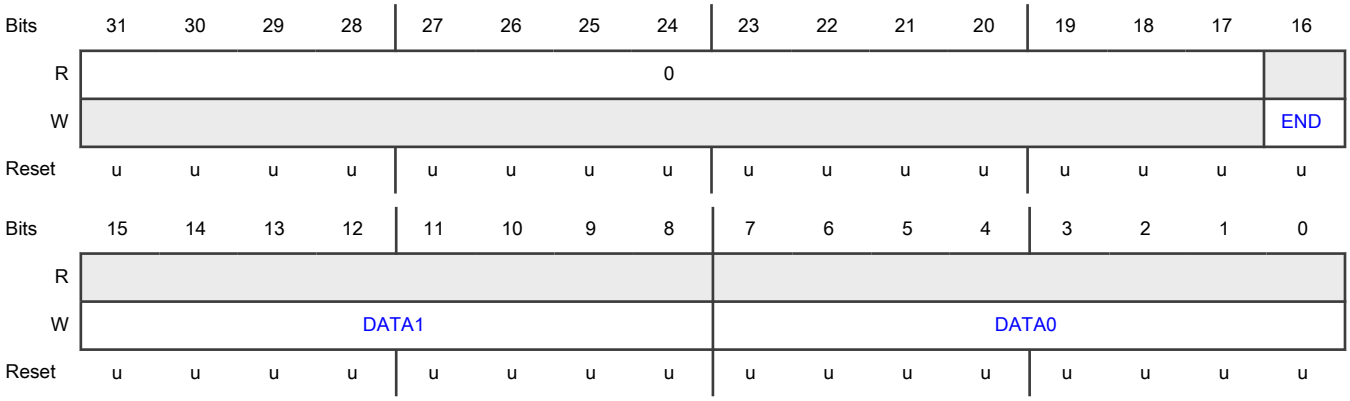
Register	Offset
MWDATAH	B8h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used, sending the low byte followed by the high byte. An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword (SWDATAH).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Indicates the end of a message. For this register, this field always marks DATA1 as the end. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

72.7.40 Controller Write Data Halfword End (MWDATAHE)

Offset

Register	Offset
MWDATAHE	BCh

Function

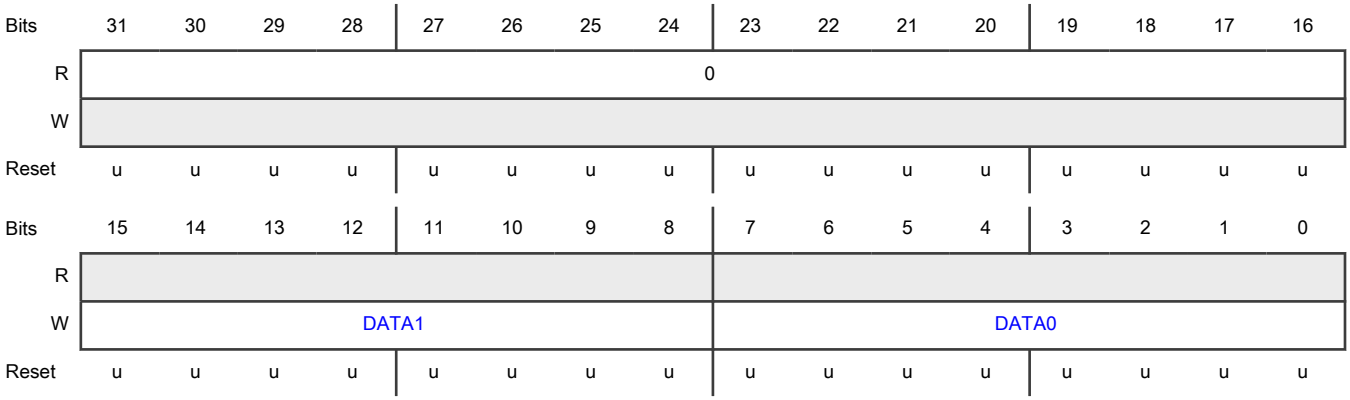
Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way as it does to Controller Write Data Halfword (MWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

You must not write a halfword unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword End (SWDATAHE).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

72.7.41 Controller Read Data Byte (MRDATAB)

Offset

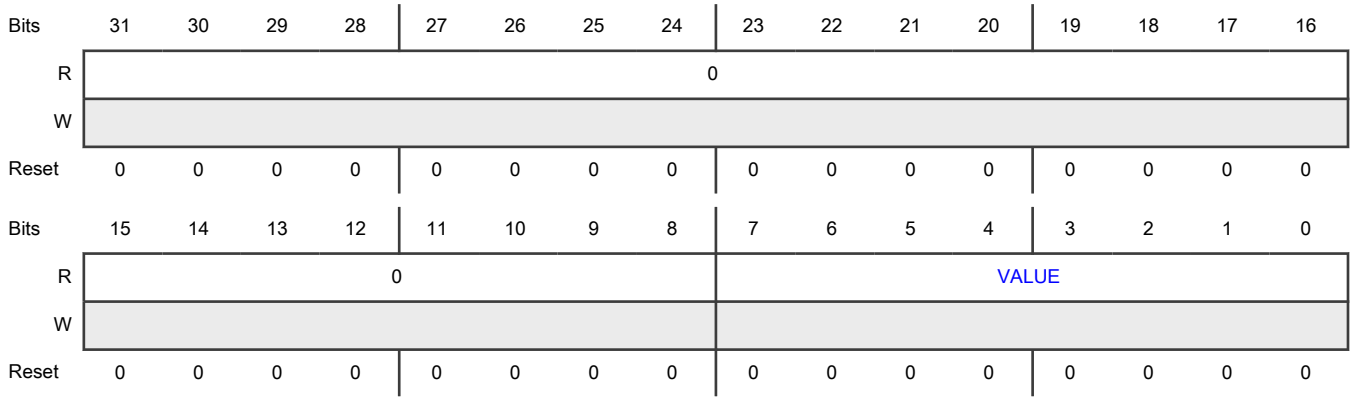
Register	Offset
MRDATAB	C0h

Function

Allows reading bytes written by the target after an SDR read, or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Read Data Byte (SRDATAB).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte read from the controller (and written by the target).

72.7.42 Controller Read Data Halfword (MRDATAH)

Offset

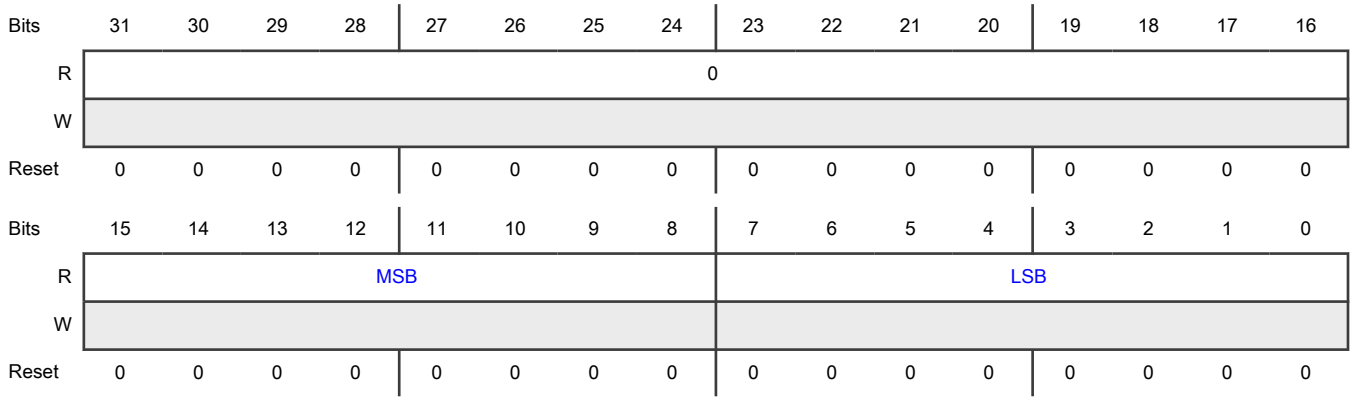
Register	Offset
MRDATAH	C8h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the receive FIFO level trigger or MDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Represents the second byte read from the controller (and written by the target).
7-0 LSB	Low Byte Represents the first byte read from the controller (and written by the target).

72.7.43 Controller Write Byte Data 1 (to Bus) (MWDATAB1)

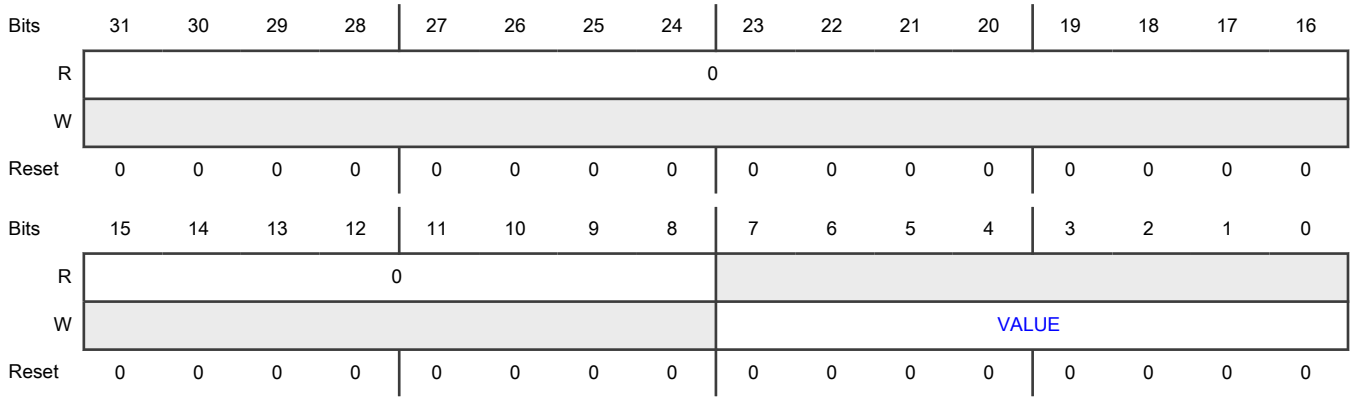
Offset

Register	Offset
MWDATAB1	CCh

Function

Allows writing bytes to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. This register does not have the END bits and is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

72.7.44 Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Allows setting up and writing 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal and has two modes—control and data:

- For the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- For subsequent writes, this register functions as MWMSG_SDR_DATA.
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

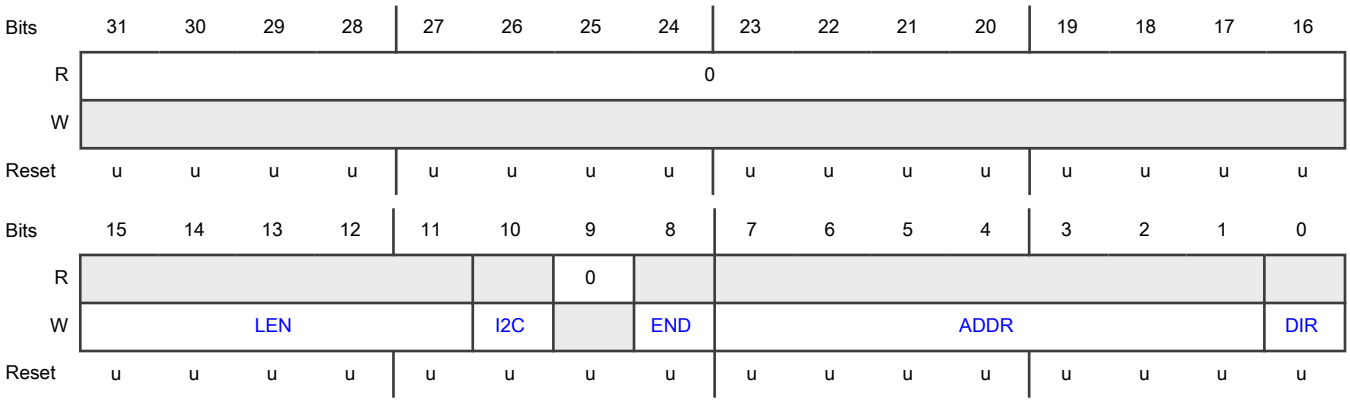
When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the length (see the LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 2 (MSGSDR) and MSTATUS[BETWEEN] = 0, the register (at this offset address) functions as the MWMSG_SDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_SDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode.

The control word contains the byte length (6-bit), address, direction, and how it ends (stop, ready for next, continuation with more length). If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_SDR_CONTROL register (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-11 LEN	Length Indicates the byte length of the message. If LEN = 0, then only END is used (and it does not use the address if stopped). LEN = 1 must not be used. The minimal LEN size is 2 bytes (LEN = 2).
10 I2C	I2C Specifies whether the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR Message Indicates the end of SDR message. MSTATUS[COMPLETE] = 1 when done. The end can happen: • Before LEN bytes are read in I3C mode, if a target ends sooner. • Before LEN bytes are written in I2C mode, if a target NACKs. If this field is 0, the SDR message ends waiting for a new SDR message (issues a Repeated START for a new message). If this field is 1, the SDR message ends at the STOP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not the end 1b - End
7-1 ADDR	Address Contains the address to be written.
0 DIR	Direction 0b - Write 1b - Read

72.7.45 Controller Write Message Data in SDR mode (MWMSG_SDR_DATA)

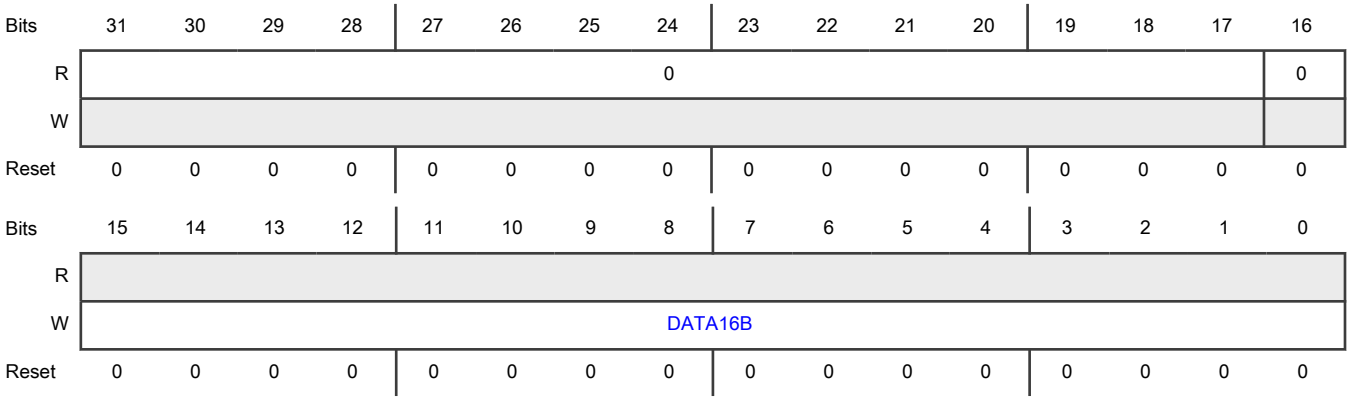
Offset

Register	Offset
MWMSG_SDR_DATA	D0h

Function

Contains the 16-bit word to be written in Single Data Rate (SDR) mode. This register functions in a way similar to MWMSG_SDR_CONTROL.

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 —	Reserved
15-0 DATA16B	Data

72.7.46 Controller Read Message in SDR mode (MRMSG_SDR)

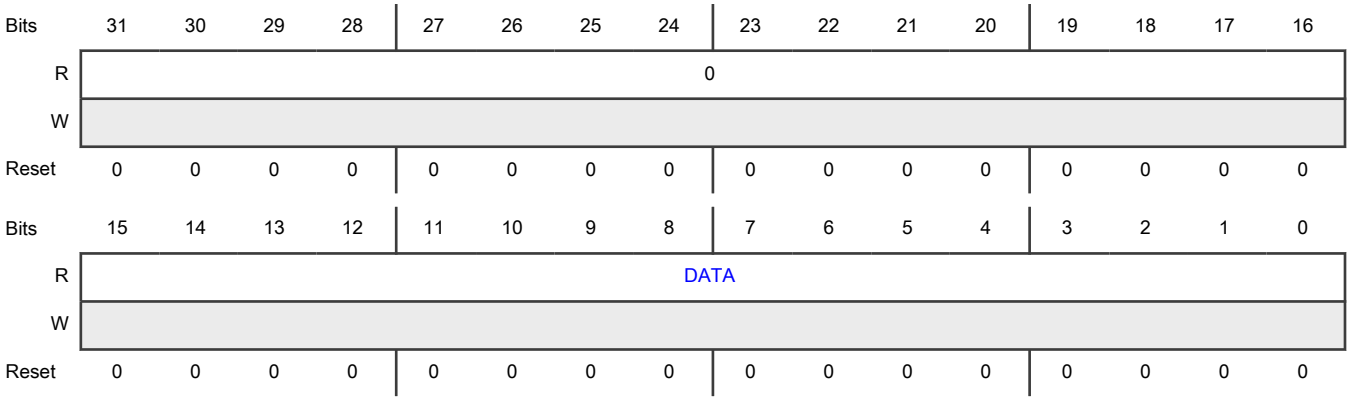
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Allows reading 16-bit words from a target in SDR Message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from the target: • If the length (LEN) is an odd number, the upper byte is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the target ends before LEN is finished, the module treats the read as completed. • If the target is not done before LEN is finished and END is not a continuation, the read is terminated.

72.7.47 Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Allows setting up and writing 16-bit words in DDR mode. The register has three modes:

- The first write to set up a new message functions as the MWSMSG_DDR_CONTROL register.
- The second write contains the functions as shown in the MWMSG_DDR_CONTROL2 register.
- For subsequent writes, this register functions in a way similar to Controller Write Message Data in DDR mode (MWMSG_DDR_DATA).
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the length (see LEN field) counts down or until data with END = 1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 4 (MSGDDR) and MSTATUS[BETWEEN] = 0, then the register (at this offset address) functions as the MWMSG_DDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_DDR_CONTROL register, as long as MSTATUS[STATE] is not in another mode.

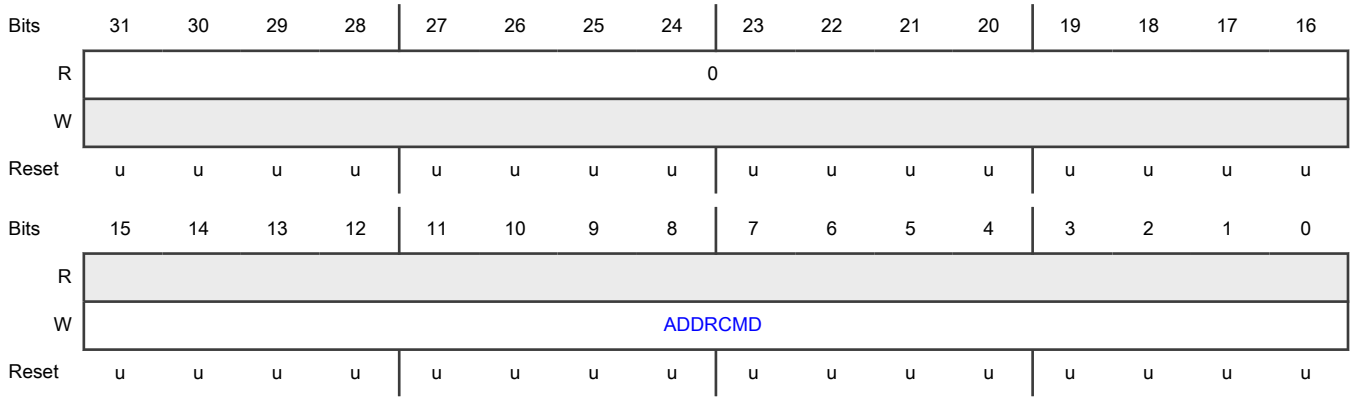
The main control word contains the 16-bit word length and how it ends (stop, ready for next, continuation with more length). Then the command word contains the command and address for read or write. If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_DDR_CONTROL, MWMSG_DDR_CONTROL2, and MWMSG_DDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_DDR_CONTROL register (instead of using MCTRL and MxDATAB).

NOTE

The module handles preamble, parity, and CRC.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ADDRCMD	Address Command Indicates the first data write after control write, with LEN ≠ 0. This is formatted as: • Bits 15:9: target address to read or write • Bit 8: reserved, must be 0 • Bit 7: 1 if read, 0 if write • Bits 6:0: CMD as 7-bit value, always for controller

72.7.48 Controller Write Message in DDR Mode Control 2 (MWMSG_DDR_CONTROL2)

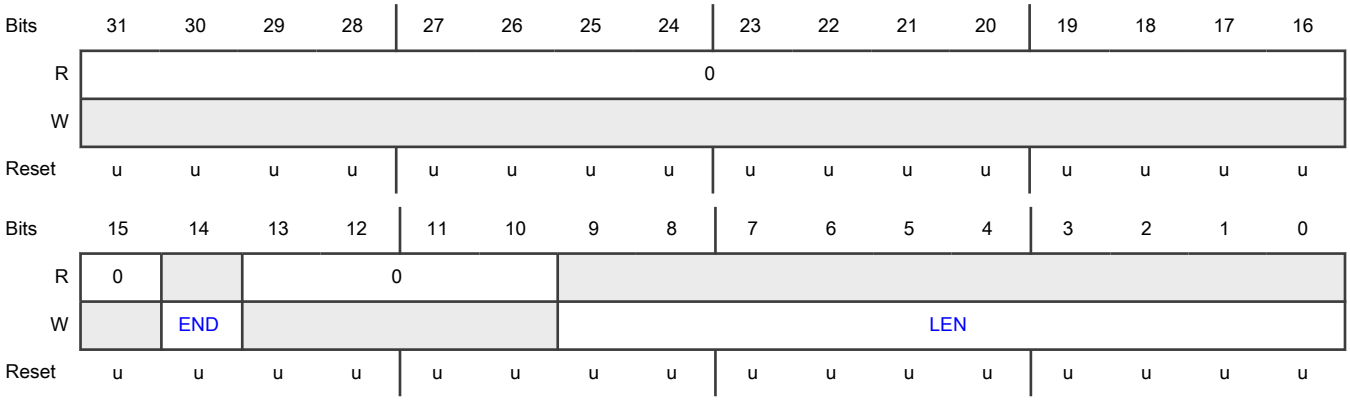
Offset

Register	Offset
MWMSG_DDR_CONTROL2	D8h

Function

Contains the second control word instructions with the length of message and end.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 END	End of Message Indicates the end of DDR message. MSTATUS[COMPLETE] becomes 1 when done. The end can happen before LEN bytes are read if the target ends sooner. If this field is 0, DDR message ends waiting for a new DDR message (issues an HDR restart for the new message). If this field is 1, DDR message ends on HDR exit. 0b - Not the end 1b - End
13-10 —	Reserved
9-0 LEN	Length of Message Contains the length of the message (including the command) in halfwords, up to 2046 bytes. If LEN = 0, then only END is applied: • For reads, + 1 for the CRC. For example, to read 4 bytes (2 halfwords), use 1 + 2 + 1 for CMD + 2 halfwords + CRC. • For writes, LEN is the number of halves of data bytes + 1 (for command).

72.7.49 Controller Write Message Data in DDR mode (MWMSG_DDR_DATA)

Offset

Register	Offset
MWMSG_DDR_DATA	D8h

Function

Contains the 16-bit word to be written in DDR mode. This register functions in a way similar to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL).

Diagram

72.7.50 Controller Read Message in DDR mode (MRMSG_DDR)

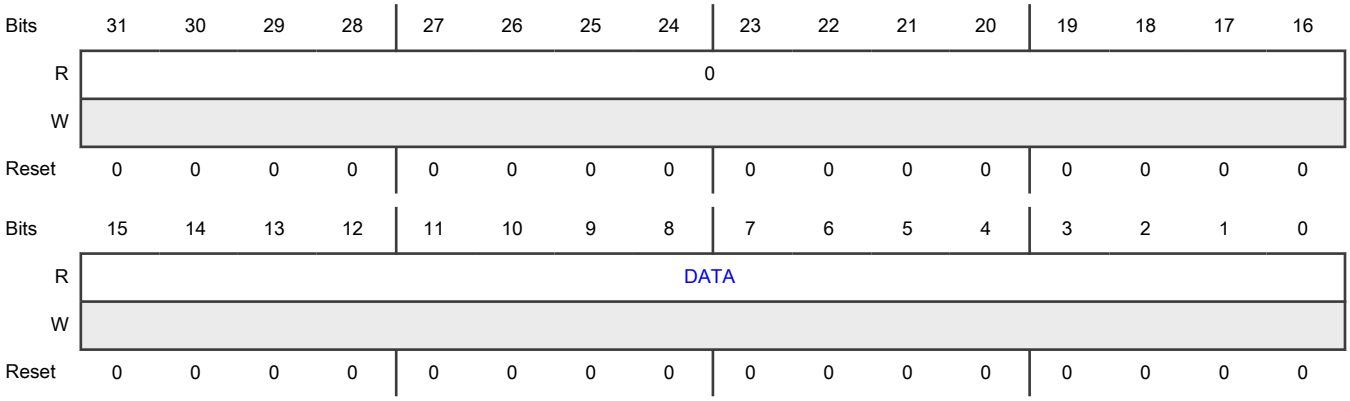
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Allows reading 16-bit words from a target in DDR Message mode from an active message started with MWMSG_DDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from a target. The first byte is the LSB, and is in DATA[7:0]. The second byte is the MSB, and is in DATA[15:8]: • If the target ends before the entire length of the message (MWMSG_DDR[LEN]) is read, the module considers the DATA read as completed. In I3C mode, the target can indicate the end of message (the last byte). Otherwise, the controller terminates the message if the message is more than the controller can accept. • If the target has not yet finished sending DATA before the entire length of the message (MWMSG_DDR[LEN]) is read and END is not a continuation, the DATA read is terminated.

72.7.51 Controller Dynamic Address (MDYNADDR)

Offset

Register	Offset
MDYNADDR	E4h

Function

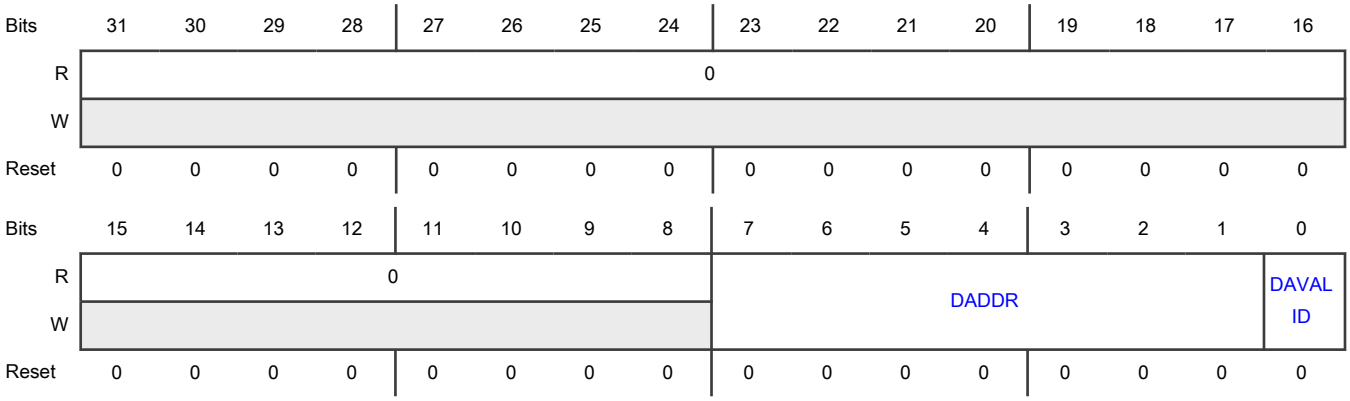
Allows the I3C module to write its own dynamic address (DA) when the module changes from Controller mode to Target mode.

If this device is the main controller (the controller during bus initialization), then the device may use this mechanism to assign itself its DA. When the device hands off control to a secondary controller, it becomes a target itself. This DA must be written before switching to Target mode and must not be changed once in Target mode (it is not clock-safe to do so). It must be written with a valid address value in DADDR if DAVALID = 1.

NOTE

The main controller also uses DEFSLVS CCC to define the target addresses, including itself. This mechanism is how secondary controllers know this address. If the controller is not the main controller, then this mechanism must not be used.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 DADDR	Dynamic Address Contains the assigned dynamic address when DAVALID = 1.
0 DAVALID	Dynamic Address Valid 0b - No valid DA assigned 1b - Valid DA assigned

72.7.52 Map Feature Control 0 (SMAPCTRL0)

Offset

Register	Offset
SMAPCTRL0	11Ch

Function

Provides map feature control.

The SMAPCTRL*n* registers are named SMAPCTRL0, SMAPCTRL1, and so on based on the number of mapped addresses. MAPCTRL0 represents the primary DA or SA with SMAPCTRL1 onwards being the mapped addresses.

The features of the SMAPCTRL*n* registers depend on configuration. SMAPCTRL0 acts differently, as described in this chapter.

In general, this mechanism is intended to replace the DYNADDR register for all MAP-related uses.

When using the Auto-MAP and DASA or AASA, the slot is changed from SA to DA. If the controller then issues RSTDAA, the application must rewrite the static addresses and enable them because they are marked disabled.

Fields

Field	Function
31-17 —	Reserved
16 —	Reserved
15-11 —	Reserved
10-8 CAUSE	Cause Indicates the cause of the most recent DA assignment, which lead to SSTATUS[DACHG] interrupt. This field has MAP enabled. If this field is 100b (auto MAP change happened last), the change may have changed this DA as well (for example, ENTDAA and SETAASA), but at least one MAP entry automatically changed after that. 000b - No information (this value occurs when not configured to write DA) 001b - Set using ENTDAA 010b - Set using SETDASA, SETAASA, or SETNEWDA 011b - Cleared using RSTDAA 100b - Auto MAP change happened last All other values are reserved.
7-1 DA	Dynamic Address Contains primary DA when ENA = 1. When ENA = 0, static address is used (but not described here). This field has MAP enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 ENA	Enable Primary Dynamic Address Indicates whether the MAP is enabled. 0b - Disabled 1b - Enabled

72.7.53 Extended IBI Data 1 (IBIEXT1)

Offset

Register	Offset
IBIEXT1	140h

Function

Contains extended IBI data.

The CTRL register is used to submit IBI, CR, and Hot-Join when enabled to do so. If allowed, an IBI may have additional bytes following the mandatory data byte (MDB). Extended IBI data is allowed when SCTRL[EXTDATA] = 1. If allowed, the extra bytes are indicated using these registers.

7-0 EXT4	Extra Byte 4 Contains the forth extra byte.

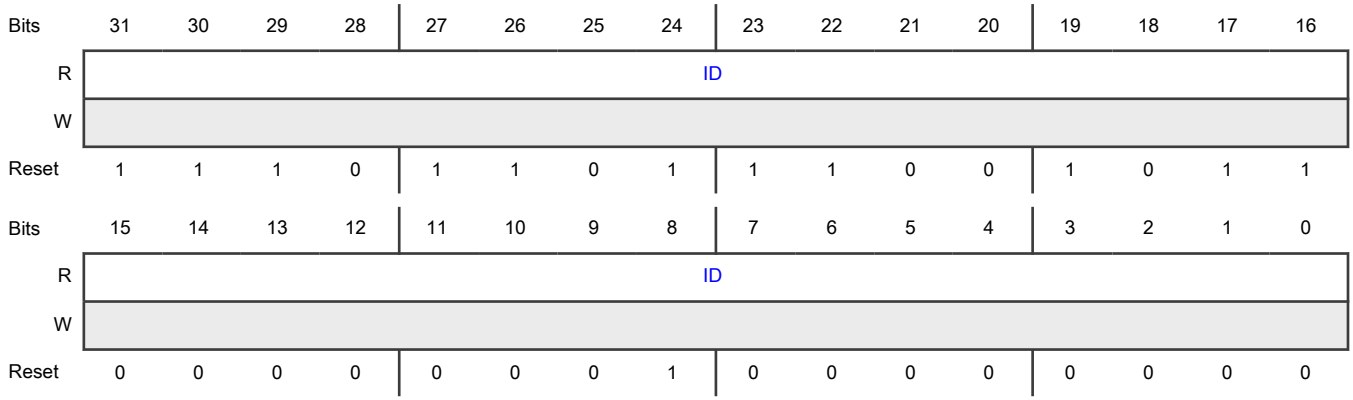
72.7.55 Target Module ID (SID)

Offset

Register	Offset
SID	FFCh

Function
Allows software to detect the module and its version information, if BlockID is enabled.

Diagram



Fields

Field	Function
31-0 ID	ID Indicates the ID. The ID meaning is specific to each use of the I3C module. ID = EDCB0100h.

Chapter 73
General Purpose Input/Output (GPIO)

73.1 Chip-specific GPIO information

Table 704. Reference links to related information

Topic	Related module	Reference
Full description	GPIO	GPIO
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

NOTE

See Peripheral Reset Control 0 (PRESETCTRL0) to know how to reset GPIO. To enable GPIO clock, see AHB Clock Control 0 (AHBCLKCTRL0).

73.1.1 Module instances

This device has six instances of the GPIO module, GPIO0, GPIO1, GPIO2, GPIO3, GPIO4, and GPIO5.

73.1.2 Security considerations

The GPIO module implements Access protection that can be used to configure secure/non-secure and privileged/non-privileged access on a per pin basis. The interrupt, DMA, or trigger functionality for each pin can also be configured for secure/non-secure and privileged/non-privileged access.

Each GPIO module is also instantiated to use two module slots (for example, GPIO0 and GPIO0_alias). At the Secure AHB controller, one slot can be configured for secure access while the other is configured for non-secure access. This allows each GPIO module to be accessed by both secure and non-secure masters using the appropriate slot, while the Secure AHB controller's MISC_CTRL_REG[DISABLE_STRICT] option is configured for strict mode. Each GPIO module's pin and interrupt, DMA, or trigger secure/non-secure access protections are then used to restrict access according to the level used by that particular GPIO slot.

73.1.3 Interrupt, DMA request, and trigger outputs

GPIO modules can be used to trigger interrupts, DMA requests, or trigger outputs (see the INPUTMUX and WUU chapters for details). See the table below for details on the chip-level interrupt, DMA request, and trigger output capability for each GPIO instantiation:

Table 705. Interrupt, DMA request, and trigger outputs for GPIO

GPIO module	Interrupt	DMA request	Trigger output
GPIO0/GPIO0_alias1	Yes	Yes	No
GPIO1/GPIO1_alias1	Yes	Yes	Yes
GPIO2/GPIO2_alias1	Yes	Yes	Yes
GPIO3/GPIO3_alias1	Yes	Yes	Yes
GPIO4/GPIO4_alias1	Yes	Yes	No
GPIO5/GPIO5_alias1	Yes	Yes	Yes

73.1.4 Power domains/modes

The GPIO module can be implemented in different power domains which has implications for low power mode usage and wake-up capability. See Table 333 and Table 335 in Power Management chapter for GPIO0/1/2/3/4/5 implementation in different power modes.

73.1.5 GPIO wakeup via WAKEUP_b pin

The GPIO module can assert two interrupts into the VBAT module's IRQ0_DET and IRQ1_DET. These interrupts can optionally be enabled as source to assert the WAKEUP_b pin. When the device is operating in the VBAT power mode, you can transition the device back to active mode by configuring an external circuitry to recognize the WAKEUP_b assertion and request for a system power on. See the VBAT chapter for more details.

73.2 Overview

GPIO communicates to the processor core via a zero wait-state interface for maximum pin performance.

73.2.1 Block diagram

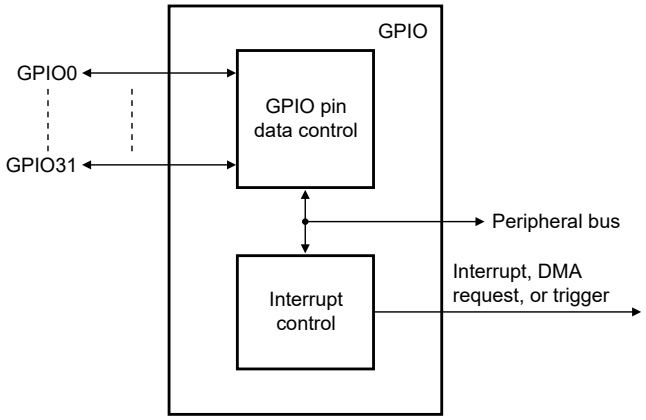


Figure 437. Block diagram

73.2.2 Features

- Port Data Input (PDIR) displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt modules for that pin are enabled.
- Port Data Output (PDOR), with corresponding set, clear, and toggle registers, controls the output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) controls disabling of the input for each general-purpose pin.
- Pin interrupts:
  - Interrupt flags and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt, peripheral trigger, or DMA request is configured for each pin.
  - Support for edge-sensitive (rising, falling, or both) or level-sensitive (low, high) interrupts is configured for each pin.
  - Asynchronous wake-up in Low-Power mode.
  - GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, output trigger, or DMA request.

- Protection registers:
  - Each pin is configured for secure or nonsecure and privileged or nonprivileged access.
  - Each interrupt, trigger, and DMA request domain is configured for secure or nonsecure and privileged or nonprivileged access.

73.3 Functional description

73.3.1 Low-Power mode

You can configure GPIO to exit Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

73.3.2 Debug mode

GPIO remains functional in Debug mode.

73.3.3 General-purpose input

The logic state of each pin is available via Port Data Input (PDIR) if:

- The corresponding field in Port Input Disable (PIDR) is 0.
- The pin is configured for a digital function.

73.3.4 General-purpose output

The logic state of each pin is controlled via Port Data Output (PDOR) and Port Data Direction (PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input or output.

Table 706. General-purpose output

If	Then
A pin is configured for the GPIO function and the corresponding PDDR field is 0	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR field is 1	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR field.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allow one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

73.3.5 Clocking

GPIO receives a single clock, which is used for register access and synchronization with external pin inputs. There are no special considerations.

73.3.6 Reset

GPIO receives a single reset, which resets the peripheral. There are no special considerations.

73.3.7 External interrupts

The external interrupt capability of GPIO is available in all digital pin muxing modes.

GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests. You can configure each pin individually for interrupt, output trigger, or DMA requests:

- Each output implements a separate interrupt status flag (ISF) register for that domain.

- Each output generates a single interrupt.
- Each output generates a single DMA request.
- Each output generates a single peripheral trigger output.

You can configure each pin individually for any of the external interrupt modes shown in the following table.

Table 707. Available pin configurations for external interrupts

Signal conditions	Software polling using flags	Peripheral triggers	Interrupts	DMA requests
Rising-edge	Yes	—	Yes	Yes
Falling-edge	Yes	—	Yes	Yes
Rising- and falling-edge	Yes	—	Yes	Yes
High-level	—	Yes	Yes	—
Low-level	—	Yes	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless GPIO is in Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

GPIO generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to either ISFR0[ISF*n*] or ICR0[ISF].

GPIO generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit Low-Power mode.

GPIO generates a peripheral trigger output that asserts if any pin configured for the active-high trigger is logic 1, or any pin triggered for the active-low trigger is logic 0. The peripheral trigger output asynchronously updates from the value on the configured pins.

73.3.8 Global interrupt control

The two global interrupt control registers (Global Interrupt Control Low (GICLR) and Global Interrupt Control High (GICHR)) allow a single register write to update the upper 16 bits of Interrupt Control a (ICR0 - ICR31) for up to 16 pins, all with the same value.

These global interrupt control registers allow you to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read 0.

73.3.9 DMA

GPIO generates 2 requests. For each pin, you can configure DMA requests to assert for either rising, falling, or both edge detection. See External interrupts for more information.

73.3.10 Access protection

GPIO implements access protection registers (PCNS and PCNP) for each pin, as shown in Table 708.

Table 708. PCNS and PCNP register access protection implementation

Access	Description
Secure	You can write to or read the pins configured for secure access only in the Secure state.
Nonsecure	You can write to or read the pins configured for nonsecure access only in the Nonsecure state.
Privilege	You can write to the pins configured for privilege access only in the Privilege state.
Nonprivilege	You can write to the pins configured for nonprivilege access in both the Privilege and Nonprivilege states.

GPIO implements access protection registers (ICNS and ICNP) for each interrupt, trigger output, and DMA request as shown in Table 709.

Table 709. ICNS and ICNP register access protection implementation

Access	Description
Secure	You can configure the outputs programmed for secure access only in the Secure state.
Nonsecure	You can configure the outputs programmed for nonsecure access only in the Nonsecure state.
Privilege	You can configure the outputs programmed for privilege access only in the Privilege state.
Nonprivilege	You can configure the outputs programmed for nonprivilege access in both the Privilege and Nonprivilege states.

You can write to the access protection registers (PCNS, PCNP, ICNS, and ICNP) only in the Secure-Privilege state; you can optionally lock these registers until the next reset.

Configuring a pin interrupt, trigger output, or DMA request requires the following access permissions:

- Access permission to configure the pin.
- Access permission to either configure to the desired interrupt, trigger output, or DMA request, or writing 0 to ICR*n*[IRQC].
- Access permission to either configure with the existing interrupt, trigger output, or DMA request, or if the current value of ICR*n*[IRQC] is 0.
- The interrupt configuration is not locked.

73.4 External signals

Table 710. External signals

Signal	Description		Direction
GPIO31–GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each chip. See the "Signal Multiplexing" chapter for the number of GPIO pins within each port available on this chip.

73.5 Initialization

To initialize GPIO:

1. Initialize the GPIO pins for the output function:
   a. Configure the output logic value for each pin by using Port Data Output (PDOR).
   b. Configure the direction for each pin by using Port Data Direction (PDDR).
2. Initialize the interrupt function by writing to Interrupt Control a (ICR0 - ICR31) for the corresponding pins and desired configuration. If the pin is previously used for a different function, first write 0100_0000h to Interrupt Control a (ICR0 - ICR31) to disable the previous function and clear the flag.

73.6 Application information

GPIO includes the following applications:

- Reading the state of a single pin by performing a byte read of Pin Data (P0DR - P31DR).
- Updating the state of a single pin by performing a byte write to Pin Data (P0DR - P31DR).
- Reading the state of multiple pins by reading Port Data Input (PDIR).
- Updating the state of multiple pins by using the following ways:
  - Writing to Port Data Output (PDOR).
  - Writing to Port Set Output (PSOR) to write 1 to Port Data Output (PDOR).
  - Writing to Port Clear Output (PCOR) to write 0 to Port Data Output (PDOR).
  - Writing to Port Toggle Output (PTOR) to toggle Port Data Output (PDOR).

73.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the "Signal Multiplexing" chapter for the exact control bits of each port.

PDOR	40h

Function

Configures the logic levels that are driven on each general-purpose output pin.

NOTE

Do not modify the pin configuration registers associated with pins that are not available in your selected package. By default, these unbonded pins are set to the Disable state for lowest power consumption.

Diagram

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 GIWEn	Global Interrupt Write Enable Indicates whether the upper 16 bits of the corresponding Interrupt Control a (ICR0 - ICR31) are updated with the value in GIWD. 0b - Not updated. 1b - Updated

73.7.1.20 Interrupt Status Flag (ISFR0 - ISFR1)

Offset

Register	Offset
ISFR0	120h
ISFR1	124h

Function

Indicates whether the related configured interrupt is detected on each pin. The pin interrupt configuration is valid in all digital pin muxing modes. The ISF for each pin is also visible in the corresponding Interrupt Control register, and each flag can be cleared in either location.

There is a separate ISF register for each interrupt, trigger, or DMA request domain. Each status flag is only visible in the register that corresponds to that flag's domain, as configured in ICR*n*[IRQS].

Chapter 74
Pin Interrupt and Pattern Match (PINT)

74.1 Chip-specific PINT information

Table 711. Reference links to related information

Topic	Related module	Reference
Full description	PINT	PINT
System memory map		Memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Input multiplexing	INPUTMUX	See PINTSEL0 - PINTSEL7 registers in INPUTMUX

74.1.1 Module instances

This device has one instance of the PINT module, PINT0.

74.1.2 Initialization

1. Select up to eight external interrupt pins from all available digital port pins on ports 0 and 1 in INPUTMUX. The pin selection process is the same for pin interrupts and the pattern match engine. The two features are mutually exclusive.
2. Enable the clock to the PINT module via SYSCON AHBCLKCTRL0[PINT].
3. Clear the PINT peripheral reset via SYSCON PRESETCTRL0[PINT_RST].

74.1.2.1 Pin interrupts and Pattern match initialization

In addition to the initialization steps described above, for Pin interrupts initialization and Pattern match initialization, ensure that eight interrupt outputs from PINT are ORed together to one NVIC slot.

74.1.2.2 Configure pins as pin interrupts or as inputs to the pattern match engine

1. Determine the pins that you want to serve as pin interrupts or pattern match inputs. See the data sheet for determining the GPIO port pin number associated with the package pin.
2. For each pin selected, program the GPIO port pin number from ports 0 and 1 into one of the eight PINT_SEL registers in the INPUTMUX module.

NOTE

The port pin number serves to identify the pin to the PINT_SEL register. Any function, including GPIO, can be assigned to this pin via IOCON.

3. Enable each pin interrupt in the NVIC.

Once the pin interrupts or pattern match inputs are configured, the pin interrupt detection levels or the pattern match boolean expression can be set up.

NOTE

The inputs to the Pin interrupt select registers bypass the IOCON function selection. They do not have to be selected as GPIO in IOCON. Make sure that no analog function is selected on pins that are input to the pin interrupts.

74.2 Overview

The Pin Interrupt and Pattern Match (PINT) IP provides interrupt functionality for a selected set of GPIO pins. Per-pin edge- or level-sensitive interrupts can be generated. This IP also includes a pattern match engine that uses the selected GPIO pins as inputs to a Boolean expression. When the expression is satisfied, an interrupt is generated.

74.2.1 Block diagram

From all available GPIO pins, select up to 8 pins in the INPUTMUX module to serve as external interrupt pins (see the "INPUTMUX" chapter for more details). Each external interrupt pins connect to eight individual interrupts in the NVIC. It is possible to create external interrupt pins based either on rising or falling edges or on the input level.

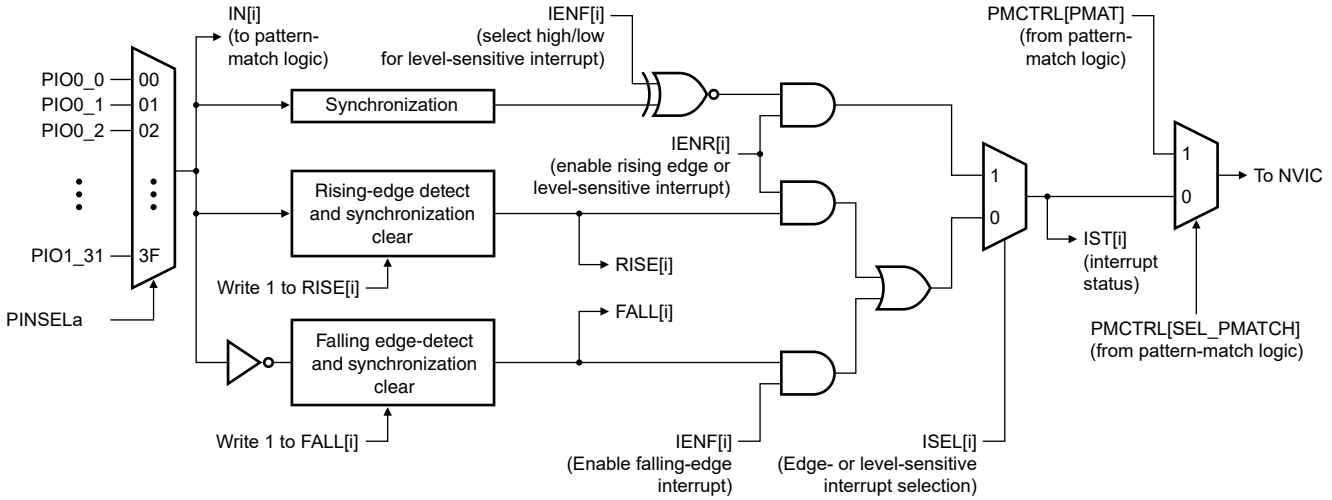

Figure 438. Pin Interrupt diagram

74.2.2 Features

- Pin interrupts
  - Select up to 8 pins from all GPIO pins on ports 0 and 1 as edge- or level-sensitive interrupt requests. Each request creates a separate interrupt in the NVIC.
  - Edge-sensitive interrupt pins interrupt on rising or falling edges or both.
  - Level-sensitive interrupt pins are high- or low-active.
- Pattern-match engine
  - Select up to 8 pins from all digital pins on ports 0 and 1 to contribute to a Boolean expression. The Boolean expression consists of specified levels and/or transitions on various combinations of these pins.
  - Each bit slice minterm (product term) consisting of the specified Boolean expression can generate its own, dedicated interrupt request.
  - You can program any occurrence of a pattern match to generate a Receive Event (RXEV) notification to the CPU.
  - Use pattern match, in conjunction with software, to create complex state machines based on pin inputs.

74.3 Functional description

74.3.1 Pattern-match engine

With pattern matching, you can construct complex Boolean expressions using the same set of 8 GPIO pins you selected for interrupts. Implement each term in the Boolean expression as one slice of the pattern-match engine. A slice consists of an input

selector and detection logic that continuously monitors the selected input and creates a HIGH output (true). If the input qualifies as detected, several terms combine to a minterm. Assertion of a pin interrupt occurs when the minterm evaluates as true.

The detection logic of each slice can detect the following events on the selected input:

- Edge with memory (sticky): A rising edge, a falling edge, or a rising or falling edge that is detected at any time after the edge-detection mechanism has been cleared. The input qualifies as detected (the detection logic output remains high) until the pattern-match engine detect logic is cleared again.
- Event (nonsticky): Every time an edge (rising or falling) is detected, the detection logic output goes HIGH. After one clock cycle, writing 1 to this bit enables the detection logic to detect another edge.
- Level: A high or low level on the selected input.

The following figure shows the details of the edge-detection logic for each slice.

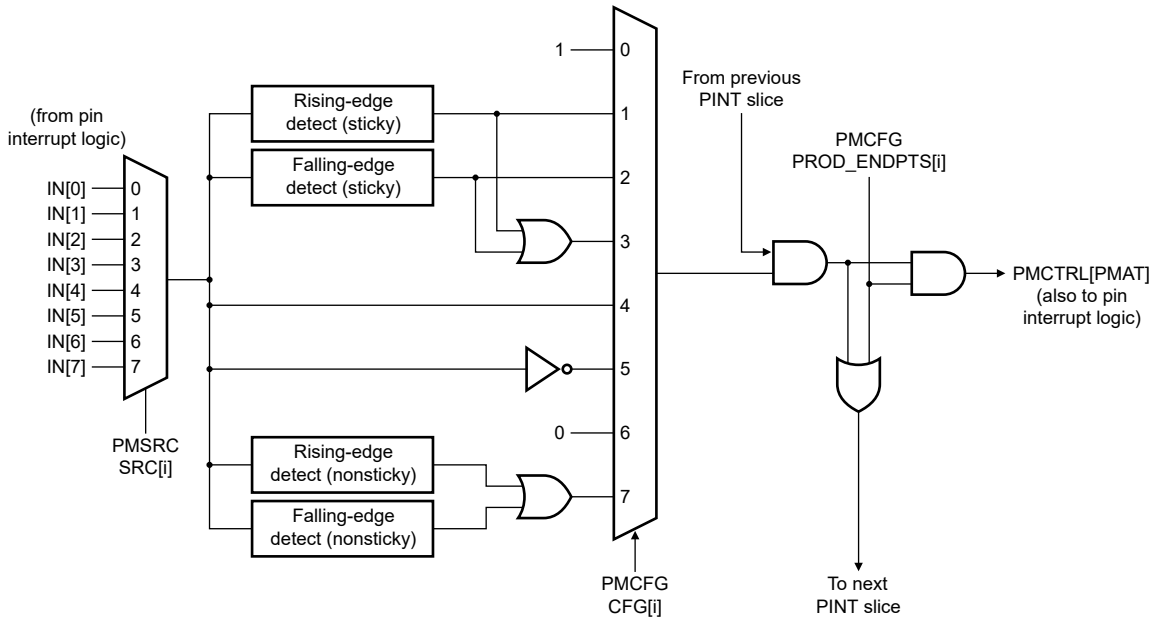

Figure 439. Pattern-match bit slice

Combined sticky and nonsticky events form a pin interrupt whenever a rising or falling edge occurs after a qualifying edge event.

Combining a level detect with an event detect can create a time window during which rising or falling edges will create a pin interrupt. See Pattern-match engine edge-detect examples for details.

The following figure shows connections between the pins and the pattern-match engine. The INPUTMUX block selects all pins that are inputs to the pattern-match engine and can be GPIO port pins or other pin functions depending on the configuration.

NOTE

The pattern-match feature requires clocks in order to operate. It cannot generate an interrupt or wake the chip during reduced power modes below sleep mode.

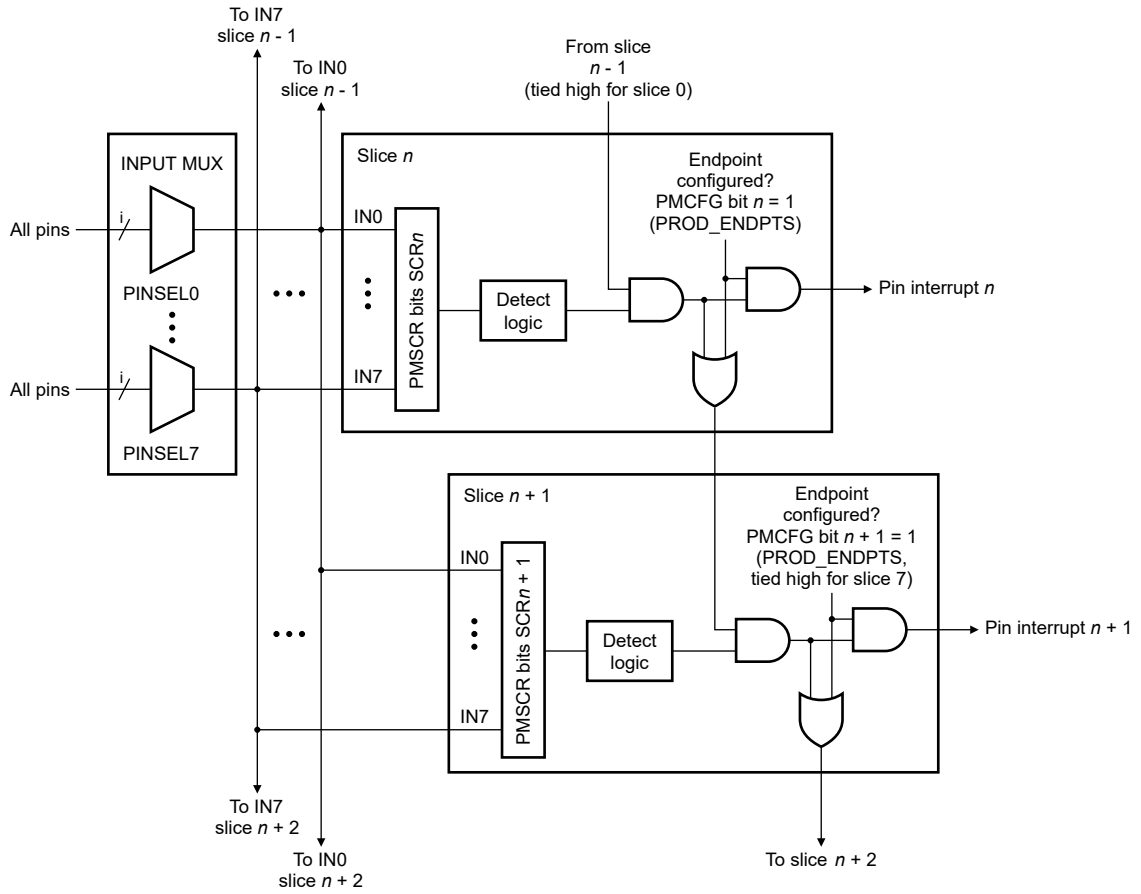

Figure 440. Pattern-match engine connections

The pattern-match logic continuously monitors the 8 inputs and generates interrupts when any one or more minterms (product terms) of the specified Boolean expression match. Each individual minterm generates a separate interrupt request.

It is also possible to enable the pattern-match module to generate RXEV output if any minterm in the Boolean expression matches.

The pattern-match function uses the same 8 interrupt request lines as the pin interrupts. Therefore, in terms of interrupt generation, these two features are mutually exclusive. Control bit generates interrupt requests based on standard pin interrupts or pattern matches. When selecting the pin interrupts, enable the RXEV request to the CPU for pattern matches.

NOTE

Do not use pattern matching to wake the part from deep-sleep mode. Pin interrupts must be selected in order to use the GPIO for wake-up.

8 bit-slice elements make up the pattern-match module. Each bit slice represents a single component in a minterm (product term) within the Boolean expression. Every time the last bit slice for a particular minterm matches, an interrupt request is asserted.

Use the pattern-match capability to create complex software state machines. Each minterm (and its corresponding individual interrupt) represents a different transition event to a new state. Then establish the new set of conditions (that is a new Boolean expression) to make a transition out of the current state.

74.3.2 Clocking

The PINT module has a single clock input, the APB PCLK.

This clock is used for its APB interface, as well as all other peripheral functionality. It must be enabled by the system for register accesses and pattern matching.

74.3.3 Interrupts

The PINT module has 8 interrupt channels, which can be configured by its registers. Each channel has its own interrupt output. Depending on how this IP is integrated, the interrupt outputs can be ORed together to use a single system-level interrupt.

74.4 External signals

PINSELa determines the inputs to the pin interrupt and pattern-match and engines. See the "INPUTMUX" chapter for more details.

74.5 Initialization

For initialization steps, see chip-specific section.

74.6 Application information

Pattern-Match Interrupt Bit-Slice Source (PMSRC) and Pattern-Match Interrupt Bit Slice Configuration (PMCFG) specify the following expression:

```
IN0 AND NOT IN1 AND IN3 rising edge OR IN1 AND IN2 OR IN0 AND NOT IN3 AND NOT IN4
```

Each term in the Boolean expression, IN0, NOT IN1, IN3 rising edge, and so on, represents one bit slice of the pattern-match engine.

- In the first AND function IN0 AND NOT IN1 AND IN3 rising edge, bit slice 0 monitors for a high level on input IN0, bit slice 1 monitors for a low level on input IN1, and bit slice 2 monitors for a rising edge on input IN3. Detecting this combination of features (all three terms are true) asserts the interrupt associated with bit slice 2.
- In the second AND function IN1 AND IN2, bit slice 3 monitors input IN1 for a high level and bit slice 4 monitors input IN2 for a high level. Detecting this combination asserts the interrupt associated with bit slice 4.
- In the third AND function IN0 AND NOT IN3 AND NOT IN4, bit slice 5 monitors input IN0 for a high level, bit slice 6 monitors input IN3 for a low level, and bit slice 7 monitors input IN4 for a low level. Detecting this combination asserts the interrupt associated with bit slice 7.
- The ORed result of all three AND functions asserts the RXEV request to the CPU. That is, any of the three terms that are true will assert the output.

74.6.1 Pattern-match engine example

Suppose you want to match the Boolean pattern

(IN1) + (IN1 * IN2) + (~IN2 * ~IN3 * IN6fe) + (IN5 * IN7ev)

with:

IN6fe = (sticky) falling edge on input 6

IN7ev = (nonsticky) event (rising or falling edge) on input 7

Each individual term in the above expression is controlled by one bit slice. To specify this expression, program the pattern-match bit slice source and configuration register fields as follows:

- Pattern-Match Interrupt Bit-Slice Source (PMSRC)
  - Because bit slice 5 is used to detect a sticky event on input 6, you can write 1 to SRC5 to clear any preexisting edge detects on bit slice 5.
  - SRC0: 001 - select input 1 for bit slice 0
  - SRC1: 001 - select input 1 for bit slice 1
  - SRC2: 010 - select input 2 for bit slice 2

- SRC3: 010 - select input 2 for bit slice 3
- SRC4: 011 - select input 3 for bit slice 4
- SRC5: 110 - select input 6 for bit slice 5
- SRC6: 101 - select input 5 for bit slice 6
- SRC7: 111 - select input 7 for bit slice 7

- Pattern-Match Interrupt Bit Slice Configuration (PMCFG)
  - PROD_ENDPTS0 = 1
  - PROD_ENDPTS2 = 1
  - PROD_ENDPTS5 = 1
  - All other slices are not product term endpoints and their PMCFG[PROD_ENDPTSn] are 0. Slice 7 is always a product term endpoint and does not have a register bit associated with it.
  - PROD_ENDPTS= 0100101 - bit slices 0, 2, 5, and 7 are product-term endpoints. (Bit slice 7 is an endpoint by default - no associated register bit).
  - CFG0: 000 - high level on the selected input (input 1) for bit slice 0
  - CFG1: 000 - high level on the selected input (input 1) for bit slice 1
  - CFG2: 000 - high level on the selected input (input 2) for bit slice 2
  - CFG3: 101 - low level on the selected input (input 2) for bit slice 3
  - CFG4: 101 - low level on the selected input (input 3) for bit slice 4
  - CFG5: 010 - (sticky) falling edge on the selected input (input 6) for bit slice 5
  - CFG6: 000 - high level on the selected input (input 5) for bit slice 6
  - CFG7: 111 - event (any edge, nonsticky) on the selected input (input 7) for bit slice 7
- Pattern-Match Interrupt Control (PMCTRL)
  - Bit0: Writing this bit selects pattern matches to generate the pin interrupts in place of the standard pin interrupt mechanism.

    For this example, detecting a match on the first product term asserts pin interrupt 0 (which, in this case, is just a high level on input 1).

    Pin interrupt 2 is asserted in response to a match on the second product term.

    Pin interrupt 5 is asserted when there is a match on the third product term.

    Pin interrupt 7 is asserted on a match on the last term.
  - Bit1: Writing this bit causes the RXEV signal to the CPU getting asserted whenever a match occurs on any of the product terms in the expression. Otherwise, the RXEV line does not get used.
  - Bit31:24: At any given time, bits 0, 2, 5, and 7 may be high if the corresponding product terms are currently matching.
  - The remaining bits are low.

74.6.2 Pattern-match engine edge-detect examples

The following figures show only pattern-match functionality in which accurate timing is not implied. Inputs (INn) are shown synchronized to the system clock for simplicity.

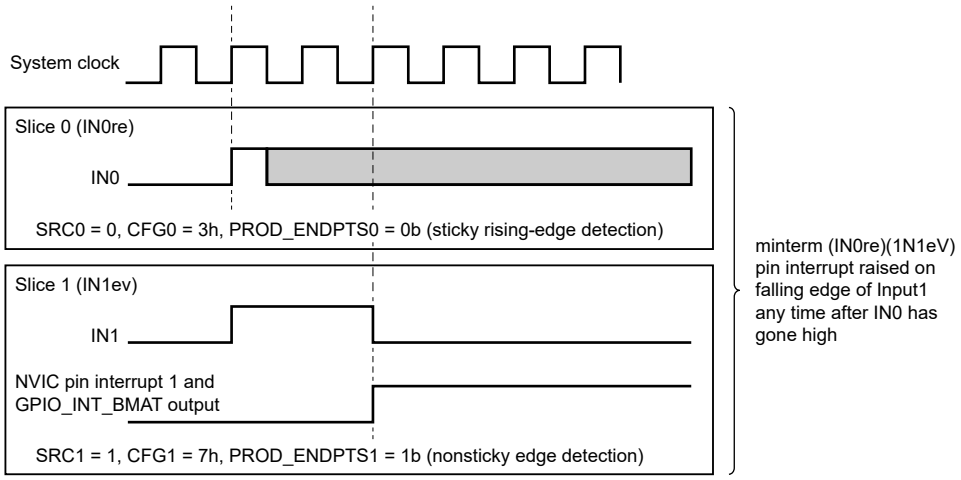

Figure 441. Pattern-match engine examples: sticky edge detect

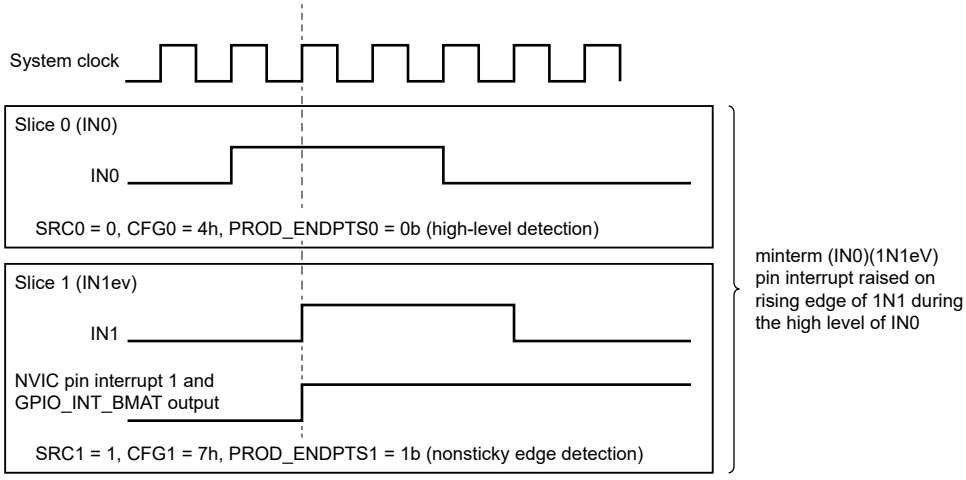

Figure 442. Pattern-match engine examples: Windowed nonsticky edge-detect evaluates as true

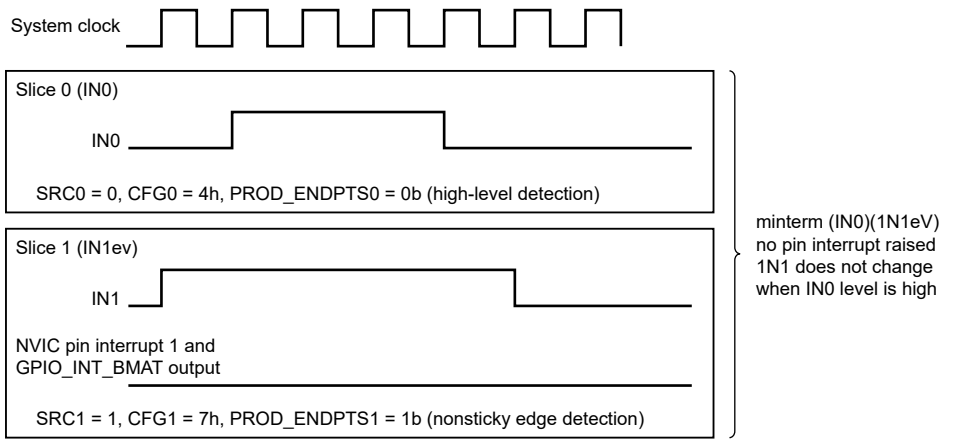

Figure 443. Pattern-match engine examples: Windowed nonsticky edge-detect evaluates as false

74.7 Memory map and register definition

This section includes the PINT memory map and detailed descriptions of all registers.

The chip includes up to 8 pins identified as interrupt sources by Pin Interrupt Select (PINSELa). The registers have 8 fields that correspond to the pins called out by PINSEL.

Table 712. Pin interrupt registers for edge- and level-sensitive pins

Name	Edge-sensitive function	Level-sensitive function
IENR	Enables rising-edge interrupts.	Enables level interrupts.
SIENR	Write to enable rising-edge interrupts.	Write to enable level interrupts.
CIENR	Write to disable rising-edge interrupts.	Write to disable level interrupts.
IENF	Enables falling-edge interrupts.	Selects active level.
SIENF	Write to enable falling-edge interrupts.	Write to select high active.
CIENF	Write to disable falling-edge interrupts.	Write to select low active.

74.7.1 Pin Interrupts and Pattern Match register descriptions

74.7.1.1 PINT memory map

PINT0 base address: 4000_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Pin Interrupt Mode (ISEL)	32	RW	See section
4h	Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR)	32	RW	See section
8h	Pin Interrupt Level or Rising-Edge Interrupt Set (SIENR)	32	W	See section
Ch	Pin Interrupt Level (Rising-Edge Interrupt) Clear (CIENR)	32	RW	See section
10h	Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF)	32	RW	See section

30h	Pattern-Match Interrupt Bit Slice Configuration (PMCFG)	32	RW	See section

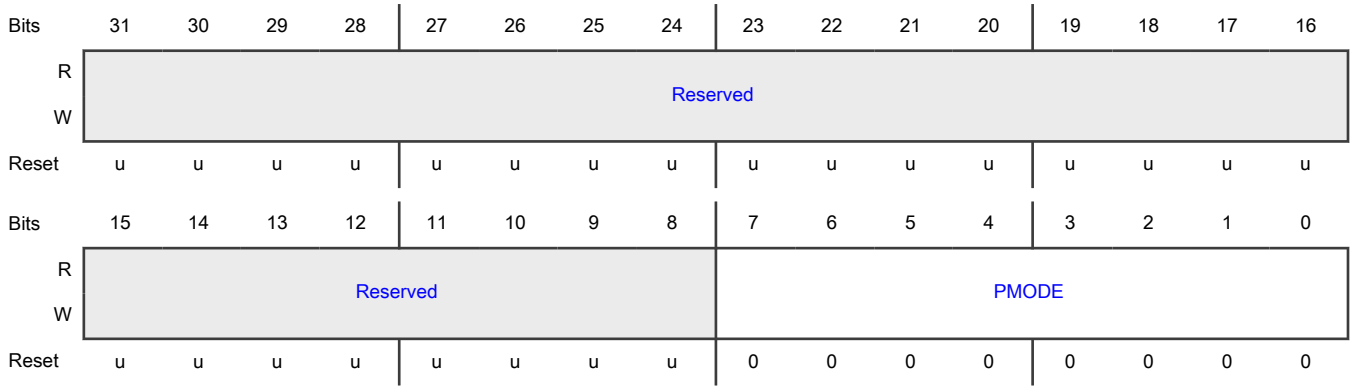
74.7.1.2 Pin Interrupt Mode (ISEL)

Offset

Register	Offset
ISEL	0h

Function
Determines whether an interrupt is edge- or level-sensitive.

Diagram



Fields

Field	Function
31-8 —	Read value is undefined; write only 0.
7-0 PMODE	Interrupt mode Selects the interrupt mode for each pin interrupt. Bit *n* configures the pin interrupt selected in PINSEL in INPUTMUX. 0000_0000b - In bit n configures the interrupt to be edge-sensitive 0000_0001b - In bit n configures the interrupt to be level-sensitive

74.7.1.3 Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR)

Offset

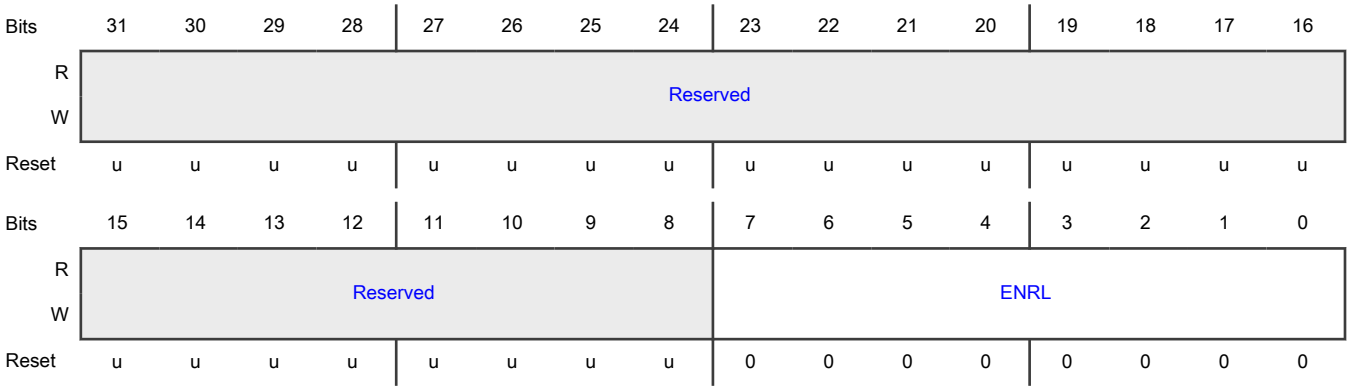
Register	Offset
IENR	4h

Function

Enables the interrupt by each field in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR), depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the rising-edge interrupt is enabled.
- If the PMODE is level sensitive (PMODE = 1), the level interrupt is enabled. Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) configures the active level (HIGH or LOW) for this interrupt.

Diagram



Fields

Field	Function
31-8 —	Read value is undefined; write only 0.
7-0 ENRL	Enables Interrupt Enables the rising edge or level interrupt for each pin interrupt corresponding to the bit index. Bit *n* configures the pin interrupt selected in PINSELa. 0000_0000b - In bit n disables the corresponding interrupt 0000_0001b - In bit n enables the corresponding interrupt

74.7.1.4 Pin Interrupt Level or Rising-Edge Interrupt Set (SIENR)

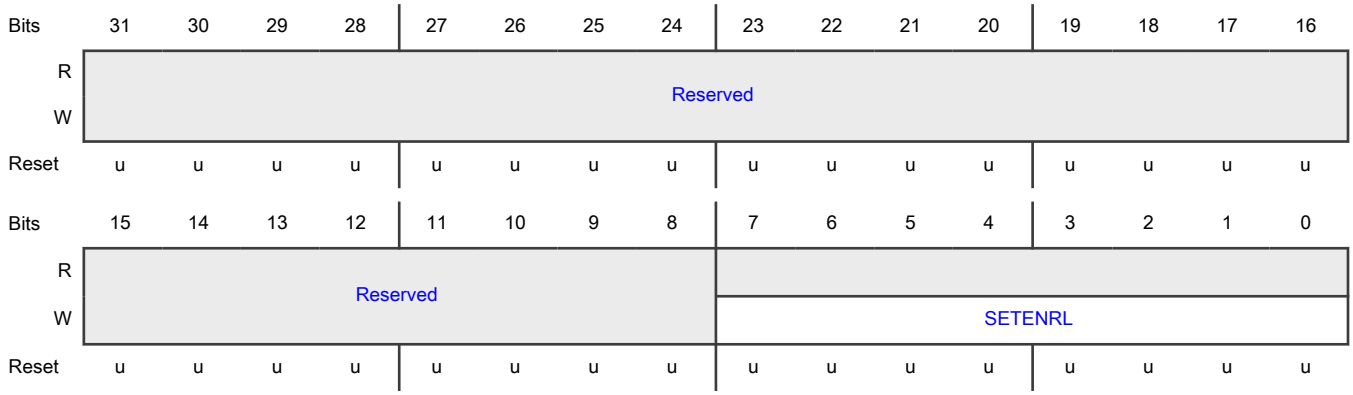
Offset

Register	Offset
SIENR	8h

Function

Configures the corresponding field in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR) by each field in Pin Interrupt Level or Rising-Edge Interrupt Set (SIENR), depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SETENRL	Configures IENR Configures IENR by writing 1s to this address. Bit *n* configures the corresponding bit in IENR. 0000_0000b - No operation for interrupt n 0000_0001b - Enable rising edge or level interrupt for interrupt n

74.7.1.5 Pin Interrupt Level (Rising-Edge Interrupt) Clear (CIENR)

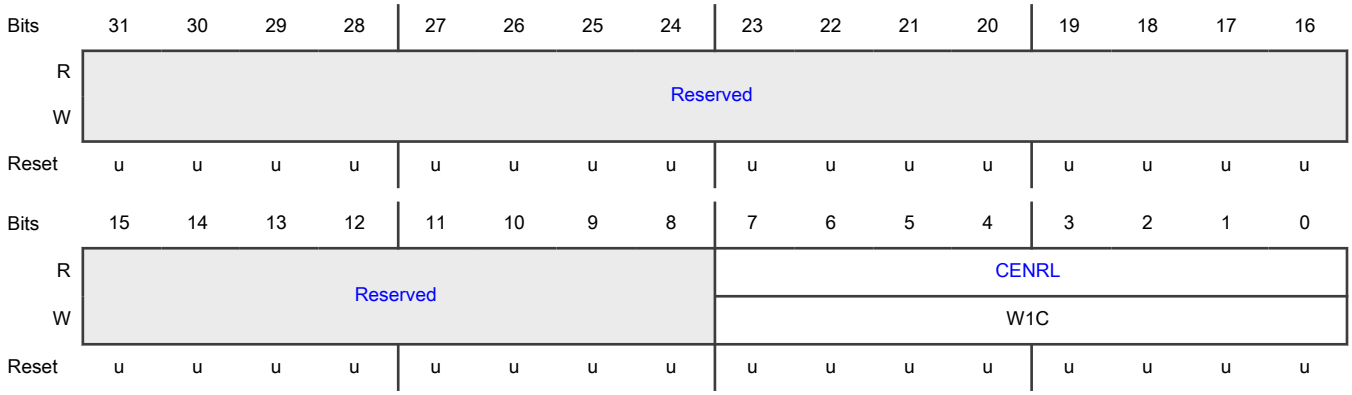
Offset

Register	Offset
CIENR	Ch

Function

Writing 0 to each bit in Pin Interrupt Level (Rising-Edge Interrupt) Clear (CIENR) adjusts the corresponding bit in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR) depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL). Writing 0 to this address configures bits in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR), effectively disabling interrupts. Writing 0 to bit *a* configures bit *n* in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 CENRL	Clear bits in IENR 0000_0000b - No operation 0000_0001b - Disable rising edge or level interrupt

74.7.1.6 Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF)

Offset

Register	Offset
IENF	10h

Function

Enables the falling-edge interrupt or configures the level sensitivity depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the falling-edge interrupt is enabled.
- If the PMODE is level sensitive (PMODE = 1), the active level of the level interrupt (HIGH or LOW) is configured.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	u	u	u	u	u	u	u	u	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 ENAF	Enables Interrupt Enables the falling edge or configures the active-level interrupt for each pin interrupt. Bit *a* configures the pin interrupt selected in PINSELa. 0000_0000b - Disable (set active interrupt level LOW) 0000_0001b - Enable (set active interrupt level HIGH)

74.7.1.7 Pin Interrupt Active Level or Falling-Edge Interrupt Set (SIENF)

Offset

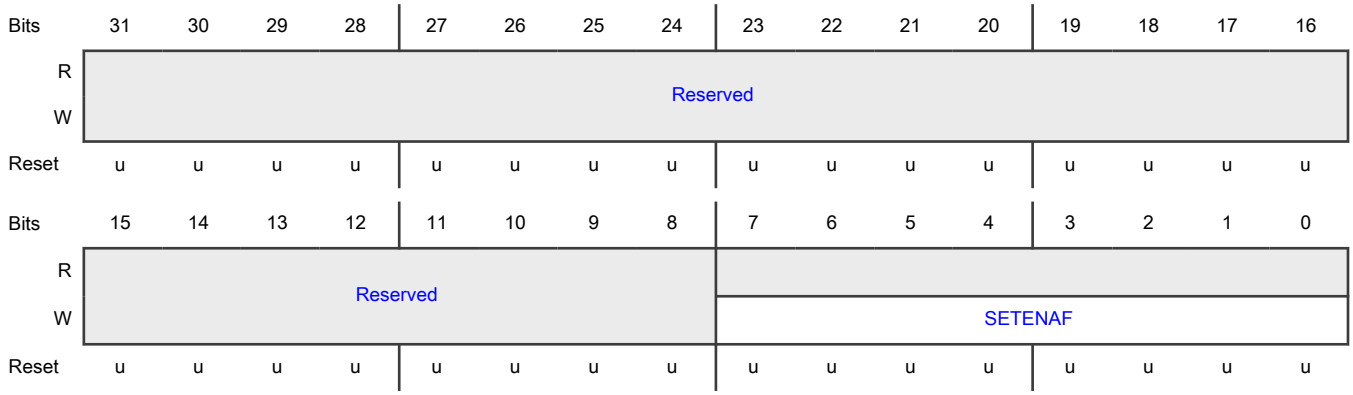
Register	Offset
SIENF	14h

Function

Sets the corresponding bit in Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) (by each bit of SIENF), depending on the PMODE configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the falling-edge interrupt becomes 1.
- If the PMODE is level sensitive (PMODE = 1), the HIGH-active interrupt is selected.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SETENAF	Write 1 to this address to clear Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) to disable interrupts. Bit *a* sets bit *n* in IENF. 0000_0000b - Writes 0 to IENF. No operation 0000_0001b - Select HIGH-active interrupt or enable falling-edge interrupt

74.7.1.8 Pin Interrupt Active Level or Falling-Edge Interrupt Clear (CIENF)

Offset

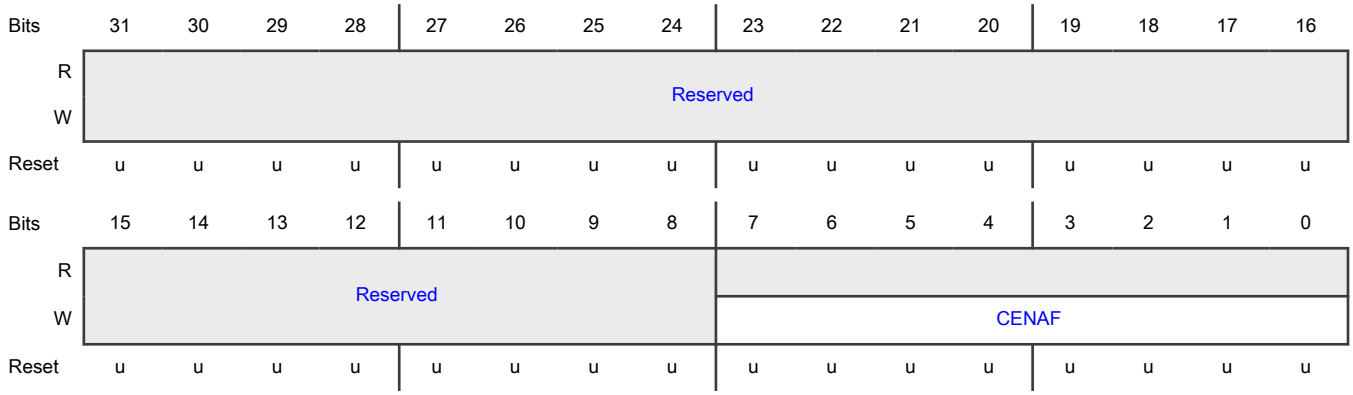
Register	Offset
CIENF	18h

Function

Sets the corresponding bit in Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) (by each bit of Pin Interrupt Active Level or Falling-Edge Interrupt Clear (CIENF), depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the falling-edge interrupt is cleared.
- If the PMODE is level sensitive (PMODE = 1), the LOW-active interrupt is selected.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 CENAF	Writes 0 to IENF Specifies that if you change Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) to 0 by writing 1 to it,this will disable interrupts. Writing 0 to bit *a* configures bit *n* in Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF). 0000_0000b - No operation 0000_0001b - LOW-active interrupt selected or falling-edge interrupt disabled

74.7.1.9 Pin Interrupt Rising Edge (RISE)

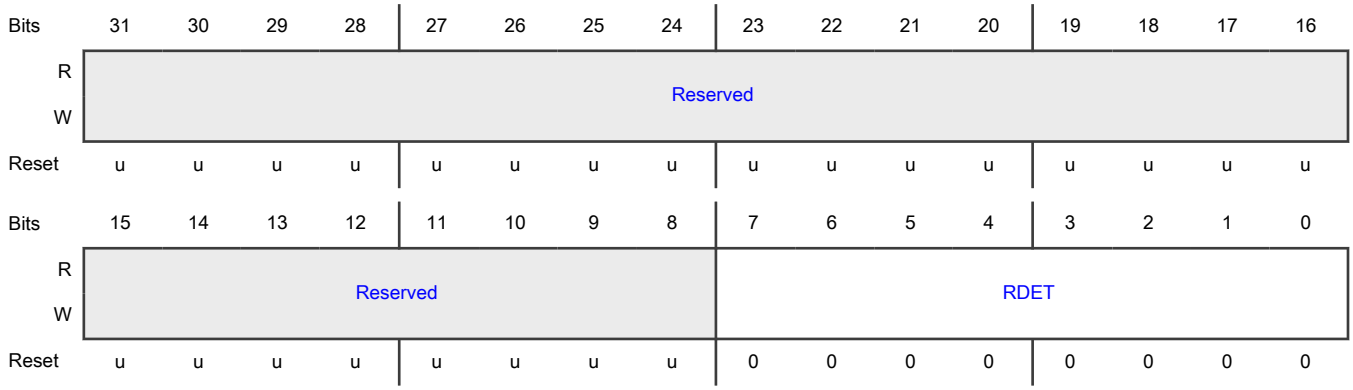
Offset

Register	Offset
RISE	1Ch

Function

Contains 1s for pin interrupts selected in PINSELa (see the "INPUTMUX" chapter for more details) on which a rising edge has been detected. Writing 1s to this register clears rising-edge detection. Ones in this register assert an interrupt request for pins that are enabled for rising-edge interrupts. All edges are detected for all pins selected by PINSEL, regardless of whether they are interrupt-enabled.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RDET	Rising-Edge Detect Bit *a* detects the rising edge of the pin selected in PINSELa. 0000_0000b - Read 0- No rising edge (since Reset or you wrote a 1 to this field last time), Write 0- No operation 0000_0001b - Read 1- Rising edge (since Reset or you wrote a 1 to this field last time), Write 1- Clear rising-edge detection for this pin

74.7.1.10 Pin Interrupt Falling Edge (FALL)

Offset

Register	Offset
FALL	20h

Function

Contains 1s for pin interrupts selected in PINSELa on which a falling edge has been detected. Writing 1s to this register clears falling-edge detection. The values (1s) in this register assert interrupt requests for pins with falling-edge interrupt capabilities. PINSELa detects all edges for all pins, regardless of whether they are interrupt-enabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								FDET							
Reset	u	u	u	u	u	u	u	u	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 FDET	Falling-Edge Detect Bit *a* detects the falling edge of the pin selected in PINSELa. 0000_0000b - Read 0- No falling edge (since Reset or you wrote a 1 to this field last time), Write 0- No operation 0000_0001b - Read 1- Falling edge (since Reset or you wrote a 1 to this field last time), Write 1- Clear falling-edge detection for this bit

74.7.1.11 Pin Interrupt Status (IST)

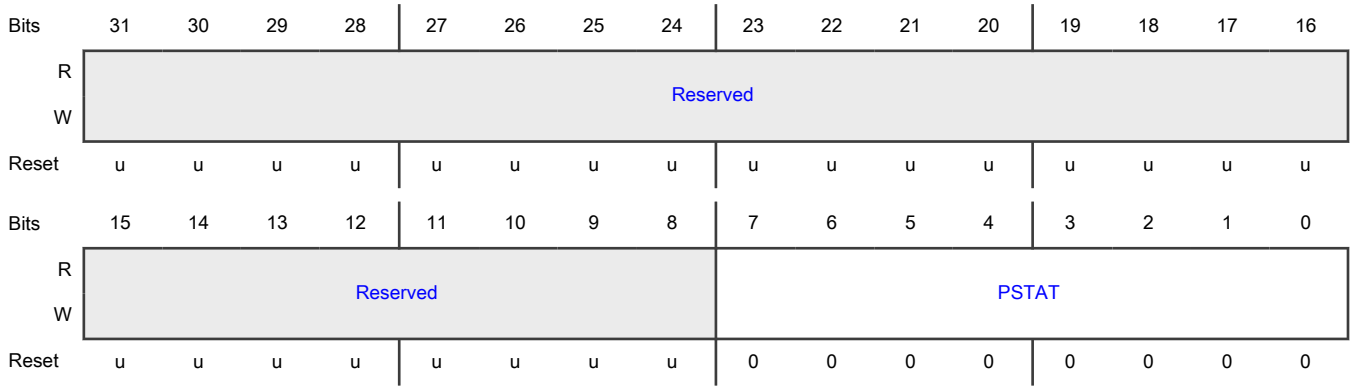
Offset

Register	Offset
IST	24h

Function

Returns 1s for pin interrupts that are currently requesting an interrupt. For edge-sensitive pins in Interrupt Select, writing 1s to this register clears both rising- and falling-edge detection for the pin. For level-sensitive pins, writing 1s inverts the corresponding bit in the active-level register, thus switching the active level on the pin.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 PSTAT	Pin Interrupt Status Bit *a* returns the status, clears the edge interrupt, or inverts the active level of the pin selected in PINSELa. 0000_0000b - Read 0- Interrupt is not requested, Write 0- No operation 0000_0001b - Read 1- Interrupt is requested, Write 1 (edge-sensitive)- clear rising- and falling-edge detection for this pin, Write 1 (level-sensitive)- switch the active level for this pin in Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF)

74.7.1.12 Pattern-Match Interrupt Control (PMCTRL)

Offset

Register	Offset
PMCTRL	28h

Function

Contains a field to select pattern-match interrupt generation (as opposed to pin interrupts which share the same interrupt request lines), and another to enable the RXEV output to the CPU. Read the current state of the pattern match in this register. If the pattern-match feature is not used (either for interrupt generation or for RXEV assertion), write 0 to PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] of this register to conserve power.

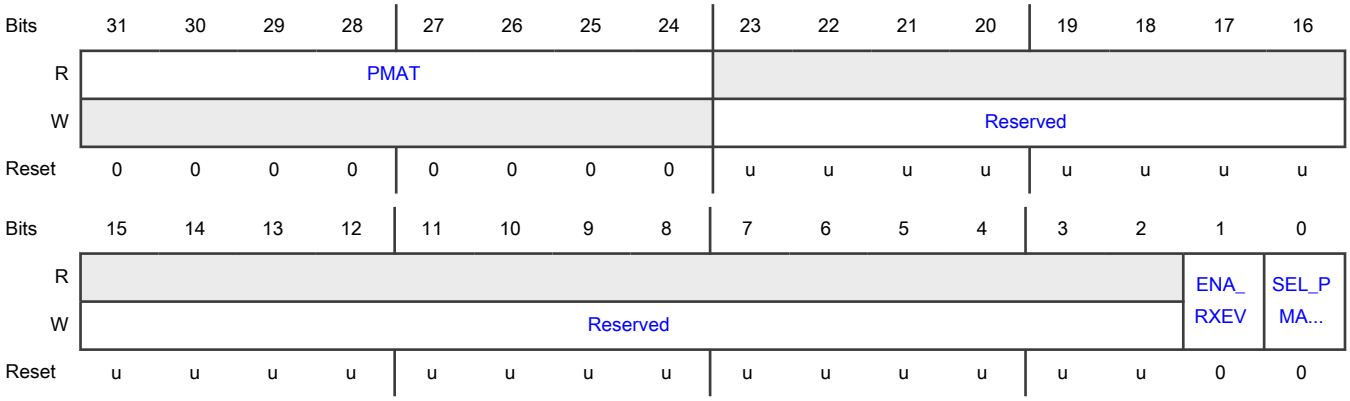
NOTE

Set up the pattern-match configuration in Pattern-Match Interrupt Bit-Slice Source (PMSRC) and Pattern-Match Interrupt Bit Slice Configuration (PMCFG) before writing to this register to enable (or reenable) the pattern-match functionality. This prevents spurious interrupts from occurring during the feature"s activation.

NOTE

The pattern-match feature requires clocks to operate and thus not generate an interrupt or wake the chip during reduced power modes below sleep mode.

Diagram



Fields

Field	Function
31-24 PMAT	Pattern Matches Displays the current state of pattern matches. 0000_0001b - The corresponding product term is matched by the current state of the appropriate inputs
23-2 —	Reserved, will read 0"s
1 ENA_RXEV	Enables the RXEV output to the CPU and/or to a GPIO output, when the specified Boolean expression evaluates to true. If this value is 0b, RXEV output to the CPU is disabled. If this value is 1b, RXEV output to the CPU is enabled. 0b - Disabled 1b - Enabled
0 SEL_PMATCH	Specifies whether the pin interrupts are controlled by the pin interrupt function or by the pattern-match function. If this value is 0b, interrupts are driven in response to the standard pin interrupt function. If this value is 1b, interrupts are driven in response to pattern matches. 0b - Pin interrupt 1b - Pattern match

74.7.1.13 Pattern-Match Interrupt Bit-Slice Source (PMSRC)

Offset

Register	Offset
PMSRC	2Ch

Function

Specifies the input source for each of the pattern-match bit slices. Each of the possible 8 inputs is selected in the pin interrupt select registers in INPUTMUX. Input 0 corresponds to the pin selected in PINSEL0, input 1 corresponds to the pin selected in PINSEL1, and so on.

NOTE

Writing any value to either Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC), or disabling the pattern-match feature by clearing both the PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] bits in Pattern-Match Interrupt Control (PMCTRL) to zeros will erase all edge-detect history.

Diagram

7-0 —	Reserved, will read 0's

74.7.1.14 Pattern-Match Interrupt Bit Slice Configuration (PMCFG)

Offset

Register	Offset
PMCFG	30h

Function

Configures the detect logic and contains bits to select from among eight alternative conditions for each bit slice that cause that bit slice to contribute to a pattern match. The seven LSBs of this register specify which bit slices are the end-points of product terms in the Boolean expression (where OR terms are to be inserted in the expression).

Two types of edge detection on each input are possible:

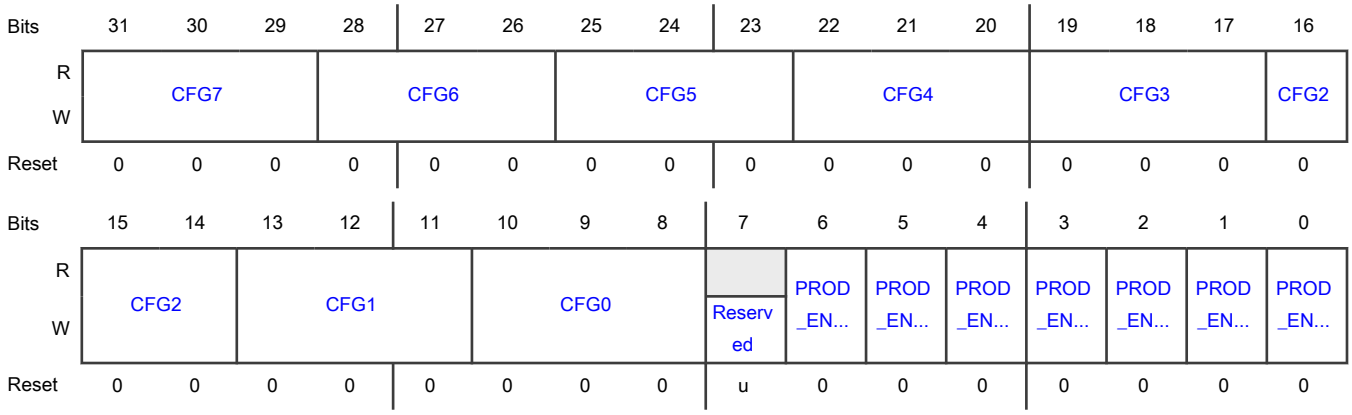
- Sticky: A rising edge, a falling edge, or a rising or falling edge that is detected at any time after the edge-detection mechanism becomes 0. The input qualifies as detected (the detect logic output remains HIGH) until the pattern-match engine detect logic becomes 0 again.
- Nonsticky: In the event of an edge (rise or fall), the detect logic output for this pin goes HIGH. One clock cycle clears this bit, allowing the edge detector to detect a second edge.

To clear the pattern-match engine detect logic, write any value to either Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC), or disable the pattern-match feature by changing both PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] to 0 by writing 1 to Pattern-Match Interrupt Control (PMCTRL). This will erase all edge-detect history.

To select whether a slice marks the final component in a minterm of the Boolean expression, write a 1 in the corresponding PROD_ENDPTSa bit. Setting a term as the final component has two effects:

1. Anytime a match to that product term occurs, this leads to an assertion of interrupt request associated with this bit slice.
2. The next bit slice will start a new, independent product term in the Boolean expression. The Boolean expression will include an OR following the element controlled by this bit slice.

Diagram



Fields

Field	Function
31-29: CFG7 28-26: CFG6 25-23: CFG5 22-20: CFG4 19-17: CFG3 16-14: CFG2 13-11: CFG1 10-8: CFG0	Match Configuration Specifies the match contribution condition for bit slice n: • If the value is 000b, this bit slice always contributes to a product term match. • If the value is 001b, edge detection for this bit slice is clear when there has been a rising edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 010b, edge detection for this bit slice is clear when there has been a falling edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 011b, edge detection for this bit slice is clear when there has been either a rising or a falling edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 100b, match for this bit slice occurs when there is a high level on the input specified for this bit slice in Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 101b, match occurs when there is a low level on the specified input. • If the value is 110b, it never contributes to a match and must be used to disable any unused bit slices. • If the value is 111b, a match occurs when the specified input first detects a rising or falling edge. This is a nonsticky version of value 0 x 3. Write 0 to this field after one clock cycle. 000b - Constant HIGH 001b - Sticky rising edge 010b - Sticky falling edge 011b - Sticky rising or falling edge 100b - High level 101b - Low level 110b - Constant 0 111b - Event (Nonsticky rising or falling edge)
7 —	Bit slice 7 is automatically considered a product endpoint.
6-0 PROD_ENDPTSn	Determines whether slice n is an endpoint. Slice n is not an endpoint. Slice n is the endpoint of a product term (minterm). Pin interrupt n in the NVIC is raised if the minterm evaluates as true. 0b - No effect 1b - Endpoint

Chapter 75
Port Control (PORT)

75.1 Chip-specific PORT information

Table 713. Reference links to related information

Topic	Related module	Reference
Full description	PORT	PORT
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

NOTE

See Peripheral Reset Control 0 (PRESETCTRL0) to know how to reset PORT. To enable PORT clock, see AHB Clock Control 0 (AHBCLKCTRL0).

75.1.1 Module instances

This device has six instances of the port module, PORT0, PORT1, PORT2, PORT3, PORT4, and PORT5.

NOTE

For PORT5, the EFT detect function can only work when VBAT = 1.8 V.

75.1.2 Normal I/O pin structure

The following diagram shows the structure of normal I/O pin.

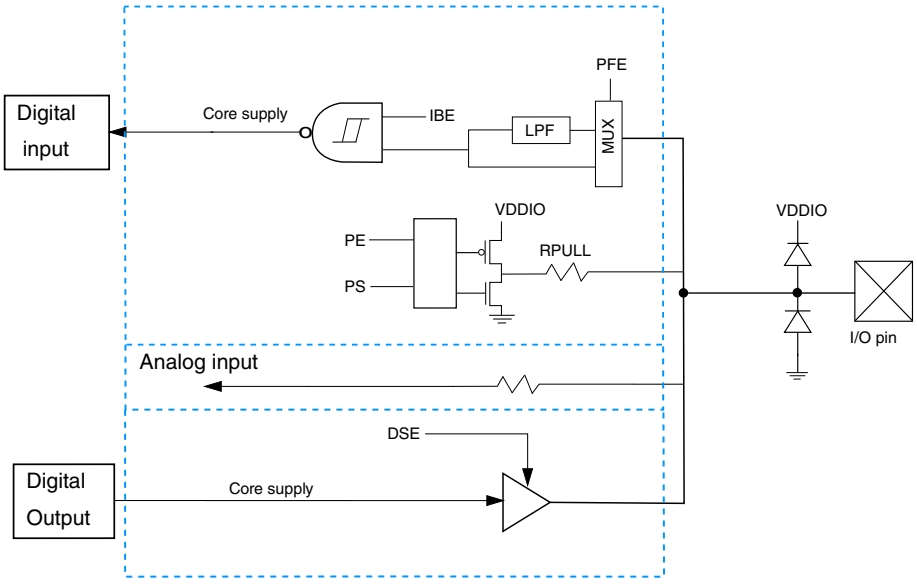


Figure 444. Basic structure of an I/O port

75.1.3 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

75.2 Overview

PORT provides support for pad control functions. You can configure most functions independently for each pin, in the 32-bit port, and affect the pin regardless of its pin multiplexing state.

There exists a single instance of the PORT module for each port, and not all pins within each port are implemented on a specific chip.

75.2.1 Block diagram

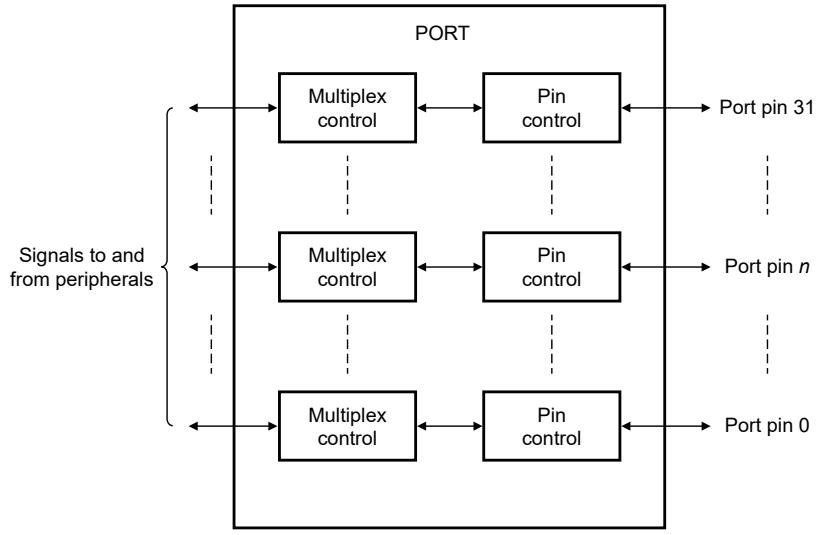

Figure 445. Block diagram

75.2.2 Features

- Individual pull control fields with pullup, pulldown, and pull-disable support
- Individual PCR*n*[PFE] fields that enable and disable individual input passive filters
- Individual PCR*n*[ODE] fields that enable and disable individual open drain outputs
- Digital input inversion to optionally invert the digital input
- Individual electrical fast transient (EFT) detect with an EFT detect flag and associated interrupt
- Digital PCR*n*[IBE] fields to configure between analog or disabled functions and digital functions
- Individual PCR*n*[MUX] fields supporting GPIO and up to 3 chip-specific digital functions

75.3 Functional description

75.3.1 Pin control

Each port pin has a corresponding Pin Control Register (PCR) associated with it that helps you configure the following functions for each pin within the 32-bit port:

- Pullup or pulldown enable
- Open drain enable
- Passive input filter enable
- Digital input inversion
- EFT detection
- Software configuration lock
- Pin multiplexing mode

These functions apply across all digital pin multiplexing modes, and individual peripherals do not override the configuration in PCR*n* unless otherwise noted. For example, if an I^2C function is enabled on a pin, it does not override the pullup or open drain configuration for that pin.

PCR*n*[LK] allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that PCR*n* are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each PCR*n* is retained when the PORT module is disabled.

When you configure a pin in a digital pin multiplexing mode, the input buffer for that pin is enabled, allowing the pin state to be read via the corresponding GPIO.PDIR or allowing a pin interrupt or DMA request to be generated. If a pin is always floating when its input buffer is enabled, it can cause an increase in power consumption. This situation must be avoided. A pin can be floating because of an input pin that is not connected or an output pin that is tristated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) ensures that a pin does not float when its input buffer is enabled. The internal pull resistor is automatically disabled whenever the output buffer is enabled, allowing PCR*n*[PE] to remain 1. Configuring Pin Multiplexing mode to disabled or analog (PCR*n*[MUX] = 0) disables the pin's input buffer and results in lowest power consumption.

75.3.2 Global pin control

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) allow a single register write to update the lower 16 bits of PCR*n* for up to 16 pins, all with the same value. You cannot write to locked registers by using Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR).

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) enable you to quickly configure multiple pins within the same port and with the same peripheral function. These are write-only registers that always read as 0.

75.3.3 EFT detection

The EFT detect circuit is active whenever PORT is powered and EDCR[EDLC] and EDCR[EDHC] are 0.

The EFT high detect circuit for each pin is reset whenever EDCR[EDHC] = 1. Likewise, the EFT low detect circuit for each pin is reset whenever EDCR[EDLC] = 1 and that pin's EFT high detect is not asserted.

75.3.4 Clocking

This module has no clocking considerations.

75.3.5 Interrupt

When EFT on a pin is detected, an interrupt request is generated to indicate the detection of EFT on that pin. This interrupt is enabled when EDIER[EDIE*n*] = 1. Writing 0 to these fields clears the interrupt request but does not affect EFT detection on the corresponding pin (EDFR[EDF*n*]).

75.3.6 Calibration

The combination of Calibration 0 (CALIB0) and Calibration 1 (CALIB1) controls the drive strength of a pin for the port and PCR*n*[DSE] for the pin.

Calibration 0 (CALIB0) and Calibration 1 (CALIB1) represent two driver configurations. If PCR*n*[DSE] = 0, the configuration in Calibration 0 (CALIB0) is used. Likewise, if PCR*n*[DSE] = 1, the configuration in Calibration 1 (CALIB1) is used.

The pulldown and pullup drivers have eight segments. The value of NCAL[5:3] represents the number of pulldown segments that are enabled when driving low, and the value of PCAL[5:3] represents the number of pullup segments that turn on when driving high. Writing 000b to these fields causes one segment to turn on, while writing 111b causes all eight segments to turn on. Upon reset, Calibration 0 (CALIB0) becomes 1 to create approximately 50 Ω driver at 3.3 V and 25 °C (3 is a typical value) and Calibration 1 (CALIB1) becomes 1 to create approximately 50 Ω driver at 1.8 V and 25 °C (7 is the typical value).

The three LSBs of CALIB0[NCAL], CALIB1[NCAL], CALIB0[PCAL], and CALIB1[PCAL] do not affect the driver's strength. Instead, they are included to improve precision when calibrating to a different impedance value. This can be done by using the following formula:

Calibration = (G × (CAL0 + 4) – 1024) >> 8, where G is a binary code representing the desired conductance and CAL0 is one of the 6-bit fields in Calibration 0 (CALIB0) and Calibration 1 (CALIB1). The value of G scales linearly with the intended conductance; G = 0 corresponds to 0 S (an open circuit), and G = 256 corresponds to 0.02 S (50 Ω). For example, the following operation configures the driver to be approximately 0.03 S (33 Ω) at 3.3 V when PCR*n*[DSE] = 1:

The value of CALIB1[NCAL] = (384 × (the value of CALIB0[NCAL] + 4) – 1024) >> 8;

The value of CALIB1[PCAL] = (384 × (the value of CALIB0[PCAL] + 4) – 1024) >> 8;

Do not overflow or underflow NCAL[5:3] or PCAL[5:3]; otherwise, this operation may have an unintended result. You can configure the drive strength for 50 Ω at 2.5 V and 25 °C by averaging the initial NCAL codes in Calibration 0 (CALIB0) and Calibration 1 (CALIB1), and averaging the initial PCAL codes in Calibration 0 (CALIB0) and Calibration 1 (CALIB1). However, the 2.5 V configuration is not as accurate or precise as the original 1.8 V and 3.3 V configuration because the drive strength is not perfectly linear with supply voltage.

NOTE

This calibration feature may not apply to all PORT pins. See the chip-specific PORT information for pins that support calibration.

75.4 Initialization

To initialize PORT, perform the following procedure:

1. Initialize the pin functions:
   - Initialize single pin functions by writing appropriate values to PCR*n*.
   - Initialize multiple pins (up to 16) with the same configuration by writing appropriate values to Global Pin Control Low (GPCLR) or Global Pin Control High (GPCHR).
2. Lock the configuration for a given pin, by writing 1 to PCR*n*[LK], so that it cannot be changed until the next reset.

75.5 Application information

75.5.1 Determine polarity of an asserted EFT detection

You can determine the polarity of an asserted EFT detect by performing this procedure:

1. Read EFT Detect Flag (EDFR).
2. Write 1 and then write 0 to EDCR[EDLC].
3. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT low detector only (no EFT high detector triggering).
4. Write 1 and then write 0 to EDCR[EDHC].
5. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT high detector. Any field that did not become 0 indicates triggering of both the EFT high and EFT low detectors.

6. Write 1 and then write 0 to both EDCR[EDLC] and EDCR[EDHC] to ensure that all detectors are reset.

75.6 Memory map and register definition

Any read or write access to the PORT memory space, outside the valid memory map, results in a bus error. All register accesses complete with zero wait states.

75.6.1.7 EFT Detect Interrupt Enable (EDIER)

Offset

Register	Offset
EDIER	44h

Function

Configures whether to generate an interrupt when an EFT event is detected.

Signal multiplexing	Port control	Signal multiplexing

76.1.1 Module instances

This device has one instance of the MICFIL module, MICFIL0.

76.2 Overview

MICFIL delivers audio from microphones to the processor in several applications, such as mobile telephones. As current digital audio systems use a multi-bit audio signal (also known as multi-bit PCM) to represent the signal, this module implements the required digital interface (a series of filters) to transform a pulse density modulated (PDM) microphone bitstream into a 24-bit PCM signal in the audio band, at a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques used in hardware. The MICFIL architecture is designed to save gate count and minimize power consumption.

You can implement MICFIL to work in a multi-channel mode. All channels have the same configuration, but you could independently turn on or turn off each input channel.

76.2.1 Block diagram

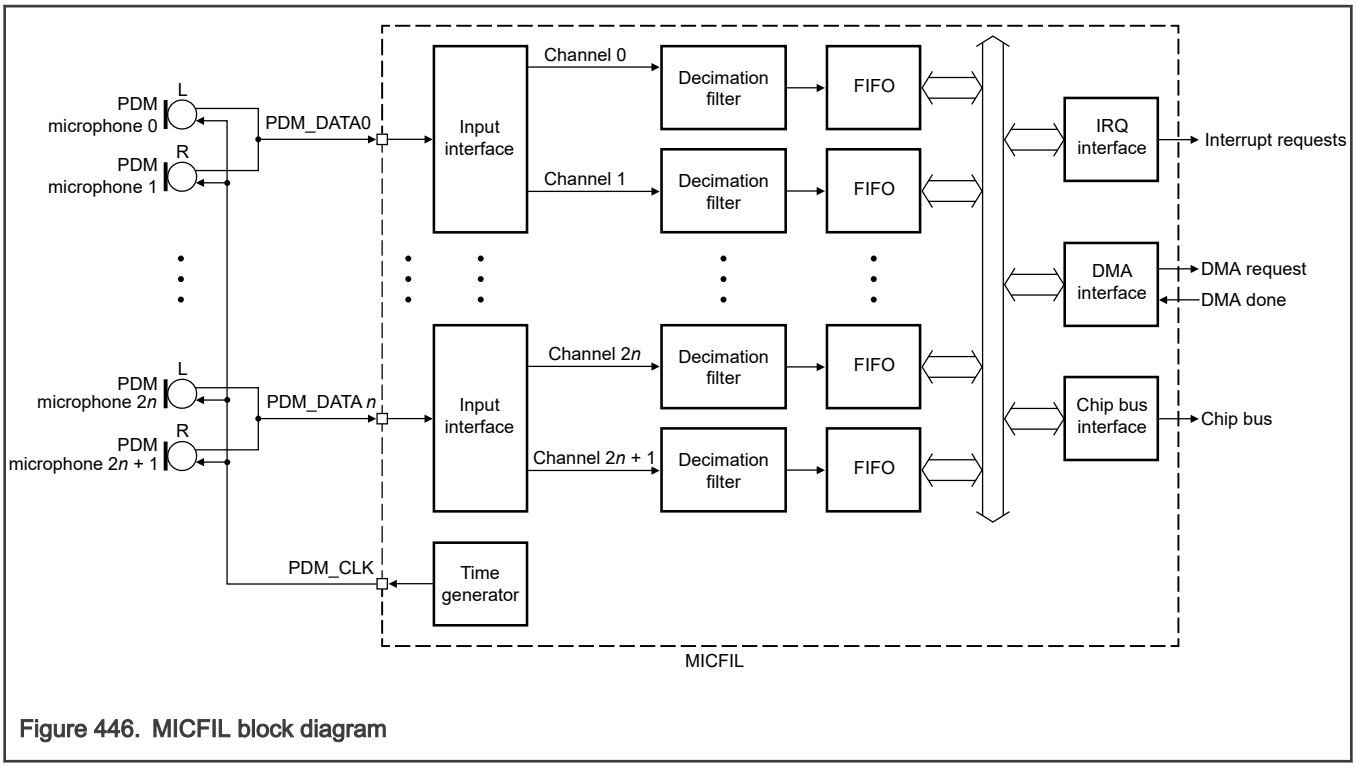

Figure 446. MICFIL block diagram

76.2.2 Features

- Decimation filters:
  - Fixed-point filtering
  - 24-bit PCM audio output
  - Internal clock divider for a programmable PDM clock generation: clock divider bypass capability for low-frequency operations
  - Frame synchronization
  - Full or partial set of channel operations with individual enable controls
  - Programmable decimation rate
  - Programmable DC remover at output
  - Range adjustment capability
- FIFOs with interrupt and DMA capability: each FIFO having a length of 16 entries

76.3 Functional description

76.3.1 Time generator

The time generator unit:

- Generates the PDM_CLK to microphones. This clock is the same and is active for all the PDM microphones, which means, it is not possible to turn off the PDM_CLK only for one single microphone.
- Delivers the PDM_CLK to all microphones that must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates audio information in two channels: left (0) and right (1). Every decimation filter, corresponding to its channel, does this processing.

There exists an internal clock divider (see CTRL_2[CLKDIV]) within the time generator that is enabled when CTRL_2[CLKDIVDIS] = 0; otherwise, the application clock directly drives the microphones.

NOTE

A soft reset affects the time generator unit (see CTRL_1[SRES]). The PDM_CLK starts with a rising edge after a soft reset is issued.

76.3.1.1 Clock divider

The sampling rate of the microphone input depends on the PDM_CLK rate, which you can trim using an internal clock divider, configuring the quality mode (see Quality modes) or trimming the MICFIL's root clock frequency (MICFIL_CLK_ROOT rate).

In case the clock divider is enabled, CTRL_2[CLKDIV] defines the internal clock divider frequency. You must configure CTRL_2[CLKDIV] by using Equation 49.

$$CLKDIV = \frac{MICFIL_CLK_ROOT\ rate}{8 \times OSR \times (output\ rate)}$$

Equation 49. CLKDIV value calculation

After calculating the value of CTRL_2[CLKDIV], you can estimate the generated PDM_CLK rate based on Equation 50, where the "K" factor value depends on the quality mode shown in Table 715 and floor(x) is the function that takes a real number x as input and gives the greatest integer less than or equal to x as output.

$$PDM_CLK\ rate = \frac{MICFIL_CLK_ROOT}{2 \times floor(K \times CLKDIV)}$$

Equation 50. PDM_CLK rate calculation

Table 715. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very-Low Quality 0	1
Low Quality, Very-Low Quality 1	2
Very-Low Quality 2	4

76.3.1.2 I/O timing requirements

The PDM microphones must meet the setup and hold timing requirements shown in Table 716 and Figure 447. The "K" factor value in Table 716 depends on the quality mode you select based on Table 715.

NOTE

These timing requirements apply only if the clock divider functionality is enabled (see CTRL_2[CLKDIV]) with (CTRL_2[CLKDIVDIS] = 0); otherwise, there are no special timing requirements.

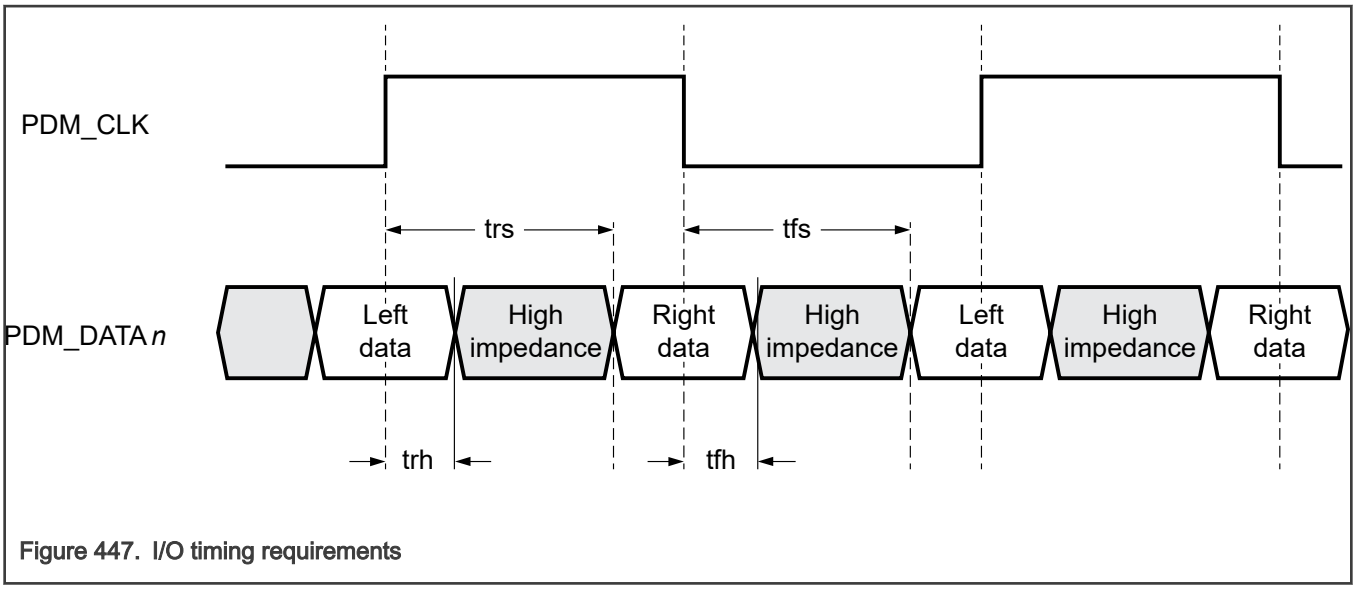

Figure 447. I/O timing requirements

Table 716. Timing parameters

Parameter	Value
trs, tfs	$\leq \frac{floor(K \times CLKDIV) - 1}{MICFIL_CLK_ROOT\ rate}$ Depending on the value of "K," you must ensure that "floor(K x CTRL_2[CLKDIV])" > 1 to avoid timing problems.
trh, tfh	≥ 0

76.3.2 Input interface

Figure 448 shows the timing diagram of the input interface signals when the clock divider is enabled. The bitstream incoming from the microphone data input "n" (PDM_DATA*n*) in the first half (right microphone) of the PDM_CLK is directed to channel "2n+1" and the data generated during the last half (left microphone) is directed to channel "2n".

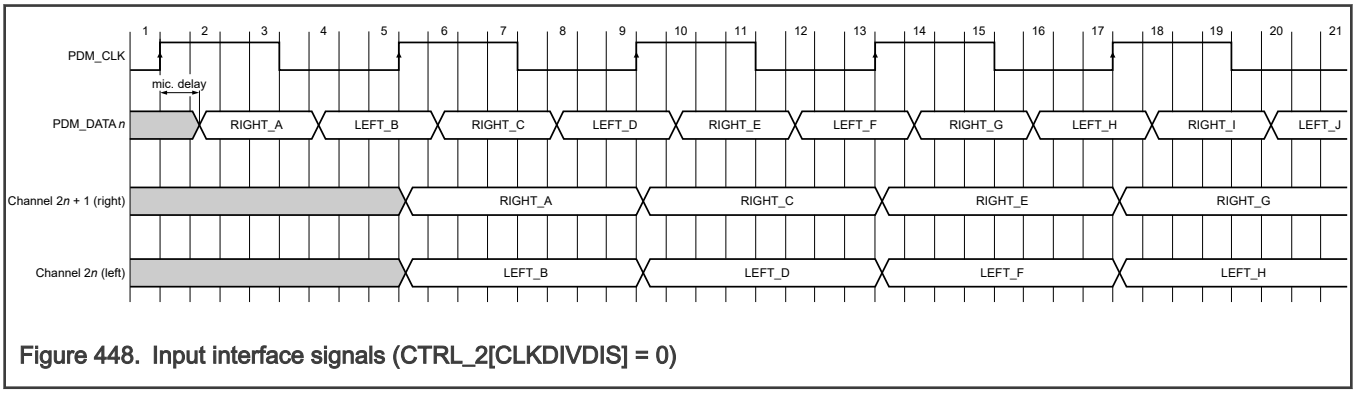

Figure 448. Input interface signals (CTRL_2[CLKDIVDIS] = 0)

76.3.3 Decimation filter

A decimation filter facilitates PDM to PCM conversion.

Figure 449 shows the block diagram of the decimation filter. The block consists of:

- A cascade integrator comb (CIC) filter, which is a low-pass filter that you commonly use to filter sigma-delta modulator output signals. The filter is implemented in the audio band (20 Hz–20.0 kHz @48 kHz output sampling rate by default) with a configurable decimation rate. You can implement it using a series of CIC, compensation, and DC remover filters.

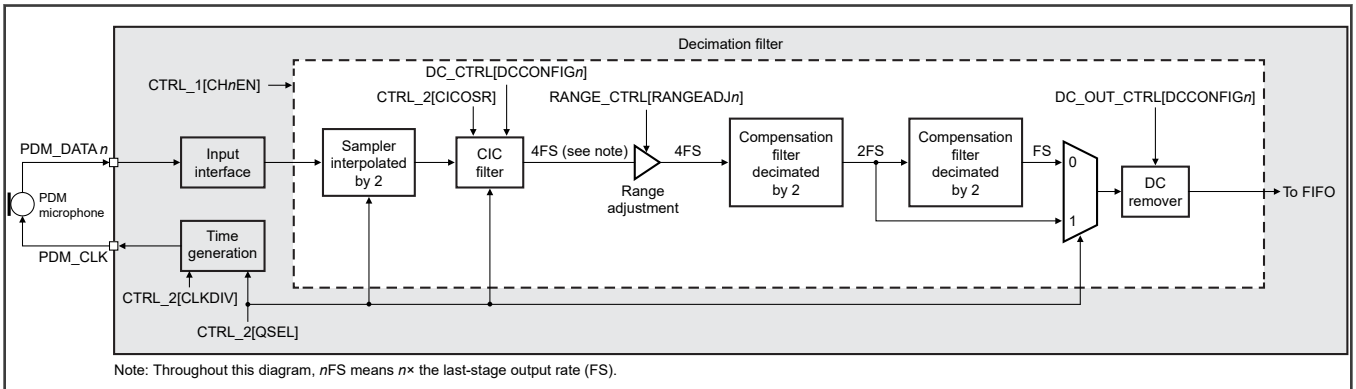
- A DC remover, which is a high-pass filter that you use to remove the DC component of the processed signal with a configurable cut-off frequency. Two DC removers exist: one in the input of the decimation filter, embedded in the CIC filter, and another in the last stage of the decimation filter.
- Two compensation filters for each channel, which implement a low-pass digital filter with decimation by 2. You can use them to compensate the high CIC drop in passband. These filters help the FIR filter block to flatten the overall passband response.

You activate the "Sampler" block depending on the quality mode selected (using CTRL_2[QSEL]). In Low-Quality and Very-Low-Quality 2 modes, the sampling rate is doubled.

The decimation filter output depends on the quality mode that you select by using CTRL_2[QSEL], based on different compensation filter output. You can supply the DC remover with the 2 FS signal, instead of the 1 FS signal, to achieve lower-power consumption, bypassing the second compensation decimation filter. The second compensation filter is bypassed when CTRL_2[QSEL] = 110b, 101b, or 100b (in Very-Low Quality modes).

You can adjust the range of each decimation filter by using a range adjustment block so that you can raise an error interrupt in case an adjustment overflow or underflow is detected.

The output of a decimation filter is stored into a FIFO buffer, and each FIFO is mapped to MICFIL Output Result (DATACH0 - DATACH3). It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.



Note: Throughout this diagram, *n*FS means *n*× the last-stage output rate (FS).

Figure 449. Decimation filter block diagram

76.3.3.1 CIC filter

The CIC filter is an optimized implementation of the low-pass SINC filter, with multiple stages. It is widely used because it requires just adders and subtracters. The CIC filter comprises an integrator and a comb as its sub-blocks. As shown in the following figure, CTRL_2[CICOSR] and the quality mode you select (see Quality modes) define the CIC decimation rate.

$$OSR = 16 - CICOSR$$

$$CIC\ decimation\ rate = \begin{cases} 2 \times OSR & ; If\ HQ,\ VLQ0 \\ OSR & ; others \end{cases}$$

Equation 51. CIC decimation rate

76.3.3.2 DC remover

Two DC removers exist in the filter chain, one in the input and another in the output. The former is integrated in the CIC filter, and the latter is placed just before the FIFO. Both can be bypassed independently.

The DC remover eliminates the DC level component of the signal using a high-pass filter with a very low cut-off frequency that you select using DC_CTRL[DCCONFIG*n*]. This filter is bypassed when the value of this field is 11b.

NOTE

See PARAM[DC_OUT_BYPASS] and PARAM[DC_BYPASS] to know whether one of the DC removers is permanently disabled in the chip.

76.3.3.3 Compensation filters

A compensation filter divides the baseband signal into two equal subbands before it could to be decimated by 2. It also compensates the CIC filter drop in passband and helps to flatten the overall passband response. MICFIL includes two compensation filter stages, with the possibility of bypassing the last one.

76.3.3.4 Filter performance

76.3.3.4.1 Overall filter gain

As shown in Equation 52, the overall filter gain depends on:

- The quality mode you select (see Quality modes).
- The CIC decimation rate (see Equation 51).
- Dynamic range adjustment of the CIC filter (see RANGE_CTRL[RANGEADJ*n*]).

NOTE

To get a better audio performance, you must configure and adjust RANGE_CTRL[RANGEADJ*n*] depending on the quality mode selected, as pointed out in the register description.

$$Overall\ filter\ gain\ (dB) = \begin{cases} 100 \times log_{10}(32 - 2 \times CICOSR) + 6.02 \times RANGE_CTRL[RANGEADJn] - 150.50 & ; if\ QSEL \in [HQ,VLQ0] \\ 100 \times log_{10}(16 - CICOSR) + 6.02 \times RANGE_CTRL[RANGEADJn] - 150.50 & ; others \end{cases}$$

Equation 52. Overall filter gain

Finally, the input and output dBFS levels relate to each other, as shown in Equation 53.

$$Output\ (dBFS) = input\ (dBFS) + overall\ filter\ gain\ (dB)$$

Equation 53. Filter input and output relationship

76.3.3.4.2 Overall passband

The decimation filter passband depends on the quality mode and output rate (FS). For instance, the overall filter passband for different output data rates when MICFIL is in High (HQ), Medium (MQ), and Low-Quality (LQ) modes is shown in Table 717.

Table 717. Filter passband in HQ, MQ, and LQ modes (DC_CTRL[DCCONFIG*n*] = 0)

Output data rate	Overall filter passband
FS	**0.0004FS - 0.4167FS**
16 kHz	6.67 Hz - 6.67 kHz
48 kHz	20 Hz - 20 kHz

The overall filter passband for different output data rates when MICFIL is in Very-Low Quality (VLQ) modes is shown in Table 718.

Table 718. Filter passband in VLQn modes (DC_CTRL[DCCONFIG*n*] = 0)

Output data rate	Overall filter passband
FS	**0.0002FS - 0.2083FS**
16 kHz	3.33 Hz - 3.33 kHz
48 kHz	10.00 Hz - 10.00 kHz
96 kHz	20 Hz - 20 kHz

76.3.3.5 Frame synchronization

If CTRL_1[FSYNCEN] = 1, MICFIL sends data to FIFOs in frame size defined by FSYNC[FSYNCLEN]. In this way, if a channel is enabled while MICFIL is running (CTRL_1[PDMIEN] = 1), MICFIL starts sending data to its respective FIFO after the current frame is sent completely. If the channel is disabled:

- if at least one other channel is still enabled, the corresponding channel stops sending data after the current frame is sent completely.
- if after that no channel is enabled, MICFIL stops sending data immediately, even if the act of sending frames is incomplete.

Below example shows the above behavior when two channels, DATACH0 and DATACH2 are enabled, and then disabled one after the other.

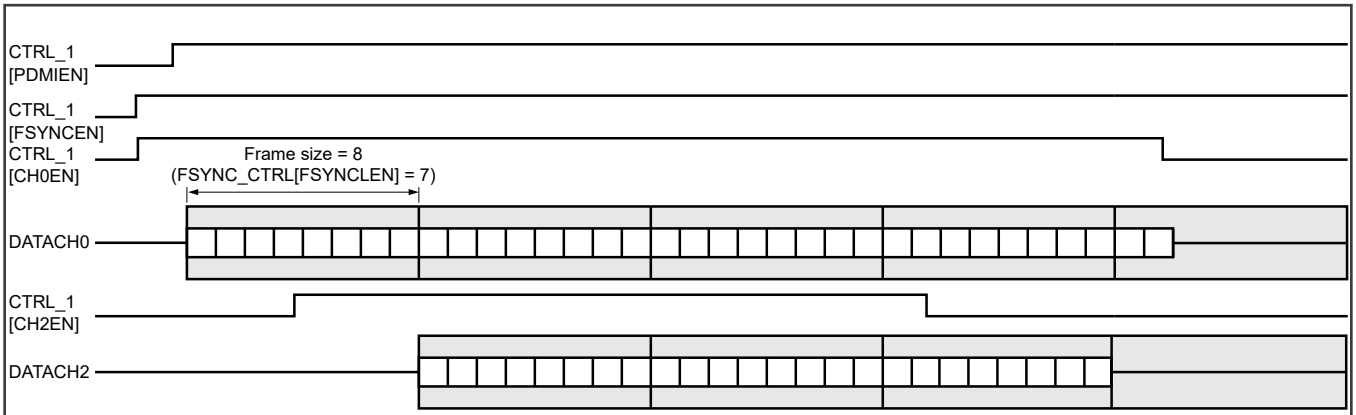


Figure 450. Frame synchronization example

76.3.3.6 Quality modes

If the decimation filter is running independently on the selected power mode, MICFIL can operate in multiple different quality modes that you can select by using CTRL_2[QSEL]. The decimation and interpolation rates in internal blocks are shown in Table 719, where the oversampling rate (OSR) depends on the value of CTRL_2[CICOSR], as shown in the following equation.

$$OSR = 16 - CICOSR$$

Equation 54. OSR

You can configure the selected quality dynamically when the decimation filter is running; the output rate is maintained in every quality selected.

The passband of the decimation filter depends on the quality mode (see Overall passband).

To maintain the same output rate in the decimation filter when the quality is changed, the PDM_CLK rate changes depending on the quality selected. For more on PDM_CLK, see Time generator.

You can enable or disable the sampler and compensation filters according to the selected quality. When they are disabled, you can achieve a low-power consumption. The selected quality also determines whether the CIC filter decimation rate is doubled. For more, see Decimation filter.

With an increase of the clock rate and OSR, you can expect a better signal-to-noise ratio (SNR) performance, which in turn leads to a higher audio quality.

Table 719. Quality modes

Quality mode	CTRL_2[QSEL]	Sampler interpolation	CIC filter decimation	First-compensation filter decimation	Second-compensation filter decimation	PDM_CLK rate	Passband
High Quality	001	—	:(2OSR)	:2	:2	Output rate × 8 × OSR	To ~0.5 × output rate
Medium Quality	000	—	:OSR	:2	:2	Output rate × 4 × OSR	To ~0.5 × output rate
Low Quality	111	× 2	:OSR	:2	:2	Output rate × 2 × OSR	To ~0.5 × output rate
Very-Low Quality 0	110	—	:(2OSR)	:2	—	Output rate × 4 × OSR	To ~0.25 × output rate
Very-Low Quality 1	101	—	:OSR	:2	—	Output rate × 2 × OSR	To ~0.25 × output rate
Very-Low Quality 2	100	× 2	:OSR	:2	—	Output rate × OSR	To ~0.25 × output rate

76.3.3.7 Output rate

The output rate is the sampling rate at the decimation filter output. It depends on the sampling rate of the microphone input and the configured quality mode (see Quality modes). Common audio sampling rates are 48 kHz and 16 kHz. In this chapter, the output rate is sometimes referred to as FS.

76.3.4 Bus interface

The bus interface manages DMA transactions, interrupt requests, and user register interface with the chip.

MICFIL can deliver an interrupt request or DMA request. Then, the chip or DMA, respectively, could access the filter results stored in FIFOs via the internal bus interface.

For detailed information on DMA transactions and interrupt requests, see DMA and Interrupts.

76.3.4.1 FIFO

This is the first-in, first-out (FIFO) buffer that saves the overall filtering results. The length of each FIFO is 16 entries, and there exists one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains. The push operation uses the MICFIL clock while the pop operation uses the CPU clock. The FIFO has a configurable watermark (see FIFO_CTRL[FIFOWMK]). When the amount of data in all FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]), a DMA or IRQ is requested, depending on the value of CTRL_1[DISEL]. After CTRL_1[PDMIEN] enables the filters, the initial FIR results are discarded and not written into the FIFOs. Approximately 68 initial FIR results are not stored in FIFOs. After the filter generates valid data, the results are pushed into the FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and CTRL_1[FIFOOVF*n*] becomes 1. Similarly, when trying a pop operation, if the FIFO is empty, no valid data is read and CTRL_1[FIFOUND*n*] becomes 1. In both cases, when overflow

or underflow occurs, they are flagged in MICFIL FIFO Status (FIFO_STAT) to the respective channel, and an error interrupt is generated if CTRL_1[ERREN] is 1.

When you reset the FIFO by writing 1 to CTRL_1[SRES], zero values fill all FIFO positions, as well as push and pop pointers are set to their initial positions.

76.3.5 Modes of operation

This section describes the MICFIL operation modes that depend on:

- Whether MICFIL receives a Stop request.
- The chip's Debug mode.
- The configuration of CTRL_1[MDIS], CTRL_1[DBGE], CTRL_1[DBG],and CTRL_1[DOZEN], as summarized in the following table.

Table 720. Mode selection

Mode	Normal	Debug		Low-Power		Disable/Low-Leakage (DLL)		
CTRL_1[MDIS]	0	0		0		0		1
Doze request and CTRL_1[DOZEN] = 1	0	0		0		0	1	Any
Stop request	0	0		1		1		Any
CTRL_1[DOZEN]	Any	Any		0		1		Any
CTRL_1[DECFILS]	Any	Any		1	0	Any		
Debug request or CTRL_1[DBG]	0	1		Any		Any		
CTRL_1[DBGE]	Any	1	0	Any		Any		
CPU clock	Enabled	Enabled		Gated (Externally)		Gated (Externally)	Enabled	Gated (Internally)
MICFIL internal clock	Enabled	Enabled		Enabled		Gated		
Decimation filter state	Run[1]	Run[1]	Stop	Run[1]	Stop	Stop		

1. Depends on the configuration of CTRL_1[PDMIEN] and CTRL_1[CH*n*EN].

76.3.5.1 Normal mode

This is the default operational mode for MICFIL. In this mode, you can enable the channel functionality to perform the filtering operation.

76.3.5.2 Debug mode

You could use this mode to check the status of the module, when requested. In this mode, you can stop MICFIL after the remaining data processing is complete, depending on the value of CTRL_1[DBGE]. You can activate this mode by writing 1 to CTRL_1[DBG].

If CTRL_1[DBGE] = 0, and CTRL_1[DBG] = 1 when MICFIL is running, MICFIL stops after processing the remaining data. Otherwise, if [DBGE] = 1, MICFIL continues to run.

MICFIL cannot enter Debug mode after entering DLL or Low-Power mode.

The Debug mode affects all channels in MICFIL. Access to output buffers, as well as their related flags, remains operational.

76.3.5.3 Low-Power mode

MICFIL enters Low-Power mode when MICFIL receives a Stop request and CTRL_1[DOZEN] = 0. In Low-Power mode, MICFIL is able to filter the PDM microphone data and can generate a wake-up event through asynchronous DM or IRQ requests, depending on the values of CTRL_1[CH*n*EN] and CTRL_1[PDMIEN].

After MICFIL enters Low-Power mode:

- If CTRL_1[DECFILS] = 1, Stop request is acknowledged immediately and the decimation filter keeps running.
- If CTRL_1[DECFILS] = 0, the decimation filter processes the last input sample. After that, Stop request is acknowledged and the filter is stopped from running.

You can generate DMA and IRQ requests asynchronously to wake up the CPU.

NOTE

The asynchronous DMA or interrupt requests are generated only in this mode.

76.3.5.4 Disable/Low-Leakage (DLL) mode

In this mode, MICFIL stops after the remaining data processing is complete. MICFIL is in DLL mode when:

- MICFIL receives a Stop request and CTRL_1[DOZEN] = 1.
- CTRL_1[MDIS] = 1.

If you request DLL mode when MICFIL is running, MICFIL stops after completion to process the remaining data.

You can write only to CTRL_1 and CTRL_2, with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES], which are ignored. However, you can still read these fields.

76.3.6 Clocking

Table 721. MICFIL clocks

Clock name	Description
CPU clock (MICFIL_CLK, MICFIL_CLK_S)	Clock that controls the registers
MICFIL internal clock (MICFIL_CLK_APP)	Application clock that operates the filter

Besides the above clock signals, MICFIL generates PDM_CLK for PDM microphones based on MICFIL internal clock frequency and the value in CTRL_2[CLKDIV].

76.3.7 Interrupts

If CTRL_1[DISEL] = 10b, an interrupt request indicates that filtering results are stored in the FIFOs to be read by the CPU. In this case, you can read the data in DATACH*n*[DATA], and STAT[CH*n*F] becomes 1 for the enabled channels when the CHn FIFO surpasses the watermark level.

When MICFIL is in Low-Power mode, the CPU clock is disabled, but the MICFIL clock remains enabled. In this case, an asynchronous interrupt is delivered to the system. This wakes up the CPU clock, which returns to Normal mode. The system could read the FIFO data, after which it must clear STAT[CH*n*F] to get a new interrupt request.

An error interrupt request can also be generated when an exceptional condition happens, such as an overflow or underflow in a channel output, or an overflow or underflow of a FIFO buffer.

CTRL_1[ERREN] enables error interruption and the respective status flag signalizes the type of error:

- OUTOVFn and OUTUNFn for channel outputs errors
- FIFO_STAT[FIFOOVF*n*] and FIFO_STAT[FIFOUND*n*] for FIFO errors

76.3.8 DMA

If CTRL_1[DISEL] = 1, the FIFO stored samples are read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark levels, the output interface makes a request for a DMA transaction.

If CTRL_1[PDMIEN] = 1 and the filters start to operate, you must wait until the filter results stabilize and no filter results are stored in the FIFOs. Therefore, the first DMA request takes longer to occur than the ones that follow.

STAT[CH*n*F] becomes 0 after a DMA transaction is complete.

If MICFIL is in Low-Power mode and the watermark level is surpassed, an asynchronous DMA request is delivered to the system. Then, the system wakes up the CPU clock, returning to Normal mode to read the FIFO data.

76.4 External signals

Table 722. PDM microphone interface external signals

Signal	Description	Direction
PDM_DATA*n*	Data bitstream received from the nth PDM microphone pair throughout the input interface (see Input interface)	I
PDM_CLK	Clock that is delivered to the PDM microphones from the clock generator (see Time generator)	O

NOTE

MICFIL does not provide metastability protection or filtering for input data. You must generate the data using the provided PDM_CLK.

76.5 Initialization

76.5.1 Procedure

Perform this procedure for MICFIL initialization (by using only decimation filters):

1. Program CTRL_2[CLKDIV], CTRL_1[CH*n*EN], FIFO_CTRL[FIFOWMK], CTRL_1[DISEL], CTRL_1[ERREN], and so on, as required.
2. Start the module operation by writing 1 to CTRL_1[PDMIEN].

The module is ready to receive data from the input ports of the enabled channels.

76.6 Application information

76.6.1 Reconfiguration procedure

Perform this procedure to reconfigure MICFIL:

1. Write 0 to CTRL_1[PDMIEN].
2. Wait until STAT[BSY_FIL] becomes 0.
3. Run a soft-reset cycle.
4. Run an initialization procedure as described in Procedure.

76.7 MICFIL register descriptions

This section provides the memory map and detailed description of all MICFIL registers. Any access to reserved areas can issue a slave bus error indication.

You must implement the registers allocated in this memory map for up to 2 pairs of microphones, indicating that 4 channels are available.

76.7.1 MICFIL memory map

MICFIL0 base address: 4010_C000h

Offset	Register	Width (In bits)	Access	Reset value
0h	MICFIL Control 1 (CTRL_1)	32	RW	0000_0000h
4h	MICFIL Control 2 (CTRL_2)	32	RW	0000_0000h
8h	MICFIL Status (STAT)	32	RW	0000_0000h
10h	MICFIL FIFO Control (FIFO_CTRL)	32	RW	0000_000Fh
14h	MICFIL FIFO Status (FIFO_STAT)	32	RW	0000_0000h
24h - 30h	MICFIL Output Result (DATACH0 - DATACH3)	32	R	0000_0000h
64h	MICFIL DC Remover Control (DC_CTRL)	32	R	0000_00FFh
68h	MICFIL Output DC Remover Control (DC_OUT_CTRL)	32	RW	0000_0000h
74h	MICFIL Range Control (RANGE_CTRL)	32	RW	0000_0000h
7Ch	MICFIL Range Status (RANGE_STAT)	32	RW	0000_0000h
80h	Frame Synchronization Control (FSYNC_CTRL)	32	RW	0000_0000h
84h	Version ID (VERID)	32	R	020F_0000h
88h	Parameter (PARAM)	32	R	0000_0742h

76.7.2 MICFIL Control 1 (CTRL_1)

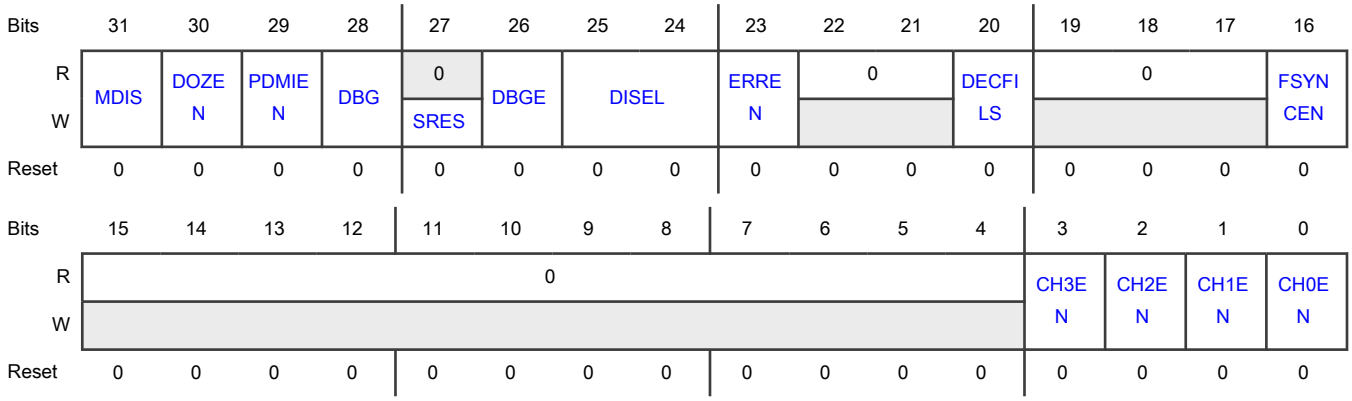
Offset

Register	Offset
CTRL_1	0h

Function

Contains control fields for MICFIL.

Diagram



Fields

Field	Function
31 MDIS	Module Disable Places MICFIL in DLL mode (see Disable/Low-Leakage (DLL) mode). The generated PDM_CLK stops, and consequently, the microphone generates no data. **NOTE** When this field = 1, only writes to MICFIL Control 1 (CTRL_1) and MICFIL Control 2 (CTRL_2) are allowed with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES]. A slave bus error indication is issued if you write to any other register. 0b - Normal mode 1b - DLL mode
30 DOZEN	Stop Enable When MICFIL receives a Stop request and this field is active, MICFIL enters DLL mode (see Disable/Low-Leakage (DLL) mode). 0b - Disables 1b - Enables
29 PDMIEN	MICFIL Enable Starts the module operation. Only the channels that CTRL_1[CH*n*EN] enables start operating. When this field becomes 0, MICFIL stops after it completes the remaining filter processing. **NOTE** You must enable this field as the last step when initializing the module (see Initialization). 0b - Stops MICFIL operation 1b - Starts MICFIL operation
28 DBG	Debug Mode Specifies the mode (Debug or Normal) that MICFIL operates in.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	MICFIL operates in Debug mode, depending on the value of CTRL_1[DBGE]. When Debug mode is disabled, MICFIL operates in Normal mode. See Debug mode for more on Debug mode. **NOTE** You can write to this field only when CTRL_1[MDIS] = 0. 0b - Normal 1b - Debug
27 SRES	Software Reset Provides the CPU with the capability to initialize MICFIL through the slave-bus interface. The field always reads 0, and is effective only when CTRL_1[MDIS] = 0. It is a self-clearing field. **NOTE** You must write 1 to this field only when STAT[BSY_FIL] = 0. You can use this field to clear data in all filters. It resets the following blocks and registers: • All internal buffers in decimation filters • All FIFOs • STAT[CH*n*F] and MICFIL FIFO Status (FIFO_STAT) • Time generator 0b - No action 1b - Software reset
26 DBGE	Module Enable in Debug Enables operation in Debug mode (see Debug mode). 0b - Disables after completing the current frame 1b - Enables operation
25-24 DISEL	DMA Interrupt Selection Specifies the type of interrupt requests (DMA or filter) that MICFIL performs when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels for which CTRL_1[CH*n*EN] = 1. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 00b - Disables DMA and interrupt requests 01b - Enables DMA requests 10b - Enables interrupt requests 11b - Reserved
23	Error Interruption Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERREN	Enables error interrupts (exceptions). The following conditions can lead to errors: • An overflow or underflow in the FIFOs (indicated by FIFO_STAT[FIFOOVF*n*] or FIFO_STAT[FIFOUND*n*], respectively) • An overflow or underflow in the decimations filters (indicated by RANGE_STAT[RANGEOVF*n*] or RANGE_STAT[RANGEUNF*n*], respectively) **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Disables 1b - Enables
22-21 —	Reserved
20 DECFILS	Decimation Filter Enable in Stop Enables decimation filters to run when MICFIL receives a Stop request. 0b - Stops decimation filter 1b - Keeps decimation filter running
19-17 —	Reserved
16 FSYNCEN	Frame Synchronization Enable Enables frame synchronization (see Frame synchronization). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Disables 1b - Enables
15-4 —	Reserved
3-0 CHnEN	Channel n Enable Enables the decimation filter channel n (see Initialization for more information).

76.7.3 MICFIL Control 2 (CTRL_2)

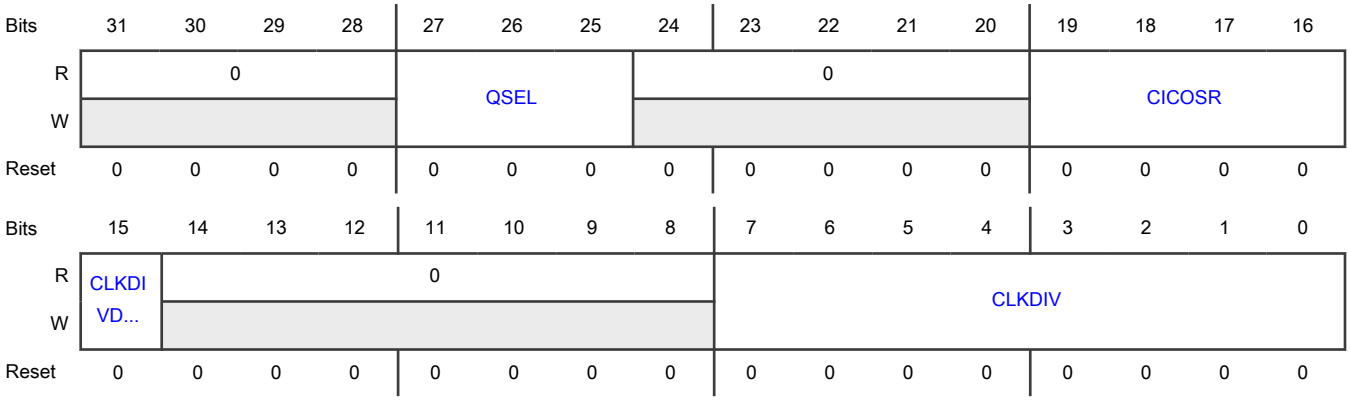
Offset

Register	Offset
CTRL_2	4h

Function

Contains control fields for MICFIL.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-25 QSEL	Quality Mode Defines the actual quality mode (see Quality modes) of the decimation filter. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 000b - Medium-Quality mode 001b - High-Quality mode 100b - Very-Low-Quality 2 mode 101b - Very-Low-Quality 1 mode 110b - Very-Low-Quality 0 mode 111b - Low-Quality mode
24-20 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 CICOSR	CIC Decimation Rate Configures the CIC filter decimation rate (see Equation 51 for more information). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0000b - CIC oversampling rate = 0 0001b - CIC oversampling rate = 1 0010b-1110b - ... 1111b - CIC oversampling rate = 15
15 CLKDIVDIS	Clock Divider Disable Disables and bypasses the internal clock divider (see Clock divider) to drive microphones directly with the application clock. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Enables 1b - Disables
14-8 —	Reserved
7-0 CLKDIV	Clock Divider Configures the internal clock divider value (see Clock divider for more information) using the following equation: $$PDM_CLK\ rate = \frac{MICFIL_CLK_ROOT}{2 \times floor(K \times CLKDIV)}$$ **NOTE** • You must not change the value of this field when STAT[BSY_FIL] = 1. • [CLKDIV] = 0 has the same effect as [CLKDIV] = 1. In Medium Quality mode, [CLKDIV] = 0 or 1 has the same effect as [CLKDIV] = 2. In High Quality mode, [CLKDIV] = 0 or 1 is not allowed. 0000_0000b - Internal clock divider value = 0 0000_0001b - Internal clock divider value = 1 0000_0010b-1111_1110b - ... 1111_1111b - Internal clock divider value = 255

76.7.4 MICFIL Status (STAT)

Offset

Register	Offset
STAT	8h

Function

Contains status flags for MICFIL.

Diagram

Fields

Field	Function
31 BSY_FIL	Busy Flag Signalizes when at least a decimation filter channel is running and the PDM_CLK is being generated. You could use this field as a confirmation that all decimation filters are stopped in a transition to Debug mode (when CTRL_1[DBGE] = 0) or DLL mode. 0b - MICFIL is stopped 1b - MICFIL is running
30 —	Reserved
29 —	Reserved
28-16 —	Reserved
15-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
3-0 CHnF	Channel n Output Data Flag Indicates whether this channel's FIFO has surpassed its watermark value and the data is available in MICFIL Output Result (DATACH0 - DATACH3). This flag contributes to generate an interrupt or DMA request if CTRL_1[DISEL] enables it. Write 1 to CTRL_1[DISEL] to clear this flag. If the DMA request is set (CTRL_1[DISEL] = 1), [CHnF] is set according to the watermark level . In other cases (IRQ included), [CHnF] is set according to the watermark level and is cleared when you write 1 to it. **NOTE** If DMA is enabled, this flag clears itself after the DMA transaction is complete. 0b - Not surpassed 1b - Surpassed

76.7.5 MICFIL FIFO Control (FIFO_CTRL)

Offset

Register	Offset
FIFO_CTRL	10h

Function

Chapter 77
Touch Sensing Input (TSI)

77.1 Chip-specific TSI information

Table 723. Reference links to related information

Topic	Related module	Reference
Full description	TSI	TSI
System memory map		Memory map
Clocking		Clock distribution
Power management		Power management
Signal multiplexing	Port control	Signal multiplexing

77.1.1 Module instances

This device has one instance of the TSI module, TSI0.

77.1.2 Hardware triggers

LPTMR0 and LPTMR1 are used as the hardware triggers to TSI input source in this device. See TSI_TRIG register in INPUTMUX for details.

77.2 Overview

TSI provides touch sensing detection on capacitive touch sensors. The external capacitive touch sensor is typically formed on a printed circuit board (PCB) and the sensor electrodes are connected to TSI input channels through the I/O pins in the chip. The TSI module operates in switching-integration style to achieve low-power, high-sensitivity, and advanced electromagnetic compatibility (EMC) robustness.

The module supports:

- Self-Capacitance mode: In this mode, TSI requires only one pin for each touch sensor.
- Mutual-Capacitance mode: In this mode, TSI performs sensing using capacitive touch matrix in various TX-RX configurations. TSI requires one pin per TX and RX line.

TSI fully supports NXP touch library based on SDK, which provides a solid capacitive measurement module for the implementation of touch keyboard, rotaries, and sliders.

77.2.1 Block diagram

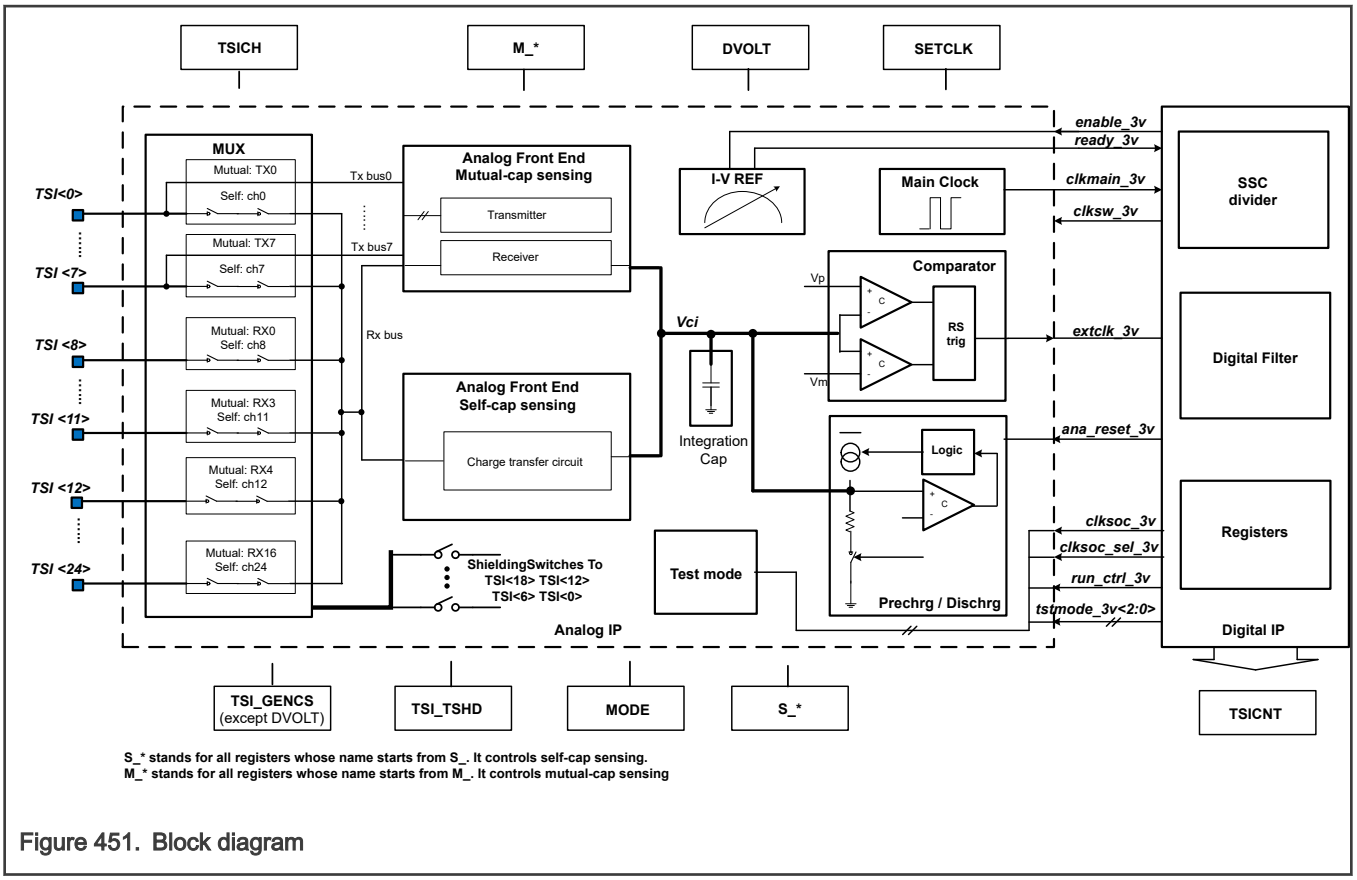

Figure 451. Block diagram

77.2.2 Features

- Achieves advanced EMC robustness
- Supports both Self-Capacitance and Mutual-Capacitance modes
- Requires one pin per electrode—no external components
- Provides adjustable touch sensing resolution and sensitivity for sensing various overlay materials and thicknesses
- Consumes low power
- Wakes up MCU from low-power modes for low-power application
- Supports DMA data transfer
- Supports NXP touch library that is based on SDK (see AN12709: NXP Touch Development Guide)

For electrode design recommendations, see AN3863: Designing Touch Sensing Electrodes.

77.3 Functional description

77.3.1 Touch sensor

77.3.1.1 Self-capacitance touch sensor

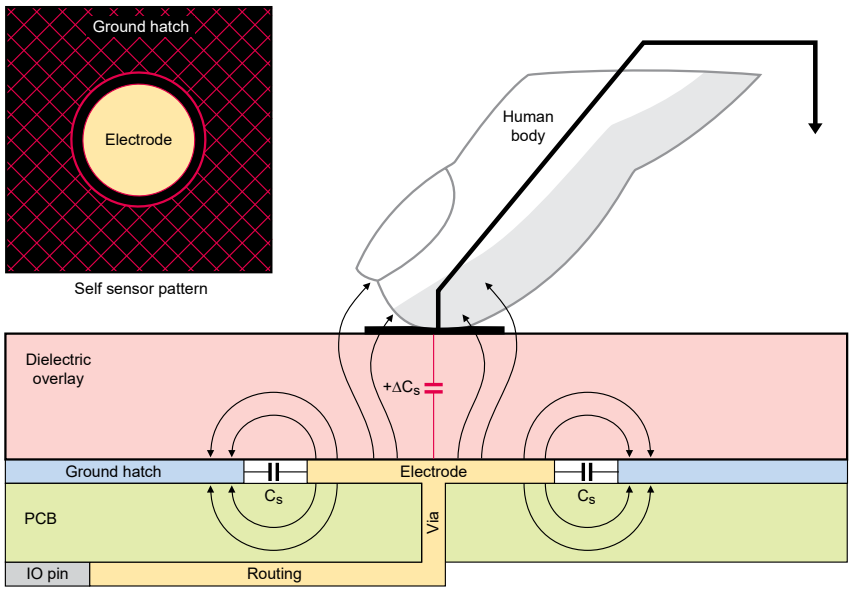

Figure 452. Self-capacitance touch sensor structure and electric field

Sensor structure:

- C_s is the intrinsic self-capacitance sensor (10 pF ~ 50 pF as usual).
- ΔC_s is the touch-generated self-capacitance sensor (0.3 pF ~ 2 pF as usual).
- $\Delta C_s \div C_s$ is the sensitivity of the sensor (1% ~ 10% as usual).

Intrinsic performance depends on the electrode pattern design, thickness, and dielectric of overlay, and PCB routing.

77.3.1.2 Mutual-capacitance touch sensor

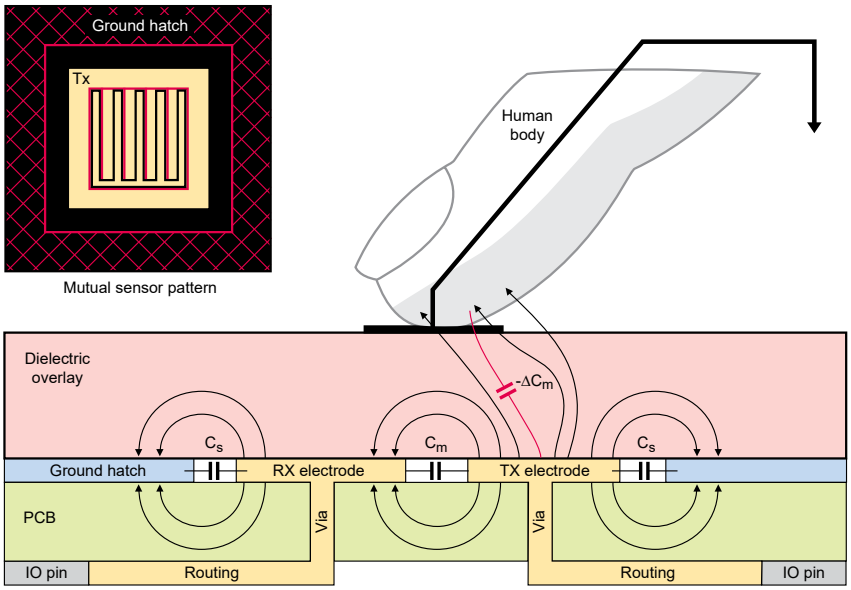

Figure 453. Mutual-capacitance touch sensor structure and electric field

Sensor structure:

- C_m is the intrinsic mutual-capacitance sensor (2 pF ~ 10 pF as usual).
- ΔC_m is the touch-reduced mutual-capacitance sensor (0.3 pF ~ 2 pF as usual).
- C_s is the parasitic self-capacitance sensor (10 pF ~ 50 pF as usual).
- $\Delta C_m \div C_m$ is the sensitivity of sensor (1% ~ 20% as usual).

Intrinsic performance depends on the electrode pattern design, thickness, and dielectric of overlay, and PCB routing.

77.3.2 Brief timing and operation of TSI

TSI operates by switching integration, whether under Self-Capacitance mode or Mutual-Capacitance mode.

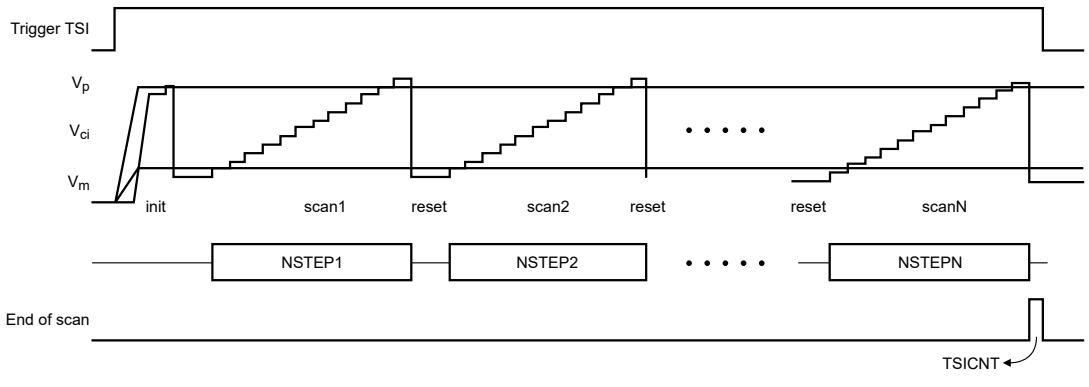

Figure 454. Brief timing of the TSI operation

$$TSICNT = NSTEP \times \frac{DECIMATION^{ORDER}}{CUTOFF}$$

$$SCANTIME = TNSTEP \times DECIMATION \times ORDER$$

Equation 55. Formula for calculating TSICNT and SCANTIME

where:

- DECIMATION specifies the times of scan, defined by the configuration of SINC[DECIMATION].
- ORDER specifies the order of sum up, defined by the configuration of SINC[ORDER].
- NSTEP specifies the analog integration steps that the module configuration and sensor define.
- TNSTEP is the scan time for getting each NSTEP.
- SCANTIME is the total scan time for getting the value of DATA[TSICNT].
- CUTOFF is the value of shifting out lower bits of the counter, defined by SINC[CUTOFF].

Operation

- TSI needs a very short initialization time for each trigger before it starts scanning the touch sensor (see Touch sensor for more).
- When scanning, the analog front end senses the self-capacitance or mutual-capacitance value and generates voltage steps on the integration capacitor. The step voltage depends on the touch sensor and module configuration.
- After the step voltage (V_{ci}) reaches threshold V_p of the comparator, the integration capacitor and analog front-end reset. The voltage V_{ci} discharges to V_m for next scanning.
- For each TSI trigger, you can set many scan times by using registers. Software uses the final count value, which is the summation of step numbers of each scan.
- The count relates to touch sensor capacitance (self-capacitance or mutual-capacitance) through formulas, and you can use it to sense touch event.

77.3.2.1 Self-capacitance sensing mode

Charge transfer operates through nonoverlapping clocks, ph1 and ph2, and a trans-conductance amplifier. The charge accumulates in integration capacitor C_i, which creates step voltage V_{ci}. See Equation 56 for NSTEP and TSINCT calculation.

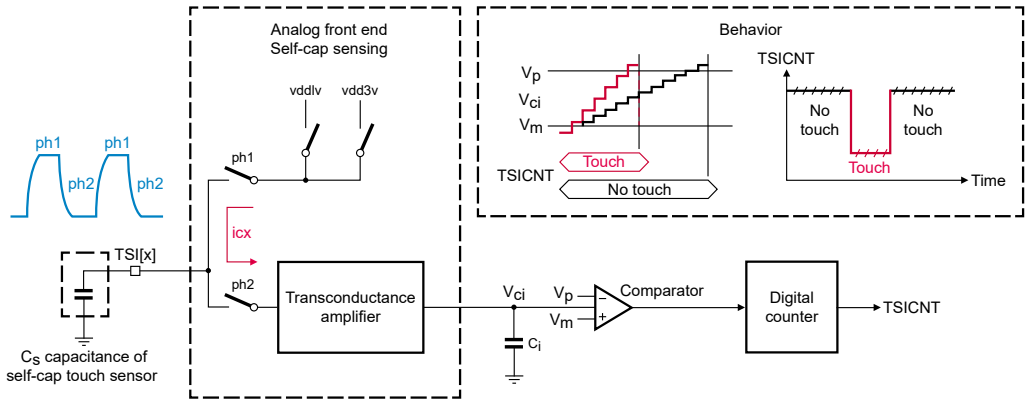

Figure 455. Self-capacitance sensing mode

$$NSTEP = \frac{C_i \times (V_p - V_m)}{vdd3v \times C_s \times S_XIN \times S_XCH}$$

$$TNSTEP = \frac{C_i \times (V_p - V_m)}{vdd3v \times C_s \times S_XIN \times S_XCH} \times \frac{1}{F_{sw}}$$

Equation 56. Formula to calculate NSTEP and TNSTEP

where:

- C_i is the integration capacitance (50 pF).
- V_p, V_m are dual reference voltages that you can configure using GENCS[DVOLT].
- vdd3v is the analog power supply voltage (3.3 V).
- S_XIN, and S_XCH are parameters for analog front-end that you can configure using CONFIG[S_XIN] and CONFIG[S_XCH], respectively.
- F_{sw} is the switching frequency that the SSC hardware module controls.
- C_s is the self-capacitance of touch sensor.

You can use GENCS[DVOLT], CONFIG[S_XIN], and CONFIG[S_XCH] to adjust the sensing resolution.

If the touch sensor intrinsic sensitivity is limited because of parasitic, you can write 1 to CONFIG[S_SEN] to activate the sensitivity boost feature. See Equation 57 to calculate NSTEP:

$$NSTEP = \frac{C_i \times (V_p - V_m)}{vdd3v \times \left(C_s - S_CTRIM \times \frac{S_XDN}{S_XCH}\right) \times S_XIN \times S_XCH}$$

Equation 57. NSTEP calculation

where:

- S_CTRIM is the internal trim capacitance, which you configure using CONFIG[S_CTRIM].
- S_XDN is a parameter of analog front-end, which you configure using CONFIG[S_XDN].

You can use CONFIG[S_CTRIM], CONFIG[S_XDN], and CONFIG[S_XCH] to adjust the sensitivity. The intrinsic sensitivity of the sensor is $\Delta C_s \div C_s$. See Equation 58 to calculate improved sensitivity:

$$\frac{\Delta C_S}{C_S - S_CTRIM \cdot \frac{S_XDN}{S_XCH}}$$

Equation 58. Improved sensitivity

If the touch sensor encounters a strong low-frequency noise, you can write 1 to CONFIG[S_NOISE] to activate noise cancelation. See Equation 59 to calculate NSTEP:

$$NSTEP = \frac{2C_i \times (V_p - V_m)}{(vdd3v - vddlv) \times C_s \times S_XIN \times S_XCH}$$

Equation 59. NSTEP calculation

where, vddlv is the internal pre-charge voltage (1.2 V).

During noise cancelation mode, vdd3v and vddlv are dual sample voltages. The analog front-end circuit samples the touch key twice, first using vdd3v (charging phase) and then using vddlv (discharging phase). At the end of each second phase, low-frequency noise is subtracted. In a long integration period, you can cancel noise-induced errors.

For example,

In a typical case, C_i = 50 pF, C_x = 25 pF, vdd3v = 3.3 V, DVOLT = 1 V, S_XIN = 1 ÷ 8, S_XCH = 1 ÷ 8; Dec = 8, Order = 2. Then, NSTEP = 38; TSICNT = 2432; SCANTIME = 0.62 ms.

NOTE

Do not write 1 to CONFIG[S_SEN] and CONFIG[S_NOISE] simultaneously.

77.3.2.2 Mutual-capacitance sensing mode

Mutual-capacitance sensing includes a transmitter and a receiver. Under clocking, the transmitter outputs pulses that couple through mutual-capacitance and then reach the receiver, which amplifies the signal and converts to charge current on integration capacitance C_i that creates step voltage V_{ci}.

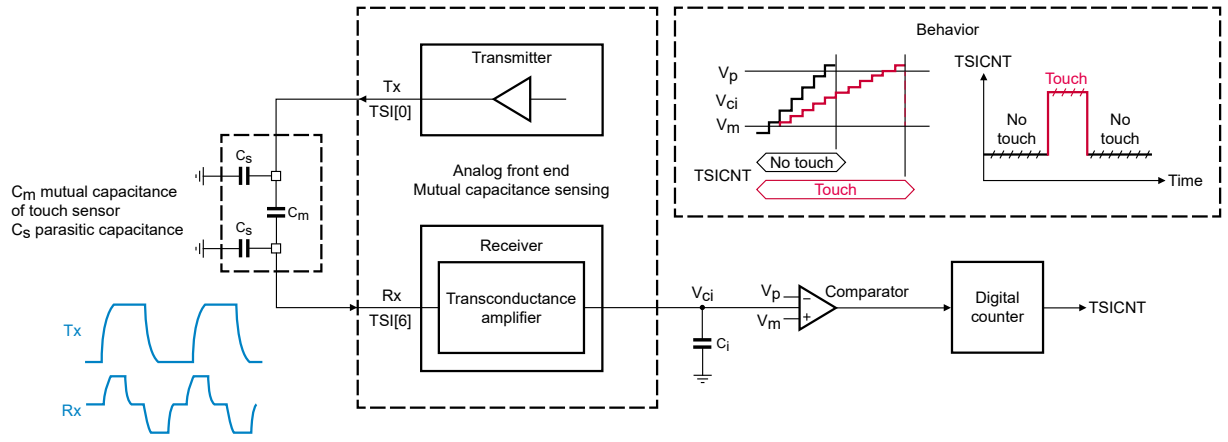

Figure 456. Mutual-capacitance sensing mode

Following are the formulas to calculate NSTEP and TNSTEP.

$$NSTEP = \frac{C_i \times (V_p - V_m) \times R_s}{\Delta V} \times \frac{M_PMIRRORL}{M_PMIRRORR} \times \frac{1}{t3}$$

Equation 60. NSTEP calculation

$$TNSTEP = \frac{C_i \times (V_p - V_m) \times R_s}{\Delta V} \times \frac{M_PMIRRORL}{M_PMIRRORR} \times \frac{T_{sw}}{t3}$$

Equation 61. TNSTEP calculation

where:

- C_i is the integration capacitance (50 pF).
- V_p, V_m are dual reference voltages that you can configure using GENCS[DVOLT].
- F_{sw} is the switching frequency that the spread spectrum clocking (SSC) hardware module controls (see SSC for more).
- T_{sw} is the switching period, and $T_{sw} = 1 \div F_{sw}$.
- t3 is the SSC output low period.
- R_s is a parameter for analog front-end that you can configure using SHIELD[M_SEN_RES].
- M is a parameter that CONFIG_MUTUAL[M_PMIRRORR] and CONFIG_MUTUAL[M_PMIRRORL] define.
- ΔV is signal voltage received.

$\Delta V = vdd3v \times C_m \div (C_m + C_s)$, which can be tens to hundreds of volts.

C_m, C_s are the mutual-capacitance and parasitic capacitance of the sensor.

If the touch sensor intrinsic sensitivity is limited because of parasitic, you can configure CONFIG_MUTUAL[M_SEN_BOOST] to activate the sensitivity boost feature. The basis average charge current is subtracted by boost current, which enlarges the signal current.

For example,

In a typical case, ΔV = 100 mV, R_s = 10 kΩ, $V_p - V_m$ = 1 V, C_i = 50 pF, M_PMIRRORL = 8, M_PMIRRORR = M_NMIRROR = 2, T_{sw} = 1 µs, t3 = 0.25 µs. NSTEP = 144, TNSTEP = 80 µs. Dec = 8, Order = 2, TSICNT = 80 × 64 = 5120, SCANTIME = 80 µs × 8 × 2 = 1280 µs.

NOTE

Let the configuration of CONFIG_MUTUAL[M_PMIRRORR] and CONFIG_MUTUAL[M_NMIRROR] be the same.

77.3.3 Enable TSI

TSI is fully functional in Run, Wait, and Low-Power modes. You must write 1 to GENCS[TSIEN] to enable TSI in Run and Wait modes. When GENCS[STPE] = 1, it allows TSI to work in Low-Power mode.

77.3.4 Wake-up MCU from low-power modes

In low-power modes, when enabled by GENCS[STPE], TSI can bring MCU out of its low-power modes (STOP, VLPS, and so on) by using either the end-of-scan or out-of-range interrupt. This means, if GENCS[ESOR] = 1, the end-of-scan interrupt is selected. Otherwise, the out-of-range interrupt is selected.

77.3.5 Software and hardware triggers

TSI allows a software or hardware trigger to start a scan. When you apply a software trigger (GENCS[STM] = 0), you must write 1 to GENCS[SWTS] to start the scan electrode channel that CONFIG[TSICH] identifies. When a hardware trigger is applied (GENCS[STM] = 1), TSI does not start scanning until the hardware trigger arrives. The hardware trigger differs depending on the MCU configuration. Generally, it could be an event that RTC overflows. See the chip configuration section for more information.

77.3.6 Scan times

TSI provides a multi-scan function. SINC[DECIMATION] indicates the number of scans that allow the scan number to be configured from 1 to 32. If you write 0 to SINC[DECIMATION] (only once), a single scan is engaged. The 16-bit counter accumulates all scan results until the number of scan times reaches the value of SINC[DECIMATION], and you can read DATA[TSICNT] to get this accumulation. When you enable DMA transfer, the DMA engine can also read out the counter values.

77.3.7 Reference voltage

You must use a reference voltage to set up the rampup threshold. It determines TSICNT and SCANTIME. TSI offers dual reference voltages for both comparators. The internal reference voltage can work in low-power modes even when the MCU regulator is partially powered down, which is ideally for low-power touch detection.

You can configure reference voltage by using GENCS[DVOLT]. The following table shows all delta voltage configurations.

Table 724. Delta voltage configuration

DVOLT	V_m (V)	V_p (V)	ΔV (V)
000	0.6	1.7	1.1
001	0.6	1.9	1.3
010	0.6	2.1	1.5
011	0.6	2.3	1.7
100	0.6	2.5	1.9
101	0.6	2.7	2.1

77.3.8 End of scan

After the scan completes, DATA[EOSF] becomes 1. If GENCS[ESOR] = 1 and GENCS[DMAEN_EOS] = 0, an interrupt is submitted to CPU for post-processing immediately. You can also use the interrupt to wake up the MCU to execute ISR if it is in a low-power mode. You can enable the DMA function by writing 1 to GENCS[DMAEN_EOS]. As soon as the scan completes, a DMA transfer request is asserted to the DMA controller for data movement. Generally, the DMA engine fetches TSI conversion result from TSI Data and Status (DATA), stores it in another memory space, and then refreshes the TSI scan channel index (CONFIG[TSICH]) for the next loop. After a DMA transfer completes, DATA[EOSF] becomes 0 automatically.

77.3.9 Modes

Table 725. Modes

Mode	Description
Stop and Low-Power Stop	TSI is fully functional in all stop modes if GENCS[STPE] = 1. CONFIG[TSICH] specifies the channel for scanning upon the trigger. After a scan completes, you can select either the end-of-scan or out-of-range interrupt to bring MCU out of low-power modes.
Wait	TSI is fully functional in this mode. After a scan completes, TSI submits an interrupt request to CPU if the interrupt is enabled.
Run	TSI is fully functional in this mode. After a scan completes, TSI submits an interrupt request to CPU if the interrupt is enabled.

77.3.10 Clocking

Switching clock with frequency F_{sw} drives both self-capacitance front-end and mutual-capacitance front-end. It is derived from the SSC clock with flatten emission energy. In addition, TSI SSC 0 (SSC0), TSI SSC 1 (SSC1), and TSI SSC 2 (SSC2) configure the frequency of switching clock (see SSC for more information). The SSC clock source is the main clock module in TSI. You can configure the frequency of the main clock by using GENCS[SETCLK].

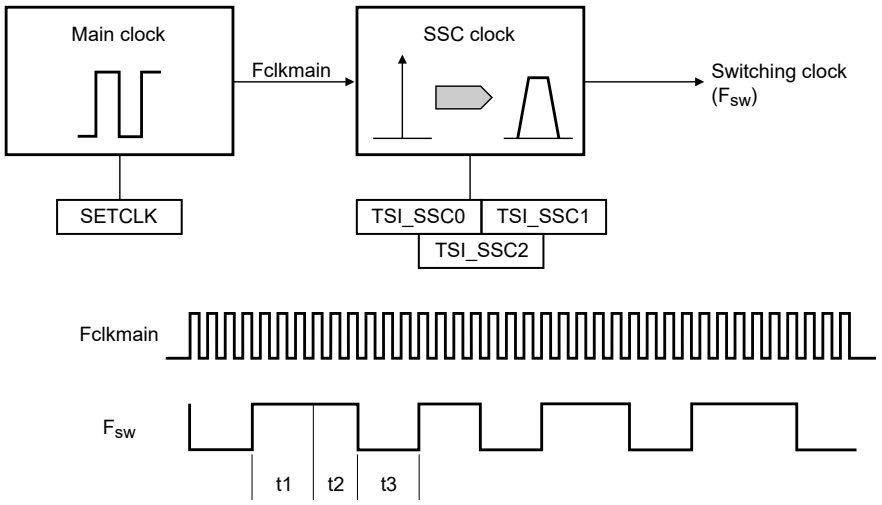

Figure 457. Clocking

For example,

- To use a non-SSC switching clock with a frequency of 1 MHz:
  1. Write 011 to GENCS[SETCLK] for Fclkmain = 16.65 MHz.
  2. Write 10 to SSC0[SSC_MODE] to disable the SSC function.
  3. Write 0000–0111 to SSC0[SSC_PRESCALE_NUM] for Fclkmain ÷ 8. If SSC mode is disabled, the frequency formula is Fclkmain ÷ [(SSC_PRESCALE_NUM + 1) × 2].

Let TSI SSC 0 (SSC0), TSI SSC 1 (SSC1), and TSI SSC 2 (SSC2) retain their default values. Then, F_{sw} = 16.65 MHz ÷ (8 × 2) = 1.04 MHz. F_{sw} is square wave pulse.

- To use Pseudo-Random Binary Sequence (PRBS) mode having SSC switching clock with a central frequency of 1 MHz:
  1. Write 011 to GENCS[SETCLK] for Fclkmain = 16.65 MHz. Then, the period of main clock is Tclkmain.
  2. Write 00 to SSC0[SSC_MODE] to enable PRBS SSC mode.
  3. Write 0100 to SSC0[BASE_NOCHARGE_NUM] to set t1 = 5 × Tclkmain × (SSC_PRESCALE_NUM + 1).
  4. Write 0110 to SSC0[CHARGE_NUM] to set t3 = 7 × Tclkmain × (SSC_PRESCALE_NUM + 1).
  5. Write 0110 to SSC0[PRBS_OUTSEL] to set t2 range from 1 × Tclkmain to 6 × Tclkmain. The average t2 is 3.5 × Tclkmain × (SSC_PRESCALE_NUM + 1).

Let TSI SSC 0 (SSC0), TSI SSC 1 (SSC1), and TSI SSC 2 (SSC2) retain their default values. Then, F_{sw} = 16.65 MHz ÷ [(5 + 3.5 + 7) × (0 + 1)] = 1.074 MHz. F_{sw} is the spectrum spread pulse.

77.3.10.1 SSC

In capacitance touch sense systems, the baseband signal is narrowband and nearing the DC, and the noise is a wideband noise. For lower cost, the cut-off frequency of the antialiasing low-pass filter at analog front-end is not low enough compared to the sampling frequency. Therefore, when sampling, the noises for which the frequency is nearing sampling frequency are overlapped to baseband. For solving this problem in capacitance touch sense systems, you can involve a low-cost SSC. The SSC center frequency and frequency span range must be flexible enough for handling various frequency noises.

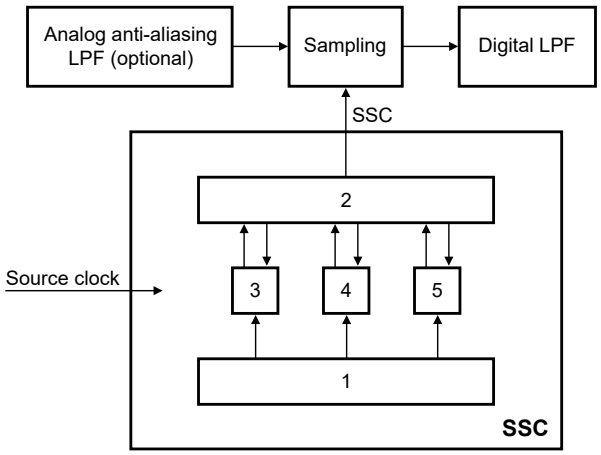

Figure 458. SSC

With this SSC, the noises for which the frequency is nearing sampling frequency can be spanned to a wider frequency range instead of a single-peak frequency noise, and only parts of the noise overlap into baseband (because baseband is a narrowband). This promotes signal-to-noise ratio (SNR).

SSC comprises five components that work together and generate a configurable center frequency and span frequency range:

- Configurable registers, generating all configurable settings for components 3, 4, and 5, by using TSI SSC 0 (SSC0), TSI SSC 1 (SSC1), and TSI SSC 2 (SSC2).
- State machine engine, controlling and monitoring components 3, 4, and 5.
- A configurable counter to generate logic 1 in the SSC output clock; SSC0[BASE_NOCHARGE_NUM] controls the max value of the counter.
- A configurable up-down counter or a PRBS method to generate logic 1 in the SSC output clock. When using the up-down counter, SSC2[MOVE_NOCHARGE_MIN] and SSC2[MOVE_NOCHARGE_MAX] limit the counter value. When using the PRBS method, the output of the PRBS method controls the length of logic 1.
- A configurable up-down counter to generate logic 0 in the SSC output clock; SSC0[CHARGE_NUM] controls the max value of the counter.

Figure 459 illustrates the timing of the input system clock and SSC output bit.

- t1: Component 3 and SSC0[BASE_NOCHARGE_NUM] control it.
- t2: When using the up-down counter, component 4, SSC2[MOVE_NOCHARGE_MIN], and SSC2[MOVE_NOCHARGE_MAX] control it. When using the PRBS method, the PRBS output controls it.
- t3: Component 5 and SSC0[CHARGE_NUM] control it.

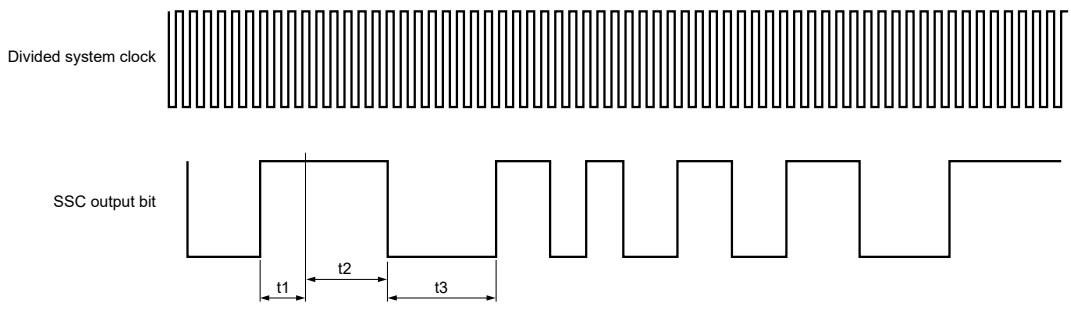

Figure 459. Timing of SSC

Equation 62 defines the average frequency of the SSC output.

$$\text{frequency}_{SSC} = \frac{\text{frequency}_{system}}{(t1 + t2 + t3) \times (SSC_PRESCALE_NUM + 1)}$$

Equation 62. SSC average frequency

Figure 460 shows the linear feedback shift register (LFSR) circuit that is used for generating the SSC output bit by using the PRBS method.

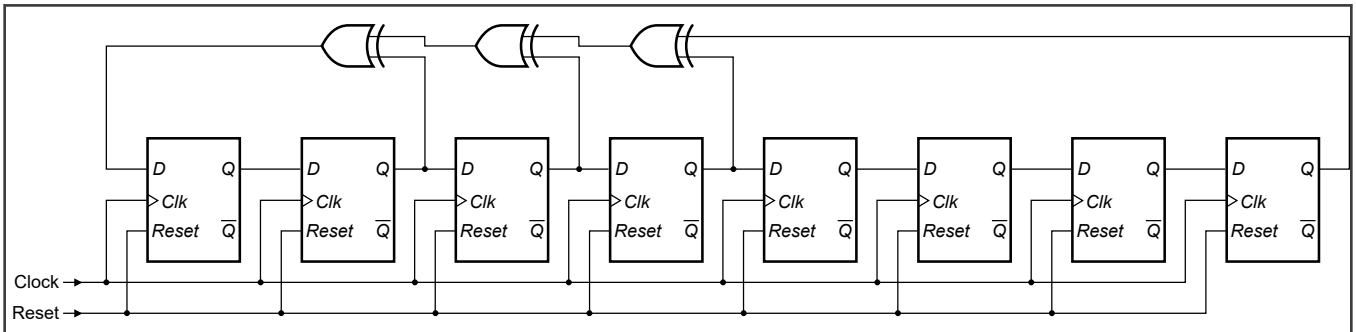

Figure 460. LFSR circuit

77.3.11 Reset

There is only one reset on this module, ipg_hard_async_reset_b. After it becomes 0, all TSI registers reset to their default values.

77.3.12 Interrupts

If enabled, TSI scans the electrode that CONFIG[TSICH] specifies, as soon as the trigger arrives. DATA[OUTRGF] generates a TSI interrupt request if GENCS[OUTRG_EN] becomes 0. With this configuration, after the end-of-electrode scan, the electrode capacitance is converted and stored in DATA[TSICNT]. The out-of-range interrupt is only requested if TSI Threshold (TSHD) defines a considerable capacitance change. For instance, when in a low-power mode, the electrode capacitance does not vary, and the out-of-range interrupt does not interrupt the CPU. You can use TSI Threshold (TSHD) for out-of-range interrupt generation.

77.3.13 DMA

DMA supports transmit only when GENCS[DMAEN_OUTRG] or GENCS[DMAEN_EOS] = 1. A DMA transfer request is asserted when DATA[EOSF] or DATA[OUTRGF] is set. Then the on-chip DMA controller detects this request and transfers data between the memory space and TSI register space. After data transfer, DMA is asserted to clear DATA[EOSF] or DATA[OUTRGF] automatically. The DMA controller uses this function normally to get the conversion result from DATA[TSICNT] upon an end-of-scan or out-of-range event and then refreshes the channel index (DATA[TSICNT]) for the next trigger.

77.4 External signals

TSI contains up to 25 external pins for touch sensing. The following tables describe each of the TSI external pins.

Table 726. Signal description (self-capacitance sensing)

Name	Port	Direction	Function	Reset state
TSI[24:0]	TSI	I/O	TSI sensing pins or GPIO pins	I/O

Table 727. Signal description (mutual-capacitance sensing)

Name	Port	Direction	Function	Reset state
TSI[7:0]	TSI	I/O	TSI TX pins or GPIO pins	I/O
TSI[24:8]	TSI	I/O	TSI RX pins or GPIO pins	I/O

77.4.1 TSI[24:0]

When the TSI functionality is enabled, the TSI analog portion uses the corresponding channel to connect external onboard touch capacitors. The PCB connection between the pin and touch pad must be as short as possible to reduce parasitic capacity on board.

77.5 Initialization

This module does not require initialization.

77.6 Application information

To enable TSI:

1. Specify all the registers needed to pick up the functions to use (for example, channel number, scan mode, decimation, clock setting, V_p, V_m value, and SSC mode).
2. Write 1 to GENCS[TSIEN].
3. Send a software or hardware trigger to the TSI module. See Software and hardware triggers for more information.
4. Read the scan counter value after DATA[EOSF] becomes 1.

To disable TSI, write 0 to GENCS[TSIEN].

77.7.1.2 TSI CONFIG (TSI_CONFIG) for Self-Capacitor (CONFIG)

Offset

Register	Offset
CONFIG	0h

Function

Provides self- and mutual-capacitor control and configuration information for TSI. Two configuration registers share one address.

NOTE

As CONFIG and CONFIG_MUTUAL registers share the same offset, CONFIG[MODE] controls their reset value. After a system reset occurs, when CONFIG[MODE] becomes 1, the reset values of CONFIG and CONFIG_MUTUAL registers automatically change to 4000001h.

NOTE

When CONFIG[MODE] = 0, this register provides self-capacitor control and configuration information for TSI.

77.7.1.3 TSI CONFIG (TSI_CONFIG) for Mutual-Capacitor (CONFIG_MUTUAL)

Offset

Register	Offset
CONFIG_MUTUAL	0h

Function

Provides self- and mutual-capacitor control and configuration information for TSI. Two configuration registers share one address.

NOTE

As CONFIG and CONFIG_MUTUAL registers share the same offset, CONFIG[MODE] controls their reset value. After a system reset occurs, when CONFIG[MODE] becomes 1, the reset values of CONFIG and CONFIG_MUTUAL registers automatically change to 4000001h.

NOTE

When CONFIG[MODE] = 1, this register provides mutual-capacitor control and configuration information for TSI.

4-3 M_PMIRRORR	PMOS Current Mirror on Right Side Specifies the PMOS current mirror on the right side. 00b - m = 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - m = 2 10b - m = 3 11b - m = 4
2-1 M_NMIRROR	NMOS Current Mirror Specifies the NMOS current mirror. 00b - m = 1 01b - m = 2 10b - m = 3 11b - m = 4
0 MODE	Mode Specifies the sensing mode for self capacitance and mutual capacitance. For both, the address is TSI_CONFIG. 0b - Self capacitance 1b - Mutual capacitance

77.7.1.4 TSI Threshold (TSHD)

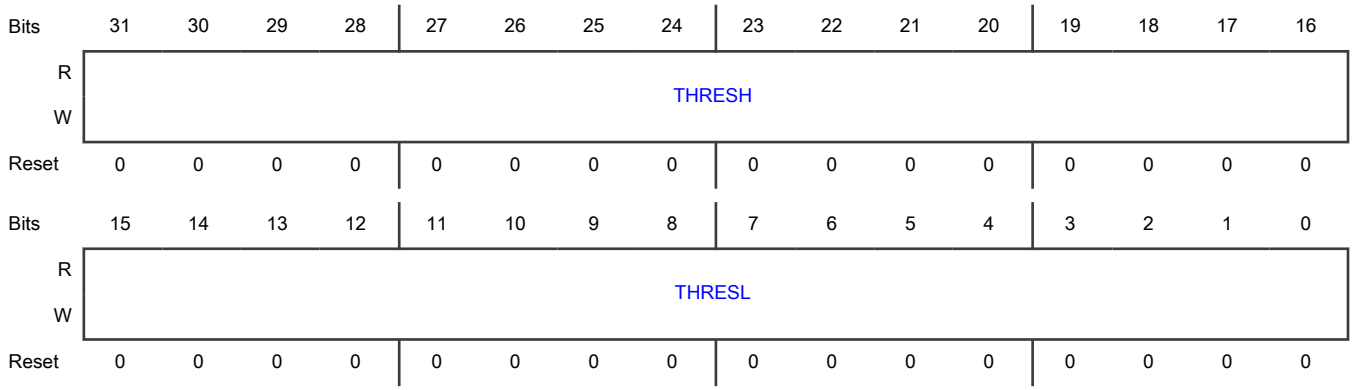
Offset

Register	Offset
TSHD	4h

Function

Defines the high and low thresholds of the count value.

Diagram



Fields

Field	Function
31-16 THRESH	TSI Wakeup Channel High Threshold Specifies the high threshold of the wakeup channel. The threshold values can be used as low-power wakeup thresholds.
15-0 THRESL	TSI Wakeup Channel Low Threshold Specifies the low threshold of the wakeup channel. The threshold values can be used as low-power wakeup thresholds.

77.7.1.5 TSI General Control and Status (GENCS)

Offset

Register	Offset
GENCS	8h

Function

Provides control and configuration information for TSI.

NOTE

When TSI is working, you must not change the configuration fields, GENCS[TSIEN] and GENCS[STM].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 —	Reserved
30	Out-of-Range Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
OUTRG_EN	Enables the out-of-range interrupt. 0b - Disables 1b - Enables
29-28 —	Reserved
27 ESOR	End-of-Scan Interrupt Enable Enables the end-of-scan interrupt. 0b - Disables 1b - Enables
26-24 SETCLK	Set Clock Sets the main clock frequency. 000b - 27.37 MHz 001b - 22.23 MHz 010b - 18.73 MHz 011b - 16.65 MHz 100b - 14.27 MHz 101b - 12.73 MHz 110b - 11.49 MHz 111b - 10.46 MHz
23 —	Reserved
22 S_PROX_EN	Proximity Enable Signal Enables the proximity function. 0b - Disables 1b - Enables
21 —	Reserved
20-16 DEBOUNCE	Debounce Sets the debounce function by specifying the number of out-of-range events that can generate an interrupt. 0_0000b - 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0001b - 2 1_1111b - 31 1_xxxxb - n
15 —	Reserved
14-12 DVOLT	Delta Voltage Selects the comparator V_m, V_p. 000b - Vm = 0.6 V, Vp = 1.7 V 001b - Vm = 0.6 V, Vp = 1.9 V 010b - Vm = 0.6 V, Vp = 2.1 V 011b - Vm = 0.6 V, Vp = 2.3 V 100b - Vm = 0.6 V, Vp = 2.5 V 101b - Vm = 0.6 V, Vp = 2.7 V
11-9 CTRIM_FINE	Capacitor Fine Trim Specifies additional trim bits for sense boost adjust. 000b - 0.3125 pF 001b - 0.625 pF 010b - 0.3125 × 3 pF 011b - 0.3125 × 4 pF 100b - 0.3125 × 5 pF 101b - 0.3125 × 6 pF 110b - 2.1875 pF 111b - 2.5 pF
8 —	Reserved
7 SWTS	Software Trigger Start Specifies whether software trigger start takes effect. If GENCS[STM] = 0, writing 1 to this field starts a scan. Read value is always 0. 0b - No effect 1b - Takes effect
6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 TSIEN	TSI Enable Enables TSI. 0b - Disables 1b - Enables
4 STPE	TSI Stop Enable Enables TSI to function in low-power modes (stop, VLPS, and so on). If this field = 0, MCU goes into a low-power mode. If this field = 1, TSI continues to run in all low-power modes. 0b - Disables 1b - Enables
3 STM	Scan Trigger Mode Specifies the trigger mode used. You are allowed to change this field when TSI is not working. 0b - Software trigger scan 1b - Hardware trigger scan
2 DMAEN_OUTRG	Out-of-Range DMA Transfer Request Enable Enables the DMA request at the out-of-range event. 0b - Disables 1b - Enables
1 —	Reserved
0 DMAEN_EOS	In-Progress DMA Transfer Request Enable Enables the DMA request at the end-of-scan event. 0b - Disables 1b - Enables

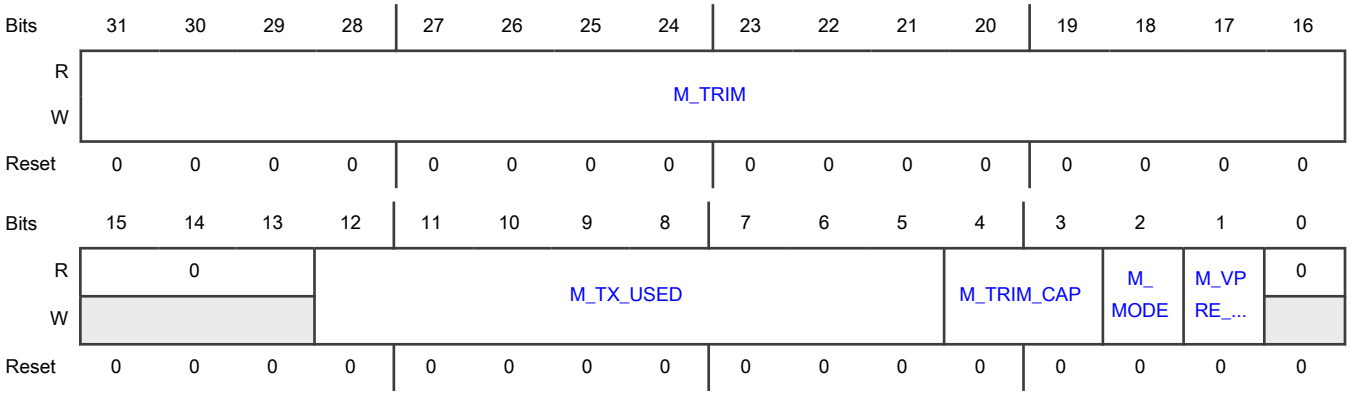
77.7.1.6 TSI Mutual-Capacitance (MUL)

Offset

Register	Offset
MUL	Ch

Function
Provides control for Mutual-Capacitance mode.

Diagram



Fields

Field	Function
31-16 M_TRIM	Mutual-Capacitance Trim Specifies the mutual-capacitance trim function.
15-13 —	Reserved
12-5 M_TX_USED	Mutual-Capacitance TX Used Indicates the channel that is used for mutual-capacitance TX when CONFIG[MODE] = 1. 0000_0000b - GPIO 0000_0001b - Mutual capacitance
4-3 M_TRIM_CAP	Mutual-Capacitance Trim Cap Adjusts Cp in Mutual-Capacitance mode. 00b - 0 pF 01b - 10 pF 10b - 10 pF 11b - 20 pF
2 M_MODE	Mutual-Capacitance Mode Controls TX drive mode. 0b - – 5 V ~ + 5 V 1b - 0 V ~ + 5 V
1 M_VPRE_CHOOSE	Mutual-Capacitance Prevoltage Specifies the digital control signal for pre-voltage selection. 0b - Internal 1.2 V 1b - External 1.2 V from PMC

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 —	Reserved

77.7.1.7 TSI SINC Filter (SINC)

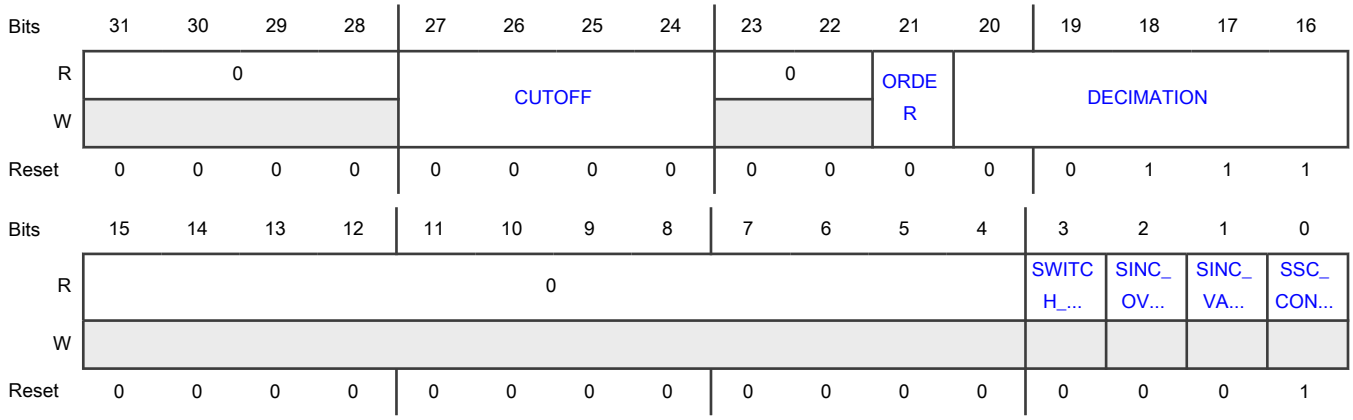
Offset

Register	Offset
SINC	10h

Function

Defines the configuration of the SINC filter, which is a digital decimation filter for filtering out low-frequency noise from EMC.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 CUTOFF	Cutoff Specifies the value of shifting out the lower bits of the counter. 0000b - div = 1 0001b - div = 2 0010b - div = 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0011b - div = 8 0100b - div = 16 0101b - div = 32 0110b - div = 64 0111b - div = 128 1000b - Do not use 1001b - Do not use 1010b - Do not use 1011b - Do not use 1100b - Do not use 1101b - Do not use 1110b - Do not use 1111b - Do not use
23-22 —	Reserved
21 ORDER	Order Selects the order of the SINC filter. 0b - Order 1 1b - Order 2
20-16 DECIMATION	Decimation Selects the decimation value of the SINC filter. DATA[TSICNT] determines the counter value of scan periods. 0_0000b - 1 0_0001b - 2 0_0010b - 3 0_0011b - 4 0_0100b - 5 0_0101b - 6 0_0110b - 7 0_0111b - 8 0_1000b - 9 0_1001b - 10

Table continues on the next page...

15-4 —	Reserved
3 SWITCH_ENABLE	Switch Enable Indicates the ssc state for digital testing. Use the SSC function for spreading frequency of the sampling clock, thus reducing EMC (see SSC for more). 0b - Disabled 1b - Enabled
2 SINC_OVERFLOW_FLAG	SINC Overflow Flag Indicates whether the counter result in DATA[TSICNT] had an overflow occurrence in the last scan process.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field has no default value. If necessary, force it to 0 or deposit it. 0b - No overflow 1b - Overflow
1 SINC_VALID	SINC Valid Indicates the state of the SINC filter for the purpose of digital testing. 0b - Disabled 1b - Enabled
0 SSC_CONTROL_OUT	SSC Output Control Indicates the state of the SSC output value for the purpose of digital testing. 0b - 0 1b - 1

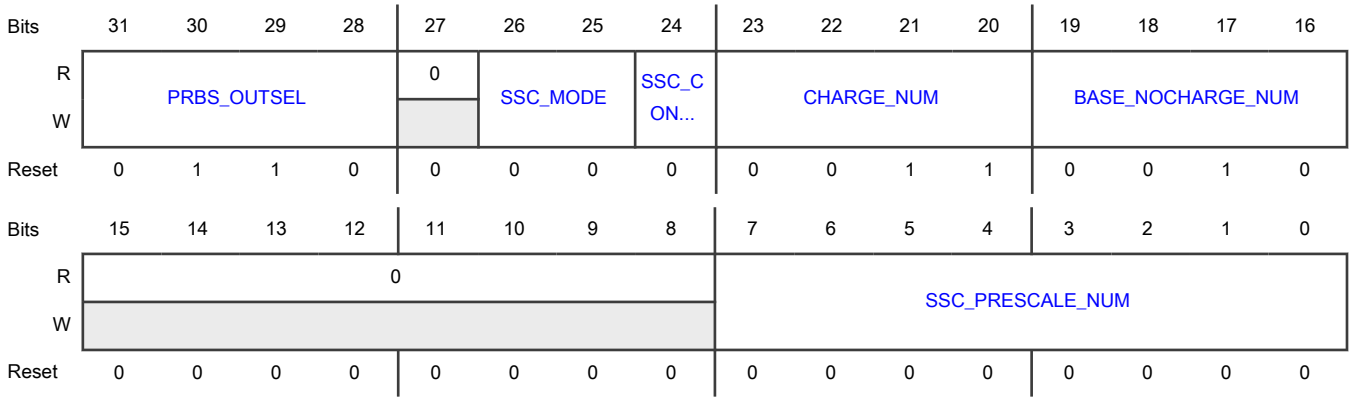
77.7.1.8 TSI SSC 0 (SSC0)

Offset

Register	Offset
SSC0	14h

Function
Provides SSC control 0.

Diagram



Fields

Field	Function
31-28 PRBS_OUTSEL	PRBS Output Selection If SSC0[SSC_MODE] = 2'b00, selects the length of the PRBS method. 0000b - Do not use 0001b - Do not use 0010b - 2 0011b - 3 0100b - 4 0101b - 5 0110b - 6 0111b - 7 1000b - 8 1001b - 9 1010b - 10 1011b - 11 1100b - 12 1101b - 13 1110b - 14 1111b - 15
27 —	Reserved
26-25 SSC_MODE	SSC Mode Specifies SSC mode for generating SSC output using the PRBS mode or Up-Down Counter mode. 00b - PRBS mode 01b - Up-Down Counter mode 10b - Disables SSC function 11b - Do not use
24 SSC_CONTROL_REVERSE	SSC Control Reverse Indicates whether the polarity of the SSC output bit is reversed. 0b - Polarity retained 1b - Polarity reversed
23-20 CHARGE_NUM	Charge Number Specifies the period of the SSC output bit 0's period, when using Up-Down Counter mode. The SSC output bit 0's period is integer times of the system clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - 1 0001b - 2 0010b - 3 0011b - 4 0100b - 5 0101b - 6 0110b - 7 0111b - 8 1000b - 9 1001b - 10 1010b - 11 1011b - 12 1100b - 13 1101b - 14 1110b - 15 1111b - 16
19-16 BASE_NOCHARGE_NUM	Base Nocharge Number Specifies the basic period of the SSC output bit 1's period, when using Up-Down Counter mode. Together with SSC2[MOVE_NOCHARGE_MAX] and SSC2[MOVE_NOCHARGE_MIN], this field determines the SSC output 1's period. The SSC output bit 1's period is integer times of the system clock. 0000b - 1 0001b - 2 0010b - 3 0011b - 4 0100b - 5 0101b - 6 0110b - 7 0111b - 8 1000b - 9 1001b - 10 1010b - 11 1011b - 12 1100b - 13

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1101b - 14 1110b - 15 1111b - 16
15-8 —	Reserved
7-0 SSC_PRESCALE_NUM	SSC Prescale Number Specifies the divider ratio of the clock used for generating the SSC output bit. The clock frequency is main_clock ÷ (SSC_PRESCALE_NUM + 1) before going into SSC logic. When SSC is enabled, the clock frequency is Fmain_clock ÷ (SSC_PRESCALE_NUM + 1), and when it is disabled, the clock frequency is Fmain_clock ÷ [(SSC_PRESCALE_NUM + 1) ÷ 2]. SSC_PRESCALE_NUM and the detailed SSC configuration determine the average SSC output frequency. 0000_0000b - div = 1 0000_0001b - div = 2 0000_0011b - div = 4 0000_0111b - div = 8 0000_1111b - div = 16 0001_1111b - div = 32 0011_1111b - div = 64 0111_1111b - div = 128 1111_1111b - div = 256

77.7.1.9 TSI SSC 1 (SSC1)

Offset

Register	Offset
SSC1	18h

Function
Provides SSC control 1.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PRBS_WEIGHT_HI								PRBS_WEIGHT_LO							
Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PRBS_SEED_HI								PRBS_SEED_LO							
Reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Fields

Field	Function
31-24 PRBS_WEIGHT_HI	PRBS High Weight Works with SSC1[PRBS_WEIGHT_LO] to select the PRBS feeding back nodes, when using the PRBS method to generate the SSC output bit. The nodes with a corresponding value 1 are fed back and connected to the XOR input.
23-16 PRBS_WEIGHT_LO	PRBS Low Weight Works with SSC1[PRBS_WEIGHT_HI] to select the PRBS feeding back nodes, when using the PRBS method to generate the SSC output bit. The nodes with a corresponding value 1 are fed back and connected to the XOR input.
15-8 PRBS_SEED_HI	PRBS High Seed Works with SSC1[PRBS_SEED_LO] to select the initial value of the PRBS method, when using the PRBS method to generate the SSC output bit.
7-0 PRBS_SEED_LO	PRBS Low Seed Works with SSC1[PRBS_SEED_HI] to select the initial value of the PRBS method, when using the PRBS method to generate the SSC output bit.

77.7.1.10 TSI SSC 2 (SSC2)

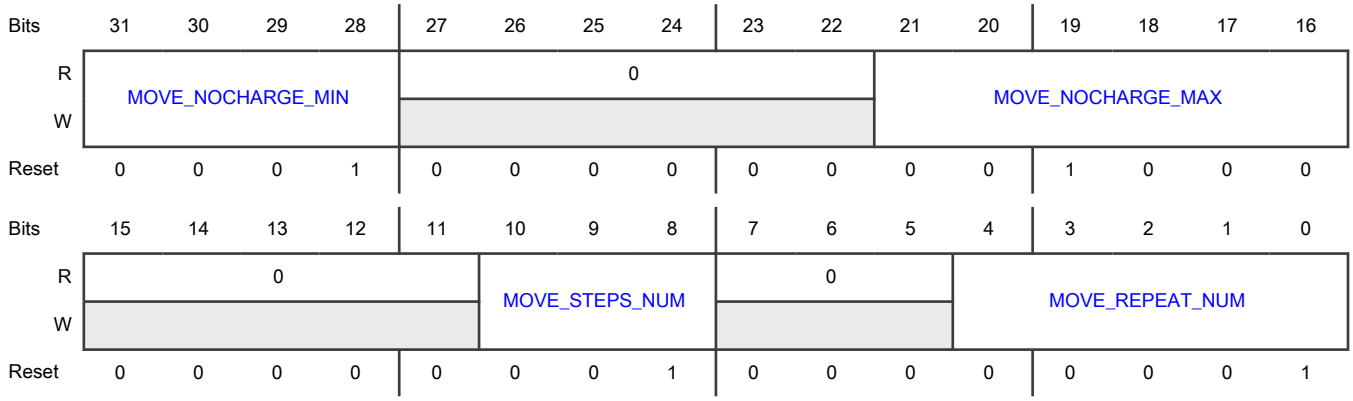
Offset

Register	Offset
SSC2	1Ch

Function

Provides SSC control 2.

Diagram



Fields

Field	Function
31-28 MOVE_NOCHARGE_MIN	Move Nocharge Minimum Specifies the minimum period of the SSC output bit 1's period, when using Up-Down Counter mode. Together with SSC0[BASE_NOCHARGE_NUM] and SSC2[MOVE_NOCHARGE_MAX], this field determines the SSC output 1's period. The SSC output bit 1's minimum period is integer times of the divided system clock. 0000b - (1 + SSC0[BASE_NOCHARGE_NUM]) 0001b - (2 + SSC0[BASE_NOCHARGE_NUM]) 0010b - (3 + SSC0[BASE_NOCHARGE_NUM]) 0011b - (4 + SSC0[BASE_NOCHARGE_NUM]) 0100b - (5 + SSC0[BASE_NOCHARGE_NUM]) 0101b - (6 + SSC0[BASE_NOCHARGE_NUM]) 0110b - (7 + SSC0[BASE_NOCHARGE_NUM]) 0111b - (8 + SSC0[BASE_NOCHARGE_NUM]) 1000b - (9 + SSC0[BASE_NOCHARGE_NUM]) 1001b - (10 + SSC0[BASE_NOCHARGE_NUM]) 1010b - (11 + SSC0[BASE_NOCHARGE_NUM]) 1011b - (12 + SSC0[BASE_NOCHARGE_NUM]) 1100b - (13 + SSC0[BASE_NOCHARGE_NUM]) 1101b - (14 + SSC0[BASE_NOCHARGE_NUM]) 1110b - (15 + SSC0[BASE_NOCHARGE_NUM]) 1111b - (16 + SSC0[BASE_NOCHARGE_NUM])
27-22 —	Reserved
21-16	Move Nocharge Maximum

Table continues on the next page...

Table continued from the previous page...

Field	Function
MOVE_NOCHARGE_MAX	Specifies the maximum period of the SSC output bit 1's period, when using Up-Down Counter mode. The functioning of this field is similar to that of SSC2[MOVE_NOCHARGE_MIN]. Together with SSC0[BASE_NOCHARGE_NUM] and SSC2[MOVE_NOCHARGE_MIN], this field determines the SSC output 1's period.
15-11 —	Reserved
10-8 MOVE_STEPS_NUM	Move Steps Number Specifies the added value for the up-down counter. This field helps you select the steps for the counters of SSC0[BASE_NOCHARGE_NUM], SSC2[MOVE_NOCHARGE_MAX], and SSC2[MOVE_NOCHARGE_MIN], when using Up-Down Counter mode. 000b - 0 001b - 1 010b - 2 011b - 3 100b - 4 101b - 5 110b - 6 111b - 7
7-5 —	Reserved
4-0 MOVE_REPEAT_NUM	Move Repeat Number Specifies the sample-charge cycles for which the up-down counter is updated. This field helps you select the repeat times for the same setting of SSC0[BASE_NOCHARGE_NUM], SSC2[MOVE_NOCHARGE_MAX], and SSC2[MOVE_NOCHARGE_MIN], when using Up-Down Counter mode. Only after this repeat time is reached, you can change these settings to their next values. 0_0000b - 1 0_0001b - 2 0_0010b - 3 0_0011b - 4 0_0100b - 5 0_0101b - 6 0_0110b - 7

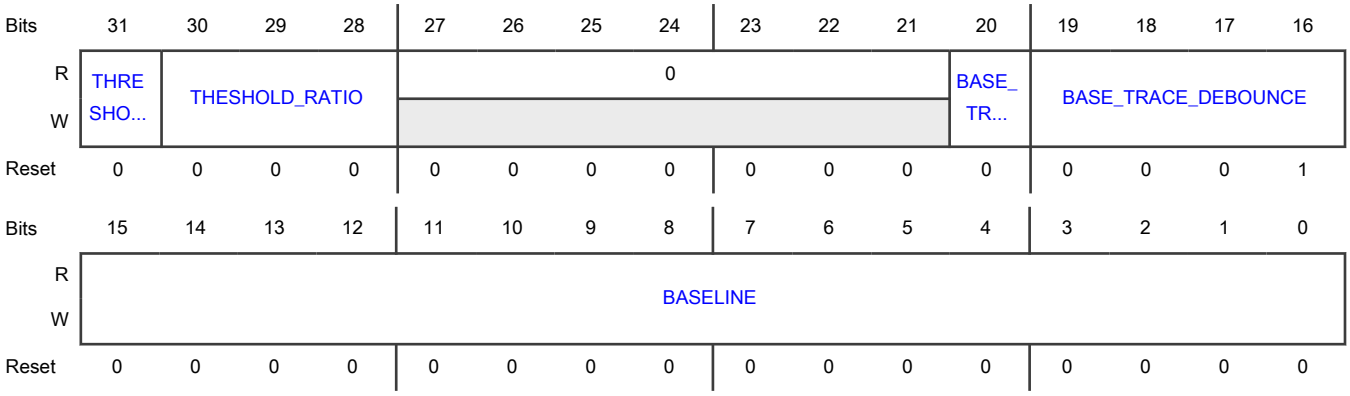
77.7.1.11 TSI Baseline (BASELINE)

Offset

Register	Offset
BASELINE	20h

Function
Provides baseline controls.

Diagram



Fields

Field	Function
31 THRESHOLD_TRACE_EN	Threshold Trace Enable Enables the threshold trace function. 0b - Disables 1b - Enables
30-28 THESHOLD_RATIO	Threshold Ratio Specifies auto-calibration trim bits, which work when BASELINE[THRESHOLD_TRACE_EN] = 1. 000b - thresholdh = (baseline + counter) ÷ 2 and thresholdl = (baseline – counter) ÷ 2 001b - thresholdh = (baseline + counter) ÷ 4 and thresholdl = (baseline – counter) ÷ 4 010b - thresholdh = (baseline + counter) ÷ 8 and thresholdl = (baseline – counter) ÷ 8 011b - thresholdh = (baseline + counter) ÷ 16 and thresholdl = (baseline – counter) ÷ 16 100b - thresholdh = (baseline + counter) ÷ 32 and thresholdl = (baseline – counter) ÷ 32 101b - thresholdh = (baseline + counter) ÷ 64 and thresholdl = (baseline – counter) ÷ 64 110b - thresholdh = (baseline + counter) ÷ 128 and thresholdl = (baseline – counter) ÷ 128 111b - thresholdh = (baseline + counter) ÷ 256 and thresholdl = (baseline – counter) ÷ 256

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-21 —	Reserved
20 BASE_TRACE_EN	Baseline Trace Enable Enables the trace function enable signal, which works only in a low-power mode and supports only one channel baseline auto trace.
19-16 BASE_TRACE_DEBOUNCE	Base Trace Debounce Specifies the baseline auto-trace ratio that the current counter value takes. 0000b - 0 0001b - 1 / 16 0010b - 2 / 16 0011b - 3 / 16 1111b - 15 / 16 1xxxb - n / 16
15-0 BASELINE	Baseline Sets the baseline only support in one channel scan case.

77.7.1.12 TSI Channel Merge (CHMERGE)

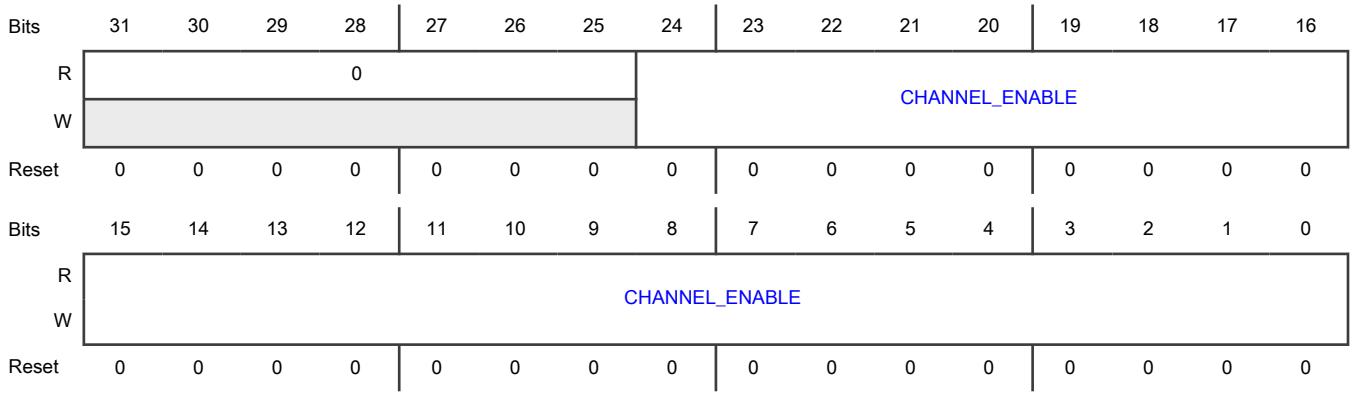
Offset

Register	Offset
CHMERGE	24h

Function

Provides the configuration for the proximity function.

Diagram



Fields

Field	Function
31-25 —	Reserved
24-0 CHANNEL_ENABLE	Channel Enable Enables the proximity channel merge pad selection for Self-Capacitance mode. 0_0000_0000_0000_0000_0000_0000b - Channel not chosen for proximity pad 0_0000_0000_0000_0000_0000_0001b - Channel chosen for proximity pad

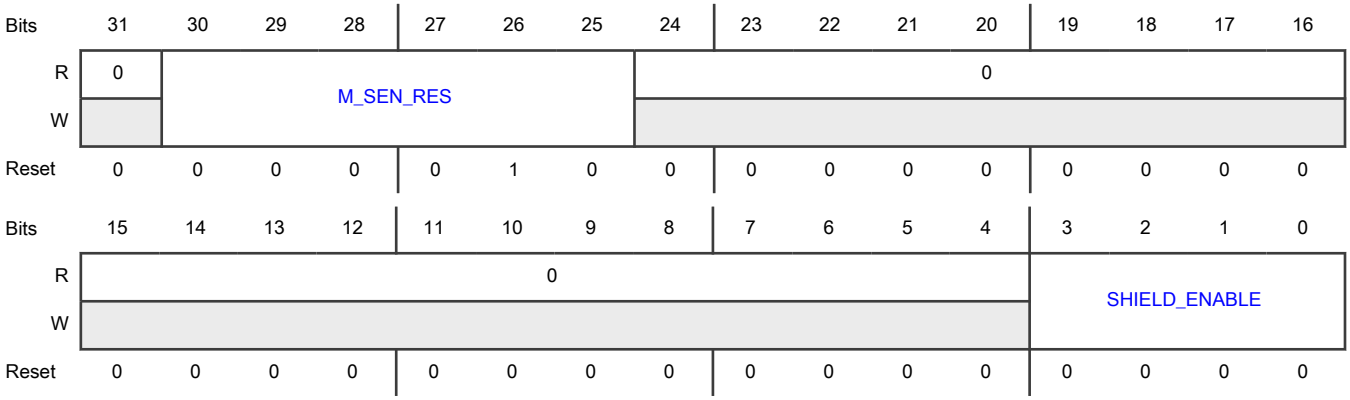
77.7.1.13 TSI Shield (SHIELD)

Offset

Register	Offset
SHIELD	28h

Function
Provides control of the shield function.

Diagram



Fields

Field	Function
31 —	Reserved
30-25 M_SEN_RES	Mutual-Capacitance Sensitivity Resistor Specifies the electrical resistance of the resistor used in the internal current generator.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00_0000b - 10 kΩ 00_0001b - 10 kΩ + (2.5 ÷ 3) kΩ (just for auto-calibration) 00_0010b - 12.5 kΩ (default) 00_1110b - 25 kΩ
24-4 —	Reserved
3-0 SHIELD_ENABLE	Shield Enable When CONFIG[MODE] = 0 (Self-Capacitor mode), enables water shield feature. Selects the shield pin function: bit 3 for TSI[18]; bit 2 for TSI[12]; bit 1 for TSI[6]; bit 0 for TSI[0]. 0000b - Disables 0001b - Enables

77.7.1.14 TSI Data and Status (DATA)

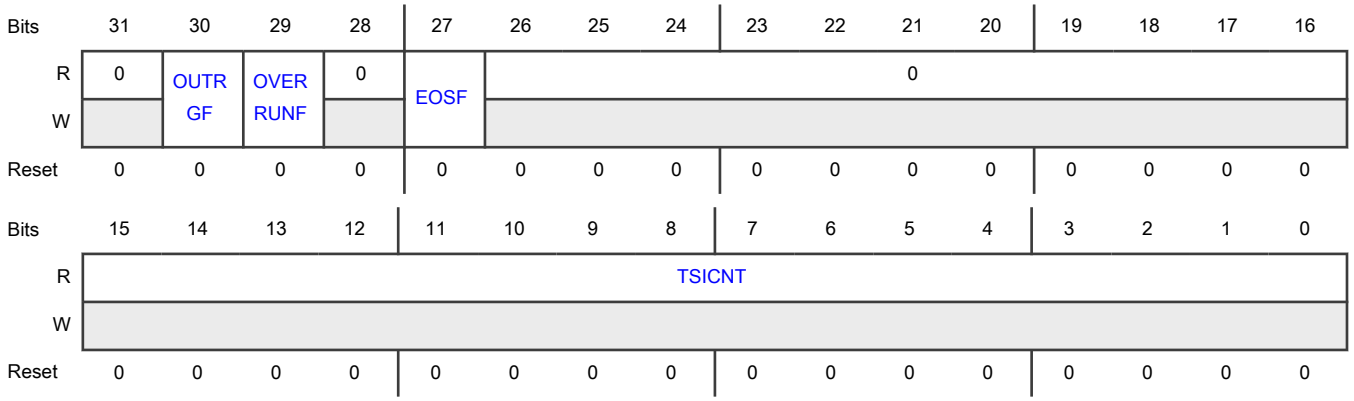
Offset

Register	Offset
DATA	100h

Function

Provides the TSI count result and related flags.

Diagram



Fields

Field	Function
31 —	Reserved
30 OUTRGF	Out-of-Range Flag Specifies whether the result register of the enabled electrode is out of range, as defined by TSI Threshold (TSHD). This flag sets when it happens. You can read the flag when the CPU wakes. When this flag is set, write 1 to clear it.
29 OVERRUNF	Overrun Flag Specifies whether a new trigger or register configuration has happened (not in Prefetch mode) if a scan is still in progress. This flag sets when it happens. 0b - No 1b - Yes
28 —	Reserved
27 EOSF	End-of-Scan Flag Specifies whether all the active electrodes have completed scanning after a scan trigger. This flag sets when it happens, and you can write 1 to clear it.
26-16 —	Reserved
15-0 TSICNT	TSI Conversion Counter Value Records the accumulated scan counter value ticked by the reference oscillator.

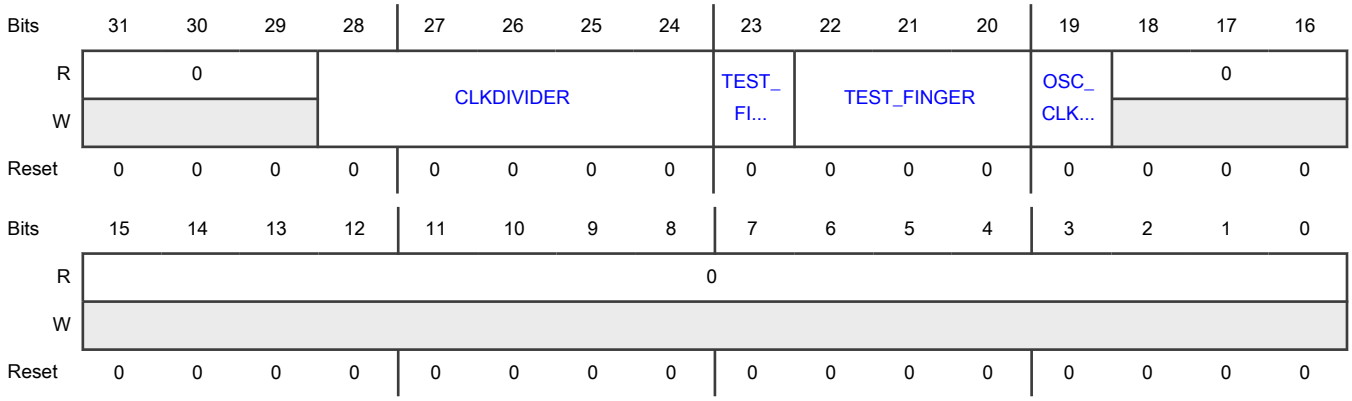
77.7.1.15 TSI Miscellaneous (MISC)

Offset

Register	Offset
MISC	108h

Function
Provides configuration for clock source, clock divider, and finger-test simulation.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 CLKDIVIDER	TSI Clock Divider Divides the internal IRC clock frequency.
23 TEST_FINGER_EN	Test Finger Function Enable Signals Enables the test-finger function. 0b - Disables 1b - Enables
22-20 TEST_FINGER	Test Finger Specifies auto-calibration trim bits, which work when MISC[TEST_FINGER_EN] = 1. 000b - Finger capacitor is 148 pF 001b - Finger capacitor is 296 pF 010b - Finger capacitor is 444 pF 011b - Finger capacitor is 592 pF 100b - Finger capacitor is 740 pF 101b - Finger capacitor is 888 pF 110b - Finger capacitor is 1036 pF 111b - Finger capacitor is 1184 pF
19 OSC_CLK_SEL	Oscillator Clock Select Specifies the TSI functional clock source. 0b - Analog oscillator 1b - Chip

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-0 —	Reserved

77.7.1.16 TSI AUTO TRIG (TRIG)

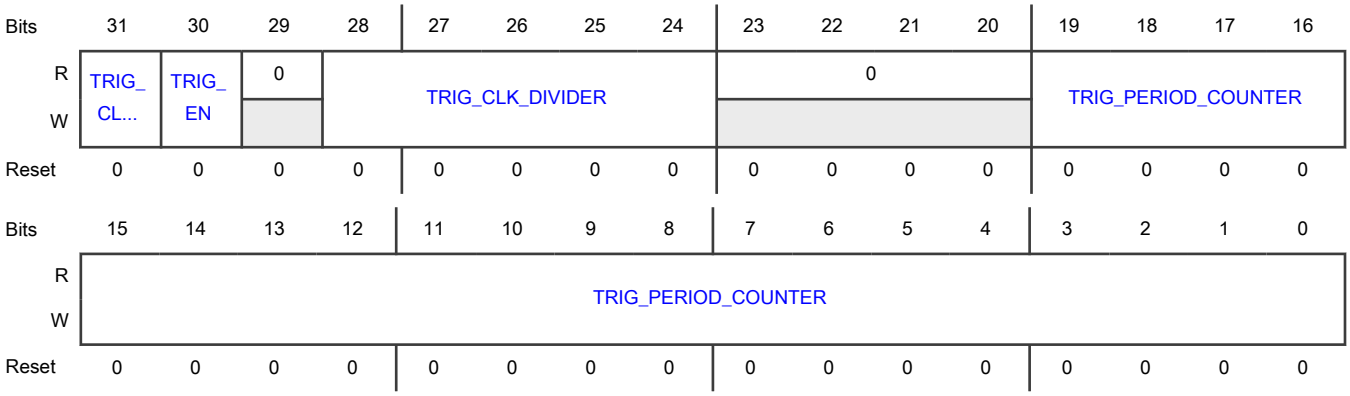
Offset

Register	Offset
TRIG	10Ch

Function

Provides controls for the automatic trigger function.

Diagram



Fields

Field	Function
31 TRIG_CLK_SEL	Trigger Clock Select Selects the clock used for automatic trigger. 0b - 32 k clock 1b - clksoc
30 TRIG_EN	Trigger Enable Indicates whether the automatic trigger function is enabled. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 —	Reserved
28-24 TRIG_CLK_DIVIDER	Trigger Clock Divider Specifies the divider for trigger clock. 0_0000b - No divider 0_0001b - Divided by 2 0_0010b - Divided by 3 0_0011b - Divided by 4 1_xxxxb - Divided by n
23-20 —	Reserved
19-0 TRIG_PERIOD_COUNTER	Trigger Period Counter Specifies the period of the trigger counter.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Hazardous voltage — Although basic supply voltages of the product may be much lower, circuit voltages up to 60 V may appear when operating this product, depending on settings and application. Customers incorporating or otherwise using these products in applications where such high voltages may appear during operation, assembly, test etc. of such application, do so at their own risk. Customers agree to fully indemnify NXP Semiconductors for any damages resulting from or in connection with such high voltages. Furthermore, customers are drawn to safety standards (IEC 950, EN 60 950, CENELEC, ISO, etc.) and other (legal) requirements applying to such high voltages.

AEC unqualified products — This product has not been qualified to the appropriate Automotive Electronics Council (AEC) standard Q100 or Q101 and should not be used in automotive applications, including but not limited to applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors accepts no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is for the customer's own risk.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Suitability for use in non-automotive qualified products — Unless this document expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

HTML publications — An HTML version, if available, of this document is provided as a courtesy. Definitive information is contained in the applicable document in PDF format. If there is a discrepancy between the HTML document and the PDF document, the PDF document has priority.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.
