MCX W72 Reference Manual

Contents

Chapter 1 About This Manual..... 13
1.1 Audience.....13
1.2 Organization..... 13
1.3 Module descriptions.....13
1.4 Register descriptions..... 16
1.5 Conventions.....18
1.6 Editorial changes.....20

Chapter 2 Introduction..... 21
2.1 Introduction.....21
2.2 Functional overview.....21
2.3 Block diagram.....30
2.4 Ordering information.....30

Chapter 3 Core Overview..... 32
3.1 Introduction.....32
3.2 Cortex-M33 Code and System Buses..... 32
3.3 Nested Vectored Interrupt Controller (NVIC).....32
3.4 System memory map.....36
3.5 Peripheral bridge2 (PBRIDGE2).....39
3.6 Fast peripherals.....42
3.7 PPB memory map..... 43

Chapter 4 Localization Compute Engine (LCE).....45
4.1 Overview.....45
4.2 Functional description.....46

Chapter 5 Low Power Cache Controller (LPCAC).....47
5.1 Chip-specific LPCAC information..... 47
5.2 Overview.....48
5.3 Functional description.....48
5.4 Signal descriptions..... 49
5.5 Memory regions and input control description.....49

Chapter 6 Peripheral Bridge2 (PBRIDGE2).....51
6.1 Chip-specific PBRIDGE2 information.....51
6.2 Overview.....51
6.3 Functional description.....51
6.4 External signals..... 52
6.5 Initialization.....52
6.6 Memory maps.....52

Chapter 7 Crossbar Switch (AXBS).....53
7.1 Chip-specific AXBS information.....53
7.2 Overview.....54

7.3 Memory map and register definition..... 54
7.4 Functional description.....63
7.5 External signals..... 66
7.6 Initialization/application information.....66
7.7 Glossary..... 66

Chapter 8 Flash Memory Controller (FMC).....67
8.1 Chip-specific FMC information..... 67
8.2 Overview.....67
8.3 Functional description.....69
8.4 External signals..... 70
8.5 Initialization and application information.....70

Chapter 9 System Performance Monitor (SYSPM).....71
9.1 Chip-specific SYSPM information.....71
9.2 Overview.....72
9.3 Functional description.....73
9.4 Memory Map and register definition..... 74

Chapter 10 Trusted Resource Domain Controller (TRDC)..... 91
10.1 Chip-specific TRDC information..... 91
10.2 Overview.....92
10.3 Functional description.....94
10.4 External signals..... 99
10.5 Initialization.....99
10.6 Application information..... 100
10.7 Register descriptions..... 101

Chapter 11 Enhanced Direct Memory Access (eDMA).....212
11.1 Chip-specific eDMA information..... 212
11.2 Overview.....214
11.3 Functional description.....217
11.4 Memory map and register definition..... 222
11.5 External signals..... 259
11.6 Initialization.....259

Chapter 12 Miscellaneous System Control Module (MSCM).....272
12.1 Chip-specific MSCM information..... 272
12.2 Overview.....273
12.3 Functional Description.....274
12.4 MSCM Memory Map/Register Definition..... 274

Chapter 13 Miscellaneous Control Module (MCM)..... 324
13.1 Chip-specific MCM information.....324
13.2 Overview.....324
13.3 Functional description.....325
13.4 External signals..... 325
13.5 Application information..... 325
13.6 Memory map and register descriptions..... 326

Chapter 14 Memories..... 347
14.1 Introduction.....347
14.2 Memory architecture.....347
14.3 Memory hierarchy.....347
14.4 TCM SRAMs.....347
14.5 L1 Cache..... 348
14.6 Read Only Memory (ROM).....349
14.7 Internal flash.....349

Chapter 15 ROM Bootloader..... 352
15.1 Introduction.....352
15.2 Boot ROM.....352
15.3 ROM API..... 417

Chapter 16 Flash Memory Unit (FMU).....435
16.1 Chip-specific FMU information..... 435
16.2 Overview.....435
16.3 Functional description.....437
16.4 External signals..... 453
16.5 Initialization.....453
16.6 Memory map and registers.....453
16.7 Glossary..... 465

Chapter 17 System Register File (REGFILE)..... 467
17.1 Chip-specific REGFILE information.....467
17.2 Overview.....467
17.3 Memory Map and Registers..... 467
17.4 Functional description.....471

Chapter 18 Signal Muxing and Pinout..... 472
18.1 Introduction.....472
18.2 Package pinout.....472
18.3 Pinouts diagram.....478

Chapter 19 Port Control (PORT).....480
19.1 Chip-specific PORT information..... 480
19.2 Overview.....483
19.3 Functional description.....484
19.4 Initialization.....485
19.5 Application information..... 485
19.6 Memory map and register definition..... 485

Chapter 20 General-purpose Input and Output (GPIO)..... 575
20.1 Chip-specific GPIO information..... 575
20.2 Overview.....575
20.3 Functional description.....576
20.4 External signals 578
20.5 Initialization.....579
20.6 Application information..... 579

20.7 Memory map and register definition..... 579

Chapter 21 Debug.....601
21.1 Introduction.....601
21.2 Trace component reset sources.....601
21.3 Test and debug port connectivity.....602
21.4 Cortex M33 debug.....603
21.5 Cross Trigger Interface (CTI).....605
21.6 Low power debug..... 606

Chapter 22 Reset.....607
22.1 Introduction.....607
22.2 Power reset sources.....607
22.3 External reset sources.....608
22.4 Internal reset sources.....609
22.5 Reset type..... 610

Chapter 23 Clocking..... 613
23.1 Introduction.....613
23.2 Clock definitions..... 614
23.3 MRCC clock outputs.....615
23.4 Clock gating.....615
23.5 Module/Peripheral clocking..... 615

Chapter 24 System Clock Generator (SCG).....620
24.1 Chip-specific SCG information..... 620
24.2 Introduction.....621
24.3 Functional description.....622
24.4 External signals..... 625
24.5 Initialization.....625
24.6 Memory Map/Register Definition..... 625

Chapter 25 Module Reset and Clock Control (MRCC)..... 646
25.1 Chip-specific MRCC information..... 646
25.2 Introduction.....646
25.3 Features..... 646
25.4 Functional description.....647
25.5 Memory map and register definition..... 647

Chapter 26 Signal Frequency Analyser (SFA).....704
26.1 Chip-specific SFA information..... 704
26.2 Overview.....705
26.3 Functional Description.....706
26.4 Memory Map Register Definition..... 714

Chapter 27 32 kHz Clock Control Module (CCM32K).....730
27.1 Chip-specific CCM32K information.....730
27.2 Overview.....730

27.3 Functional description....731
27.4 External signals....733
27.5 Initialization....733
27.6 Memory Map and register definition....733

Chapter 28 Power Management....748
28.1 Introduction....748
28.2 Power domains....748
28.3 Power modes....751
28.4 Module operation in low power modes....754
28.5 Power supply configurations....757
28.6 Power optimization....758
28.7 Smart power switch....760

Chapter 29 Core Mode Controller (CMC)....763
29.1 Chip-specific CMC information....763
29.2 Overview....765
29.3 Functional description....766
29.4 External signals....773
29.5 Initialization....773
29.6 Application information....773
29.7 Memory map and register descriptions....774

Chapter 30 System Power Control (SPC)....807
30.1 Chip-specific SPC information....807
30.2 Overview....810
30.3 Functional description....812
30.4 External signals....818
30.5 Initialization....819
30.6 Application information....819
30.7 SPC register descriptions....819

Chapter 31 Smart Power Switch (VBAT)....870
31.1 Chip-specific VBAT information....870
31.2 Overview....870
31.3 Functional description....871
31.4 External signals....873
31.5 Initialization....873
31.6 Application information....873
31.7 Memory map and register definition....873

Chapter 32 External Watchdog Monitor (EWM)....892
32.1 Chip-specific EWM information....892
32.2 Overview....892
32.3 Functional Description....893
32.4 External signals....895
32.5 Memory Map....896

Chapter 33 Trigger Multiplexer (TRGMUX)....903

33.1 Chip-specific TRGMUX information....903
33.2 Overview....906
33.3 Functional description....907
33.4 External signals....907
33.5 Initialization....907
33.6 TRGMUX register descriptions....907

Chapter 34 Wakeup Unit (WUU)....937
34.1 Chip-specific WUU information....937
34.2 Overview....939
34.3 Functional description....941
34.4 External signals....942
34.5 Initialization....942
34.6 Application information....943
34.7 Memory map and register definition....943

Chapter 35 Watchdog Timer (WDOG)....987
35.1 Chip-specific WDOG information....987
35.2 Overview....988
35.3 Functional description....989
35.4 External signals....993
35.5 Initialization....993
35.6 Application information....993
35.7 Memory map and register definition....994

Chapter 36 Cyclic Redundancy Check (CRC)....1002
36.1 Chip-specific CRC information....1002
36.2 Overview....1002
36.3 Functional description....1003
36.4 External signals....1005
36.5 Initialization....1005
36.6 Use cases....1006
36.7 Memory map and register descriptions....1008

Chapter 37 16-bit Analog-to-Digital Converter (ADC)....1013
37.1 Chip-specific ADC information....1013
37.2 Overview....1015
37.3 Functional description....1016
37.4 External signals....1026
37.5 Initialization....1026
37.6 ADC register descriptions....1028

Chapter 38 Low Power Comparator (LPCMP)....1078
38.1 Chip-specific LPCMP information....1078
38.2 Overview....1078
38.3 Functional Description....1081
38.4 External signal descriptions....1094
38.5 Initialization....1094
38.6 Application information....1095
38.7 LPCMP register descriptions....1095

Chapter 39 Voltage Reference (VREF)..... 1109
39.1 Chip-specific VREF information..... 1109
39.2 Overview..... 1109
39.3 Functional description..... 1110
39.4 External signals..... 1112
39.5 Initialization..... 1112
39.6 Register descriptions..... 1113

Chapter 40 Real Time Clock (RTC)..... 1118
40.1 Chip-specific RTC information..... 1118
40.2 Overview..... 1118
40.3 Functional description..... 1119
40.4 External signals..... 1122
40.5 Initialization..... 1122
40.6 Register descriptions..... 1123

Chapter 41 Low-Power Timer (LPTMR)..... 1144
41.1 Chip-specific LPTMR information..... 1144
41.2 Overview..... 1145
41.3 Functional description..... 1145
41.4 External signals..... 1148
41.5 Initialization..... 1148
41.6 Application information..... 1148
41.7 Memory map and register definition..... 1149

Chapter 42 Low Power Periodic Interrupt Timer (LPIT)..... 1156
42.1 Chip-specific LPIT information..... 1156
42.2 Overview..... 1156
42.3 Functional description..... 1157
42.4 Initialization..... 1177
42.5 Memory map and registers..... 1178

Chapter 43 Timer/PWM Module (TPM)..... 1196
43.1 Chip-specific TPM information..... 1196
43.2 Overview..... 1196
43.3 Functional description..... 1198
43.4 External signals..... 1218
43.5 Initialization..... 1218
43.6 Application information..... 1219
43.7 Memory map and register definition..... 1220

Chapter 44 Low Power Inter-Integrated Circuit (LPI2C)..... 1253
44.1 Chip-specific LPI2C information..... 1253
44.2 Overview..... 1253
44.3 Functional description..... 1255
44.4 External signals..... 1266
44.5 Initialization..... 1267
44.6 Application information..... 1268
44.7 Memory map and registers..... 1268

Chapter 45 Improved Inter-Integrated Circuit (I3C)..... 1322
45.1 Chip-specific I3C information.....1322
45.2 Overview.....1322
45.3 Functional description.....1324
45.4 External signals..... 1337
45.5 Initialization.....1337
45.6 Application information..... 1339
45.7 I3C register descriptions.....1340

Chapter 46 Low Power Serial Peripheral Interface (LPSPI)..... 1449
46.1 Chip-specific LPSPI information.....1449
46.2 Overview.....1449
46.3 Functional description.....1451
46.4 External signals..... 1463
46.5 Initialization.....1464
46.6 Memory map and registers.....1464

Chapter 47 Low Power Universal Asynchronous Receiver/Transmitter (LPUART).....1499
47.1 Chip-specific LPUART information..... 1499
47.2 Overview.....1499
47.3 LPUART register descriptions..... 1502
47.4 Functional description.....1538
47.5 External signals..... 1550
47.6 Initialization.....1550

Chapter 48 CAN (FlexCAN).....1551
48.1 Chip-specific FlexCAN information.....1551
48.2 Overview.....1553
48.3 Functional description.....1555
48.4 External signal descriptions 1607
48.5 Memory map and register definition..... 1607
48.6 Initialization and application information.....1706
48.7 Glossary..... 1707

Chapter 49 Flexible I/O (FlexIO)..... 1709
49.1 Chip-specific FLEXIO information..... 1709
49.2 Overview.....1709
49.3 Functional description.....1711
49.4 External signals..... 1721
49.5 Initialization.....1721
49.6 Application information..... 1721
49.7 Memory map and registers.....1741

Chapter 50 Semaphores2 (SEMA42)..... 1788
50.1 Chip-specific SEMA42 information..... 1788
50.2 Overview.....1788
50.3 Memory map/register definition..... 1789
50.4 Functional description.....1793

50.5 External signals..... 1796
50.6 Initialization..... 1796

Chapter 51 Messaging Unit (MU)..... 1797
51.1 Chip-specific MU information..... 1797
51.2 Overview..... 1797
51.3 Functional description..... 1798
51.4 External signals..... 1801
51.5 Initialization..... 1802
51.6 Application information..... 1802
51.7 Register definition..... 1807

Chapter 52 Radio Platform..... 1854
52.1 Chip-specific Radio Platform information..... 1854
52.2 Introduction..... 1854
52.3 RFMC..... 1857
52.4 2.4GHz Radio..... 1898

Chapter 53 Data Stream Buffer (DSB)..... 3226
53.1 Overview..... 3226
53.2 Functional description..... 3227
53.3 External signals..... 3228
53.4 Initialization..... 3228
53.5 Memory map and register definition..... 3229

Chapter 54 RF Core Mode Controller (RF_CMC)..... 3237
54.1 Overview..... 3237
54.2 Functional description..... 3238
54.3 External signals..... 3239
54.4 Initialization..... 3239
54.5 Application Information..... 3240
54.6 Register descriptions..... 3240

Chapter 55 Radio Flash Management Unit (RF_FMU1)..... 3252
55.1 Overview..... 3252
55.2 Functional description..... 3253
55.3 External signals..... 3269
55.4 Initialization..... 3269
55.5 Memory map and registers..... 3269
55.6 Glossary..... 3281

Chapter 56 Radio Flash..... 3283
56.1 Overview..... 3283
56.2 Memory Map and register definition..... 3283

Chapter 57 FRO Clock Generator (FRO192M)..... 3286
57.1 Overview..... 3286
57.2 Functional description..... 3286

57.3 External signals.....3287
57.4 Initialization.....3287
57.5 Memory Map/Register Definition.....3287

Appendix A General changes.....3291
A.1 General changes.....3291

Appendix B Release Notes.....3292
B.1 About This Manual changes.....3292
B.2 Introduction changes.....3292
B.3 Core Overview changes.....3292
B.4 LCE module changes.....3292

Chapter 1
About This Manual

1.1 Audience

This reference manual (RM) is intended for system software, hardware developers, and applications programmers who need to develop products using this chip. It assumes that its users understand operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual has two main sets of chapters.

- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

Select the paperclip icon on the left side of the PDF window to see the list of attachments.

1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.

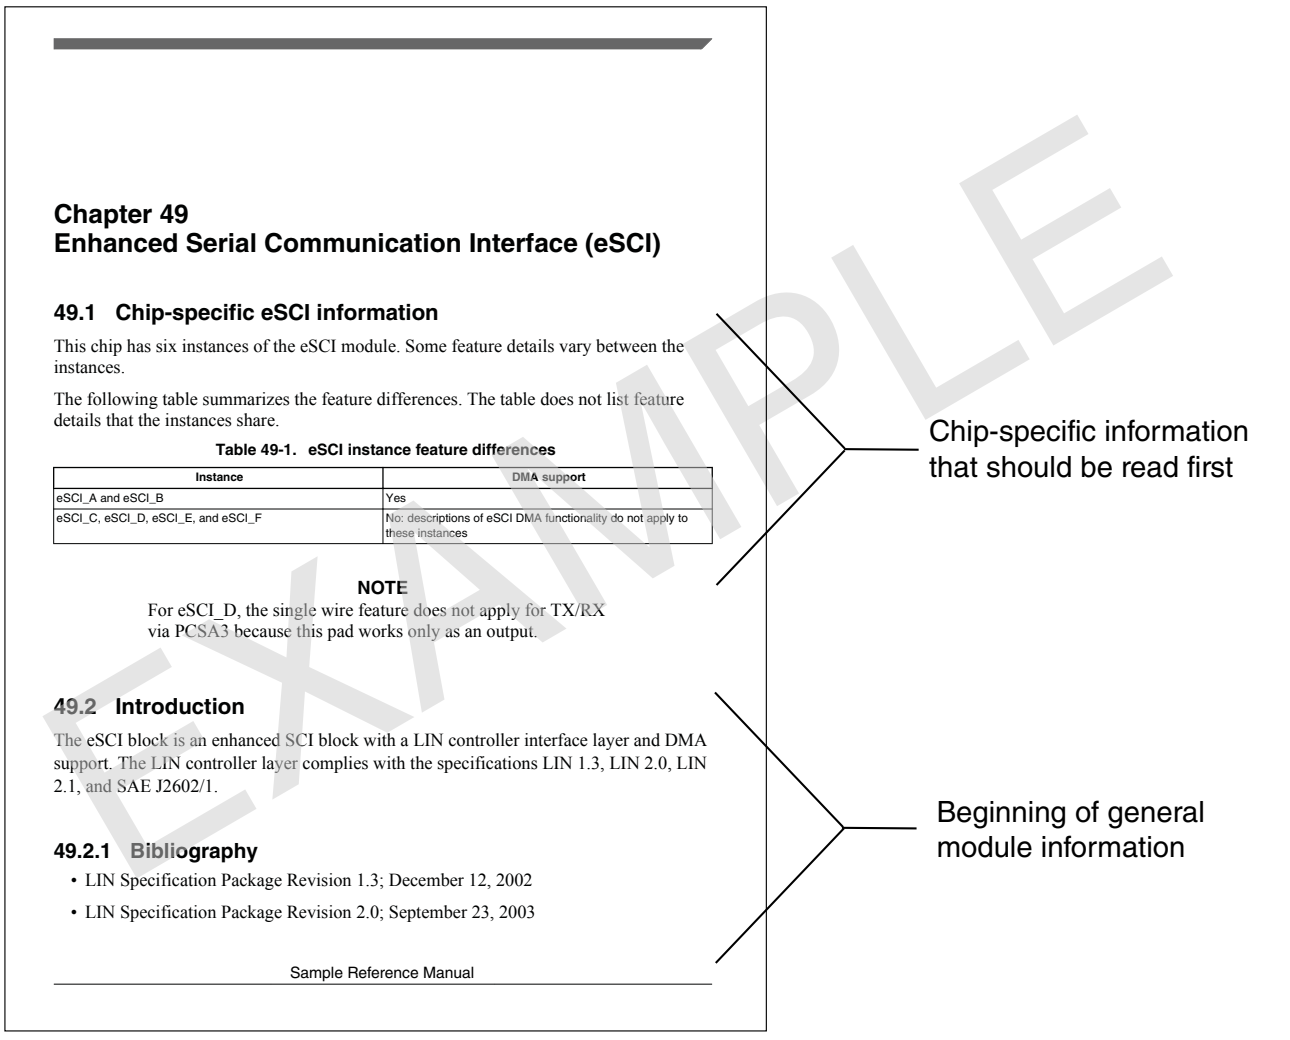

Figure 1. Example of chapter chip-specific information and general module information

1.3.1 Chip-specific information that clarifies content in the same chapter

The following figure shows an example of chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.

System Integration Unit Lite2 (SIUL2)

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

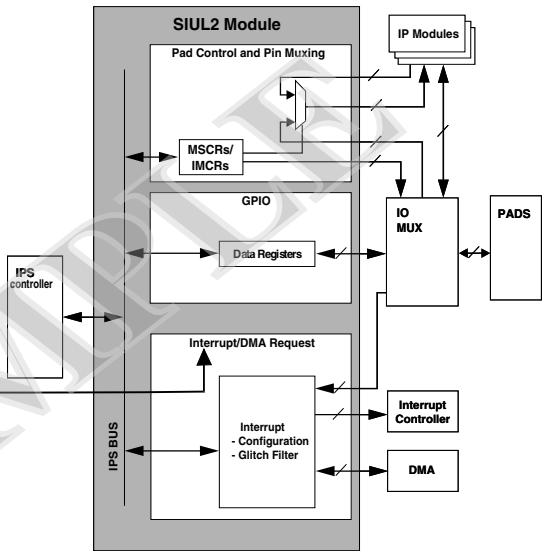

Figure 23. System Integration Unit Lite2 block diagram

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

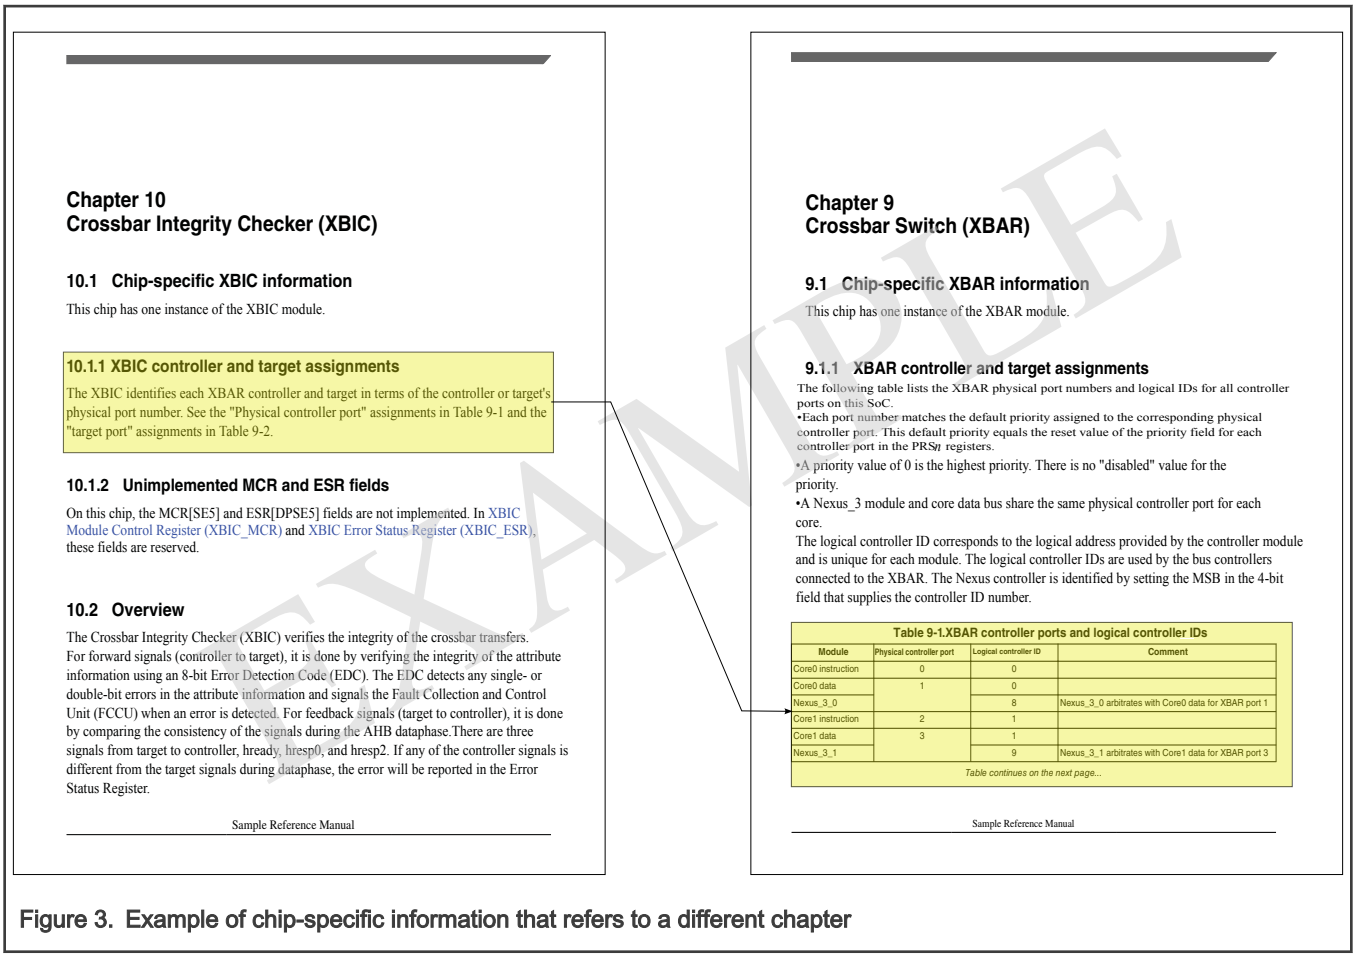
Sample Reference Manual
NXP Semiconductors

EXAMPLE

Figure 2. Example of chip-specific information that clarifies content in the same chapter

1.3.2 Chip-specific information that refers to a different chapter

Related chip-specific information may be provided in different chapters of the manual. The following figure shows an example of two such connected pieces of information. In this case, read both before you proceed.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC controller and target assignments

The XBIC identifies each XBAR controller and target in terms of the controller or target's physical port number. See the "Physical controller port" assignments in Table 9-1 and the "target port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (controller to target), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (target to controller), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from target to controller, hready, hresp0, and hresp2. If any of the controller signals is different from the target signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR controller and target assignments

The following table lists the XBAR physical port numbers and logical IDs for all controller ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical controller port. This default priority equals the reset value of the priority field for each controller port in the PRSn registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical controller port for each core.

The logical controller ID corresponds to the logical address provided by the controller module and is unique for each module. The logical controller IDs are used by the bus controllers connected to the XBAR. The Nexus controller is identified by setting the MSB in the 4-bit field that supplies the controller ID number.

Table 9-1.XBAR controller ports and logical controller IDs

Module	Physical controller port	Logical controller ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

EXAMPLE

Figure 3. Example of chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

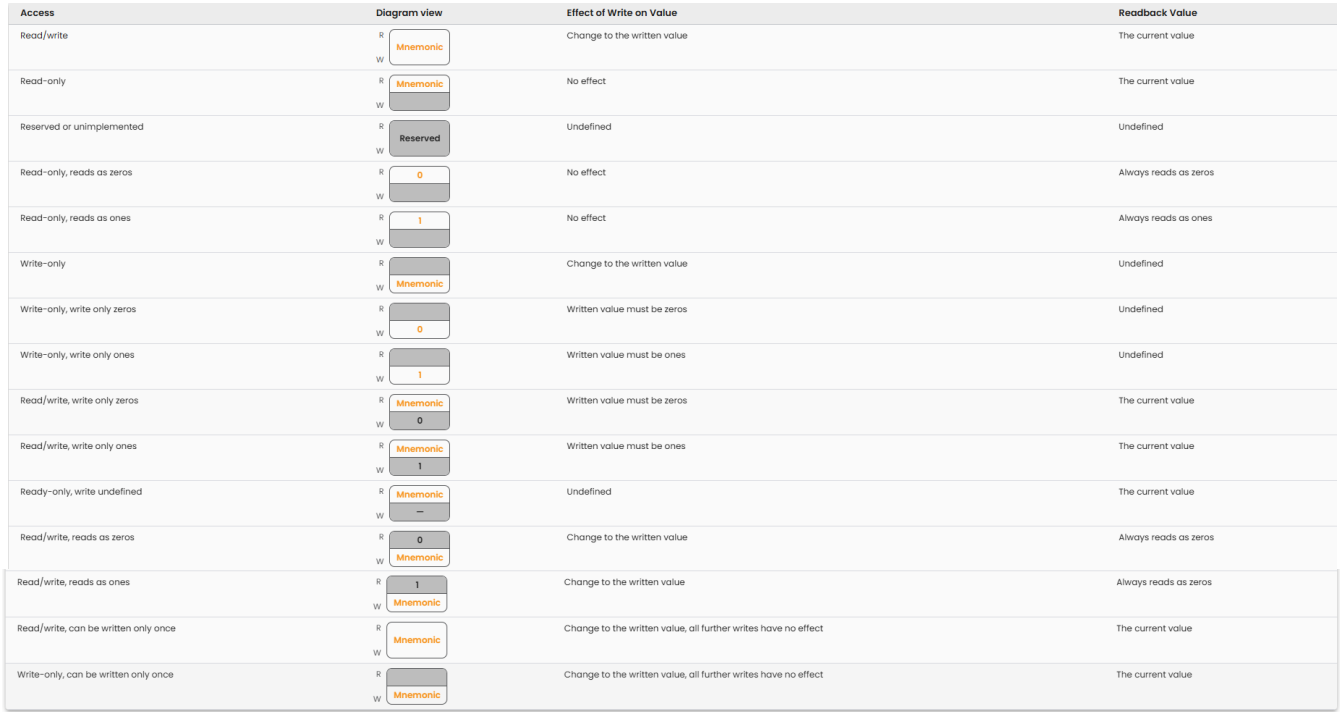


Figure 4. Register access types

NOTE

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

Table 1. Modified write values

Modified write values	Description
Write one to clear	Writing a 1 clears the corresponding bit in the field to zero. Writting 0 has no effect.
Write one to set	Writing a 1 sets the corresponding bit in the field to one. Writting 0 has no effect.
Write one to toggle	Writing a 1 toggles the corresponding bit in the field. Writting 0 has no effect.
Write zero to clear	Writing a 0 clears the corresponding bit in the field to zero. Writting 1 has no effect.
Write zero to set	Writing a 0 sets to one the corresponding bit in the field to one. Writting 1 has no effect.
Write zero to toggle	Writing a 0 toggles the corresponding bit in the field. Writting 1 has no effect.
Write always clears	Writing any value clears all bits in the field to zeros.
Write always sets	Writing any value sets all bits in the field to ones.
Modification in an unspecified way	Writing any value modifies all bits in the field in an unspecified way.

Table continues on the next page...

Table 1. Modified write values (continued)

Modified write values	Description
Write the value as is	The written value is stored in the field as-is. The most common behavior for control and data registers.

Table 2. Read action

Read action	Description
Read to clear	The field is cleared to zeros after the read operation.
Read to set	The field is set to ones after the read operation.
Read to modify	The field is modified in an unspecified way after the read operation.
Read to modify external	The field, and possibly fields in other registers, are modified in an unspecified way after the read operation.
Read without any side effect	The field is not modified after the read operation. The most common behavior for control and data registers.

1.5 Conventions

1.5.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

Table 3. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

1.5.3 Typographic notation

The following typographic notations are used throughout this document:

Table 4. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example: • SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

1.5.4 Special terms

The following terms have special meanings.

Table 5. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must:

Table continues on the next page...

Table 5. Special terms (continued)

Term	Meaning
	• Before writing to a location which contain reserved bits user must make sure the write operation will write the reserved bit with value specified as the reset value in NXP reference manual. • Consider undefined locations in memory to be reserved as reset value 0 shall be assumed. You might get a BERR(transfer error) response on access to undefined locations in memory. • If user reads data from memory area containing reserved bit, the value of reserved bits should be ignored and not used for any functional purposes. **NOTE** BootROM could modify the reserved bit values after reset. Please refer to the BootROM settings attachment.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

1.6 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting
- Presentation
- Navigation

Chapter 2
Introduction

2.1 Introduction

The MCX W72 microcontroller is a low-power, highly secure, Arm® Cortex-M33-based wireless device targeting these applications:

- Smart Home IoT
  - Smart Home environmental, occupancy and security sensors
  - Home Gateways and Bridges
  - Smart Lighting
  - Smart Plugs
  - Access Control
  - HVACs and Thermostats
  - Window Shades
- Industrial/IoT
  - Positioning/Localization
  - Building Control and Monitoring
  - Process/Factory Automation
  - Access Control

The device includes these key features:

Highly secure	• Arm Trustzone-M • Trusted resource domain controller (TRDC) providing access policies for embedded memory and peripherals • NXP's EdgeLock® Secure Enclave providing secure key management and storage plus hardware acceleration of cryptographic algorithms • Internal flash memory with on-the-fly encryption and decryption using a PRINCE XEX block cipher mode • Factory Root of Trust programming • Secure boot, debug and firmware updates
Power-efficient operating modes	• Less than 35 µA/MHz active current at 96 MHz • Less than 2 µA in Power Down mode with FRO32K active and 32 KB SRAM retention • Less than 1 µA in Deep Power Down mode with FRO32K active

2.2 Functional overview

The following figure shows a top-level organization of the modules within the device organized by functional category.

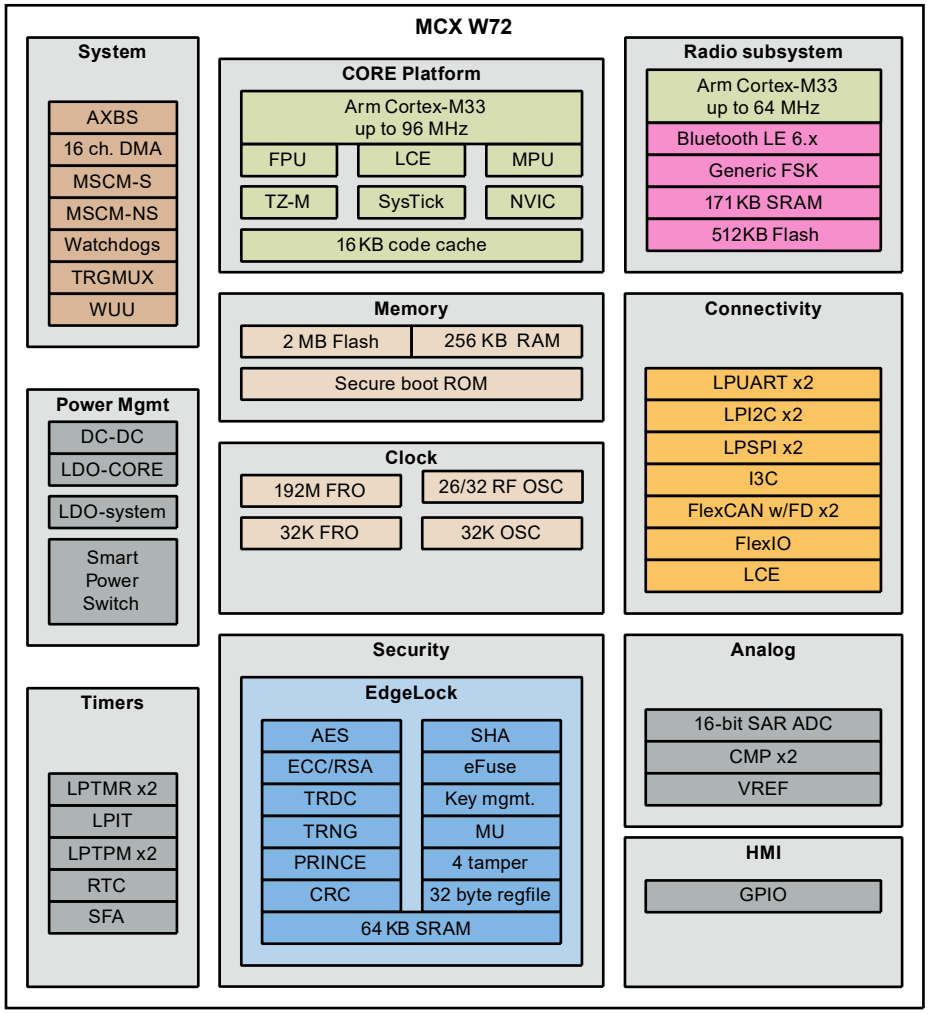

Figure 5. Features block diagram

Table 6. Module functional categories

Module category	Description
Core	The Arm® Cortex®-M33 is a member of the Cortex® M Series of processors targeting microcontroller cores focused on cost sensitive, deterministic, interrupt driven environments. The Cortex® M33 processor is based on the Arm®v8-M Architecture and ThumbR-2 ISA and is upward compatible with the Cortex® M7, M4, M3, M1 and M0/M0+. **LCE Accelerator** - LCE is a SIMD processor with 32-bit data path supporting 4x8-bit, 2x16-bit and 1x32-bit SIMD operations. Most C/C++ integer math, floating-point math and logical operations are supported in SIMD form Special Arithmetic Unit (SAU) supporting efficient 1/x, sqrt(x), 1/sqrt(x) and exp(j*w*n+p) operations.
System	• AHB Cross-Bar Switch (AXBS)

Table continues on the next page...

Table 6. Module functional categories (continued)

Module category	Description
	• Core Mode Controller (CMC) • Direct Current / Direct Current Converter - Low Voltage (DCDC-LV) • Direct Memory Access (DMA) controller • External Watchdog Monitor (EWM) • Low Drop Out Regulator - Core (LDO_CORE) • Low Drop Out Regulator - System (LDO_SYS) • Miscellaneous System Control Module (MSCM) • Secure Miscellaneous System Control Module (SMSCM) • Semaphore Module (SEMA42) • System Power Controller (SPC) • Trigger Multiplexer (TRGMUX) • Wake-Up Unit (WUU) • Watchdog (WDOG)
Memory	• Flash Management Unit (FMU) • Read Only Memory - Boot (ROM_BOOT) • Register File - REGFILE • Static Random Access Memory (SRAM)
Clock	• Crystal Oscillator - Real Time Clock (OSC_RTC) • Free Running Oscillator - 32 kHz (FRO_32K) • Free Running Oscillator - 16 kHz (FRO_16K) • Free Running Oscillator - 192 MHz (FRO_192M) • Radio Free Running Oscillator - 192 MHz (RFRO_192M) • Module Reset and Clock Control (MRCC) • System Clock Generator (SCG) • Signal Frequency Analyzer (SFA)
Security	• EdgeLock Secure Enclave • Trusted Resource Domain Controller (TRDC) • Cyclic Redundancy Check (CRC) • Non-Volatile Memory PRINCE XEX (NPX) encryption/decryption • Up to 4 digital tamper pins
Timer	• Real Time Clock (RTC) • Low-Power Timer (LPTMR)

Table continues on the next page...

Table 6. Module functional categories (continued)

Module category	Description
	• Low Power Periodic Interrupt Timers (LPIT) • Timer/PWM Module (TPM)
Communication	• Flexible Input/Output (FlexIO) • Low Power Inter-Integrated Circuit (LPI2C) • Improved Inter-Integrated Circuit (I3C) • Low Power Serial Peripheral Interface (LPSPI) • Low Power Universal Asynchronous Receive/Transmit (LPUART)
HMI	• General Purpose Input/Output (GPIO) • Port Control (PORT)
Analog	• Analog-to-Digital Converter - General Purpose (ADC) • Low Power Comparator (LPCMP) • Voltage Reference (VREF)
Radio	• Radio Frequency - 2.4 GHz (RF-2.4G)

2.2.1 Core

The following core modules are available on this device.

Table 7. Core modules

Module	Description
CPU0	CPU0 is an Arm® Cortex®-M33, a member of the Cortex® M Series of processors targeting microcontroller cores focused on cost-sensitive, deterministic, interrupt-driven environments. **LCE Accelerator** - LCE is a SIMD processor with 32-bit data path supporting 4x8-bit, 2x16-bit and 1x32-bit SIMD operations. Most C/C++ integer math, floating-point math and logical operations are supported in SIMD form Special Arithmetic Unit (SAU) supporting efficient 1/x, sqrt(x), 1/sqrt(x) and exp(j*w*n+p) operations.
Code Cache Memory (CACHE-CODE)	The CACHE-CODE is an 16-KB cache for memory attached to the Code bus.
Digital Signal Processing Extensions (DSP)	The Cortex-M33 processor features extended single-cycle Multiply Accumulate (MAC) instructions, optimized Single Instruction Multiple Data (SIMD) arithmetic, and saturating arithmetic instructions.
Floating Point Unit (FPU)	The FPU provides single-precision floating point computation compliant to the IEEE Standard for Floating-Point Arithmetic (IEEE 754).
Memory Protection Unit (MPU)	The MPU provides support for eight unified protection regions, overlapping protection regions with ascending region priority, and access permissions. MPU mismatches and permission violations

Table continues on the next page...

Table 7. Core modules (continued)

Module	Description
	invoke the HardFault handler. See the Armv8-M Architecture Reference Manual for more information.
Nested Vectored Interrupt Controller (NVIC)	The Armv8-M exception model and Nested-Vectored Interrupt Controller (NVIC) implement a relocatable vector table supporting many external interrupts, a single non-maskable interrupt (NMI), and priority levels.
System Timer (SysTick)	See the Armv8-M Architecture Reference Manual for more information about this system timer.
TrustZone - M (TZM)	The TZM is an Arm security feature related to hardware-enforced access control mechanisms.

2.2.2 Debug

The following Debug (DBG) modules are available on this device:

Table 8. Debug modules

Module	Description
Cross Trigger Interface (CTI)	The CTI enables the device's debug logic to interact with (cross trigger) each other.
Data Watchpoint and Trace (DWT)	The DWT is a generic name for several modules that allow debug access of the Cortex-M33. The DWT is composed of the Debug Watchpoint and Trace (DWT) module and the Flash Patch and Breakpoint (FPB) unit.
Debug Access Port (DAP)	The DAP enables real-time access to the device registers from an external debugger without halting the processor cores.
Instruction Trace Macrocell (ITM)	The ITM provides a memory-mapped register interface that applications can use to write logging or event words for profiling software.
Serial Wire Debug (SWD)	The SWD is a serial communication interface used for debugging devices with multiple cores while only requiring a single external interface.
Trace Port Interface Unit (TPIU)	The TPIU acts as a bridge between the on-chip trace data from the modules such as the Embedded Trace Macrocell (ETM) or the Instrumentation Trace Macrocell (ITM), which have separate system IDs, to the external world.

2.2.3 System

The following System (SYS) modules are available on this device:

Table 9. System modules

Module	Description
AHB Cross-Bar Switch (AXBS)	The AXBS connects bus masters and bus slaves, allowing all bus masters to access different bus slaves simultaneously and providing arbitration among the bus masters when they access the same slave.
Core Mode Controller (CMC)	The CMC provides control and protection on entry and exit to each power mode, control for the System Power Controller (SPC), and reset entry and exit for the complete device.
Direct Current / Direct Current Converter - Low Voltage (DCDC-LV)	An efficient voltage converter for generating the low voltage supply for internal Low Drop Out (LDO) regulators.
Direct Memory Access 3 (DMA3) controller	The DMA3 controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.
External Watchdog Monitor (EWM)	Similar to the Watchdog timer, the EWM monitors internal and external system operations and forces a reset in case of failure.
Low Drop Out Regulator - Core (LDO-CORE)	A voltage regulator for generating the core voltage for the device.
Low Drop Out Regulator - System (LDO-SYS)	A voltage regulator for generating the system voltage for the device.
Miscellaneous System Control Module (MSCM)	The MSCM contains CPU configuration registers and on-chip memory controller registers.
Secure Miscellaneous System Control Module (SMSCM).	The SMSCM contains configuration registers related to security.
Semaphore Module (SEMA42)	The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.
System Power Controller (SPC)	The SPC provides control over the operation and configuration of the system power generation modules to optimize power consumption for the level of functionality needed.
Trigger Multiplexer (TRGMUX)	The TRGMUX allows the trigger output of one peripheral to be connected to the trigger input of a second peripheral.
Wake-Up Unit (WUU)	The WUU provides a mechanism for external or internal sources to initiate the exit of certain low-power modes.
Watchdog (WDOG)	The WDOG monitors internal system operation and forces a reset in case of failure. It can run from multiple clocks with a programmable refresh window to detect deviations in program flow or system frequency.

2.2.4 Clocks

The following Clock (CLK) modules are available on this device:

Table 10. Clock sources

Module	Description
Crystal Oscillator - Radio Frequency (OSC-RF)	The OSC-RF, in conjunction with an external crystal or resonator, generates a reference clock for the Radio that can also be used by the device.
Crystal Oscillator - Real Time Clock (OSC-RTC)	The OSC-RTC oscillator, in conjunction with an external 32 kHz crystal, generates a 32 kHz reference clock for the RTC that can also be used by the radio and other modules of the device.
Free Running Oscillator - 32 kHz (FRO-32K)	The FRO-32K is an internal clock source that generates a 32 kHz reference clock for the RTC that can also be used by the radio and other modules of the device.
Free Running Oscillator - 16 kHz (FRO-16K)	The FRO-16K is an internal clock source that generates a 16 kHz reference clock that is used by the Smart Power Switch domain.
Free Running Oscillator - 192 MHz (FRO-192M)	The FRO-192M is an internal clock source that generates a 192 MHz frequency for use by the modules other than the radio of the device.
Radio Free Running Oscillator - 192 MHz (RFRO-192M)	The RFRO-192M is an internal clock source that generates a 192 MHz frequency for use by the radio module of the device.
Module Reset and Clock Control (MRCC)	The MRCC provides the user with access to the configuration control registers for the peripherals of the device.
System Clock Generator (SCG)	The SCG provides the user with access to the configuration control registers for the system level clock sources.
Signal Frequency Analyzer (SFA)	The SFA provides facilities for measurement of clock period/frequency as well as time between triggers.

2.2.5 Memory

The following Memory and Memory Interface (MEM) modules are available on this device:

Table 11. Memory modules

Module	Description
Flash Memory	Programmable flash memory — non-volatile flash memory that can store executable program code or data.
Flash Management Unit (FMU)	The FMU manages the interface between the device and the on-chip flash memory.
Read Only Memory - Boot (ROM-BOOT)	Provisions the internal flash with an embedded firmware image during manufacturing or at any time during the life of the device.
Register File - REGFILE	32-byte register file that can be retained in all power modes.
Static Random Access Memory (SRAM)	Internal system SRAM memory. Each individual block of SRAM can be configured to be retained in low-power modes.

2.2.6 Security

The following Security modules are available on this device:

Table 12. Security modules

Module	Description
Cyclic Redundancy Check (CRC)	Hardware CRC generator provides error detection for all single, double, and many multi-bit errors.
Non-Volatile Memory PRINCE XEX (NPX)	Provides on-the-fly encryption/decryption of the embedded flash contents using a PRINCE XEX block cipher.
Trusted Resource Domain Controller (TRDC)	Provides programmable access control mechanisms for independent processing domains. Unique isolation and access mechanisms for memory and peripheral resources are configured on a domain basis.

2.2.7 Timers

The following Timer (TMR) modules are available on this device:

Table 13. Timer modules

Module	Description
Real Time Clock (RTC)	32-bit seconds counter with 32-bit Alarm Independent power supply
Low-Power Timer (LPTMR)	32-bit time or pulse counter with compare feature
Low Power Periodic Interrupt Timers (LPIT)	Four general purpose interrupt timers with 32-bit counter resolution and DMA support
Timer/PWM Module (TPM)	Six channel timer with DMA support for electric motor and power management applications. Clocked by an asynchronous clock that can remain enabled in low power modes.

2.2.8 Communications

The following Communication (COM) modules are available on this device:

Table 14. Communication modules

Module	Description
Flexible Input/Output (FlexIO)	Functions in Sleep/Deep Sleep modes. DMA support
Low Power Inter-Integrated Circuit (LPI2C)	Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.
Improved Inter-Integrated Circuit (I3C)	I3C is an extension of the I2C bus protocol supporting higher speeds.

Table continues on the next page...

Table 14. Communication modules (continued)

Module	Description
Low Power Serial Peripheral Interface (LPSPI)	Synchronous serial bus for communication to an external device.
Low Power Universal Asynchronous Receive/ Transmit (LPUART)	Asynchronous serial bus communication interface with programmable 8- or 9-bit data format.

2.2.9 Radio

The following are Radio Frequency (RF) modules.

Table 15. Radio modules

Module	Description
Radio Frequency - 2.4 GHz (RF-2.4G)	The 2.4 GHz band radio covers 2.36-2.4835 GHz and is built to support multiple protocols: • Bluetooth Low Energy V6.0 • Generic 2-level FSK/GFSK/MSK/GMSK • IEEE 802.15.4-2015

2.2.10 Human Machine Interface

The following Human Machine Interfaces (HMI) modules are available on this device:

Table 16. HMI modules

Module	Description
General Purpose Input/Output (GPIO)	All General Purpose Input / Output (GPIO) pins are capable of interrupt and DMA request generation.
Port Control	The Port Control (PORT) module provides support for pad control functions.

2.2.11 Analog

The following Analog (ANA) modules are available on this device:

Table 17. Analog modules

Module	Description
Dual Single End Analog-to-Digital Converter (ADC)	A Dual 16-bit Single End Successive-Approximation Register (SAR) Analog-to-Digital Converter (ADC)
Low Power Comparator (LPCMP)	Compares two analog input voltages across the full range of the supply voltage.
Voltage Reference (VREF)	The VREF module supplies an accurate voltage output that can be used by internal or external peripherals.

2.3 Block diagram

The following figure shows a detailed block diagram of the device.

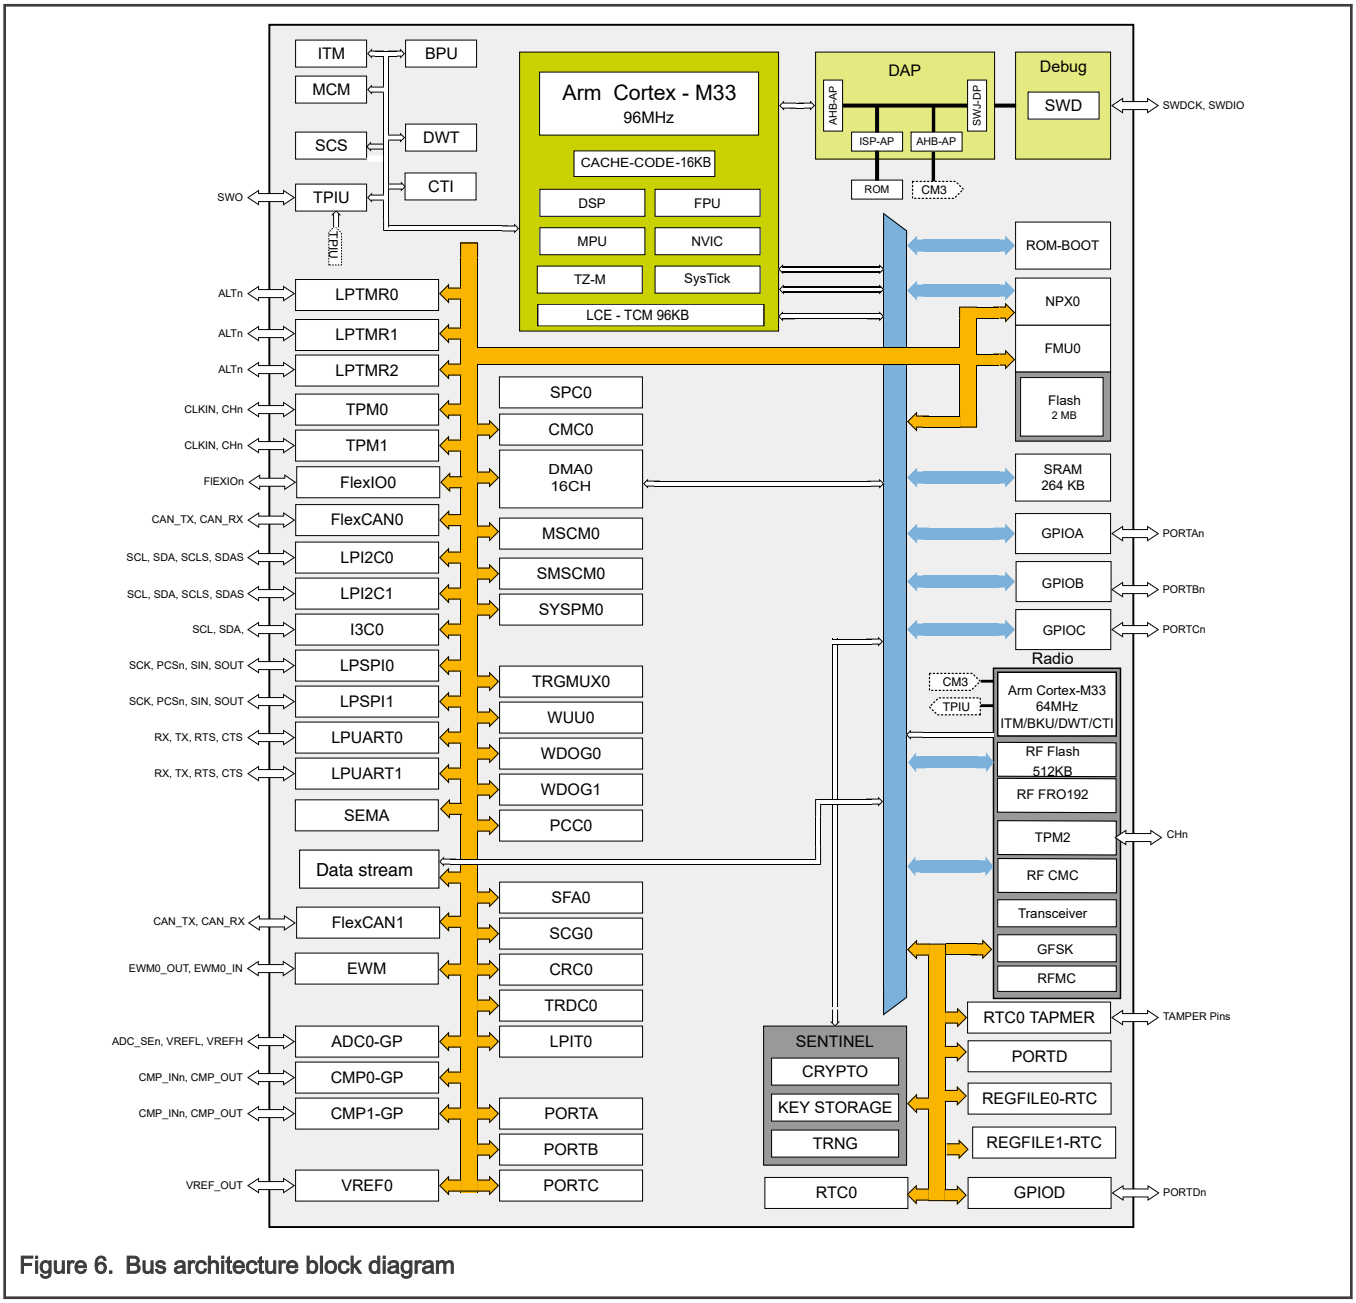

Figure 6. Bus architecture block diagram

2.4 Ordering information

The following table summarizes the part numbers of the devices covered by this document.

Table 18. Ordering information [1]

Part number	Marking	Core Speed (MHz)	Flash	SRAM	GPIOs	Pin Count	Package	Packing	LCE	CAN
MCXW727DMFTBT	MCXW727DMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tray	Yes	No
MCXW727AMFTBT	MCXW727AMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tray	No	No
MCXW727CMFTBT	MCXW727CMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tray	Yes	Yes
MCXW727DMFTBR	MCXW727DMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tape and Reel	Yes	No
MCXW727AMFTBR	MCXW727AMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tape and Reel	No	No
MCXW727CMFTBR	MCXW727CMFTB	96MHz	2 MB + 512 KB	264 KB + 171 KB	29	48	HVQFN	Tape and Reel	Yes	Yes

1. To confirm current availability of orderable part numbers, go to http://www.nxp.com and perform a part number search.

Chapter 3
Core Overview

3.1 Introduction

This section covers the core modules included in this device.

3.2 Cortex-M33 Code and System Buses

The Cortex-M33 processor implements a modified Harvard memory architecture using two 32-bit bus interfaces: the Code and System buses. The bus interfaces are activated by address range and can include both instruction fetches and operand data references on a given bus port. (A traditional Harvard architecture strictly separates instruction fetches and operand data references onto specific bus ports regardless of access address.)

The Code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. The bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M33 implementations can generate both types of references on each bus.

NOTE

It is recommended that performance critical code be located such that it fetches from the Code bus interface as defined by addresses < 0x2000_0000.

3.2.1 Code Bus access

Code Bus accesses are routed to the Code TCM if they are mapped to that space. All other Code Bus accesses are routed to the Code Cache Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable accesses or forwarding the cache write-through and cache miss accesses to the downstream memories through the master port of this cache controller.

3.2.2 System bus access

System Bus accesses are routed to the System TCM if they are mapped to that space. All other System Bus accesses are routed to the target address in destination memories through S1 port.

3.2.3 Access control

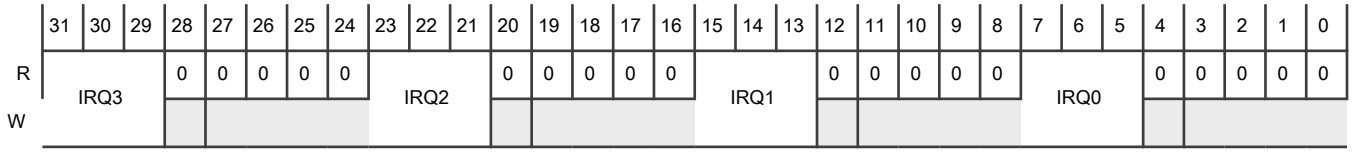
All core Code and System Bus accesses are checked by the core access control logic, that is, IDAU/SAU and MPU. All requests that miss or bypass the cache are checked by downstream TRDC logic. The caches include protection control signals (HPROT[3:0]) and processing domain bits as part of the tags. If a fetch address hits the cache but the protection control and/or domain bits are different, the cache controller forces a miss with the allocate location the same as the address hit location in the cache. This policy allows all the downstream checks to take place, and this new miss is loaded in the cache with the updated protection control and domain bits overwriting the line with the same address. This keeps the cache coherent while always checking accesses that need to see the downstream checks.

All requests are checked by normal platform slave bus checks in the corresponding Memory Block Controller (MBC).

3.3 Nested Vectored Interrupt Controller (NVIC)

3.3.1 Interrupt priority levels

This device supports 8 priority levels for interrupts. Therefore, in the NVIC each source in the IPR registers contains 3 bits. For example, IPR0 is shown below:



3.3.2 Non-Maskable Interrupt (NMI) configuration

The Non-Maskable Interrupt (NMI) request to the NVIC is controlled by the external NMI_b signal. The pin the NMI_b signal is multiplexed on, must be configured for the Non-Maskable Interrupt function to generate the non-maskable interrupt request.

3.3.3 Interrupt channel assignments

The interrupt source assignments are defined in the following table.

- Vector number — the value stored on the stack when an interrupt is serviced.
- IRQ number — non-core interrupt source count, which is the vector number minus 16.

The IRQ number is used within Arm's NVIC documentation.

Table 20. Interrupt Vector Assignments

Address	Vector	IRQ	NVIC non-IPR register number	NVIC IPR register number	Alias	Source Description
0000_0000	0	-	-	-	Cortex-M33	Initial Stack Pointer
0000_0004	1	-	-	-	Cortex-M33	Initial Program Counter
0000_0008	2	-	-	-	Cortex-M33	Non-Maskable Interrupt (NMI)
0000_000C	3	-	-	-	Cortex-M33	Hard Fault
0000_0010	4	-	-	-	Cortex-M33	MemManage Fault
0000_0014	5	-	-	-	Cortex-M33	Bus Fault / TRDC
0000_0018	6	-	-	-	Cortex-M33	Usage Fault
0000_001C	7	-	-	-	Cortex-M33	Secure Fault
0000_0020	8	-	-	-	Reserved	-
0000_0024	9	-	-	-	Reserved	-
0000_0028	10	-	-	-	Reserved	-
0000_002C	11	-	-	-	Cortex-M33	Supervisor Call (SVCall)
0000_0030	12	-	-	-	Cortex-M33	Debug Monitor
0000_0034	13	-	-	-	Reserved	-
0000_0038	14	-	-	-	Cortex-M33	Pendable request for system service (Penable SrvReq)
0000_003C	15	-	-	-	Cortex-M33	System Tick Timer
0000_0040	16	0	0	0	Cortex-M33	Cross Trigger Interface interrupt

Table continues on the next page...

Table 20. Interrupt Vector Assignments (continued)

Address	Vector	IRQ	NVIC non-IPR register number	NVIC IPR register number	Alias	Source Description
0000_0044	17	1	0	0	CMC0	Core Mode Controller interrupt
0000_0048	18	2	0	0	DMA0	DMA0 channel 0 error or transfer complete
0000_004C	19	3	0	0	DMA0	DMA0 channel 1 error or transfer complete
0000_0050	20	4	0	1	DMA0	DMA0 channel 2 error or transfer complete
0000_0054	21	5	0	1	DMA0	DMA0 channel 3 error or transfer complete

3.4 System memory map

The following table shows the device's high-level memory map. Additionally, the various sections are split into "Secure" and "Non-Secure" apertures for each IP. Although these apertures address the same IP, access through the "Secure" aperture can only be performed by code with the appropriate security settings.

Table 21. CPU0 memory map

Start address	Default [1]	Description	Alias	Size	Access	Cached
0000_0000	Non-Secure	Program Flash	FLASH	2 MB	All Masters except data stream and RF	Code Cache

1. This is the default Targeted Security Attribute for the memory region at reset. It is set by the IDAU and the SAU configuration. The attribute listed is the intended use case for users of TrustZone-M (TZM) security function.

3.5 Peripheral bridge2 (PBRIDGE2)

The Peripheral Bridge2 (PBRIDGE2) is the portion of the bus fabric that connects the peripherals to the processor elements. Each peripheral has a base address where the processor elements can access them. The following sections provide the memory map of the peripherals connected to the PBRIDGE2.

3.5.1 Peripheral Bridge2 (PBRIDGE2) memory map

Table 22. Peripheral Bridge 0

Chapter 4
Localization Compute Engine (LCE)

4.1 Overview

LCE is a platform that provides the digital signal processing unit (LPU ZV2117) and support modules around it as depicted in Block diagram.

4.1.1 Block diagram

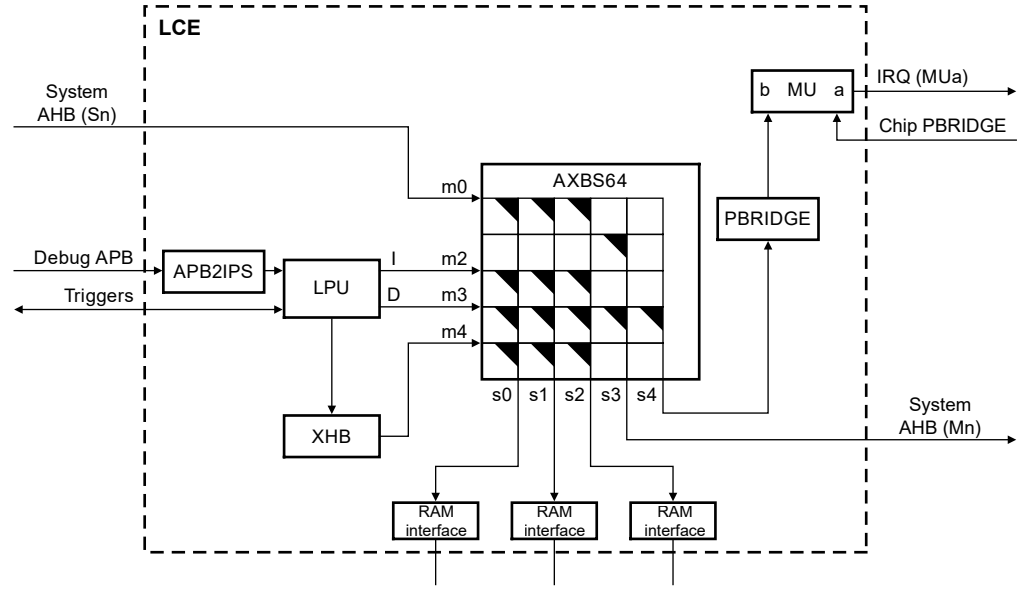

Figure 7. LCE overview diagram

4.1.2 Features

The following features are included in LPU ZV2117:

- 32-bit data path supporting 4 × 8-bit, 2 × 16-bit and 1 × 32-bit SIMD operations
- Most C/C++ integer math, floating-point math and logical operations are supported in SIMD form
- Special arithmetic unit (SAU) supporting efficient 1/x, sqrt(x), 1/sqrt(x) & exp(j*w*n+p) operations
- Instructions for efficient FFT computation
- Dedicated 64-bit AXI bus for SIMD operations
- 16 entry × 64-bit integrated SIMD data cache
- Memory page address size 17 bits
- Direct support for 16-bit complex multiplication and accumulation
- Double precision SIMD accumulator
- Support for all C/C++ {8,16,32}-bit data types
- Support for AI/ML 8-bit and 16-bit floating point data types
- Support for 2^n scaling factor for input and output operands
- Fixed size 32-bit vector instructions

4.2 Functional description

4.2.1 LPU

LPU has a single-instruction multiple-data (SIMD) data path. SIMD operations can be introduced in C/C++ software through the use of special SIMD data types. SIMD data types can be mixed with other integer or floating-point data types and the compiler will choose the proper instructions to make sure the variables are processed using the appropriate data path.

It is important to note that the LPU has a dedicated, 64-bit, AXI data path for its vector data.

Code for the LPU is loaded through the 32-bit AHB I bus and, similarly, data is accessed through the 32-bit AHB D bus.

4.2.1.1 LPU configuration

LPU configuration information is provided by a set of user registers.

LPU has an AXI3 master interface to retrieve data to process and to write computation results. The LPU AXI3 bus has a data width of 64 bits. See the AXI documentation for standard signal definitions and operation of the protocol.

LPU also contains a small smart cache (SC) to assist in maintaining a local working set. Various pointer configurations are available to assist in vector processing.

4.2.2 Integrated system

4.2.2.1 Memory and buses

The platform is integrated with the necessary components to access local memory.

The AXBS64 bus fabric provides arbitration to the 3 available memories. It is natively 64-bit to preserve the bandwidth of the LPU vector memory interface. All three memories are considered equivalent to provide the user with the ability to allocate as needed. A typical configuration might be code in RAM0 and ping-pong data buffers in RAM1 and RAM2.

Furthermore, ports are provided for the chip to access the memories (Sn) and for the LPU to access the chip (Mn).

All necessary width and protocol conversions are performed within the platform.

4.2.2.2 Messaging Unit (MU) block

The platform also integrates an MU block to assist with software abstraction with a host core. See MU chapter for details.

It can be accessed by the LPU through the integrated PBRIDGE or from the chip on the PBRIDGE bus.

Chapter 5
Low Power Cache Controller (LPCAC)

5.1 Chip-specific LPCAC information

Signal multiplexing	Port control	Signal multiplexing
Additional Cache Control and Status	MCM	Miscellaneous Control Module (MCM)
	SMSCM	Secure Miscellaneous System Control Module (SMSCM)
	MSCM	Miscellaneous System Control Module (MSCM)

5.1.1 Module instances

This device has one instance of the LPCAC module.

5.1.2 Additional cache control and status

In this device, the primary controls for the cache from outside the LPCAC include :

- Miscellaneous Control Module (MCM):
  - ISCR[CWBEE] - Should always set as 0 to disable the interrupt for cache write buffer error
  - ISCR[CWBER] - This field indicates whether the cache write buffer error is received.
  - FATR register - This register indicates the faulting attributes, when a properly-enabled cache write buffer error interrupt event is detected.
  - FADR register - This register captures the faulting address when a properly-enabled cache write buffer error interrupt event is detected.
  - FDR register - This register indicates the captured faulting data, when a properly-enabled cache write buffer error interrupt event is detected.
  - CPCR2 register - This register controls several code cache features like cache buffering, bus size, and bus control bitfields.
- Secure Miscellaneous System Control Module (SMSCM):
  - OCMDR0[OCMCF2] bitfields provides control bits to enable flash cache and options for instruction and data fetch.
  - **NOTE**

    Flash cache is enabled by default and can be disabled or configured in a different way through SMSCM : OCMDR0[OCMCF2] bitfield.
- Miscellaneous System Control Module (MSCM):
  - There are status registers related to cache
    - CPxCFG0- This register provides read-only instruction and data cache size info, if it is valid.
    - CPxCFG1- This register provides read-only instruction cache info, if it is valid.

5.2 Overview

LPCAC provides low-latency access to instructions or data. This decouples processor performance from system memory performance, increasing bus availability for other modules and improving system performance.

LPCAC has a 32-bit data path AMBA-AHB input bus and a 32-bit data path AMBA-AHB output bus.

5.2.1 Block diagram

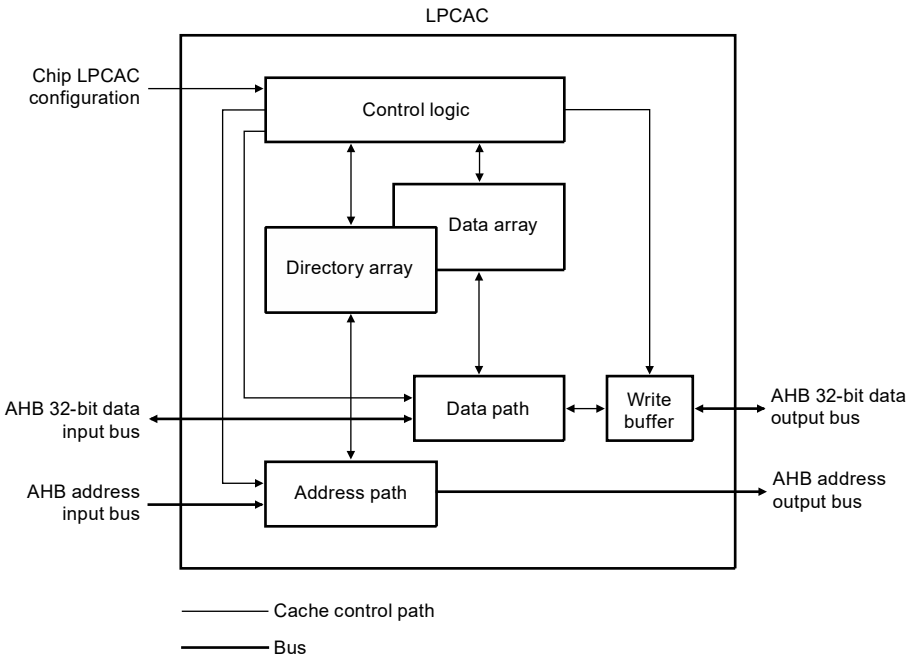

Figure 8. Block diagram

5.2.2 Features

LPCAC supports the following features:

- Nonblocking and write-through cache mode
- 16 KB total cache size
- Cache organization as an 8-way, 8-set-associative design based on 256-byte superpages
- Each way or superpage contains up to sixteen sequential 16-byte pages

5.3 Functional description

This section provides further information on the LPCAC module operation.

A reset signal clears and enables this module.

LPCAC examines every valid AHB input access. If the access hits the cache memory region and the cache is enabled, the access goes to the cache portion of the module. If the access is not cacheable, the access is passed directly to the AHB output bus.

The LPCAC cache has a 256-byte line subdivided into sixteen 16-byte sublines:

- Cache read accesses that are cache misses perform an aligned 16-byte subline-size burst cache read miss to the module's AHB output bus. Then the cache loads the needed data in the cache’s data storage. The cache miss uses a 4-beat (32 bits per beat), wrapped burst bus access to fetch the cache miss data.

- Cache read accesses that are cache hits return the desired read data from the cache.
- Cache write accesses that are cache misses perform the desired write operation only to the module's AHB output bus (for write-through mode accesses, LPCAC has a no allocation on write-miss policy).
- Cache write accesses that are cache hits perform the desired write operation to the cache and the module's AHB output bus.

LPCAC has a one entry write buffer. When LPCAC is enabled and available, cache write accesses with a bufferable attribute use the buffer, which allows write from the processor to receive an immediate (zero wait state) bus termination.

5.3.1 Cache functional description

The LPCAC cache is an 8-way, 8-set-associative, 256-byte per line write-through design. It supports a total cache capacity of 16 KB for a 32-bit wide cache miss data path.

5.3.1.1 Cache controls

This module has controls to enable, disable, and clear the cache.

The cache control inputs are as follows:

- clr_lpcac: clear lpcac
- dis_lpcac: disable lpcac
- dis_lpcac_wtbf: disable write buffer
- lim_lpcac_wtbf: limit write buffer
- frc_no_alloc: force no allocation
- mode_ctl_hprot: ignore LPCAC Memory Regions

See chip-specific section for more information on how these signals are connected or controlled on a given device.

5.3.2 Clocks

The core clock domain defines the module's clock domain.

5.3.3 Reset

A reset signal clears and enables this module. See the chip-integration information for the resets that affect LPCAC.

5.3.4 Interrupts

This module has no interrupts.

5.4 Signal descriptions

This module has no external signals.

5.5 Memory regions and input control description

5.5.1 Memory regions

LPCAC decodes cacheable address regions. The cache memory region may be composed of one or more disjointed memory regions and the total size may be larger than the cache storage.

Any address not in the cacheable memory region is in the pass-through memory region. All accesses to the pass-through memory regions are non-cacheable. For all accesses to the cacheable memory regions, the access is cacheable if the attributes of the access indicate that it can be cached, else the access is non-cacheable.

The following table defines the memory map.

Table 28. Memory map

Cache memory range	Cache memory range	Cache total memory address space
0000_0000h–07FF_FFFFh (128 MB)	1000_0000h–1FFF_FFFFh (256 MB)	384 MB

5.5.2 Input controls

The LPCAC does not have a module-resident programming model. An external block supplies the needed LPCAC control inputs.

Table 29. Control inputs for LPCAC

Function	Control input	Description
clear lpcac	clr_lpcac	One cycle active-high pulse clears the lpcac.
disable lpcac	dis_lpcac	• 0 = lpcac enabled (reset configuration) • 1 = lpcac disabled, all cacheable accesses pass from LPCAC input to output bus
disable write buffer	dis_lpcac_wtbf	• 0 = write buffer enabled • 1 = write buffer disabled
limit write buffer	lim_lpcac_wtbf	• 0 = If write buffer is enabled, buffer all writes to spaces that are bufferable • 1 = If write buffer is enabled, buffer all writes to spaces that are both bufferable and cacheable
force no allocation	frc_no_alloc	When frc_no_alloc is asserted and the cache is enabled, all accesses to the cache search the cache. If they hit a valid entry that was loaded before frc_no_alloc was asserted, they operate normally. That is, read hits return cache data without going through the cache and write hits update cache data and write through the cache. If they miss, they bypass the cache (that is, even though a read access is to a cacheable space, it does not allocate on a cache miss). This control input is useful for debug. If there is a software breakpoint, halting the processor. Then, using the debug port, cacheable memory and other address spaces are accessed. These debug accesses go through the processor, through the cache, and to the rest of the system. The idea is during the debug accesses the cache is placed on frc_no_alloc mode. In this way, debug access through the core and then through the cache do not disturb the state of the cache. Before restarting the processor, frc_no_alloc mode is negated. When the processor restarts, the cache state is the same or at least very similar as the cache state when the breakpoint was hit. • 0 = normal allocation on cache miss • 1 = no allocation on cache miss
ignore CACHE_MAP	mode_ctl_hprot	• 0 = use LPCAC Memory Regions to determine if an access to a given address may be cached. Then, if the attributes of the access indicate it can be cached, the access is cached. • 1 = Use only the attributes of the access to indicate it can be cached.

Chapter 6
Peripheral Bridge2 (PBRIDGE2)

6.1 Chip-specific PBRIDGE2 information

Table 30. Reference links to related information

Topic	Related module	Reference
Full description	PBRIDGE	PBRIDGE
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

6.1.1 Module instances

This device has one PBRIDGE2.

6.2 Overview

PBRIDGE2 converts an AMBA AHB interface to a peripheral interface, which includes peripheral module enables that allow the controller to interface with multiple peripherals.

PBRIDGE2 includes:

- A configurable data path width (32-bit or 64-bit) for the AMBA AHB input bus.
- 8-, 16-, and 32-bit data path peripheral output buses.

Each peripheral bridge occupies a configurable amount of the address space, which is divided into either 128 slots of 4 KB or 64 KB. It is possible that not all expansion slots are used. See the "Memory Map" chapter for details on slot assignments.

6.2.1 Features

- Supports expansion slots with 8-, 16-, and 32-bit data path width
- Includes separate clock enable inputs for each of the slots to accommodate slower peripherals
- Includes separate powered down inputs for each of the slots to accommodate powering down individual peripherals

6.2.2 Number of peripheral bridges

This chip contains 1 peripheral bridge(s).

6.3 Functional description

This section provides further information on the PBRIDGE2 operation.

The peripheral bridge functions as a bus protocol translator between an AMBA AHB bus and the subordinate peripheral bus. The peripheral bridge manages all transactions destined for the attached subordinate devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

PBRIDGE2 examines every valid AHB input access. If the access hits an expansion slot that is configured but not powered down and the access width is less than or equal to the slot data width, the access goes to that slot peripheral bus. If access to the slot is error-free on the slot peripheral bus, the AHB access is error-free too. If the AHB accesses an expansion slot that is not configured, is powered down, has a width greater than the slot data width, or the access to the slot completes with an error on the slot peripheral bus, the AHB access terminates with a bus error.

6.3.1 Access support

PBRIDGE2 supports the following accesses:

- Aligned 32-bit, 16-bit, and byte accesses for 32-bit peripherals
- Aligned 16-bit and byte accesses for 16-bit peripherals
- Byte accesses for 8-bit peripherals

PBRIDGE2 performs all accesses to the peripherals with a single peripheral bus transfer. Resize all accesses to the expansion slots to be less than or equal to the designated expansion slot size. If the access attempt is larger than the targeted expansion slot size, PBRIDGE2 generates an AHB bus error response.

6.3.2 Clocking

This module has no clocking considerations.

6.3.3 Interrupts

This module has no interrupts.

6.4 External signals

This module has no external signals.

6.5 Initialization

This module does not require initialization.

6.6 Memory maps

Use peripheral bridges to access most of the peripheral module registers on this chip. See the "Memory Map" chapter for the memory slot assignment for each module.

Chapter 7
Crossbar Switch (AXBS)

7.1 Chip-specific AXBS information

Table 31. Reference links to related information

S2	STCM2, STCM3
S3	STCM0, STCM1, STCM4
S4	STCM5
S5	PBRIDGE2
S6	GPIOA, GPIOB, GPIOC
S7	Radio

7.2 Overview

This section provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus initiators and bus targets using a crossbar switch structure. This structure allows all bus initiators to access different bus targets simultaneously, while providing arbitration among the bus initiators when they access the same target. A variety of bus arbitration methods and attributes may be programmed on a target-by-target basis.

7.2.1 Features

- Symmetric crossbar bus switch implementation
  - Allows concurrent access from different Initiators to different Targets
  - Target arbitration attributes configured on a Target-by-Target basis
- Single-clock 32-bit transfer
- Support for burst transfers of 64 bits of data
- Support for low-power park mode
- 32-bit AHB crossbar bus switch compatible with ARM's AMBA Specification v2.0

7.3 Memory map and register definition

Each target port of the crossbar switch contains configuration registers. Read- and write transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed as read-only to prevent changes to their configuration. After being read-only protected, future writes to them terminate with a data storage error.

NOTE

This section shows the registers for all eight initiator and target ports. If a initiator or target is not used on this particular chip, then unexpected results occur when writing to its registers. See the chip configuration details for the exact initiator and target assignments for your chip.

All references to the crossbar switch registers are based on the physical port connections.

7.3.1.2 Priority Target Registers (PRS0 - PRS7)

Offset

Register	Offset
PRS0	0h
PRS1	100h
PRS2	200h
PRS3	300h
PRS4	400h
PRS5	500h
PRS6	600h
PRS7	700h

Function

The priority target registers(PRS*n*) set the priority of each initiator port on a per target port basis and reside in each target port. The priority register can be accessed only with 32-bit access. After the CRS*n*[RO] bit is set, the PRS*n* register can only be read; attempts to write to it have no effect on PRS*n* and result in a bus-error response to the initiator initiating the write.

Two available initiators must not be programmed with the same priority level. Attempts to program two or more initiators with the same priority level result in a bus-error response and the PRS*n* is not updated.

NOTE

Valid values for the M*n* priority fields depend on which initiators are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than three initiators, only one bit is valid.
- If the chip contains fewer than five initiators, only two bits are valid.
- If five or more initiators are present, all three bits of the priority field are used.

7.3.1.3 Control Register (CRS0 - CRS7)

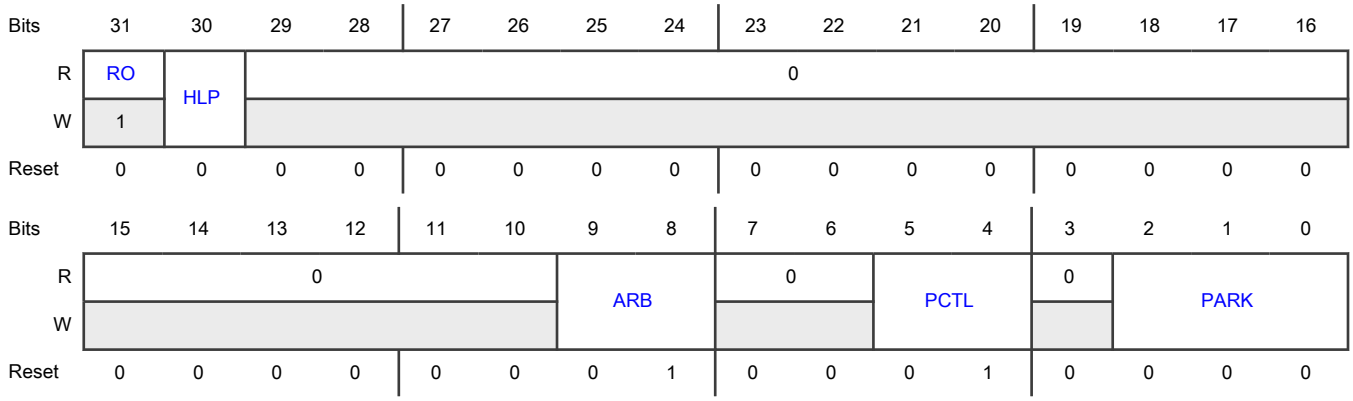
Offset

Register	Offset
CRS0	10h
CRS1	110h
CRS2	210h
CRS3	310h
CRS4	410h
CRS5	510h
CRS6	610h
CRS7	710h

Function

These registers control several features of each target port and must be accessed using 32-bit accesses. After CRS*n*[RO] is set, the PRS*n* can only be read; attempts to write to it have no effect and result in an error response.

Diagram



Fields

Field	Function
31 RO	Read Only This field forces the target port's CSR*n* and PRS*n* registers to be read-only. After setting, only a hardware reset clears it. 0b - The target port's registers are writeable. 1b - The target port's registers are read-only and cannot be written. Attempted writes do not affect the registers and result in a bus error response.
30 HLP	Halt Low Priority This field sets the initial arbitration priority for low-power mode requests. Setting this bit will not affect the request for low-power mode from attaining the highest priority after it has control of the target ports. 0b - The low-power mode request has the highest priority for arbitration on this target port. 1b - The low-power mode request has the lowest initial priority for arbitration on this target port.
29-10 —	Reserved
9-8 ARB	Arbitration Mode This field selects the arbitration policy for the target port. 00b - Fixed priority 01b - Round-robin(RR) or rotating priority 10b - Reserved 11b - Reserved
7-6 —	Reserved
5-4	Parking Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
PCTL	This field determines the target port's parking control. The low-power park feature results in overall power saving if the target port is not saturated. However, this forces an extra latency clock when a initiator tries to access the target port when not in use because it is not parked on any initiator. 00b - When no initiator makes a request, the arbiter parks the target port on the initiator port defined by the PARK field. 01b - When no initiator makes a request, the arbiter parks the target port on the last initiator to be in control of the target port. 10b - When no initiator makes a request, the target port is not parked on a initiator and the arbiter drives all outputs to a constant safe state. 11b - Reserved
3 —	Reserved
2-0 PARK	Park This field determines which initiator port the current target port parks on when no initiators are actively making requests and the PCTL bits are cleared. **NOTE** Select only those initiator ports that are present on the chip. Otherwise, undefined behavior may occur. 000b - Park on initiator port M0. 001b - Park on initiator port M1. 010b - Park on initiator port M2. 011b - Park on initiator port M3. 100b - Park on initiator port M4. 101b - Park on initiator port M5. 110b - Park on initiator port M6. 111b - Park on initiator port M7.

7.3.1.4 Initiator General Purpose Control Register (MGPCR0 - MGPCR6)

Offset

Register	Offset
MGPCR0	800h
MGPCR1	900h
MGPCR2	A00h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
MGPCR3	B00h
MGPCR4	C00h
MGPCR5	D00h
MGPCR6	E00h

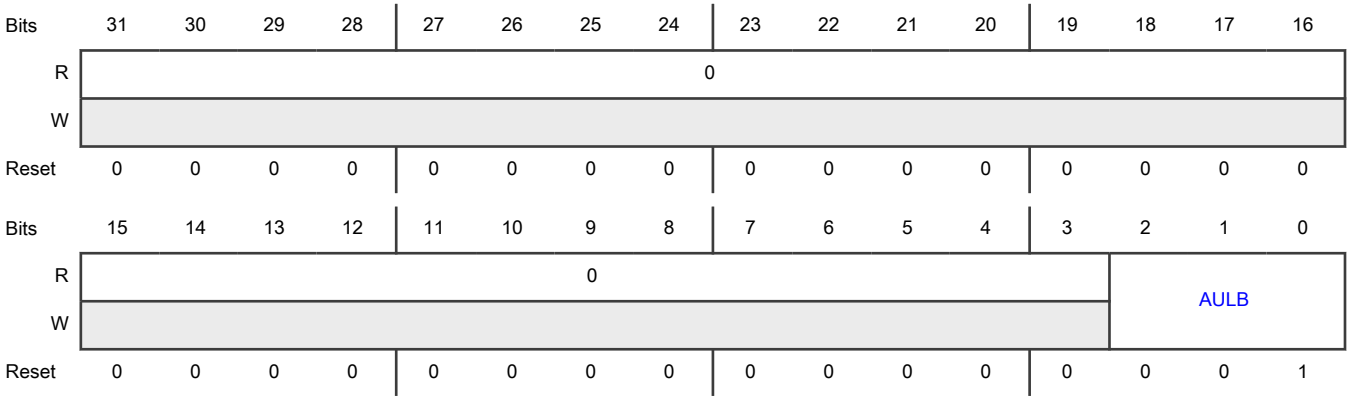
Function

The MGPCR controls only whether the initiator's undefined length burst accesses are allowed to complete uninterrupted or whether they can be broken by requests from higher priority initiators. The MGPCR can be accessed only in supervisor mode with 32-bit accesses.

NOTE

If there are fewer than eight initiator ports, only the registers associated with those initiators are present. Register addresses associated with initiator ports that are not present are reserved. See the module's chip-specific information for which initiator ports are present on this module.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 AULB	Arbitrates On Undefined Length Bursts This field determines whether, and when, the crossbar switch arbitrates away the target port the initiator owns when the initiator is performing undefined length burst accesses. 000b - No arbitration is allowed during an undefined length burst. 001b - Arbitration is allowed at any time during an undefined length burst.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - Arbitration is allowed after four beats of an undefined length burst. 011b - Arbitration is allowed after eight beats of an undefined length burst. 100b - Arbitration is allowed after 16 beats of an undefined length burst. 101b - Reserved 110b - Reserved 111b - Reserved

7.4 Functional description

Information about general operation and arbitration are provided in this section.

7.4.1 General operation

When a Initiator accesses the crossbar switch, the access is immediately taken. If the targeted target port of the access is available, then the access is immediately presented on the target port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted target port of the access is busy or parked on a different Initiator port, the requesting Initiator sees wait states inserted until the targeted target port can service the Initiator's request. The latency in servicing the request depends on each Initiator's priority level and the responding target's access time.

Because the crossbar switch appears to be just another target to the Initiator device, the Initiator device does not know whether it owns the target port it is targeting. The Initiator waits while it does not have control of the target port it is targeting.

After the Initiator acquires control of the target port, it controls the port until it relinquishes the port by running an IDLE cycle or by targeting a different target port for its next access.

The Initiator can also lose control of the target port if another higher-priority Initiator makes a request to the target port. However, if the Initiator is running a fixed- or undefined-length burst transfer, it retains control of the target port until that transfer completes. Based on MGPCR[AULB], the Initiator either retains control of the target port when doing undefined-length, incrementing burst transfers or loses the bus to a higher-priority Initiator.

The crossbar terminates all Initiator IDLE transfers, as opposed to allowing the termination to come from one of the target buses. Additionally, when no Initiator is requesting access to a target port, the crossbar drives IDLE transfers onto the target bus, even though a default Initiator may be granted access to the target port.

When a target bus is being idled by the crossbar, it can park the target port on the Initiator port indicated by CRS*n*[PARK]. This is done to save the initial clock of arbitration delay that otherwise would be seen if the same Initiator had to arbitrate to gain control of the target port. The target port can also be put into low-power park mode to save power, by using CRS*n*[PCTL].

7.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with target-port-related Initiator accesses, but instead track only with target accesses.

The MGPCRx[AULB] bits are the exception to this rule. The update of these bits is only recognized when the Initiator on that Initiator port runs an IDLE cycle, even though the target bus cycle to write them will have already terminated successfully. If the MGPCRx[AULB] bits are written between two burst accesses, the new AULB encodings do not take effect until an IDLE cycle is initiated by the Initiator on that Initiator port.

7.4.3 Arbitration

The crossbar switch supports the following arbitration algorithms:

- Fixed priority

- Round-robin

The arbitration scheme is independently programmable for each target port.

7.4.3.1 Arbitration during undefined length bursts

Arbitration points during an undefined length burst are defined by the current master's MGPCR[AULB] field setting. When a defined length is imposed on the burst via the AULB bits, the undefined length burst is treated as a single or series of single back-to-back fixed-length burst accesses.

The following figure illustrates an example:

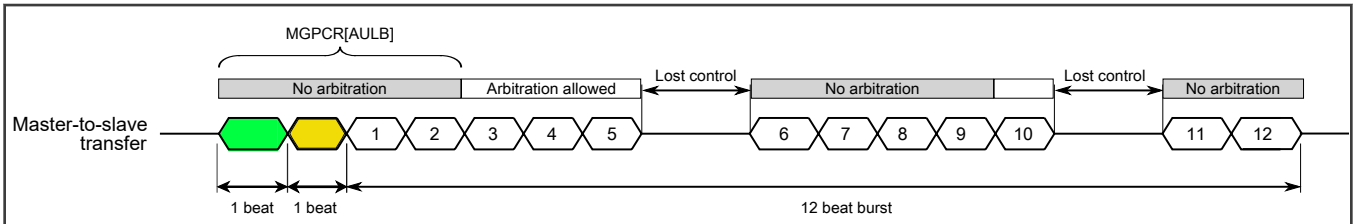


Figure 9. Undefined length burst example

In this example, a master runs an undefined length burst and the MGPCR[AULB] bits indicate arbitration occurs after the fourth beat of the burst. The master runs two sequential beats and then starts what will be a 12-beat undefined length burst access to a new address within the same slave port region as the previous access. The crossbar does not allow an arbitration point until the fourth overall access, or the second beat of the second burst. At that point, all remaining accesses are open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. After the master regains control of the slave port no arbitration point is available until after the master has run four more beats of its burst. After the fourth beat of the now continued burst, or the ninth beat of the second burst from the master's perspective, is taken, all beats of the burst are once again open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third now continued burst, or the 10th beat of the second burst from the master's perspective. After the master regains control of the slave port, it is allowed to complete its final two beats of its burst without facing arbitration.

NOTE

Fixed-length burst accesses are not affected by the AULB bits. All fixed-length burst accesses lockout arbitration until the last beat of the fixed-length burst.

7.4.3.2 Fixed-priority operation

When operating in fixed-priority mode, each initiator is assigned a unique priority level in the priority registers (PRS*n*). If two initiators request access to the same target port, the initiator with the highest priority in the selected priority register gains control over the target port.

NOTE

In this arbitration mode, a higher-priority initiator can monopolize a target port, preventing access from any lower-priority initiator to the port.

When a initiator makes a request to a target port, the target port checks whether the new requesting initiator's priority level is higher than that of the initiator that currently has control over the target port, unless the target port is in a parked state. The target port performs an arbitration check at every clock edge to ensure that the initiator, if any, has control of the target port.

The following table describes possible scenarios based on the requesting initiator port.

Table 34. Methods of how the crossbar switch grants control of a target port to a initiator

When	Then the crossbar switch grants control to the requesting initiator
Both of the following are true: • The current initiator is not running a transfer. • The new requesting initiator's priority level is higher than that of the current initiator.	At the next clock edge
Both of the following are true: • The current initiator is running a fixed-length burst transfer or a locked transfer. • The requesting initiator's priority level is higher than that of the current initiator.	At the end of the burst transfer or locked transfer
Both of the following are true: • The current initiator is running an undefined length burst transfer. • The requesting initiator's priority level is higher than that of the current initiator.	At the next arbitration point for the undefined length burst transfer **NOTE** Arbitration points for an undefined length burst are defined in the MGPCR for each initiator.
The requesting initiator's priority level is lower than the current initiator.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current target port

7.4.3.3 Round-robin priority operation

When operating in round-robin mode, each initiator is assigned a relative priority based on the initiator port number. This relative priority is compared to the initiator port number (ID) of the last initiator to perform a transfer on the target bus. The highest priority requests the initiator owns the target bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting initiator is of the ID of the last initiator.

After a initiator is granted access to a target port, a initiator may perform as many transfers as desired to that port until another initiator requests the same target port. The next initiator in line is granted access to the target port at the next transfer boundary, or possibly on the next clock cycle, if the current initiator has no pending access request.

As an example of arbitration in round-robin mode, assume that the crossbar is implemented with initiator ports 0, 1, 4, and 5. If the last initiator of the target port was initiator 1, and initiators 0, 4, and 5 make simultaneous requests, they are serviced in this order: 4,5, and then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked initiator performs a transfer. Handoff occurs to the next initiator in line after one cycle of arbitration. If the target port is put into low-power park mode, the round-robin pointer is reset to point at initiator port 0, giving it the highest priority.

7.4.3.4 Clocking

This module has no clocking considerations.

7.4.3.5 Interrupts

This module has no interrupts.

7.4.3.6 Priority assignment

Each initiator port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple initiator ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

7.5 External signals

This module has no external signals.

7.6 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, the following settings and priorities may be programmed to achieve the maximum system performance:

- During the configuration of the crossbar switch, all other initiators must be IDLE.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

7.7 Glossary

AMBA	Advanced Microcontroller Bus Architecture
IDLE	A type of transfer that a initiator uses when it does not want to perform a data transfer
ID	Initiator port number

Flash Memory Controller (FMC)

8.1 Chip-specific FMC information

Table 35. Reference links to related information

Topic	Related module	Reference
Full description	FMC	FMC
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

See SMSCM_OCMDR0 for details on flash speculation and flash cache control, refer to the Security RM.

NOTE

The FMC module includes an optional PRINCE encryption/decryption features that is not described here. For details on this feature, refer to the Security RM.

8.1.1 Module instances

This device has two instance of the FMC module.

Table 36. FMC module instances and configuration info

Instance	For information about flash configuration and controls.
Main subsystem flash	See "Secure Miscellaneous System Control Module" in the Security RM.
Radio subsystem flash	See "Radio Flash."

8.1.2 PRINCE

The FMC module includes an optional PRINCE encryption and decryption feature not described in this reference manual. For details on this feature, see the Security RM.

8.2 Overview

The Flash Memory Controller (FMC) is a memory interface and acceleration unit providing:

- An interface between the device and the nonvolatile memory
- Buffers that can accelerate flash memory transfers
  - A flash-phrase-sized(128 bits) single-entry buffer holds the most recently accessed flash phrase.
  - An optional flash-phrase-sized(128 bits) speculation buffer can prefetch the next flash phrase.
  - An optional 4-way,1-set, 128-bit line size flash cache can store previously accessed flash phrases.

The FMC manages the interface between the device and the flash memory. The FMC receives status information describing the configuration of the memory and uses this information to ensure a proper interface. The following table shows the supported read and write operations.

Flash memory type	Read	Write
Program, IFR0, IFR1 flash memory	8-bit, 16-bit, and 32-bit reads	16-byte and 128-byte writes

The FMC is controlled by a programmer's model external to the FMC module; see the chip-specific FMC information for details. The FMC's programming model provides a very configurable, high performance flexible memory controller, which can be optimized for the runtime characteristics of specific applications.

NOTE

Program the FMC's controls only while the flash controller is idle. Changing the configuration settings while a flash access is in progress can cause non-deterministic, unpredictable behavior.

8.2.1 Features

- Interface between the device and the flash memory:
  - The FMC's input bus supports 8-bit, 16-bit, and 32-bit read operations to flash memory.
  - The FMC's flash memory interface fetches a 128-bit flash phrase.
  - For input read requests, the FMC fetches a flash phrase with the desired read data from flash memory.
  - The flash memory interface can write aligned 16-byte flash write phrases or aligned 128-byte flash write pages to flash memory.
  - The FMC has a 16-byte aligned write buffer. This buffer is used once for aligned 16-byte flash write phrases or eight times for aligned 128-byte flash write pages.
  - The FMC's input bus supports 32-bit write operations for flash memory writes to fill the FMC's write buffer.
  - For input write requests, the FMC must receive the 4-word(16-byte) write of an aligned phrase in order.
  - For input write requests, the FMC supports write cancel.
  - Program flash and IFR0 support read and write requests, IFR1 only supports read requests.
- Acceleration of data transfer from flash memory to the device:
  - A flash-phrase-sized single-entry buffer that holds the current decrypted flash phrase fetched due to a FMC read request. Subsequent FMC read requests *that hit in the single-entry buffer* return data with no wait states.
  - A flash-phrase-sized prefetch speculation buffer with controls for prefetching on instructions and/or data reads. When prefetching is enabled, idle FMC-to-flash interface cycles are used to fetch the next sequential flash phrase and hold it in the prefetch buffer. Subsequent FMC read requests *that hit in the speculation buffer* return data with no wait states.
  - Input controls:
    - To disable data type speculation
    - To disable all speculation
    - To clear the flash cache,single-entry buffer and speculation buffer
    - To disable the flash cache,single-entry buffer and speculation buffer
    - To enable AHB bus stall on flash busy
    - To lock access to IFR1
    - To disable AHB bus error on flash multibit ECC error for data
    - To disable AHB bus error on flash multibit ECC error for instruction

    To enable flash speculation, enable AHB bus error on flash multibit ECC error for data and instruction. See the chip-specific section for details about controls.
  - Flash cache

- Program flash and IFR0 are cacheable, IFR1 is not cacheable.

— The flash cache has input controls:

- To disable instruction caching(disable cache loads)
- To disable data caching(disable cache loads)
- To disable all caching(disable cache loads and hits)
- To clear the cache(tag, data and valid)

See the chip-specific section for details about controls.

— The size of the flash cache in bytes is calculated as follows:

flash cache size = [number of ways] × [number of sets] × [flash phrase size (in bytes)]

For example, a flash cache with 4 ways, 1 set, and a 128-bit flash phrase (= 16 bytes) has a total flash cache size = 64 bytes

(4 ways) × (1 set) × (16 bytes per flash phrase) = 64 bytes, the size of the flash cache

NOTE

Clear the speculation buffer and flash cache before accessing recently modified flash addresses. The flash cache has a specific clear control bit. To clear the speculation buffer, first disable then re-enable the speculation via other modules.

8.3 Functional description

The FMC is a flash interface and acceleration unit, with flexible buffers for user configuration.

- The FMC's input bus can operate faster than the flash memory.
- The FMC-to-flash interface has flow control to add wait states as needed (for input bus reads that need flash accesses).
- The FMC also contains various configurable buffers that hold recent flash accesses. If an input bus read hits a valid buffer, then that access will complete with no wait states.

8.3.1 Modes of operation

The FMC only operates when a bus master accesses the flash memory.

For any device power mode where the flash memory cannot be accessed, FMC is disabled automatically.

8.3.2 Default configuration

After system reset, the FMC is configured to provide a significant level of buffering for transfers from the flash memory. For all banks:

- The single-entry and speculation buffers are cleared by reset.
- Prefetch support by speculation buffer for data and instructions is enabled.
- The flash cache is cleared by reset.
- The flash cache is configured for data or instruction replacement.

8.3.3 Configuration options

The default configuration provides a high degree of flash acceleration, but advanced users may want to customize the FMC buffer configurations to maximize throughput for their use cases. When reconfiguring the FMC for custom use cases, do not program the FMC's control registers while the flash memory is being accessed. Instead, change the control registers with a routine executing from RAM in Supervisor mode.

The FMC's flash cache and buffering controls allow other modules to tune resources to suit specific application requirements. The flash cache and buffer are each controlled individually. The controls enable caching and prefetching per access type (instruction fetch or data reference).

See the chip-specific section for details about the registers used to configure FMC.

As an application example: if both instruction fetches and data references are accessing flash memory, then control is available to send instruction fetches, data references, or both to the flash cache or the single-entry buffer. Likewise, speculation can be enabled or disabled for either type of access.

For best performance, the FMC flash cache and speculation buffering should be enabled for instruction, data fetching, or both. The following is recommended for best performance:

- If the speculation buffer is enabled for both instruction and data speculation, enable the flash cache for both instruction and data caching.
- If the speculation buffer is enabled for instruction speculation only, enable the flash cache for at least instruction caching.

8.3.4 Wait states

Because the core, crossbar switch, and bus masters can be clocked at a higher frequency than the flash clock, flash memory accesses that do not hit in the speculation buffer or cache usually require wait states.

FMC does not allow the configuration of wait states directly. Wait states can be controlled via FMU FCTRL[RWSC].

8.3.5 Speculative reads

The FMC has a speculation buffer that reads ahead to the next phrase in the flash memory if there is an idle cycle. Speculative prefetching is programmable for instruction and data accesses. Because many code accesses are sequential, using the speculative prefetch buffer improves performance in most cases.

Program flash and IFR0 support speculation reads, IFR1 doesn't support speculation reads. See the chip-specific section for information about controlling speculative reads.

When speculative reads are enabled, the FMC immediately requests the next sequential phrase address after a read completes. By requesting the next phrase immediately, speculative reads can help to reduce or even eliminate wait states when accessing sequential code and/or data.

8.3.6 Interrupts

This module has no interrupts.

8.4 External signals

The FMC has no external signals.

8.5 Initialization and application information

The FMC does not require user initialization. Flash acceleration features are enabled by default.

The FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly. To prevent the possibility of returning stale data after an application executes flash memory commands, disable and/or clear FMC's single-entry buffer, speculation buffer, and cache. If you want to disable the speculation buffer and cache in certain specific cases, we recommend disabling them all.

See the chip-specific section for details about the registers used to disable and/or clear flash cache, speculation buffer and single-entry buffer.

9.2 Overview

System Performance Monitor (SYSPM) is a memory mapped peripheral that enables the user to monitor system and/or CPU events. The SYSPM consists of sixteen 256 Byte sub-slots (SS). The first subslot is the configuration slot. The registers in the configuration SS0 describe the number of monitors, types of monitors and number of counters per monitor. Subsequent sub-slots are occupied by Performance Monitors (PERFMON) registers.

9.2.1 Features

The SYSPM includes the following features:

- Three 40-bit event counters
- Programmable event select
- Countable events that include cache, branch fetches, and stalls

Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats

9.2.2 Block diagram

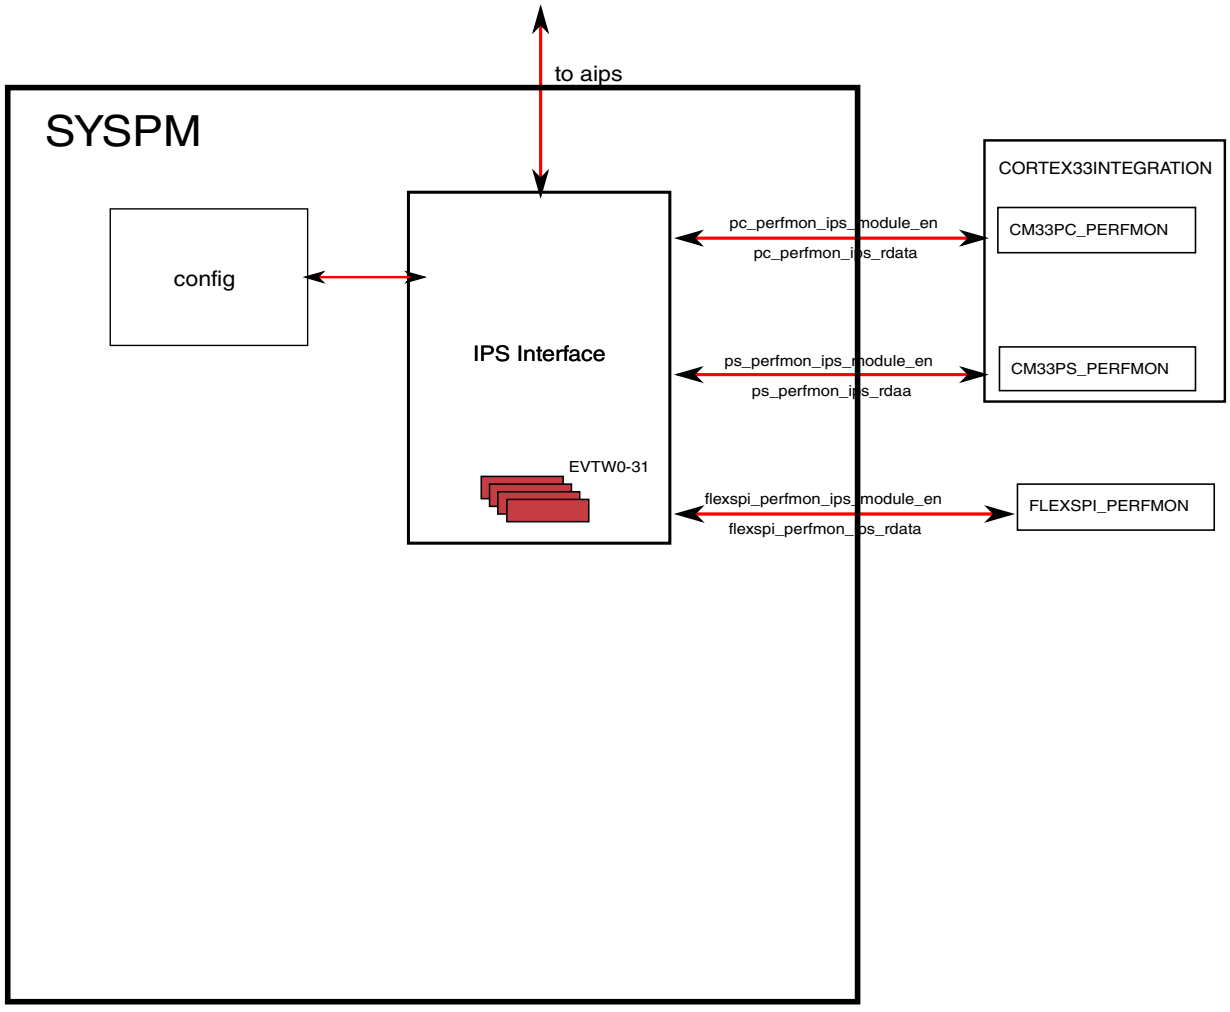

Figure 10. SYSPM Block Diagram

9.3 Functional description

9.3.1 Operating modes

There are no special operating modes for the SYSPM.

9.3.2 Operations

SYSPM routes transaction to CMX_PERFMON. See the chip-specific SYSPM information for details on the performance monitors. SYSPM also provides read-only identification registers that describe the types of monitors in each sub-slot.

9.3.3 Clocking

This module has no clocking considerations.

9.3.4 Interrupts

This module has no interrupts.

9.3.5 External signals

This module has no external signals.

9.3.6 Initialization

Initialization is not required for this module.

9.4 Memory Map and register definition

This section includes the SYSPM module memory map and detailed descriptions of all registers.

9.4.1 SYSPM register descriptions

1. The address ranges for each domain are identical. The different domains provide a mechanism for different masters to have different access permissions when accessing a given memory space. The MDA_Wr_m[DID] configures the domain ID for a given master and this is used to select which set of domain access registers to use.
2. See Peripheral Bridge2 (PBRIDGE2) memory map for details.

10.2 Overview

TRDC provides an integrated and scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus initiators, memory regions, and peripherals to processing domains to support enforcement of robust operational environments.

- First, each bus initiating resource is assigned to a domain identifier (domainID, DID). Typically, each processor is assigned to a unique domainID and all remaining non-processor bus initiators assigned to a different domainID.
- Next, the access control policies for the individual domains are programmed into any number of registers implemented in the target memory block and region checkers.
- Finally, all accesses throughout the device are monitored concurrently to determine the validity of each access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme that TRDC defines supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism with different access control policies based on read, write, and execute references, where:

SecurePriv > SecureUser > NonsecurePriv > NonsecureUser

Combined with the secure/nonsecure and privileged/user attributes, a domainID is associated with every system bus transaction and forms the hardware basis for the implementation of TRDC's access control mechanisms.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 42. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

10.2.1 Block diagram

As previously noted, the TRDC implementation is distributed across multiple submodules instantiated throughout the device. The TRDC submodules include:

- TRDC_MGR
  - The Manager (MGR) submodule coordinates all programming model reads and writes.
- TRDC_DAC
  - The Domain Assignment Controller (DAC) submodule handles resource assignments and generation of the domain identifiers.
- TRDC_MBC
  - The Memory Block Checker (MBC) submodule implements access controls for on-chip internal memories and peripherals based on a fixed-sized block format.
- TRDC_MRC
  - The Memory Region Checker (MRC) submodule implements the access controls for external off-chip memories and peripherals based on the pre-programmed region descriptor registers.

See Figure 11 for a simplified TRDC block diagram focusing on topology and connections.

NOTE

TRDC typically consists of various submodules like DAC, MGR, MBC, and MRC. However, all the submodules as shown in the block diagram below may not be present for this configuration. For chip-specific implementation details of this module's instances, see the chip-specific information.

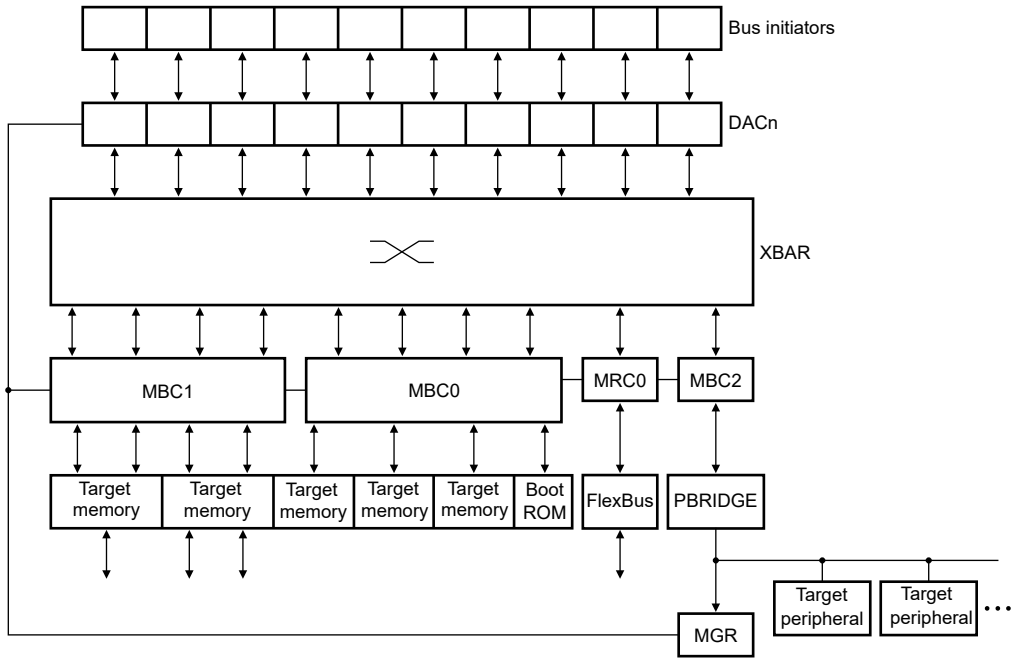

Figure 11. Block diagram

10.2.2 Features

- Ability to assign chip resources to processing "domains":
  - Processor cores, non-core bus initiators, target memories, and target peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is an attribute associated with every system bus transaction
  - Used in conjunction with secure/nonsecure, privileged/user attributes
- Generates known physical address (KPA) bus transaction attribute
- Defines access rights to targets in MBCs for on-chip memories and peripherals and in MRCs for external memories and peripherals
- Built upon a 4-level hierarchical access control model:
  - SecurePriv > SecureUser > NonsecurePriv > NonsecureUser
  - Defined by multiple sets of user-programmable R/W/X (Read, Write, Execute) flags per access state
- Distributes programming model and hardware implementation across multiple submodules:
  - Supports a broad, highly-configurable architecture definition
  - Supports efficient mechanisms for memory space context switch state changes using nonsecure enables (NSE) for memory blocks and regions

10.3 Functional description

This section provides more details on the operation and implementation of the TRDC submodules.

10.3.1 Modes of operation

TRDC does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds strictly on the basis of memory addresses of the connected system buses. TRDC evaluates domain assignment

and access control functions on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s).

10.3.2 Flash logical window (FLW)

The FLW logic provides a logical window (remapping) between a fixed physical address window and a programmable flash array window.

NOTE

The whole flash image is also available at the normal flash array addresses.

The fixed physical address base and maximum window size is determined per project:

- The fixed physical address base is available in the read-only FLW Physical Base register.
- Program the window size in the number of 32KByte blocks in the FLW Logical Block Count register to configure the functional size of the window.
- Configure the flash array address base in the FLW Array Base register.

When FLW is disabled, the physical address window is not mapped to any memory storage and all accesses to the window result in fault. When FLW is enabled, the physical address window, up to the size that you configure using the Logical Block Count, is mapped to the flash array window. The access to the window beyond the size configured by the Logical Block Count results in fault.

10.3.3 Manager (TRDC_MGR)

The MGR submodule is responsible for coordinating TRDC's programming model reads and writes.

The complete programming model is large. Additionally, the programming model is distributed across the various submodule instances (DAC, MBC, MRC).

MGR provides:

- The required hardware management for all programming model accesses.
- Generating and distributing the appropriate address decodes and write data to the DAC, MBC, and MRC submodule instances.
- Collecting and combining all the register read data buses and responses.

MGR implements:

- The Control Register
- All the read-only hardware configuration registers (HWCFG[0-1], DACFGn, MBCFG, MRCFG)
- The program-visible versions of the domain error capture registers.

To support the domain error reporting functionality, MGR collects the individual captured error indicator output signals from all the submodule instances and remaps them so that they are organized into an instance bitmap by domain that the DERRLOCn register array specifies.

10.3.4 Domain Assignment Controller (TRDC_DAC)

The DAC submodule is responsible for the generation of the domainID on every memory transaction for every bus initiator in the device. The resulting domainID, KPA, and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system. KPA indicates whether the address is physical or non-physical. You can use it to bypass SMMU.

As a simple example, assume a system with two domainIDs.

- domainID 0 is for critical tasks.
- domainID 1 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

During startup, software initializes the MDA_W[0-1] registers.

1. MDA_W0 = 0x8000_0F81
   - VLD = 1
   - DIDS = 0
   - DID = 1
2. MDA_W1 = 0x8000_0FC2
   - VLD = 1
   - DIDS = 0
   - DID = 2

A special mode is provided for driving the DID of non-processor initiators. This is enabled with the DID bypass (DIDB) bit. The DAC has a DID input that can be driven by a initiator and used directly as the DID output. This allows variability in the DID as dictated by the initiator and is intended to be used by DMA initiators that masquerade as, (that is, drive the DID of) the initiator that programmed it.

10.3.5 Access evaluation

Fundamental to the TRDC's operation is the actual access violation check performed by the memory block checker (MBC) and memory region (MRC).

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the target memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or block configuration register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the 3-bit M{B,R}ACSEL field of the selected RGD or BLK_CFG register selects the appropriate GLBAC (global access control policy). The GLBAC register defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, execute =1/non-execute=0, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
```

The resulting hierarchical access control model specifies:

```
SecurePriv , SecureUser , NonsecurePriv , NonsecureUser
```

After the access evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

10.3.6 Memory Block Checker (TRDC_MBC)

The TRDC's Memory Block Checker provides domain-based access control for all system bus references targeted to on-chip internal memories and peripherals. Using programmed block configuration registers which define the access rights per domain and block, the MBC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access rights are allowed to complete, while references that have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 8 MBC instances where each MBC can support up to 4 sub-regions (MEM[s]). Note monitoring of an AXI memory counts as 2 sub-regions since there are independent read and write channels per AXI memory. Conversely, an AHB connection counts as a single subregion.

Each sub-memory is divided up in equal sized consecutive blocks. Sub-memory 0 (MEM0) can support up to 512 blocks while sub-memory 1-3 (MEM1-MEM3) can each support up to 64 blocks. The number of blocks and size of the block is defined in MBCm_MEMs_GLBCFG[NBLKS,SIZE_LOG2] register fields, where m is the MBC instance number, and s is the sub-memory number. For example, Sub-memory 0 (MEM0) may have 16 consecutive blocks, each of size 64 KB, and corresponding MBCm_DOMd_BLK_CFG_W register to a block will control access to that block.

Each MBCm_DOMd_BLK_CFG_W contains eight access control structures. Each structure is comprised of a 1-bit NSE (NonSecure Enable) plus a 3-bit MBACSEL (Memory Block Access Control Select). The NSE controls secure/nonsecure access to the corresponding block, while the MBACSEL field selects a MBCm_MEMN_GLBACr register which controls the read/write/execute access to the corresponding block. There are 8 programmable MBCm_MEMn_GLBACr registers per block checker, each containing contain read-write-execute control flags for each of the four operating modes:

```
SPR, SPW, SPX - Secure    Privileged {Read, Write, Execute}
SUR, SUW, SUX - Secure    User       {Read, Write, Execute}
NPR, NPW, NPX - Nonsecure Privileged {Read, Write, Execute}
NUR, NUW, NUX - Nonsecure User       {Read, Write, Execute}
```

GLBAC1-7 also have a lock bit MBCm_MEMn_GLBACr[LK]. When LK=1, the GLBACr register is read-only until the next reset. Furthermore, if MBCm_DOMd_BLK_CFG_W[MBACSEL] selects a GLBAC that is locked, the 3-bit MBCACSEL field is also locked until the next reset. GLBAC0 cannot be locked.

The MBC also has MBCm_DOMd_MEMs_BLK_NSE_W registers. These registers are a bit map of the block NSE bits. Each word supports up to 32 blocks.

```
MBCm_DOMd_MEM0_BLK_NSE_W[0-15] has a maximum of 16 words to support 512 blocks
MBCm_DOMd_MEM[1-3]_BLK_NSE_W[0-1] has a maximum of 2 words to support 64 blocks.
```

The block NSE bits can be programmed by writing these registers or by writing the MBCm_MEMN_BLK_{INDEX, SET, CLR, CLR_ALL} registers.

The MBCm_MEMn_NSE_BLK_{INDEX, SET, CLR, CLR_ALL} registers provide a mechanism to efficiently and quickly manipulate the NSE bitmap with bitmasks to set or clear individual blocks within the bitmap and a single operation to perform a clear all across multiple DIDs. The BLK_INDEX register provides the control definition for the BLK_SET and BLK_CLR operations.

10.3.6.1 Memory block hit determination

MBCm_MEMs_GLBCFG[NBLK, SIZE_LOG2] is used to determine which bits of the address correspond to block number.

```
block_n_hit = (addr[MSB:LSB] == n)
where LSB=SIZE_LOG2
MSB=f{NBLKS,LSB}
```

Note that the block hit determination is based only on the address comparison of the first byte being accessed; that is, the MBC does not check the size of the access to make sure it entirely fits within the region.

10.3.6.2 Memory block access evaluation

For a block n hit, the MBC logic evaluates the access rights defined by the MBCm_DOMd_BLK_CFG_Ww registers. The domainID attribute and block number hit selects the appropriate MBCm_DOMd_BLK_CFG_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MBC global access control policy defined in MBCm_DOMd_BLK_CFG_W[MBACSEL, NSE] fields.

While TRDC_CR[GVLDB] = 1, and for each sub-memory being monitored, the MBC performs a reduction-AND of all the individual error terms from each access evaluation.

Unlike the MRC access evaluation and termination, the MBC access evaluation terminates the access with a bus error and reports an access error for only one condition - when the access doesn't have sufficient access rights. By nature, the block checker can only hit in ONE block, and by implementation, there are no "miss" accesses. Accesses outside of the range covered by the MBC

are not sent to the MBC. There also aren't any individual block valid bits. When TRDC_CR[GVLDB] = 1, checking on all blocks is always enabled.

10.3.7 Memory Region Checker (TRDC_MRC)

The TRDC's Memory Region Controller provides domain-based, hardware access control for all system bus references targeted at non-peripheral memory spaces. Using pre-programmed *region descriptors* which define memory spaces and their associated access rights per domain identifier, the MRC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 16 MRC instances, where each MRC instance can support [1-16] region descriptors, concurrently monitoring up to 8 target memory ports. Note, monitoring an AXI protocol port counts as two ports since there are independent read address and write address channels. Conversely, an AHB connection counts as a single port.

A partial, simplified one-dimensional block diagram of an instance of the MRC module is shown in Figure 12. In this figure, a single target bus port is shown. When the remaining target ports are considered, the MRC hardware's two-dimensional connection matrix, broadcasting each system bus target port access across the implemented memory region descriptors, is the resulting structure with the basic access evaluation macro shown as the replicated submodule block. In Figure 12, the system bus fabric target port is shown on the left, the memory region descriptor registers are in the middle, and the peripheral bus interface on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and, based on the domainID associated with the reference, access violations.

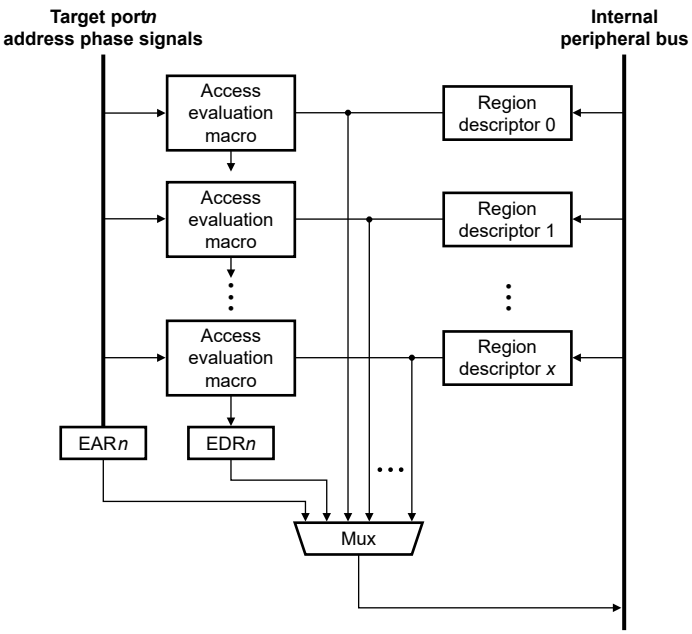

Figure 12. MRC access evaluation macro hardware structure

For each access, the MRC hardware performs a two-step evaluation process. First, the access is compared to all memory region descriptors to determine hit/miss status, and then, using the domainID associated with the reference plus the address attributes {write, nonsecure, privileged}, the access rights are examined using the method detailed in Access evaluation.

10.3.7.1 Memory region descriptor hit determination

To determine if the current reference hits in a given region, two magnitude comparators are used in conjunction with the region's start and end addresses. The boolean equation for this portion of the hit determination is defined as:

```
region_hit_n =
```

```
((addr >= start_addr) & (addr <= end_addr)) & valid
```

where `addr` is the current system reference address, `start_addr` and `end_addr` are the start and end addresses, and `valid` is the valid bit, all from memory region descriptor n.

Note there are *no hardware checks* to verify that `end_addr ≥ start_addr`, and it is software's responsibility to properly load appropriate values into these fields of the region descriptor.

Also, the region hit determination is based only on an address comparison of the first byte being accessed; that is, the MRC does *not* check the size of the access to make sure it entirely fits within the region.

10.3.7.2 Memory region access evaluation

For each region descriptor hit, the MRC logic evaluates the access rights defined by the MRCm_DOMd_RGDr_Ww registers. Specifically, the domainID attribute selects the appropriate MRCm_DOMd_RGDr_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MRC global access control policy defined in MRCm_DOMd_RGDr_W0[MRACSEL] and MRCm_DOMd_RGDr_W1[NSE] fields. See Access evaluation for additional details on this function.

While TRDC_CR[GVLDR] = 1, and for each bus target port being monitored, the MRC performs a **reduction-AND** of all the individual *(no_hit | error)* terms from each access evaluation macro. Recall as specified in Memory region descriptor hit determination, an *invalid* MRC_DOMd_RGDr_Ww (MRCm_DOMd_RGDr_W1[VLD] = 0) forces the region_hit_n evaluation to be negated.

This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. If the access does not hit in *any* region descriptor, an access error is reported.
2. If the access hits in a single region descriptor and that region signals a domain violation, then an access error is reported.
3. If the access hits in multiple (overlapping) regions and one region signals a violation, then an access error is reported.

The third condition reflects that priority is given to access denying over access allowing for overlapping regions.

Unimplemented domain IDs (DIDs) do not have any associated region descriptors and therefore have no access rights.

10.3.8 Interrupts

This module outputs an interrupt signal which can be connected to the system's interrupt controller. Please check chip-specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOCn registers are cleared. This interrupt is in addition to interrupt generated by initiator after receiving bus error due to access violation by memory block checker or memory region checker. So, system may receive interrupt through different channels but from the same access violation at checker.

10.4 External signals

The TRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit target bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the target peripheral buses as shown in TRDC block diagram.

10.5 Initialization

Out of reset, TRDC_CR[GVLDR, GVLDB, GVLDM] bits are cleared, TRDC is disabled and in deny by default mode allowing secure privileged startup code to configure the entire programming model. In deny by default mode, only the DIDs that aren't denied by default are allowed to access memory and peripherals. The allowed DIDs are implementation defined. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0,1}, DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG) to obtain the implemented hardware capabilities for the device.

2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory block configuration (MBCm_DOMd_MEMs_BLK_CFG_Ww) and memory region descriptors (MRCm_DOMd_RGDr_Ww). There are individual valid bits included in these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the TRDC programming model is loaded, the TRDC_CR is written with GVLD {R, B, M} asserted. Upon the assertion of the 3 GVLD bits, deny by default mode is exited and at that point, the TRDC is fully operational. The TRDC remains enabled until the next reset.

10.6 Application information

As described in Overview, the TRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability.

10.6.1 Initiator domain assignments

The typical use case related to initiator domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus initiator devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus initiators. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus initiators typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

10.6.2 Memory region descriptor management

There are important concepts to consider in managing the memory region descriptors.

Recall that the association between each MRCn instance and the target memory regions it monitors is SoC-dependent. The device-specific configuration specifies the number of implemented memory region descriptors in a given instance and the specific port numbers associated with the target memories being monitored.

10.6.3 Domain error capture management

Recall when a domain access violation is detected by either a memory region checker or a memory block checker, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MBC and/or MRC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address and attribute information can easily be retrieved from the domain error registers. For 32 bits address, the captured error address can be retrieved from DERR_W0_n and the attribute information can be retrieved from DERR_W1_n. For 36 bits address, the captured error address can be retrieved from DERR_W0_n and DERR_W1_n and the attribute information can be retrieved from

DERR_W2_n. The 2-bit DERR_W1_n[EST] or DERR_W2_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 13.

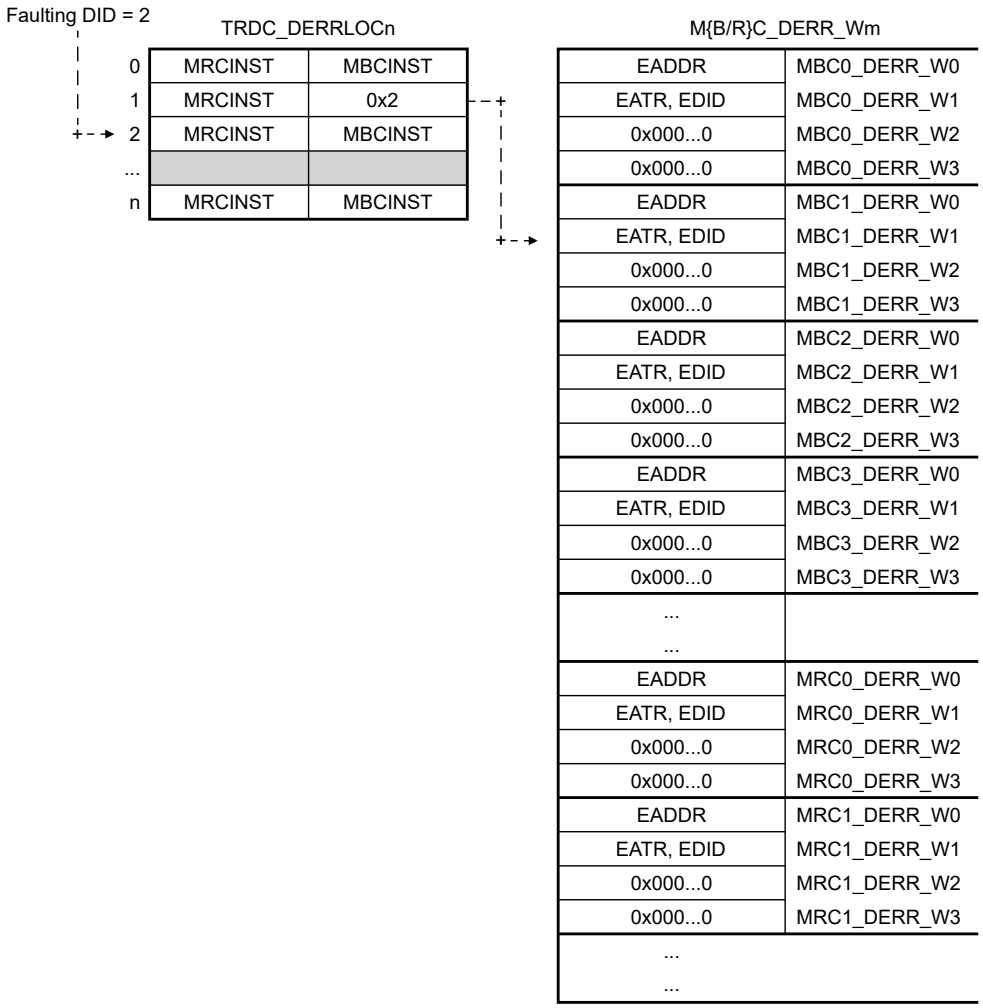

Figure 13. Two-step retrieval of domain error address and attributes

10.7 Register descriptions

The MBCm_NSE_BLK_SET, MBCm_NSE_BLK_CLR and MBCm_NSE_BLK_CLR_ALL registers exist at offset for only domain ID value 0 even when more than 1 domains exist, and address offsets for non-zero domain ID value should be considered reserved space. So, this reserved address space in MBC space does not return transfer error: 0xn14 to 0xn1C where n = (1 to NUM_DID-1) * 2 for each MBC.

If TZ-M is enabled, the TRDC programming model can only be accessed in SecurePrivileged mode. If TZ-M is disabled, it can only be accessed in Privileged mode regardless of Secure or NonSecure; that is it can't be accessed in User mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or access to reserved spaces are terminated with an error unless noted otherwise. The TRDC programming model is partitioned into these groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Initiator domain assignments
- Memory block and region checkers

It should be noted that many of the programming model registers in TRDC are organized as 2-, 3- or 4- dimensional data structures. For the 2-dimensional structures, the generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The TRDC register structure uses the naming convention of *TRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

For the 4-dimensional structures, the generic arrays contain "m", "d", "s" or "r", and "w" indices corresponding to MBC/MRC instance, domain index, sub-memory or region index and word index. The naming convention for the MBC block configuration and MRC region descriptor word registers are: *MBCm_DOMd_MEMs_BLK_CFG_Ww* and *MRCm_DOMd_RGDr_Ww*

For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

10.7.1.2 TRDC Register (TRDC_CR)

Offset

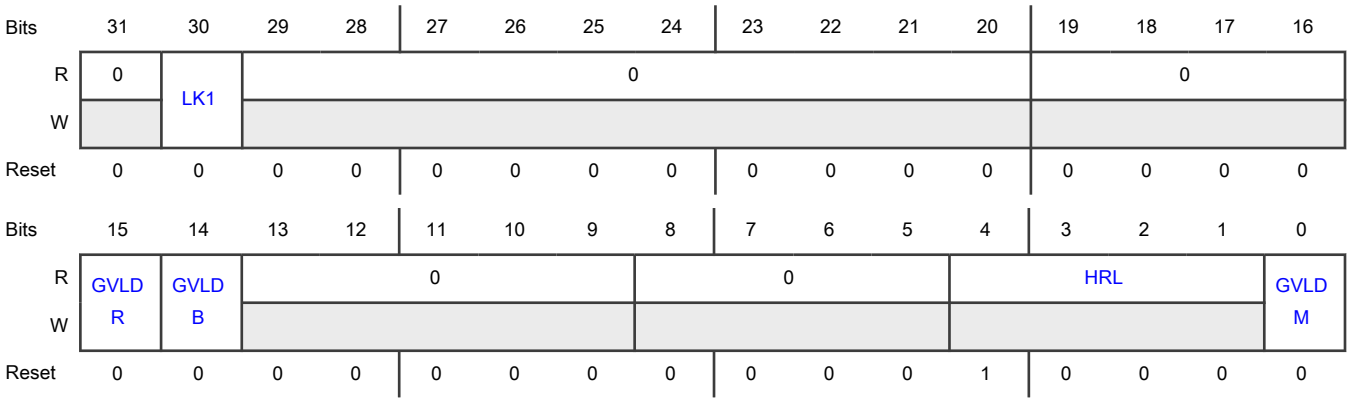
Register	Offset
TRDC_CR	0h

Function

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0b - The CR can be written by any secure privileged write. 1b - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MRCs are disabled. 1b - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC MBCs are disabled. 1b - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0b - TRDC DACs are disabled. 1b - TRDC DACs are enabled.

10.7.1.3 Hardware Configuration Register 0 (TRDC_HWCFG0)

Offset

Register	Offset
TRDC_HWCFG0	F0h

Function

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

3-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-8].

10.7.1.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

Offset

Register	Offset
TRDC_HWCFG1	F4h

Function

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-3 —	Reserved
2-0 DID	Domain identifier number This field provides the domain number [0-7] of the requesting bus initiator.

10.7.1.5 Domain Assignment Configuration Register (DACFG0 - DACFG4)

Offset

Register	Offset
DACFG0	100h
DACFG1	101h
DACFG2	102h
DACFG3	103h
DACFG4	104h

Function

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	See Register reset values.							

Register reset values

Register	Reset value
DACFG0	01h
DACFG1–DACFG4	81h

Fields

Field	Function
7 NCM	Non-CPU Initiator

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0b - Bus initiator is a processor. 1b - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

10.7.1.6 Memory Block Configuration Register (MBC0_CFG0)

Offset

Register	Offset
MBC0_CFG0	140h

Function

This register defines the hardware configuration of two of the sub-blocks within a memory block checker.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv read-only

Diagram

10.7.1.14 Memory Region Configuration Register (MRCFG0 - MRCFG7)

Offset

For r = 0 to 7:

Register	Offset
MRCFGr	160h + (r × 1h)

Function

This read-only register defines the number of implemented memory region descriptors for each MRCr, where r+1 can specify up to 16 instances. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. A zero value indicates a non-existent memory region checker instance. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

10.7.1.18 TRDC FLW Array Base (TRDC_FLW_ABASE)

Offset

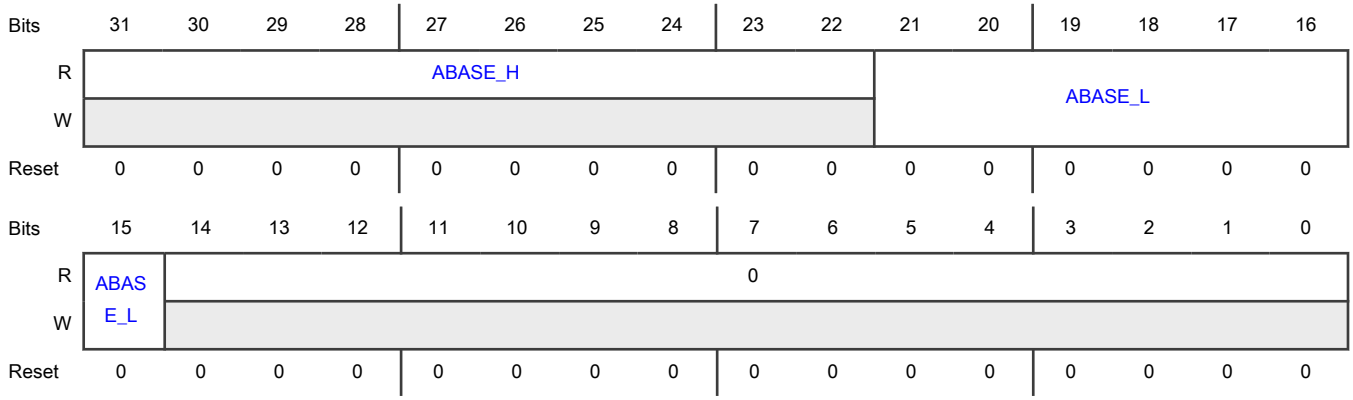
Register	Offset
TRDC_FLW_ABASE	1E8h

Function

This register gives the flash array base address of the Flash Logical Window.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram



Fields

Field	Function
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

10.7.1.19 TRDC FLW Block Count (TRDC_FLW_BCNT)

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

Function

This register gives the size of the Flash Logic Window in 32KByte blocks.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Diagram

31-15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

10.7.1.20 TRDC Fault Domain ID (TRDC_FDID)

Offset

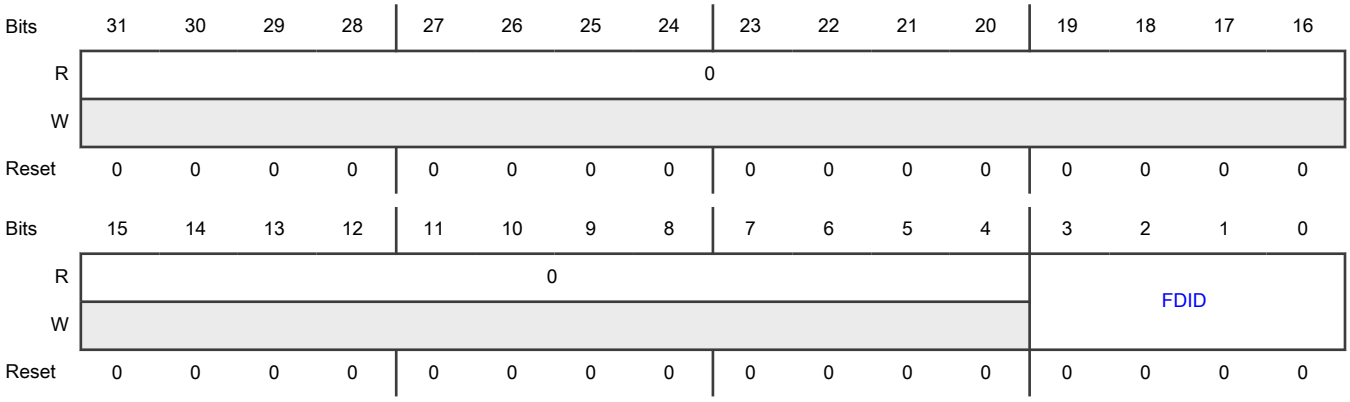
Register	Offset
TRDC_FDID	1FCh

Function

In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

10.7.1.21 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC2)

Offset

Register	Offset
TRDC_DERRLOC0	200h
TRDC_DERRLOC1	204h
TRDC_DERRLOC2	208h

Function

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

23-16	MRC instance

Table continues on the next page...

Table continued from the previous page...

Field	Function
MRCINST	This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 23) corresponds to MRC instance 7 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-12 mbc3_err_slv	MBC3 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
11-8 mbc2_err_slv	MBC2 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
7-4 mbc1_err_slv	MBC1 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3
3-0 mbc0_err_slv	MBC0 ERROR SLAVE • 0001b - Error in Slave memory 0 • 0010b - Error in Slave memory 1 • 0100b - Error in Slave memory 2 • 1000b - Error in Slave memory 3

10.7.1.22 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC2_DERR_W0)

Offset

Register	Offset
MBC0_DERR_W0	400h
MBC1_DERR_W0	410h
MBC2_DERR_W0	420h

Function

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Function
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00b - No access violation has been detected. 01b - No access violation has been detected. 10b - A single access violation has been detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000b - mbcxslv0 001b - mbcxslv1 010b - mbcxslv2 011b - mbcxslv3
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0b - Read access 1b - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000b - Secure user mode, instruction fetch access. 001b - Secure user mode, data access. 010b - Secure privileged mode, instruction fetch access. 011b - Secure privileged mode, data access. 100b - Nonsecure user mode, instruction fetch access. 101b - Nonsecure user mode, data access. 110b - Nonsecure privileged mode, instruction fetch access. 111b - Nonsecure privileged mode, data access.
7 SLV_ABORT	Bus protect error This field captures the bus protect error from target which cause access abort.
6	Secure attribute check error

Table continues on the next page...

Table continued from the previous page...

Field	Function
SLV_SA_ERR	This field captures the secure attribute check error from target.
5 SLV_PA_ERR	Privilege attribute check error This field captures the privilege attribute check error from target.
4 SLV_DID_ERR	DID check error This field captures the DID check error from target.
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

10.7.1.24 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC2_DERR_W3)

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch
MBC2_DERR_W3	42Ch

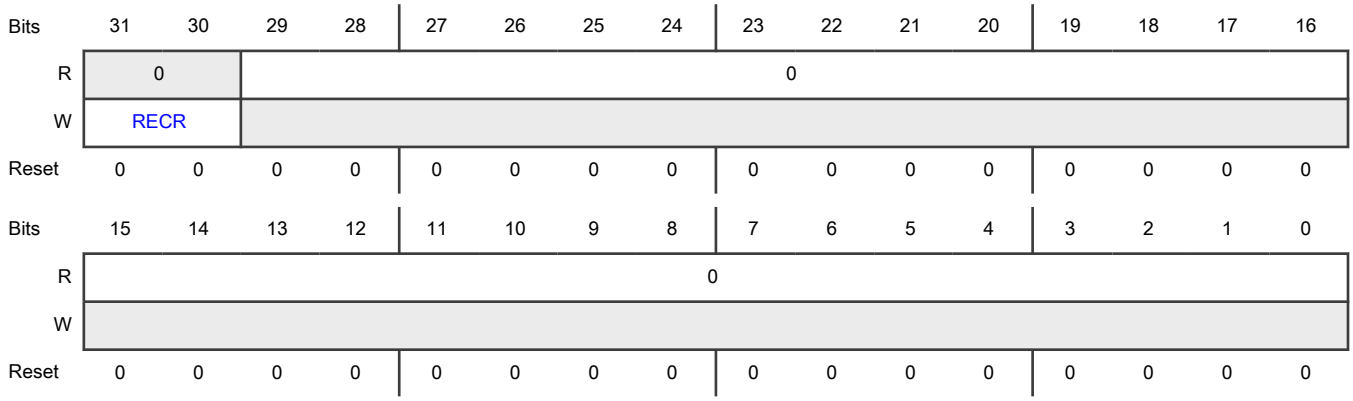
Function

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Diagram



Fields

Field	Function
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

10.7.1.25 MRC Domain Error Word0 Register (MRC0_DERR_W0)

Offset

Register	Offset
MRC0_DERR_W0	480h

Function

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

10.7.1.28 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT0)

Offset

Register	Offset
MDA_W0_0_DFMT0	800h

Function

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus initiators to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-initiator domain assignment is then repeated for each bus initiator (MDAm). Thus, m specifies the initiator number and r refers to the specific MDA register for a given bus initiator.

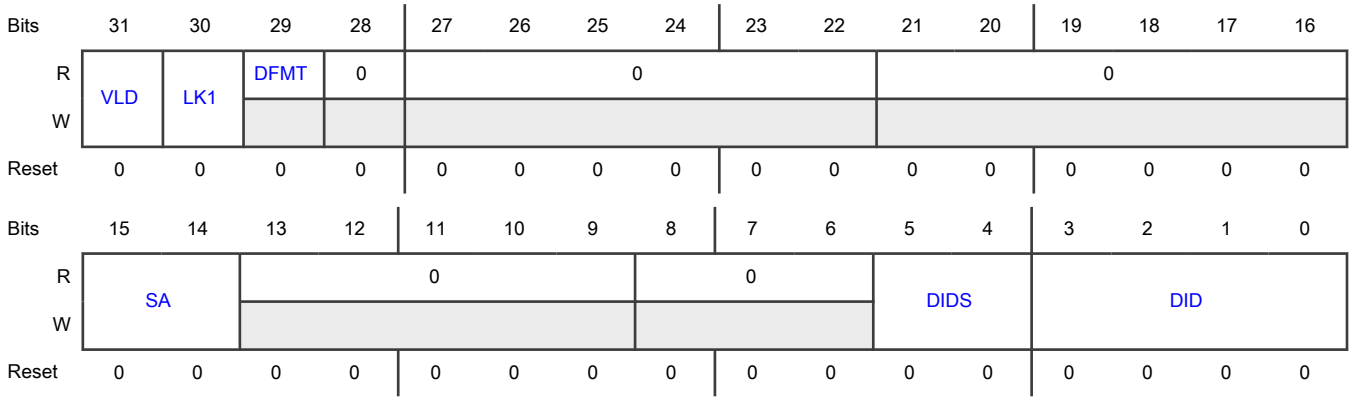
Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor initiators typically support one or more Wr domain definitions, while non-processor initiators support a single Wr. Processor initiators Domain Assignment register names use a _DFMT0 suffix. Non-processor initiators Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus initiator. If there is a single Wr for a given initiator, then the specified domain identifier is used directly. If there are multiple Wr values for a given initiator, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor initiator. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Initiator Domain Assignment (MDA_Wr_m_DFMT1) register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores. **NOTE** The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00b - Force the bus attribute for this initiator to secure. 01b - Force the bus attribute for this initiator to nonsecure. 10b - Use the bus initiator's secure/nonsecure attribute directly. 11b - Use the bus initiator's secure/nonsecure attribute directly.
13-9 —	Reserved
8-6 —	Reserved
5-4 DIDS	DID Select This field selects the source of the domain identifier. 00b - Use MDAm[3:0] as the domain identifier. 01b - Use the input DID as the domain identifier. 10b - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11b - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b. Write a value greater than the number of DIDs is illegal.

10.7.1.29 DAC Initiator Domain Assignment Register (MDA_W0_1_DFMT1 - MDA_W0_4_DFMT1)

Offset

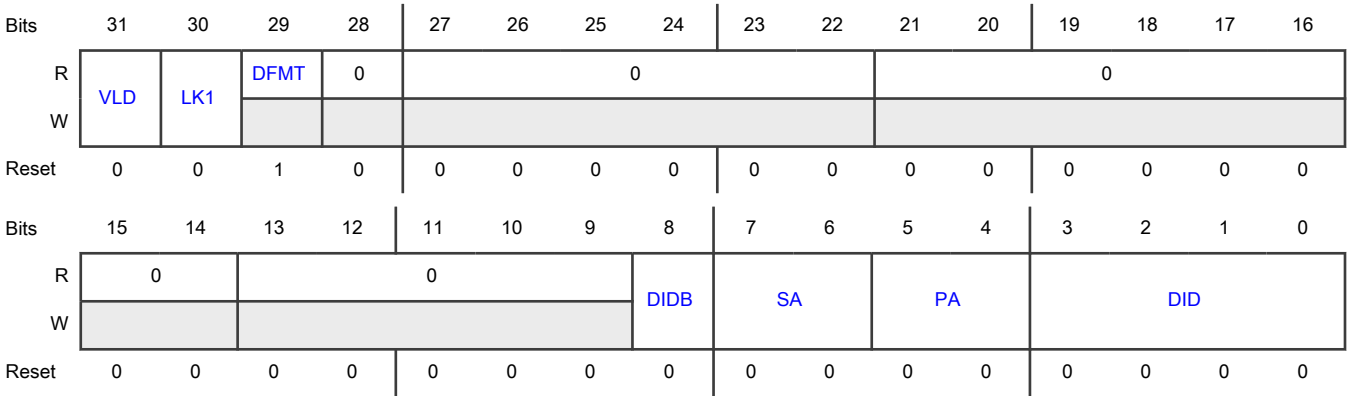
Register	Offset
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Function

This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Diagram



Fields

Field	Function
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0b - The Wr domain assignment is invalid. 1b - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Register can be written by any secure privileged write. 1b - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0b - Processor-core domain assignment 1b - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved

8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset. **DAC** / **DID Input** 0 / 0 1 / DMA Domain ID 2 / USB Domain ID 0b - Use MDAn[3:0] as the domain identifier. 1b - Use the DID input as the domain identifier.
7-6	Secure attribute

Table continues on the next page...

Table continued from the previous page...

Field	Function
SA	This field defines the secure/nonsecure attribute for non-processor cores. **NOTE** The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00b - Force the bus attribute for this initiator to secure. 01b - Force the bus attribute for this initiator to nonsecure. 10b - Use the bus initiator's secure/nonsecure attribute directly. 11b - Use the bus initiator's secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus initiator's input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00b - Force the bus attribute for this initiator to user. 01b - Force the bus attribute for this initiator to privileged. 10b - Use the bus initiator's privileged/user attribute directly. 11b - Use the bus initiator's privileged/user attribute directly.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0. Write a value greater than the number of DIDs is illegal.

10.7.1.30 MBC Global Configuration Register (MBC0_MEM0_GLBCFG - MBC2_MEM3_GLBCFG)

Offset

For m = 0 to 2; r = 0 to 3:

Register	Offset
MBCm_MEMr_GLBCFG	1000h + (m × 1000h) + (r × 4h)

Function

These MBC global configuration read-only registers contain information on the MBC's hardware configuration. Specifically, it defines the number of memory blocks and the size of each block in each MBC mem (r).

NOTE

An all zero value (SIZE_LOG2 = 0, NBLKS = 0) indicates a non-existent memory. For the number of memories implemented in the MBCs, refer to chip-specific information

MBC2_MEM2_GLBCFG	000C_0010h
MBC2_MEM3_GLBCFG	0000_0000h

Fields

Field	Function
31-30	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
29-21 —	Reserved
20-16 SIZE_LOG2	Log2 size per block For example SIZE_LOG2=0x0C is 2^12=4 KB blocks.
15-10 —	Reserved
9-0 NBLKS	Number of blocks in this memory

10.7.1.31 MBC NonSecure Enable Block Index (MBC0_NSE_BLK_INDEX - MBC2_NSE_BLK_INDEX)

Offset

Register	Offset
MBC0_NSE_BLK_INDEX	1010h
MBC1_NSE_BLK_INDEX	2010h
MBC2_NSE_BLK_INDEX	3010h

Function

This R/W register defines the selected memories that are affected by the writes to the NSE_BLK_SET and NSE_BLK_CLR registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				MEM_SEL				0				WNDX		0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 AI	Auto Increment 0b - No effect. 1b - Add 1 to the WNDX field after the register write.
30-19 —	Reserved
18-16 DID_SELn	DID Select Destination domain bitmap select. 0b - No effect. 1b - Selects NSE bits for this domain.
15-12 —	Reserved
11-8 MEM_SEL	Memory Select Destination memory bitmap select. • Bit [11] - MBC MEM 3 • Bit [10] - MBC MEM 2 • Bit [9] - MBC MEM 1 • Bit [8] - MBC MEM 0
7-6 —	Reserved
5-2 WNDX	Word index into the block NSE bitmap. It selects the BLK_NSE_Wn register, where WNDX determines the value of n.
1 —	Reserved
0 —	Reserved

10.7.1.32 MBC NonSecure Enable Block Set (MBC0_NSE_BLK_SET - MBC2_NSE_BLK_SET)

Offset

Register	Offset
MBC0_NSE_BLK_SET	1014h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
MBC1_NSE_BLK_SET	2014h
MBC2_NSE_BLK_SET	3014h

Function

A write to this register sets the appropriate NSE Bits for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	W1SET

W	W1SET															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 W1SET	Write-1 Set If set to 1, sets appropriate NSE bit for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. Write with value 0 has no effect.

10.7.1.33 MBC NonSecure Enable Block Clear (MBC0_NSE_BLK_CLR - MBC2_NSE_BLK_CLR)

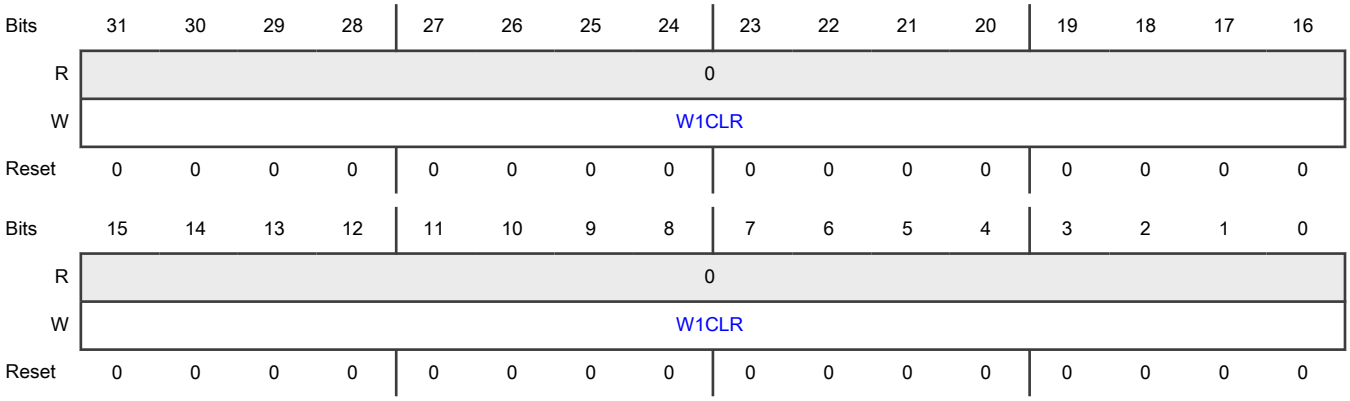
Offset

Register	Offset
MBC0_NSE_BLK_CLR	1018h
MBC1_NSE_BLK_CLR	2018h
MBC2_NSE_BLK_CLR	3018h

Function

A write to this location clears the appropriate NSE bits as defined by the W1CLR[n]=1 for the selected domains and memories Defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

Diagram



Fields

Field	Function
31-0 W1CLR	Write-1 Clear If set to 1, Clear the appropriate NSE bit for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. Write with value 0 has no effect.

10.7.1.34 MBC NonSecure Enable Block Clear All (MBC0_NSE_BLK_CLR_ALL - MBC2_NSE_BLK_CLR_ALL)

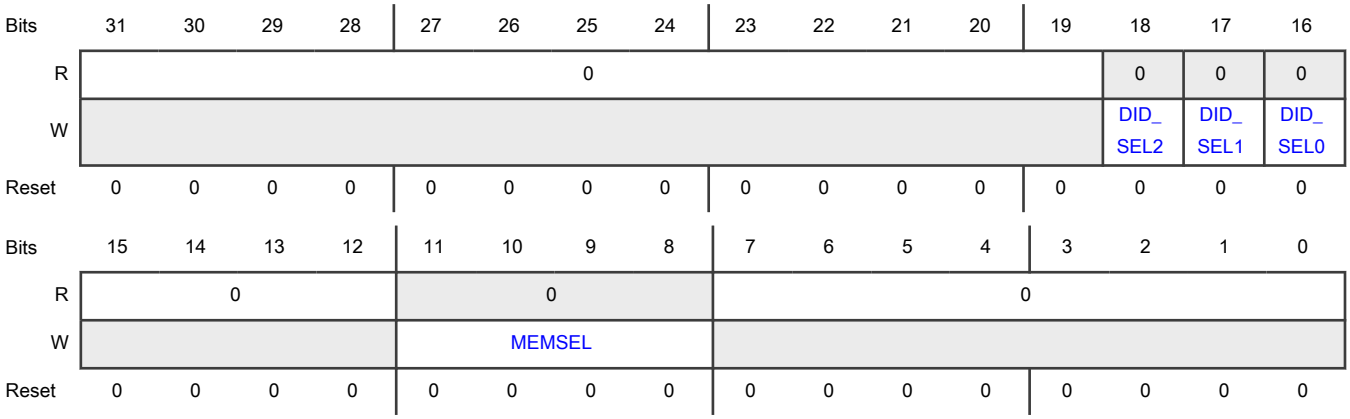
Offset

Register	Offset
MBC0_NSE_BLK_CLR_ALL	101Ch
MBC1_NSE_BLK_CLR_ALL	201Ch
MBC2_NSE_BLK_CLR_ALL	301Ch

Function

A write to this location clears all the block NSE bits for the selected domains and memories defined in the write data. This register reads as zero.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 DID_SELn	DID Select Destination domain bitmap select. 0b - No effect. 1b - Clear all NSE bits for this domain.
15-12 —	Reserved
11-8 MEMSEL	Memory Select Destination memory bitmap select. • Bit [11] - clear all MEM 3 NSE bits • Bit [10] - clear all MEM 2 NSE bits • Bit [9] - clear all MEM 1 NSE bits • Bit [8] - clear all MEM 0 NSE bits
7-0 —	Reserved

10.7.1.35 MBC Global Access Control (MBC0_MEMN_GLBAC0)

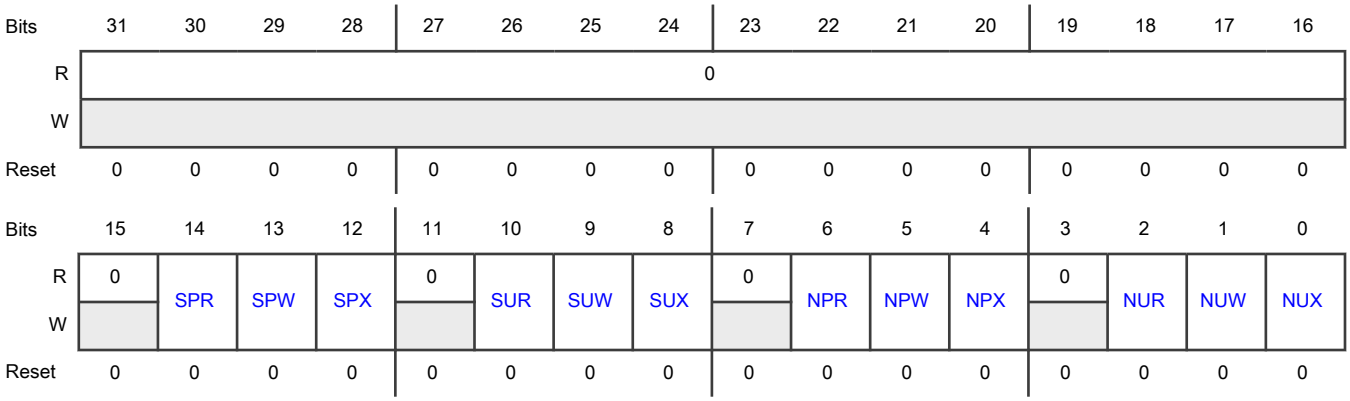
Offset

Register	Offset
MBC0_MEMN_GLBAC0	1020h

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 SPR	SecurePriv Read SecurePriv read access control flag 0b - Read access is not allowed in Secure Privilege mode. 1b - Read access is allowed in Secure Privilege mode.

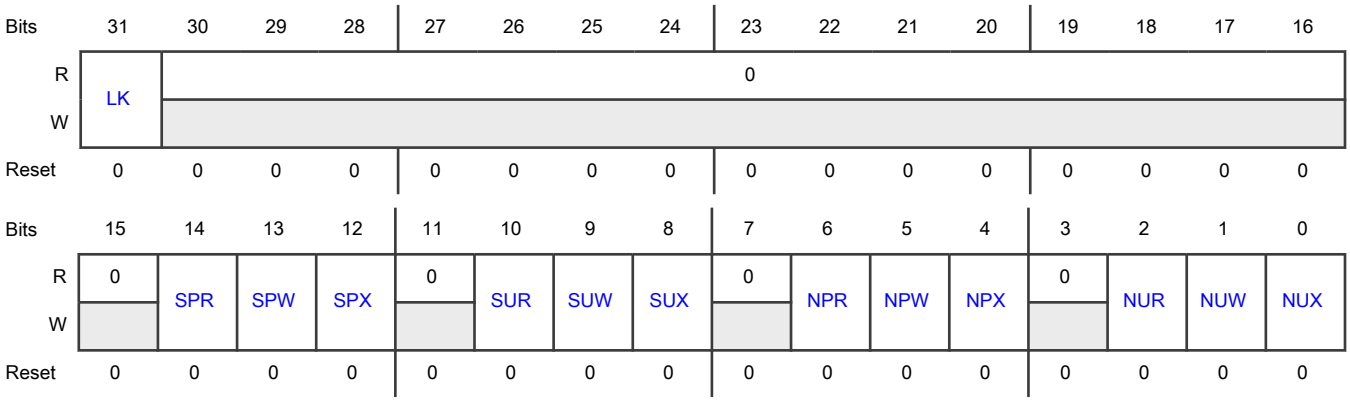
MBC0_MEMN_GLBAC5	1034h
MBC0_MEMN_GLBAC6	1038h
MBC0_MEMN_GLBAC7	103Ch

Function

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

Diagram



Fields

Field	Function
31 LK	LOCK This 1-bit field provides a mechanism to limit writes to the this register to protect its contents. Once set, this bit remains asserted until the next reset. 0b - This register is not locked and can be altered. 1b - This register is locked and cannot be altered.
30-15 —	Reserved
14 SPR	SecurePriv Read SecurePriv read access control flag 0b - Read access is not allowed in Secure Privilege mode. 1b - Read access is allowed in Secure Privilege mode.
13 SPW	SecurePriv Write SecurePriv write access control flag 0b - Write access is not allowed in Secure Privilege mode. 1b - Write access is allowed in Secure Privilege mode.
12 SPX	SecurePriv Execute SecurePriv execute access control flag 0b - Execute access is not allowed in Secure Privilege mode. 1b - Execute access is allowed in Secure Privilege mode.
11 —	Reserved
10 SUR	SecureUser Read SecureUser read access control flag 0b - Read access is not allowed in Secure User mode. 1b - Read access is allowed in Secure User mode.
9 SUW	SecureUser Write SecureUser write access control flag 0b - Write access is not allowed in Secure User mode. 1b - Write access is allowed in Secure User mode.

MBC0_DOM2_MEM3_BLK_CFG_W0	15D0h
MBC0_DOM2_MEM3_BLK_CFG_W1	15D4h

Function

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index

- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 43. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0

Function

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 44. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0

Table continues on the next page...

Table 44. Block Config Word to Block Number Relationship (continued)

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

Function

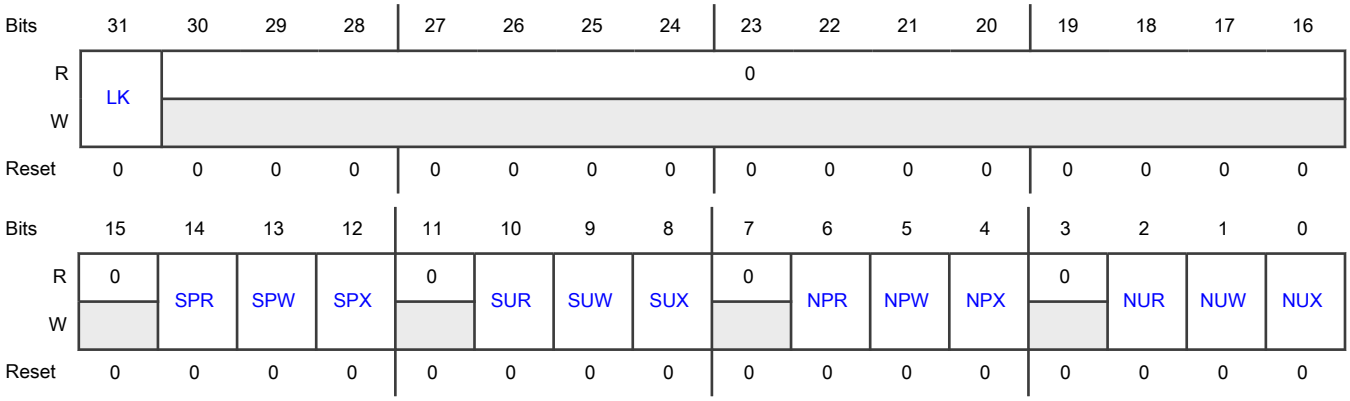
These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

Diagram



Fields

Field	Function
31 LK	LOCK This 1-bit field provides a mechanism to limit writes to the this register to protect its contents. Once set, this bit remains asserted until the next reset. 0b - This register is not locked and can be altered. 1b - This register is locked and cannot be altered.

Function

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Register	Offset
MBC2_DOM2_MEM2_BLK_NSE_W0	35C8h

Function

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 46. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64
. . .			
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

11.1.2 Direct Memory Access Multiplexer (DMAMUX)

11.1.2.1 DMAMUX0 request sources

The peripheral request line for each channel of the Enhanced Direct Memory Access Controller 0 (eDMA0) is driven from a Direct Memory Access Multiplexer (DMAMUX). This is a flexible configuration that allows the user to select the appropriate peripheral to connect to each channel of the DMA Controller. The DMAMUX for this device allows up to 64 DMA request signals to be mapped to each channel. Because of the mux, there is not a correlation between any of the DMA request sources and a specific DMA channel.

The DMAMUX is an integrated component of the DMA Controller. This allows each DMA channel and DMA Multiplexer to configured as secure or non-secure on initial configuration of the device and not be changed without the correct permissions. For more information, please refer to the DMA Controller (DMA) chapter of the reference manual.

11.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - — Source address and destination address calculations
  - — Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 49. Updated terms

11.2.1 Block diagram

Figure 14 illustrates the components of the eDMA system, including the eDMA module (engine).

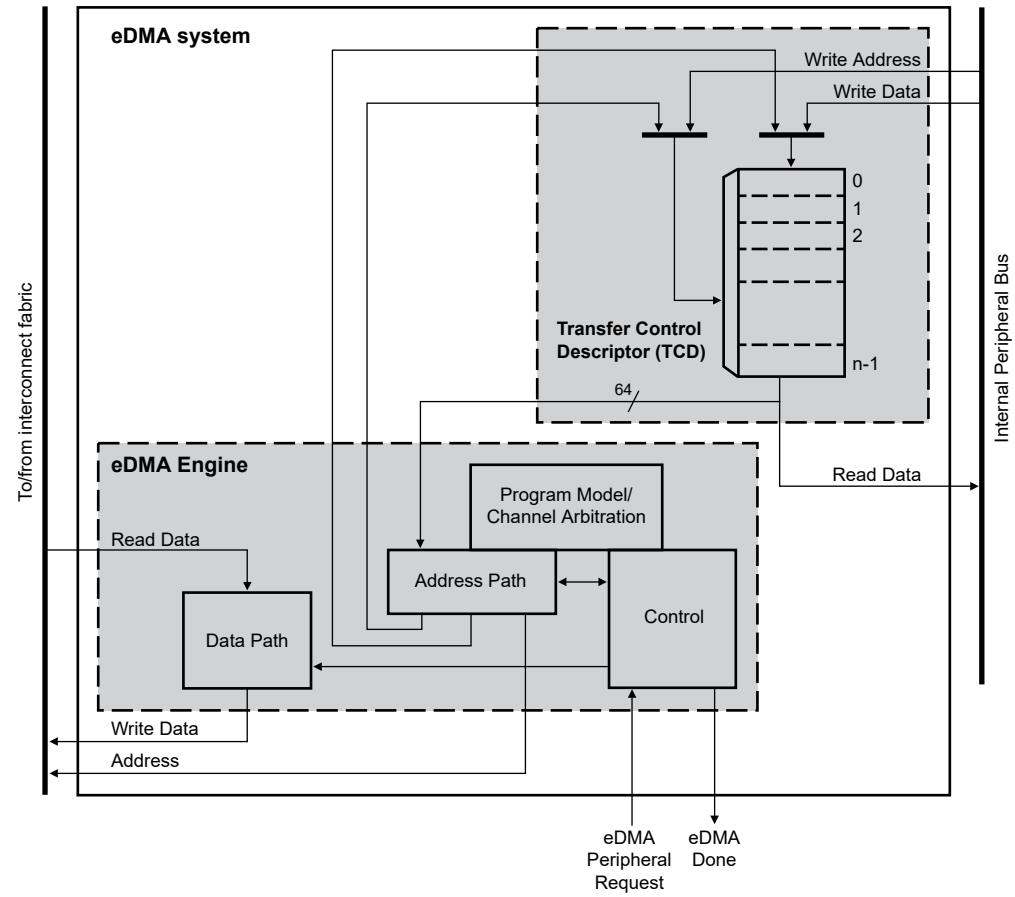

Figure 14. Block diagram

11.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 50. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all initiator bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus initiator read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 51. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

11.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 16-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers
  - Connections to the crossbar switch for bus driving the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

11.3 Functional description

The operation of eDMA is described in the following subsections.

11.3.1 Modes of operation

The eDMA operates in the following modes:

Table 52. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service

Table continues on the next page...

Table 52. Modes of operation (continued)

Mode	Description
	request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

11.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

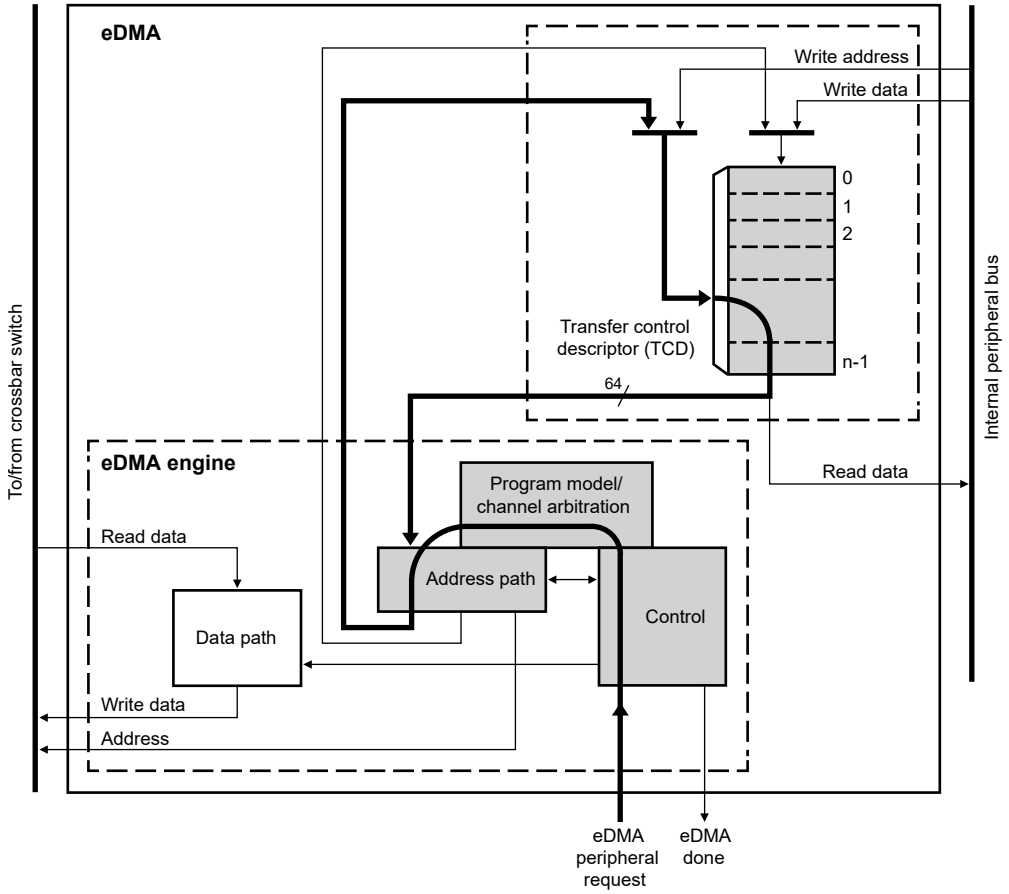

Figure 15. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the

local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

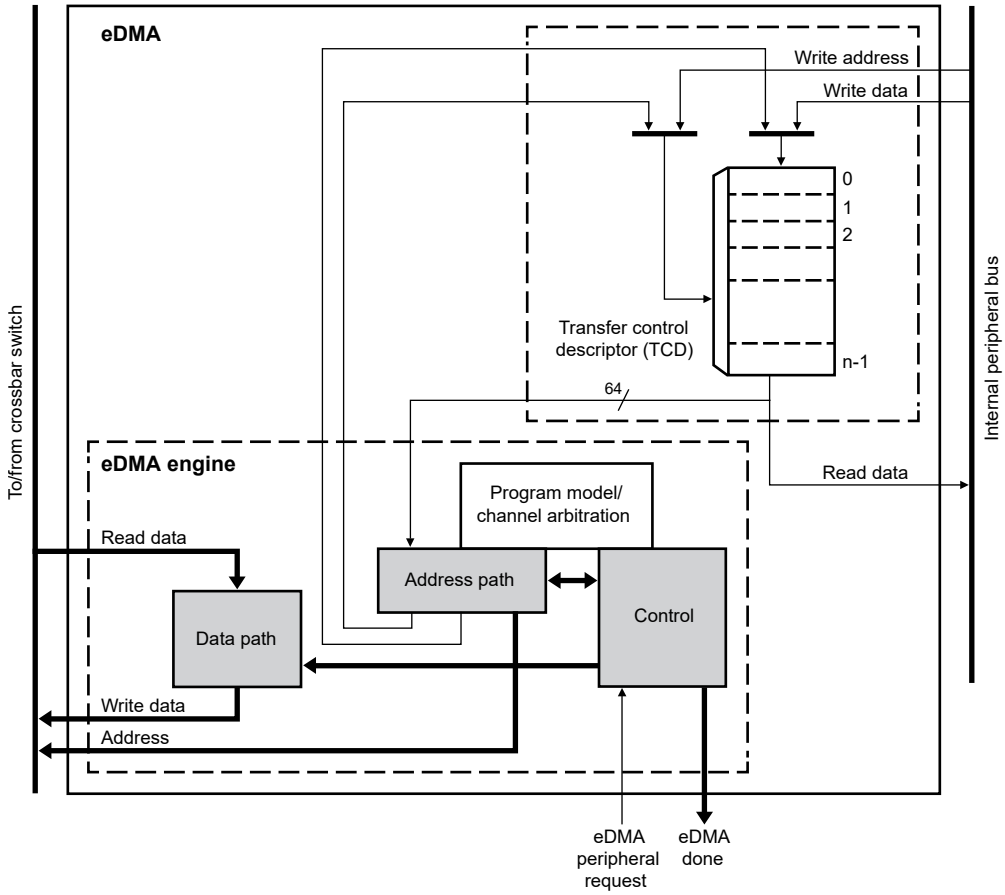

Figure 16. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

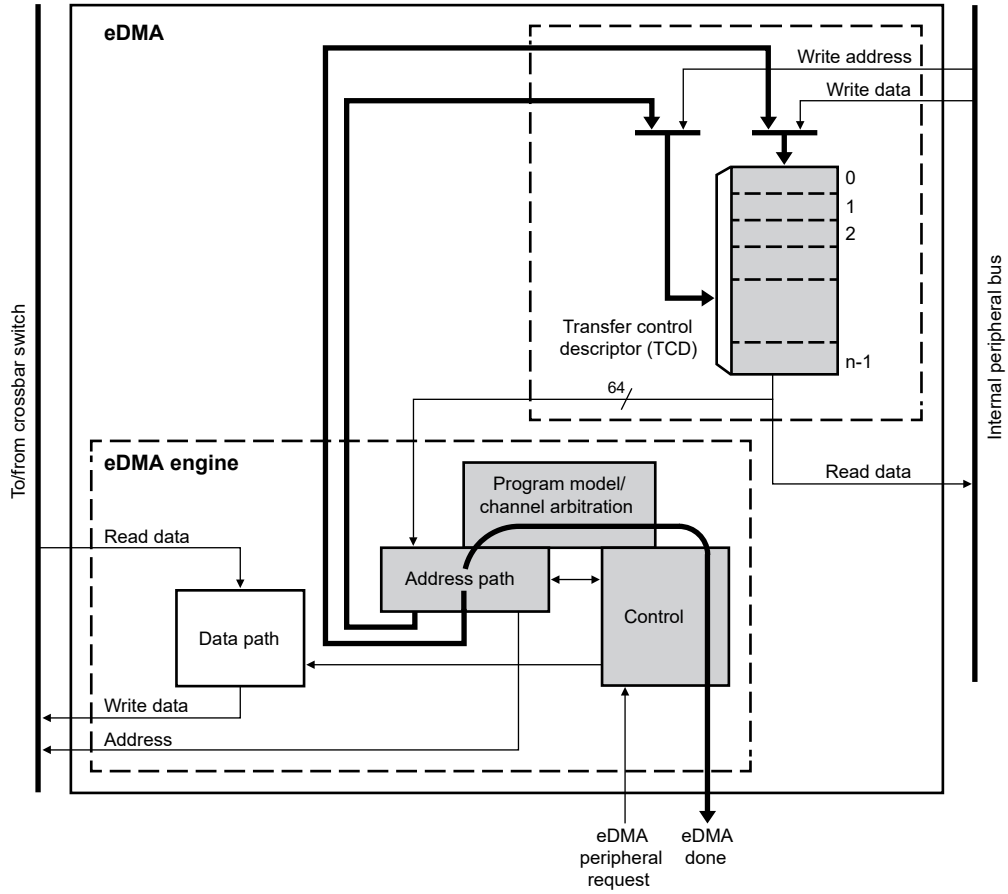

Figure 17. eDMA operation, part 3

11.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus initiator read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

11.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

It can be considered a number composed of these concatenated priority levels: CHn_GRPRI : CHn_PRI[APL]

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CH_NUM)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

11.3.5 Clocking

The following table describes the clock sources:

Table 53. Clocks

Clock	Description
hclk	Clock used for the DMA engine
ipg_clk	Clock used for the DMA programming model
dma_ram_clk	Clock used for the TCD RAMs

11.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

11.4 Memory map and register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See EDMA_TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

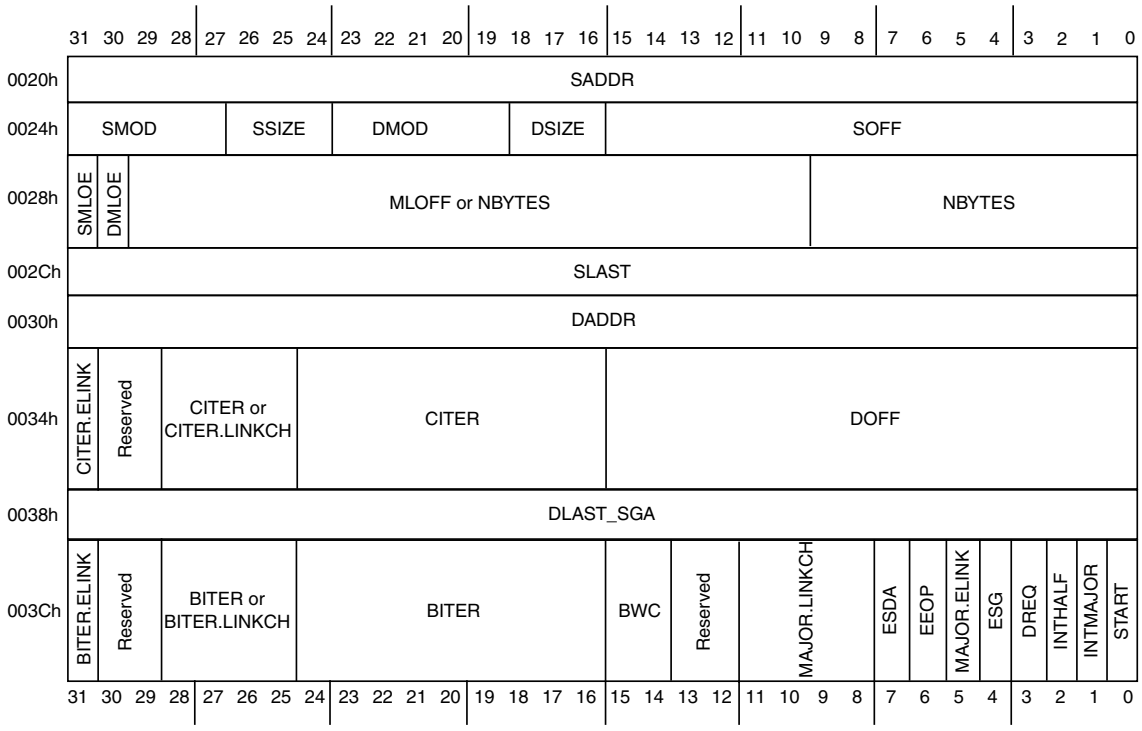

Figure 18. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

11.4.1.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel
30-28 —	Reserved
27-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Initiator ID Replication Control **NOTE** If initiator ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Initiator ID replication disabled for all channels 1b - Initiator ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6	Global Channel Linking Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
GCLC	0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

11.4.1.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

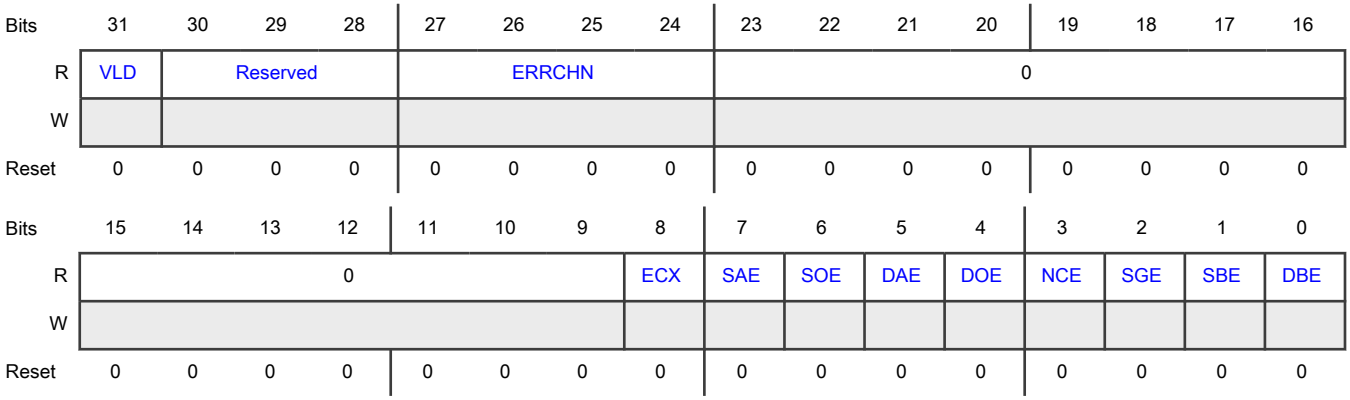
Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No source bus error 1b - Last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

11.4.1.4 Management Page Interrupt Request Status (MP_INT)

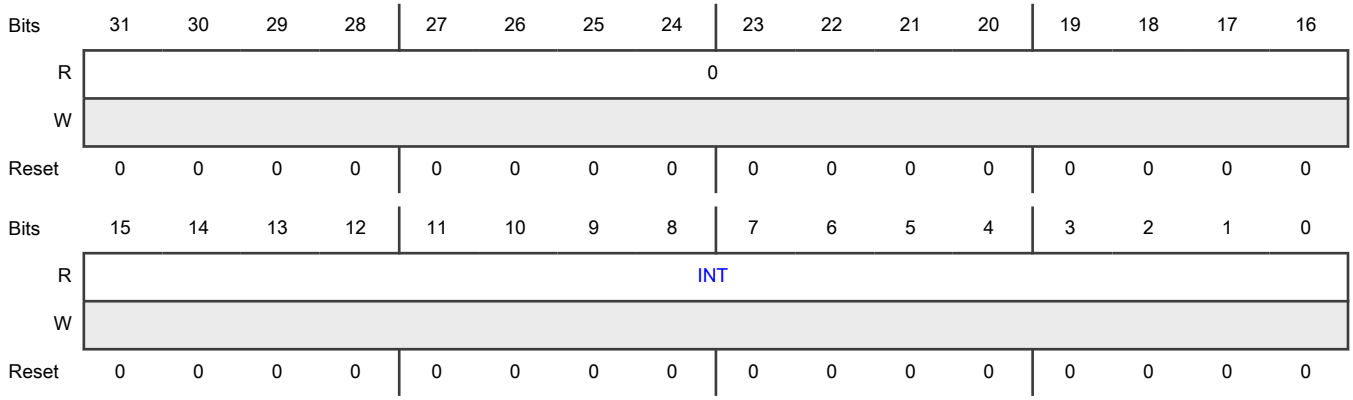
Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	on data transfer completion or an error condition. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

11.4.1.5 Management Page Hardware Request Status (MP_HRS)

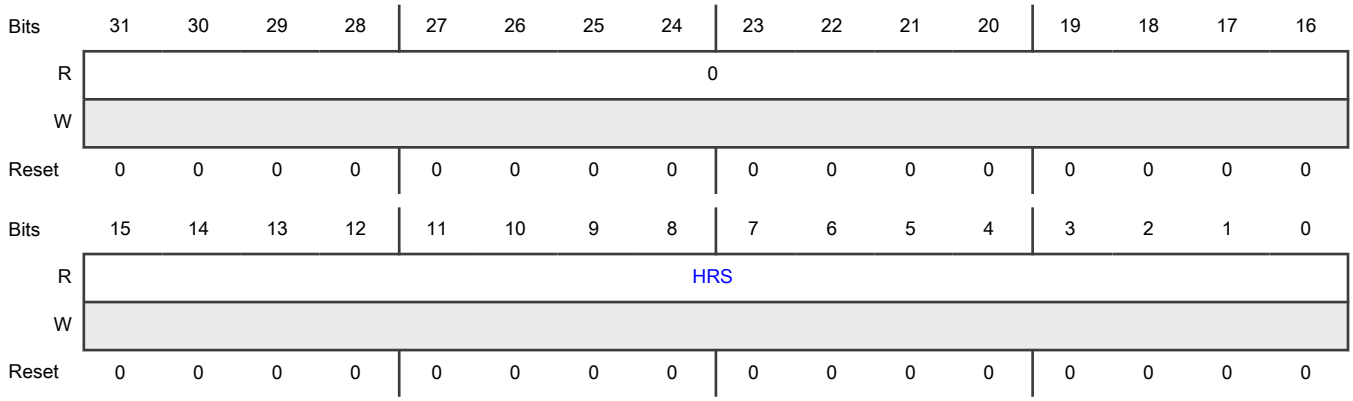
Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

11.4.1.6 Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)

Offset

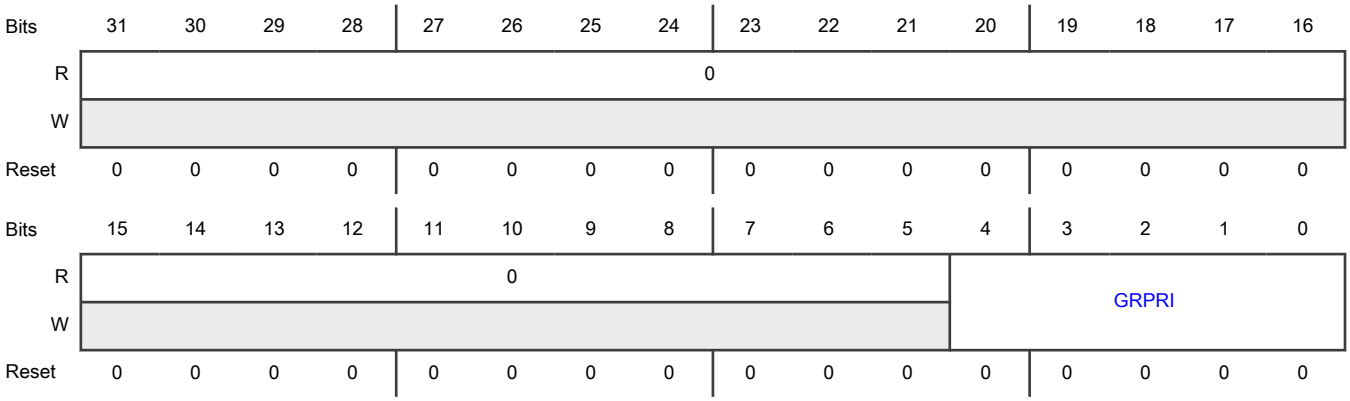
For n = 0 to 15:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 GRPRI	Arbitration Group For Channel n Fixed-priority arbitration group number.

11.4.2.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

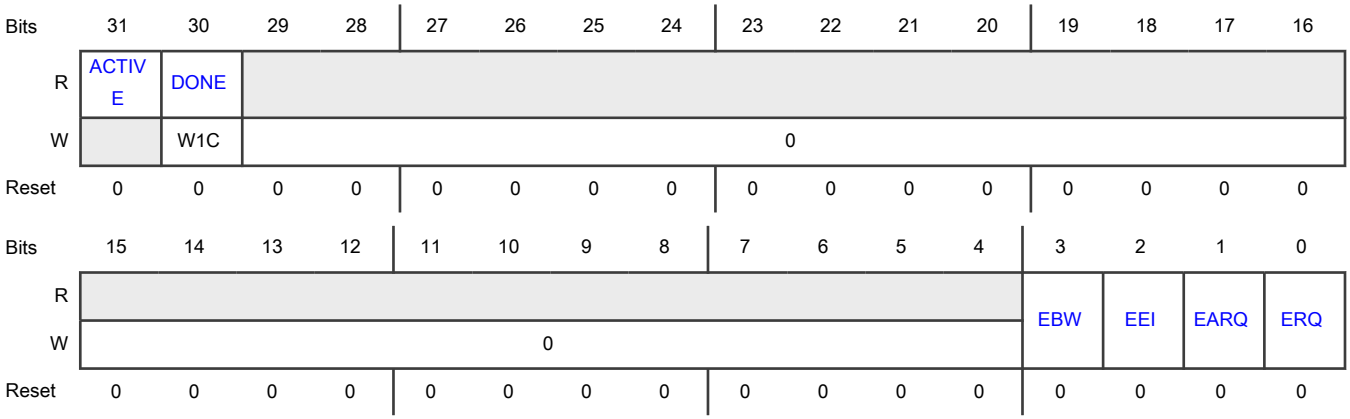
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

11.4.2.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field,

then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller. In addition, this enabled error status is logically OR'd onto the channel done interrupt, CHn_INT[INT], thus forming a done or error interrupt on a per channel basis.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

11.4.2.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion or an error condition.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Diagram

11.4.2.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

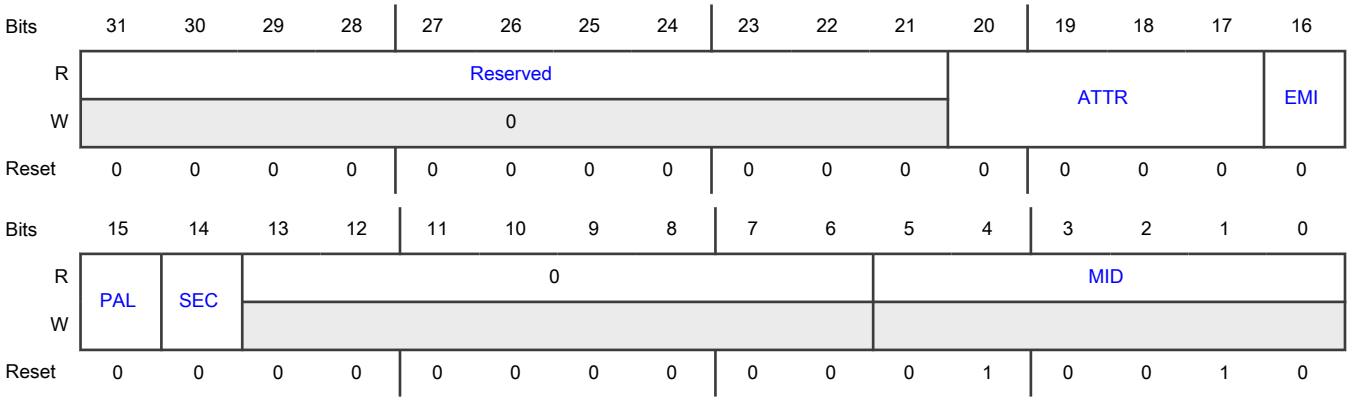
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, user protection level for DMA transfers is used. 0b - Initiator ID replication is disabled 1b - Initiator ID replication is enabled
15	Privileged Access Level

Table continues on the next page...

Table continued from the previous page...

Field	Function
PAL	This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-6 —	Reserved
5-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

11.4.2.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

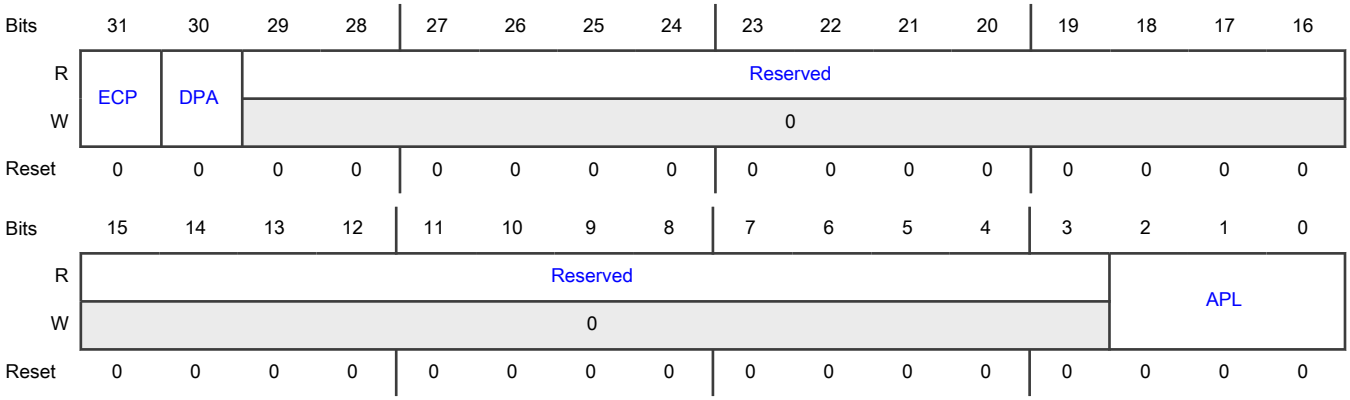
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

11.4.2.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

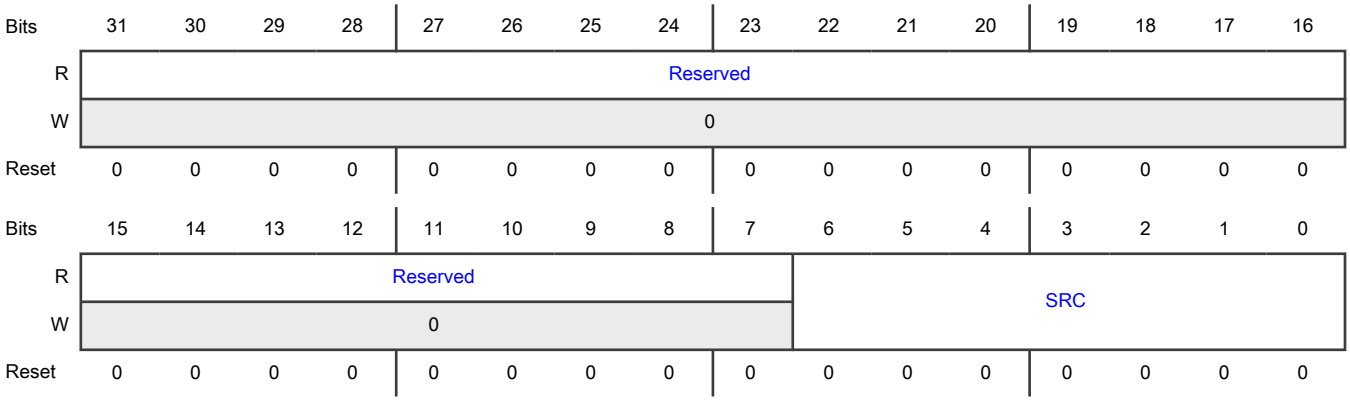
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

11.4.2.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

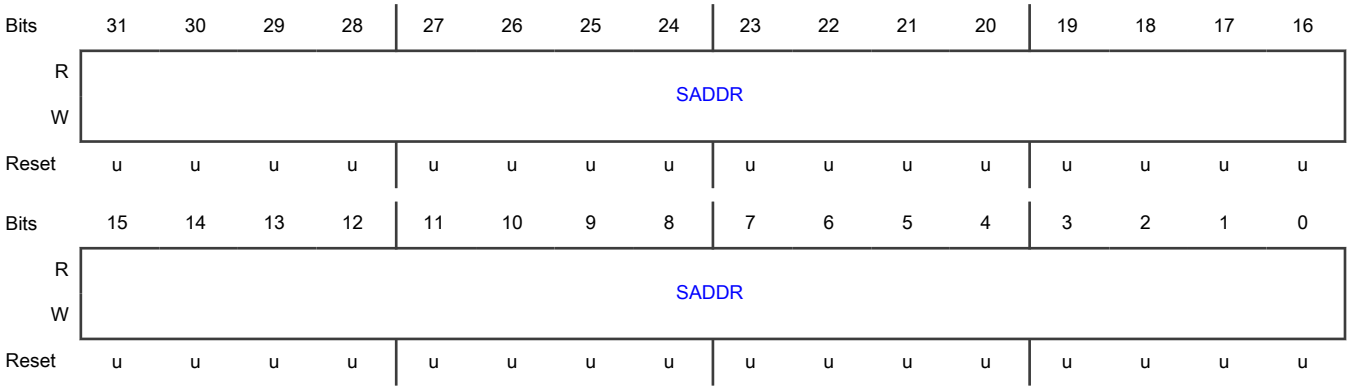
For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram



Fields

Field	Function
31-0 SADDR	Source Address Memory address pointing to the source data.

11.4.2.9 TCD Signed Source Address Offset (TCD0_SOFF - TCD15_SOFF)

Offset

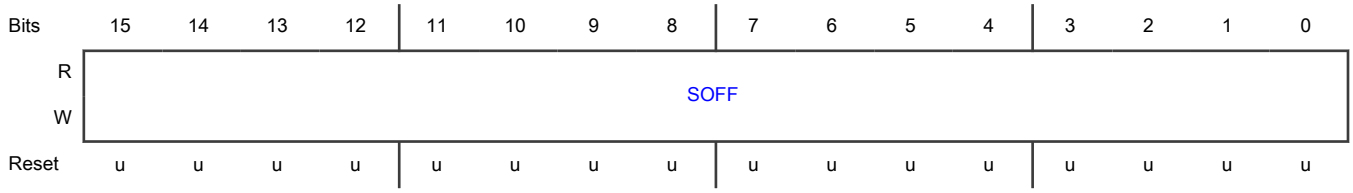
For n = 0 to 15:

Register	Offset
TCDn_SOFF	24h + (n × 1000h)

Function

This register contains the sign-extended value added to Source Address register after each read transaction.

Diagram



Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

11.4.2.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

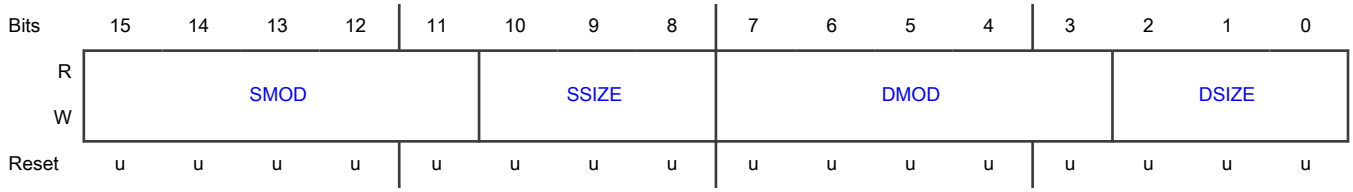
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - Reserved 111b - Reserved
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

11.4.2.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

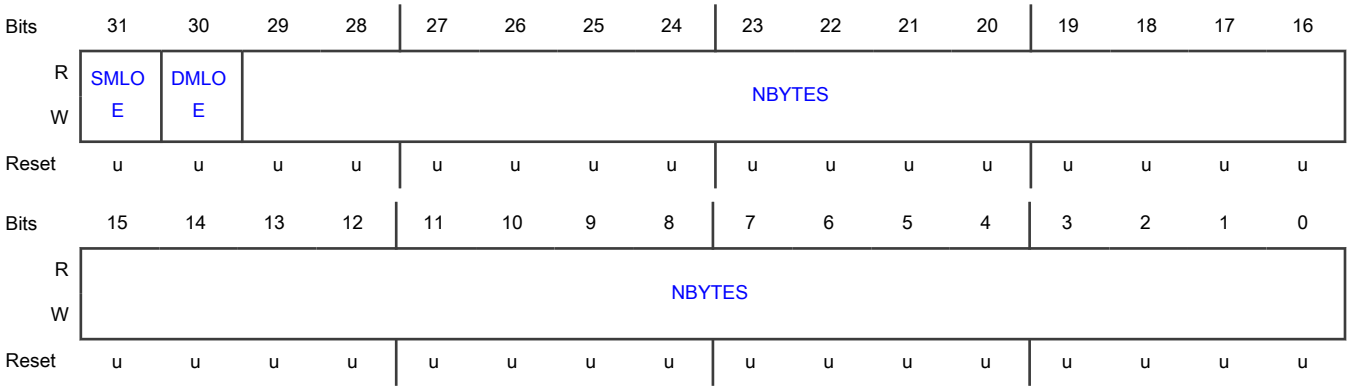
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0	Number of Bytes To Transfer Per Service Request

Table continues on the next page...

Table continued from the previous page...

Field	Function
NBYTES	Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

11.4.2.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

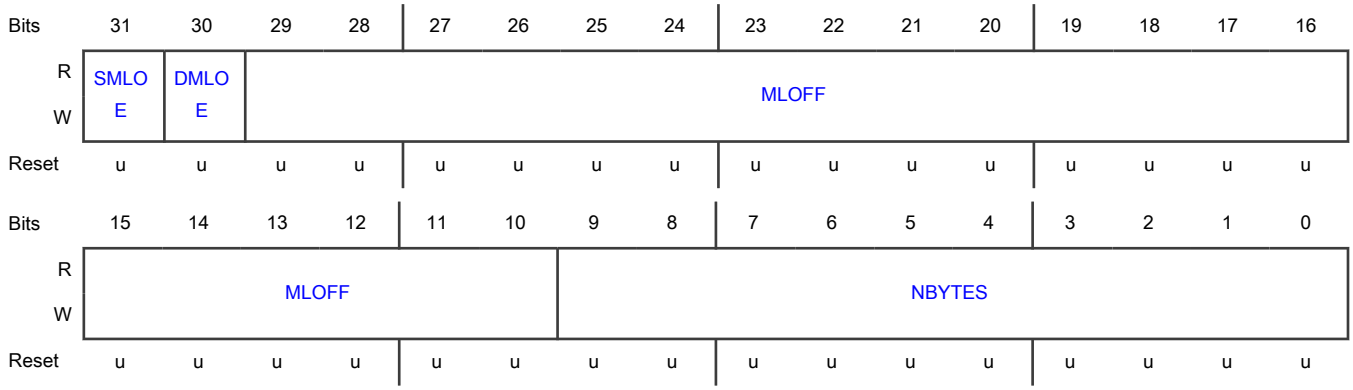
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

11.4.2.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

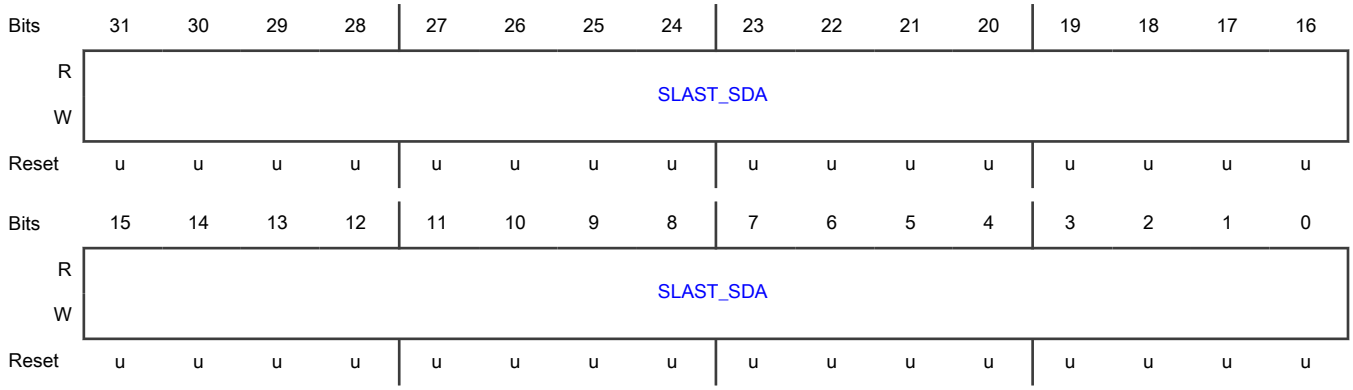
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

11.4.2.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

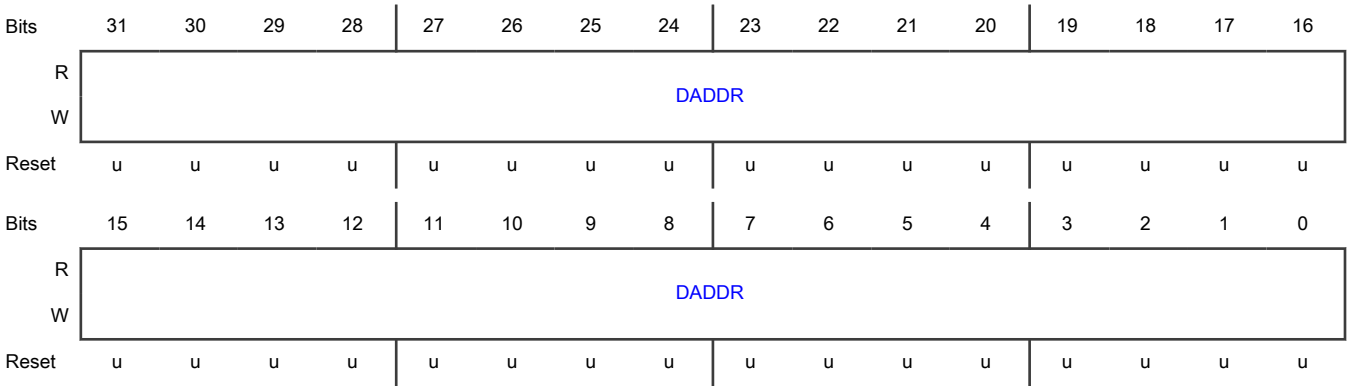
For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram



Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

11.4.2.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

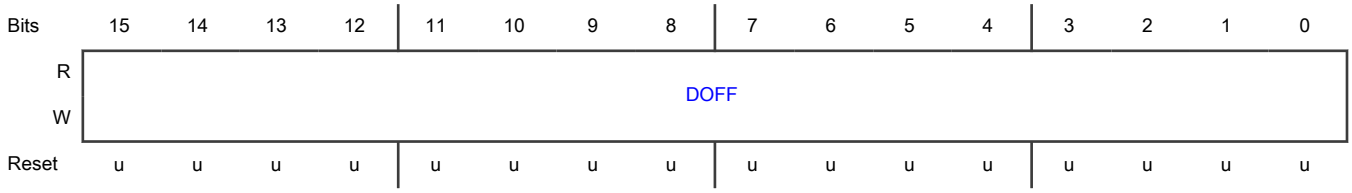
For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

11.4.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

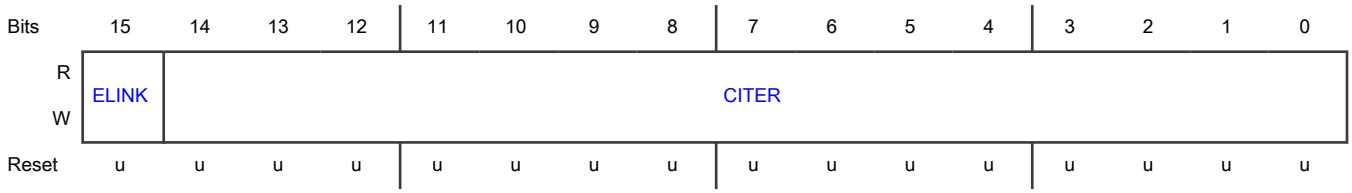
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

11.4.2.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

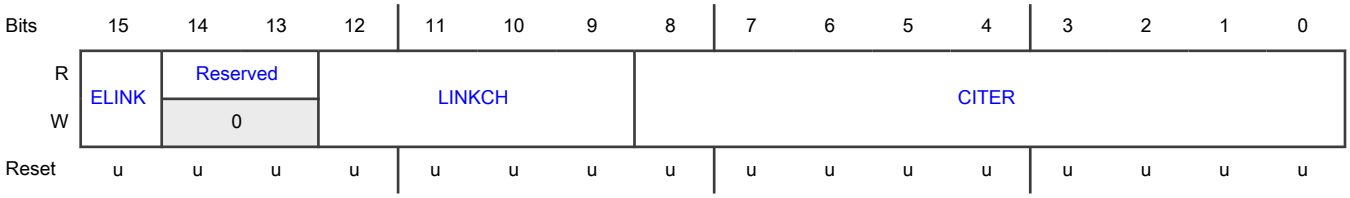
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

11.4.2.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

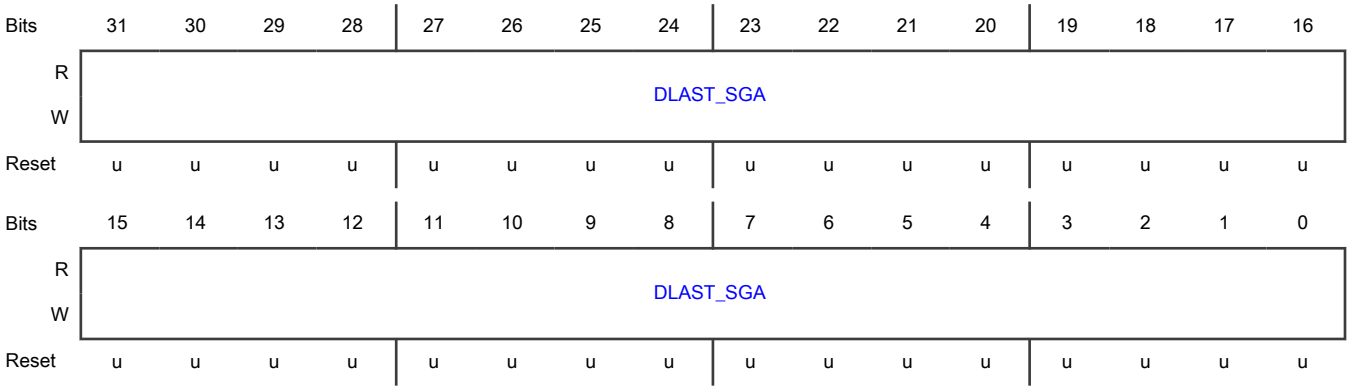
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

11.4.2.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWC				MAJORLINKCH				ESDA	EEOP	MAJO REL...	ESG	DREQ	INTHA LF	INTMA JOR	STAR T
W			0													
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled 1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2 INTHALF	Enable Interrupt If Major Counter Half-complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

11.4.2.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

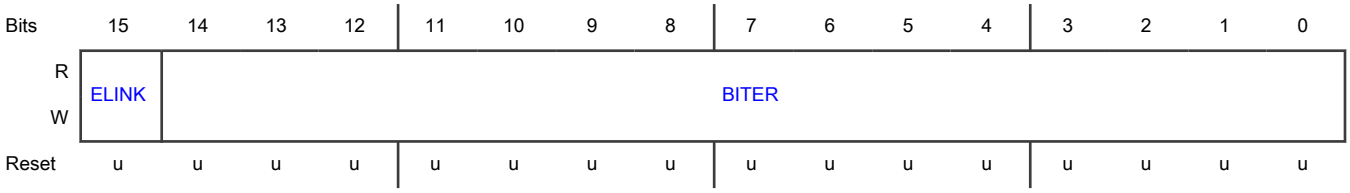
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

11.4.2.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

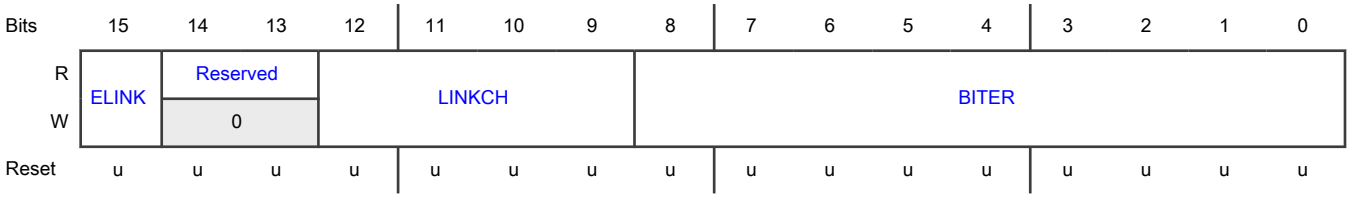
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0	Starting Major Iteration Count

Table continues on the next page...

Table continued from the previous page...

Field	Function
BITER	As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

11.5 External signals

This module has no external signals.

11.6 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

11.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.
3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: target device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 54, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 54. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing

Table continues on the next page...

Table 54. TCD control and status (TCDn_CSR) fields (continued)

TCDn_CSR field name	Description
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 55. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

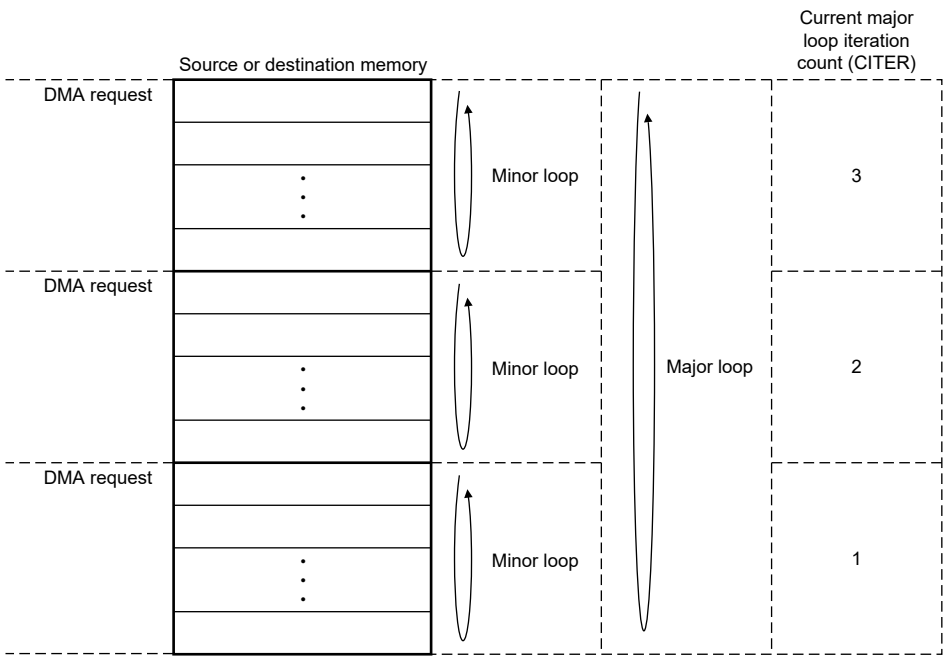


Figure 19. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

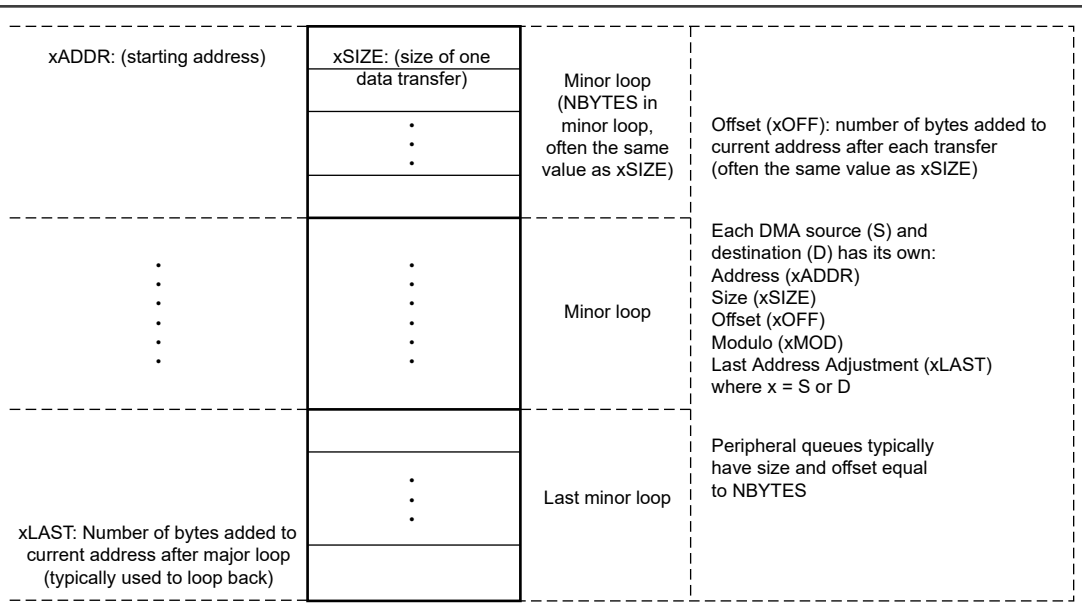

Figure 20. Memory array terms

11.6.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 56. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

11.6.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

11.6.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

11.6.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

11.6.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

11.6.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

11.6.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
```

```
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

11.6.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the target device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
h. Write 32 bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

11.6.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 57. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

11.6.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

11.6.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

11.6.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

11.6.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

11.6.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
MP_CSR[GCLC] = 1
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 58. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

11.6.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

Steps for channel linking:

1. Set GCLC = 1
2. For linking after major loop complete:
   a. Set MAJORLINKCH = target channel number
   b. Set MAJORELINK = 1, enable the major loop link
   c. Upon major loop completion (CITER decrements to 0), the link will be made.
3. For linking on minor loop completion:
   a. Set LINKCH = target channel number
   b. Set ELINK = 1, enable the minor loop link
   c. Set the beginning iteration count to the same values; LINKCH = target channel and ELINK = 1,
   d. Upon minor loop completion (that is, after each service request except when the major loop is complete) the link will be made.

11.6.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

11.6.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

11.6.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[MAJORELINK] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

11.6.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

11.6.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

11.6.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's

service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure.

11.6.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the DSPI is set as a initiator for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/DSPI transfer loop, perform the following steps:

1. Disable the DMA service request at the SPI.
2. Ensure there is no DMA service request from the DSPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

11.6.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

12.1.1 Module instances

This device has one instance of the MSCM module.

12.1.2 OCMDR1[OCMSZ]

This devices supports the following encoded values.

OCMEM Size. This read-only field provides an encoded value of the on-chip memory size.

0000b - no OCMEMn

0001b - 1KB OCMEMn

0010b - 2KB OCMEMn

0011b - 4KB OCMEMn

0100b - 8KB OCMEMn

0101b - 16KB OCMEMn

0110b - 32KB OCMEMn

0111b - 64KB OCMEMn

1000b - 96KB OCMEMn

1001b - 256KB OCMEMn

1010b - 512KB OCMEMn

1011b - 1MB OCMEMn

1100b - 2MB OCMEMn

1101b - 4MB OCMEMn

1110b - 8MB OCMEMn

1111b - 16MB OCMEMn

12.1.3 SID[FAMID]

This devices supports the following encoded values.

0001b- MCX W72

Others - Reserved

12.2 Overview

The Miscellaneous System Control Module (MSCM) contains CPU configuration registers and on-chip memory controller registers.

12.2.1 Block Diagram

The MSCM block diagram is shown below in Figure 21:

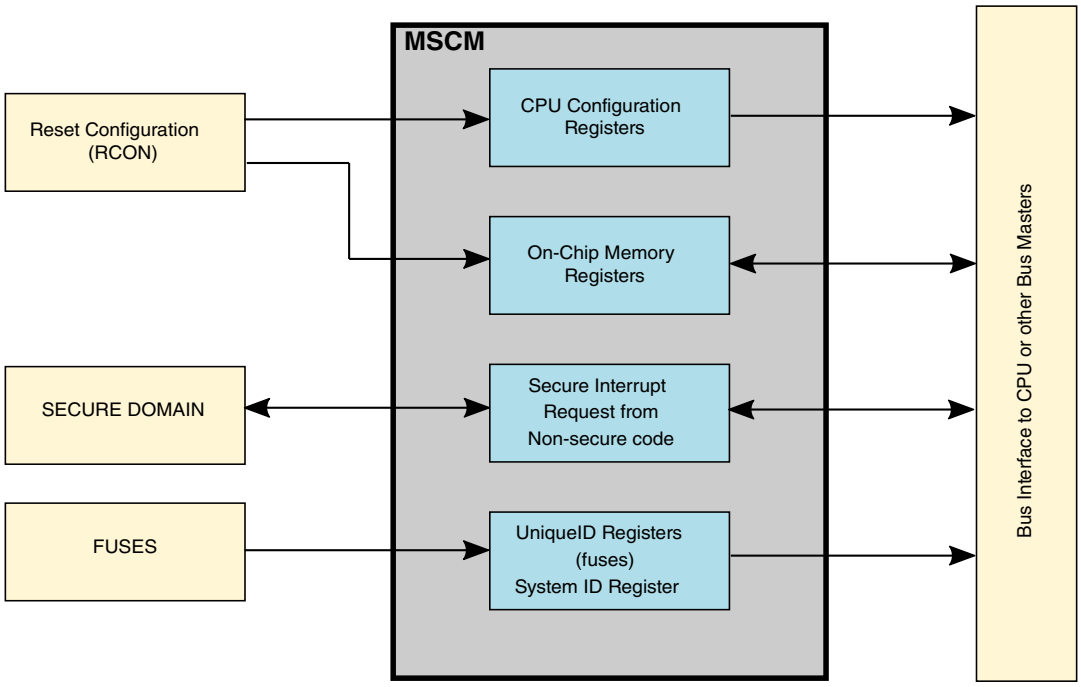

Figure 21. MSCM Block Diagram

12.2.2 Features

The MSCM has the following registers:

- Generic processor "x" configuration registers - These registers are only accessible by the main processor core
- Configuration registers containing information for processor 0 (main processor core) - These registers are accessible to any bus master
- On-Chip Memory Descriptor Registers - Provides static information about the attached memories. These registers are only accessible to the processor core or debugger
- Secure interrupt register - Provides a mechanism for non-secure code to generate a low latency pulsed exception into the secure privileged domain and can only be written in nonsecure mode
- Unique ID registers - Loaded directly from ECID fuse words
- System ID register - Loaded from IFR

12.3 Functional Description

12.3.1 Chip Configuration and Boot

The device's logical definition is controlled via chip-specific configuration bits, supported memory sizes and packing options. Collectively, these configuration bits define a reset configuration value (RCON).

Once the core has fetched the reset vector(s), core and system configuration information is read from a globally-accessible slave peripheral that properly converts the information into more appropriate values. More specifically, the core accesses configuration information from a common set of peripheral addresses and the chip configuration logic properly evaluates based on the requesting processor and returns the appropriate value for the given processor, including core identification.

As an example, there is a single 32-bit read-only location for the core identification. A 32-bit read from this location returns a 4-character ASCII string: 0x4D333301 .

The programming model associated with the core configuration information is included as part of the Miscellaneous System Control Module (MSCM). It specifically includes multiple views of the processor configuration; one view that is available generically to the core, and other views that are available to any bus masters in the system.

12.4 MSCM Memory Map/Register Definition

12.4.1 CPU Configuration Memory Map and Registers

The CPU configuration portion of the MSCM module provides a set of memory-mapped read-only addresses defining the processor set-up. This portion of the MSCM programming model can only be accessed with 32-bit read references; any other size is terminated with an error. If the processor is logically not included in the chip configuration, then reads of its configuration registers return zeroes.

The CPU Configuration registers are organized based on the logical processor number (not any type of physical port number) and partitioned into the following equal sections:

Table 60. CPU Configuration Register Sections

Offset addresses	Function
0x000 - 0x01F	Defines the generic processor "x" configuration. This region is only accessible to the processor core; reads by non-core bus masters are treated as read-as-zero (RAZ) accesses.
0x020 - 0x03F	Defines the configuration information for processor 0 (CP0). This region is accessible to any bus master.

12.4.2 MSCM register descriptions

12.4.2.2 Processor X Type Register (CPxTYPE)

Offset

Register	Offset
CPxTYPE	0h

Function

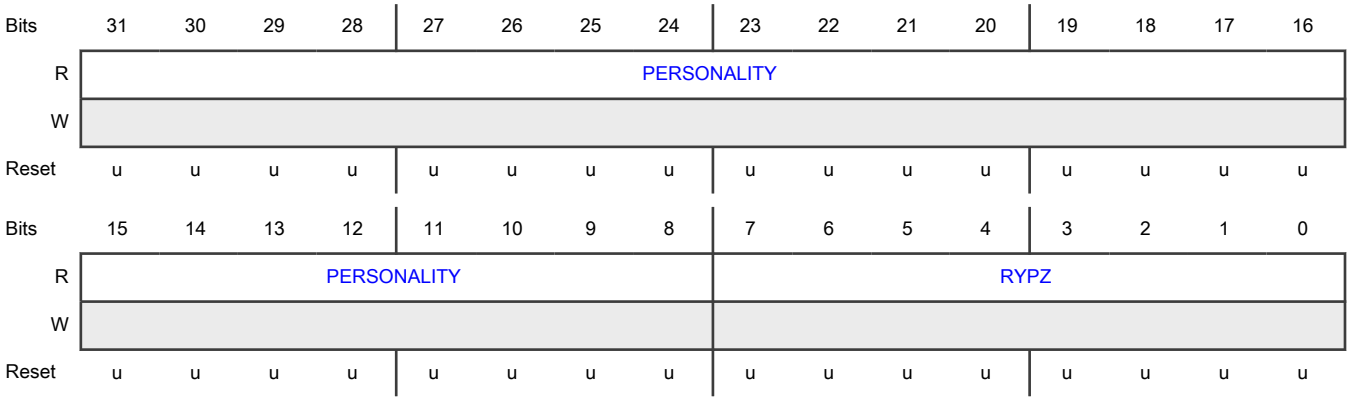
The register provides a CPU-specific response indicating the personality of the core making the access. The 32-bit response includes 3 ASCII characters that define the CPU type, along with a byte that defines the logical revision number. The logical revision number follows Arm's rYpZ nomenclature.

NOTE

CPxTYPE value(s) for this device:

- If CPU0 is making the access, then the value read is 0x4D333301
- If the read access is not from a CPU, then the value read is 0x00000000

Diagram



Fields

Field	Function
31-8 PERSONALITY	Processor x Personality This read-only field defines the processor personality for CPUx
7-0 RYPZ	Processor x Revision This read-only field defines the processor revision for CPUx: 0x00 corresponds to the r0p0 core release. 0x01 corresponds to the r0p1 core release. ...

12.4.2.3 Processor X Number Register (CPxNUM)

Offset

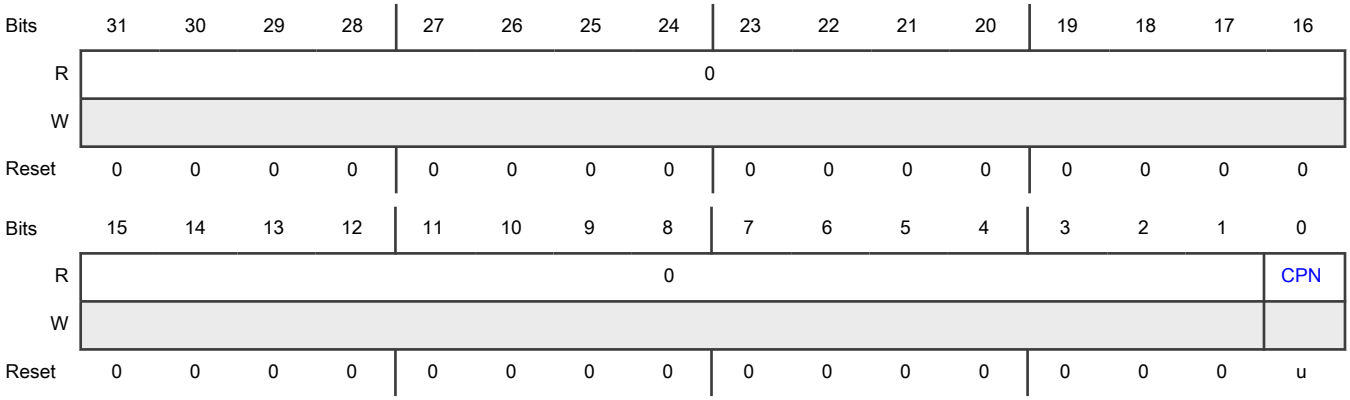
Register	Offset
CPxNUM	4h

Function

The register provides a CPU-specific response indicating the logical processor number of the core making the access. The logical processor number is always 0.

If the read access is not from a CPU, then the value read is 0x00000000.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CPN	Processor x Number This zero-filled word defines the logical processor number for CPUx If single core configuration, then CPN = 0

12.4.2.4 Processor X Master Register (CPxMASTER)

Offset

Register	Offset
CPxMASTER	8h

Function

The register provides a CPU-specific response indicating the physical bus master number of the core that is making the access. The 32-bit response defines the physical master number for processor x.

- CPxMASTER = 0x00000000

NOTE

A read from a CPU returns the appropriate processor information. Reads from a non-CPU bus master returns all zeroes. Write accesses are terminated with an error.

12.4.2.6 Processor X Configuration Register 0 (CPxCFG0)

Offset

Register	Offset
CPxCFG0	10h

Function

The CPxCFG0 register provides a CPU-specific response detailing configuration information, in this case, information on the Level 1 caches (if present).

NOTE

Reset values for the Processor X Configuration Register 0:

- For CPU0, the CPxCFG0 value read is 0x05080000
- If the read access is not from a CPU, then the value read is 0x00000000

Fields

Field	Function
31-10 —	Reserved
9-8 SBP	System Bus Ports This field defines the number of physical connections to the system bus fabric for this processor.
7 —	Reserved
6 BB	Bit Banding This field defines if the processor supports "bit banding". 0b - Bit Banding is not supported.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Bit Banding is supported.
5 CMP	Core Memory Protection unit This field indicates if the core memory protection hardware is included in the processor. 0b - Core Memory Protection is not included. 1b - Core Memory Protection is included.
4 TZ	Trust Zone This field indicates if the Trust Zone capabilities are supported in the processor. 0b - Trust Zone support is not included. 1b - Trust Zone support is included.
3 MMU	Memory Management Unit Memory Management Unit. This field indicates if the virtual memory management capabilities are supported in the processor. 0b - MMU support is not included. 1b - MMU support is included.
2 JAZ	Jazelle support This field indicates if Jazelle hardware is supported in the processor. 0b - Jazelle support is not included. 1b - Jazelle support is included.
1 SIMD	SIMD/NEON instruction support This field indicates if the instruction set extensions supporting SIMD and/or NEON capabilities are supported in the processor. 0b - SIMD/NEON support is not included. 1b - SIMD/NEON support is included.
0 FPU	Floating Point Unit This field indicates if hardware support for floating point capabilities are supported in the processor. 0b - FPU support is not included. 1b - FPU support is included.

12.4.2.18 On-Chip Memory Descriptor Register (OCMDR0)

Offset

Register	Offset
OCMDR0	400h

Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- The access permissions for this module are set in the TRDC.
- 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Writes from other bus masters are ignored.
- Any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

OCMDRn	Reset Value	On-Chip Memory Type
OCMDR0	0xEC089000	Program Flash
OCMDR1	0xD8047000	ROM
OCMDR2	0xE5041000	System RAM

12.4.2.24 On-Chip Memory Descriptor Register (OCMDR6)

Offset

Register	Offset
OCMDR6	418h

Function

This section of the programming model is an array of 32-bit generic on-chip memory descriptor registers that provide static information about the attached memories, as well as configurable controls (where appropriate).

- The access permissions for this module are set in the TRDC.
- 32-bit reads from a processor core or the debugger return the appropriate processor information.
- Reads from any other bus master return all zeroes.
- Writes from a processor core or the debugger to writeable registers update the appropriate fields.
- Writes from other bus masters are ignored.
- Any access with a size other than 32 bits are terminated with an error.

The following table describes the OCMDRn reset values and the associated memory type:

OCMDRn	Reset Value	On-Chip Memory Type
OCMDR0	0xEC089000	Program Flash
OCMDR1	0xD8047000	ROM
OCMDR2	0xE5041000	System RAM

12.4.2.25 Secure Interrupt Request (SECURE_IRQ)

Offset

Register	Offset
SECURE_IRQ	800h

Function

The SECURE_IRQ register provides a mechanism for non-secure code to generate a low latency pulsed exception into the secure privileged domain. This register is accessible in a non-secure peripheral address slot that non-secure code can write a specific value that forces an interrrupt that executes as a secure exception and enters the secure domain.

This register can only be written in both, secure mode or non-secure mode.

Diagram

Chapter 13
Miscellaneous Control Module (MCM)

13.1 Chip-specific MCM information

Table 61. Reference links to related information

Topic	Related module	Reference
Full description	MCM	MCM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Cache	LPCAC	Low Power Cache Controller (LPCAC)

13.1.1 Module instances

This device has one instance of the MCM module.

13.1.2 LMFATR[PEFSYN]

LMFATR[PEFSYN] field indicates the master that accesses the cache when the LMEM fault is detected.

- 0x0 - Core
- 0x1 - Debug tool
- Others - Reserved

13.1.3 ISCR[CWBEE]

In this device, the ISCR[CWBEE] must be configured as 0.

13.1.4 CPCR2

In this device, When configure the CPCR2[DCBC] to disable cache, also need clear cache with CPCR2[CCBC].

NOTE

After the cache is enabled, you must first disable it before clearing it to avoid subsequent accesses to miss the cache.

13.2 Overview

MCM provides many miscellaneous control functions.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 62. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

13.2.1 Features

- Error status and interrupts for the cache write buffer
- Error status and interrupts for the core's floating-point unit (FPU)

13.3 Functional description

13.3.1 Clocking

This module has no clocking considerations.

13.3.2 Interrupts

MCM generates an interrupt if any of the following is true:

- FPU input denormal interrupt is enabled (ISCR[FIDCE] = 1) and an input is denormalized (ISCR[FIDC] = 1).
- FPU inexact interrupt is enabled (ISCR[FIXCE] = 1) and a number is inexact (ISCR[FIXC] = 1).
- FPU underflow interrupt is enabled (ISCR[FUFCE] = 1) and an underflow occurs (ISCR[FUFC] = 1).
- FPU overflow interrupt is enabled (ISCR[FOFCE] = 1) and an overflow occurs (ISCR[FOFC] = 1).
- FPU divide-by-zero interrupt is enabled (ISCR[FDZCE] = 1) and a divide-by-zero occurs (ISCR[FDZC] = 1).
- FPU invalid operation interrupt is enabled (ISCR[FIOCE] = 1) and an invalid operation occurs (ISCR[FIOC] = 1).
- A PC data parity error occurs.
- A PC tag parity error occurs.
- A cache write buffer error occurs.

See Determining the source of the interrupt for more details.

13.4 External signals

This module has no external signals.

13.5 Application information

13.5.1 Determining the source of the interrupt

To determine the exact source of the interrupt, check the interrupt status flags with the corresponding interrupt enable fields.

1. Read the fields located in ISCR[31:16] and in ISCR[15:0].
2. Search the result for asserted flags, which indicate the exact interrupt sources.

NOTE

Parity interrupts are determined by LMEPECR (interrupt enable) and LMPEIR (interrupt source).

13.6 Memory map and register descriptions

The memory map and register descriptions below describe the registers using byte addresses.

NOTE

All MCM registers support only 32-bit writes. Any attempted 8-bit or 16-bit writes will result in undefined behavior.

13.6.1 MCM register descriptions

13.6.1.1 MCM memory map

MCM base address: E008_0000h

Offset	Register	Width (In bits)	Access	Reset value
Ch	Core Platform Control (CPCR)	32	RW	See section
10h	Interrupt Status and Control (ISCR)	32	RW	0000_0000h
20h	Write Buffer Fault Address (FADR)	32	R	See section
24h	Store Buffer Fault Attributes (FATR)	32	R	See section

15-11 —	Reserved
10 —	Reserved
9 CBRR	Crossbar Round-robin Arbitration Enable This field configures the crossbar target ports to fixed-priority or round-robin arbitration. 0b - Fixed-priority arbitration 1b - Round-robin arbitration
8-0 —	Reserved

13.6.1.3 Interrupt Status and Control (ISCR)

Offset

Register	Offset
ISCR	10h

Function

Configures and reports the status of core-related interrupt exception conditions. The individual event indicators are first checked with their exception enables and then logically summed to form an interrupt request sent to the core's NVIC.

The fields in bits 15–8 are indicator flags based on the processor's FPSCR register. Attempted writes to these fields are ignored. After the flags are set, they remain set until you write 0 to the corresponding FPSCR field.

The fields in bits 31–24 control the interrupt enablement. If you write 1 to an interrupt enablement control field, MCM generates an interrupt when the corresponding status field is 1.

23-22 —	Reserved
21 CPEE	Cache Parity Error Enable This field enables the generation of an interrupt in response to the cache parity error. 0b - Disable 1b - Enable
20 CWBEE	Cache Write Buffer Error Enable Enables the generation of an interrupt in response to a bus error termination reported on a system bus transfer that has been initiated from the cache's write buffer. 0b - Disable 1b - Enable
19-16 —	Reserved
15 FIDC	FPU Input Denormal Interrupt Status Contains a copy of the core's FPSCR[IDC] and indicates that an input denormalized number has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IDC]. 0b - No interrupt 1b - Interrupt occurred
14-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 FIXC	FPU Inexact Interrupt Status Contains a copy of the core's FPSCR[IXC] and indicates that an inexact number has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IXC]. 0b - No interrupt 1b - Interrupt occurred
11 FUFC	FPU Underflow Interrupt status Contains a copy of the core's FPSCR[UFC] and indicates that an underflow has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[UFC]. 0b - No interrupt 1b - Interrupt occurred
10 FOFC	FPU Overflow Interrupt Status Contains a copy of the core's FPSCR[OFC] and indicates that an overflow has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[OFC]. 0b - No interrupt 1b - Interrupt occurred
9 FDZC	FPU Divide-by-Zero Interrupt Status Contains a copy of the core's FPSCR[DZC] and indicates that a divide-by-zero has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[DZC]. 0b - No interrupt 1b - Interrupt occurred
8 FIOC	FPU Invalid Operation Interrupt Status Contains a copy of the core's FPSCR[IOC] and indicates that an illegal operation has been detected in the processor's FPU. After this field becomes 1, it remains 1 until you write 0 to FPSCR[IOC]. 0b - No interrupt 1b - Interrupt occurred
7-6 —	Reserved
5 CPES	Cache Parity Error Status Indicates whether a cache parity error is detected. You can write 1 to this field only when the corresponding enable field (CPEE) is 1. 0b - Not detected 1b - Detected
4	Cache Write Buffer Error Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
CWBER	Indicates whether a data transfer from the core's cache write buffer was terminated because of a bus error. This field can become 1 only when the corresponding enable field (ISCR[CWBEE]) = 1. The corresponding core fault address, attributes, and write data are typically retrieved from Write Buffer Fault Address (FADR), Store Buffer Fault Attributes (FATR), and Store Buffer Fault Data (FDR) registers during the interrupt handler before clearing the CWBER flag. 0b - No error 1b - Error occurred
3-1 —	Reserved
0 —	Reserved

13.6.1.4 Write Buffer Fault Address (FADR)

Offset

Register	Offset
FADR	20h

Function

Captures the faulty address if a properly enabled cache write buffer error interrupt event is detected.

MCM captures a single cache write buffer bus error event. If a subsequent error is detected before the captured error information has been read from the corresponding registers and ISCR[CWBER] is 0, then FATR[BEOVR] becomes 1. However, no additional information is captured.

MCM writes 1 to the field in this register when ISCR[CWBER] is 1. Attempted writes have no effect.

31-0 ADDRESS	Fault Address Contains the faulty address if a properly enabled cache write buffer error interrupt event is detected.

13.6.1.5 Store Buffer Fault Attributes (FATR)

Offset

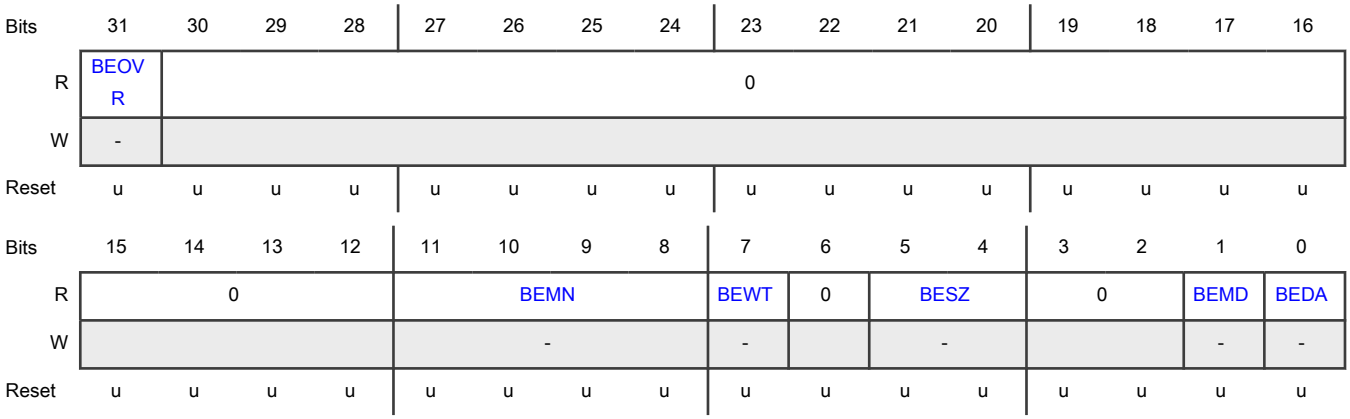
Register	Offset
FATR	24h

Function

Indicates the faulty attributes if a properly enabled cache write buffer error interrupt event is detected.

MCM writes values to the fields in this register when ISCR[CWBER] is 1b. Your attempted writes have no effect.

Diagram



Fields

Field	Function
31 BEOVR	Bus Error Overrun Indicates if another cache write buffer bus error is detected before system software has retrieved all the error information from the original event. The time window is from the detection of the original cache write buffer error termination to the time when you write 1 to ISCR[CWBER] to clear it and rearm the capture logic. MCM writes 1 to this field and it becomes 0 whenever you write 1 to ISCR[CWBER]. Write Buffer Fault Address (FADR), Store Buffer Fault Data (FDR), and the other FATR fields do not update to reflect this new bus error.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No overrun 1b - Overrun
30-12 —	Reserved
11-8 BEMN	Bus Error Initiator Number Indicates the crossbar switch bus initiator number of the captured cache write buffer bus error.
7 BEWT	Bus Error Write Indicates the type of system bus access when the cache write buffer error was detected. 0b - Read 1b - Write
6 —	Reserved
5-4 BESZ	Bus Error Size Indicates the size of the cache write buffer access when the error was detected. 00b - 8-bit 01b - 16-bit 10b - 32-bit 11b - Reserved
3-2 —	Reserved
1 BEMD	Bus Error Privilege Level Indicates the privilege level of the cache write buffer access when the error was detected. 0b - User mode 1b - Supervisor or privileged mode

13.6.1.6 Store Buffer Fault Data (FDR)

Offset

Register	Offset
FDR	28h

Function

Indicates the captured faulty data, when a properly enabled cache write buffer error interrupt event is detected.

MCM writes 1 to DATA when ISCR[CWBER] is 1. Only the accessed byte lanes contain valid data for byte and halfword writes. Contents of the other bytes are undefined. Attempted writes have no effect.

Chapter 14
Memories

14.1 Introduction

This chapter presents the hierarchical memory architecture and descriptions of memory modules available in this device. This chapter also details bus master access latency to the memory modules in the system where it is applicable.

14.2 Memory architecture

The memory architecture supports a wide range of applications and maximizes performance while maintaining low power consumption.

14.3 Memory hierarchy

The memory hierarchy is an arrangement of different types of memories with different capacities and operating speeds, to approximate the ideal memory behavior in a cost-efficient way. The following figure shows the memory hierarchical architecture implemented on this device.

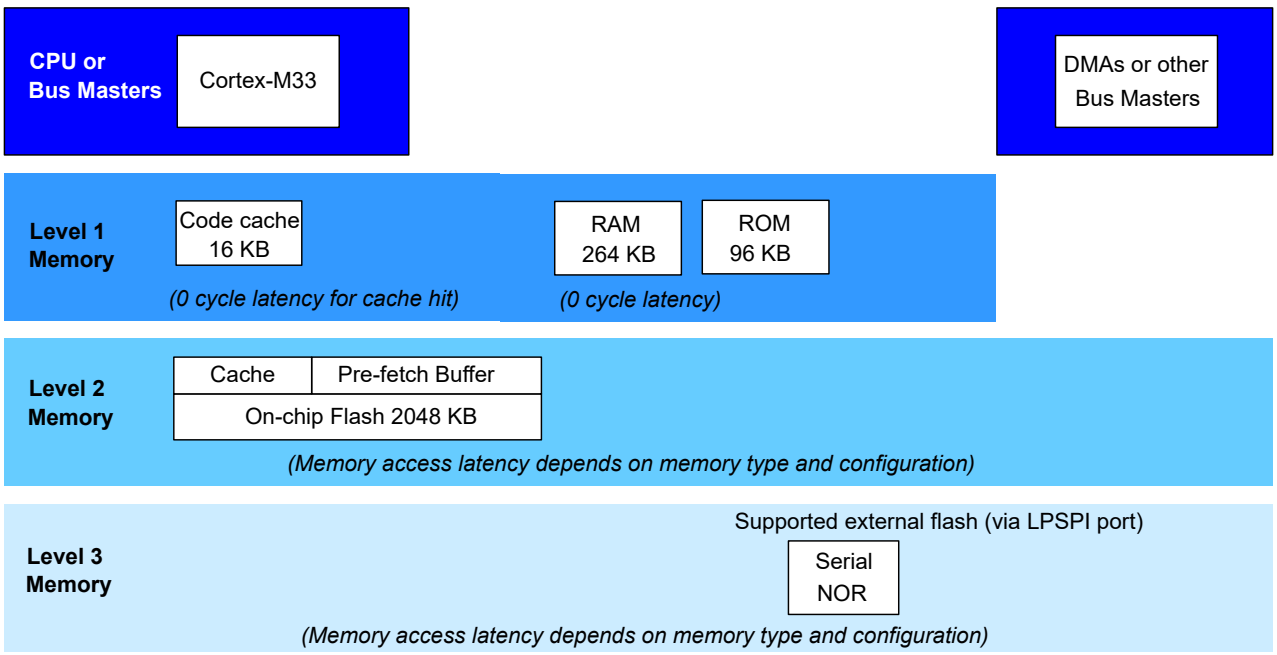

Figure 22. Memory hierarchy

14.4 TCM SRAMs

The core's local Tightly Coupled Memory (TCM) consists of two logical arrays, Code TCM (CTCM) and System TCM (STCM).

14.4.1 TCM SRAM configurations

- The CTCM is 32 KB
  - CTCM array 0: 16 KB
  - CTCM array 1: 16 KB

- The STCM is 232 KB
  - STCM array 0: 16 KB
  - STCM array 1: 16 KB
  - STCM array 2: 32 KB
  - STCM array 3: 32 KB
  - STCM array 4: 32 KB
  - STCM array 5: 32 KB
  - STCM array 6: 32 KB
  - STCM array 7: 32 KB
  - STCM array 8: 8 KB

The address ranges of the TCMs are provided in the TCM arrays section

14.4.2 TCM SRAM retention

The TCM SRAMs can be retained in Sleep, Deep Sleep, and Power Down modes. Each instantiated block of TCM SRAM can be individually power gated. This allows the user to achieve the proper balance of power savings versus data retention.

Entering Deep Power Down mode will automatically power gate all of the SRAM instantiations, and all data is lost.

The last 8 KB RAM (0x2003_8000) is from independent power switch domain which can keep data retention in all power modes.

The first 16 KB of STCM (STCM0) is reserved for ROM use, and it will be initialized when waking up from Power Down mode

14.5 L1 Cache

A cache is a block of high-speed memory locations containing address information, which is commonly known as a tag, and the associated data. The purpose is to decrease the average time of a memory access to lower-level memory. The primary cache, or Level 1 (L1) cache, resides close to the CPU and is used for temporary storage of instructions and data organized in blocks of cache-line size.

This device implements one instance of L1 - the Code cache. The Code cache is accessible through the Code bus of Cortex-M33 core.

14.5.1 L1 cache principles

L1 caches operate on two principles of locality:

- Spatial locality - An access to one location is likely to be followed by accesses to adjacent locations, such as when executing sequential instructions or accessing a data structure. The spatial locality property is used to group several locations together using the same tag. This logical block is commonly known as a cache line.
- Temporal locality - An access to an area of memory is likely to be repeated within a short time period, such as when executing a code loop.

14.5.2 L1 cache features

Each L1 cache instance has following features:

- 16 KB cache array
- 32-bit wide SRAM for data storage
- Register based tags
- 8-way set associative
- 4-word (or 16-byte) lines

- Performs 4-beat, 32-bit wrapped burst to fetch 16 bytes of the cache line when a read misses
- Entire cache can be flushed at once

14.5.3 Cache policies

The following cache interaction policies with lower-level memories are applied to the Code cache:

- Write Through (WT) - accesses to address spaces with this cache mode are cacheable.
  - A read miss in the cache causes a line read of a 16-byte aligned memory address containing the desired address in the lower-level memory. This miss data is loaded into the cache and is marked as valid and not modified.
  - A read hit to a valid cache location returns data from the cache with no bus access to lower-level memory.
  - A write miss bypasses the cache and writes to the lower-level memory; that means no allocate on write miss policy for write-through mode spaces.
  - A write hit updates the cache hit line with the write data and writes to the desired address in the lower-level memory.
- Non-Cacheable (NC) - accesses to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the lower-level memory directly.

14.5.4 Cache control

In normal operation, caches are self-managing, with the updates occurring automatically on demand. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from lower-level memory.

The Code Cache doesn't have a programming model; all control comes from the Miscellaneous Control Module (MCM). The MCM has cache enable, cache clear, and cache force-no-allocate mode control per cache instance.

14.5.5 Low Power

The caches can be put in state retention or powered down in any of low power modes. The caches need to be flushed before being powered down. This affects the time it takes for the system to transition into the new power mode.

14.6 Read Only Memory (ROM)

The internal ROM memory is used to store the boot code and time-critical software library routines. After a reset, the Cortex-M33 processor starts its code execution from this memory.

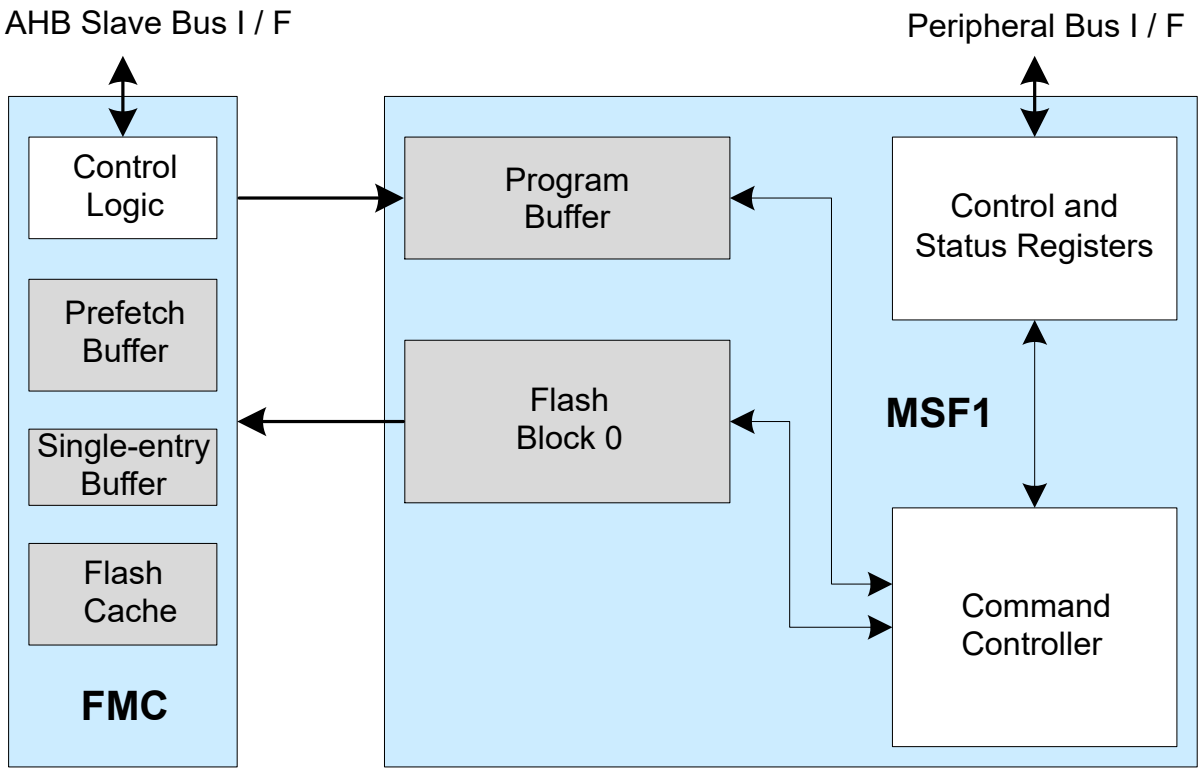
14.6.1 ROM size

The Boot ROM of this device is 96 KB.

14.7 Internal flash

This device embeds 2.00 MB of flash.

The following figure shows the high-level block diagram of the on-chip flash.



14.7.1 Flash memory controller

The Flash Memory Controller (FMC) manages accesses performed by the bus masters of the system to the flash memory. The FMC accelerates flash memory transfers to allow program code execution at higher clock frequency than flash memory.

The FMC provides three separate mechanisms for accelerating read operations to the flash memory:

- A single-entry 128-bit buffer, which can store previously accessed flash memory
- A 128-bit prefetch buffer, which can prefetch the next 128-bit flash memory location
- A 64-Byte cache organized as a one set, four way associative cache with 128-bit (or 16-Byte) size entries.

Note the FMC has no visibility into flash memory erase and program cycles because the Flash Memory module manages them directly.

14.7.1.1 Single entry buffer

The width of the bus between the FMC and the flash blocks is 128-bit. A single read of the flash will return an entire bus width worth of data. Because the flash bus is wider than the master's bus, the Single-Entry Buffer is used to store data from the last flash read for quick access times on subsequent reads if the buffer is hit.

The FMC provides invalidation control for the Single-Entry Buffer.

14.7.1.2 Prefetch buffer

When speculative reads are enabled, the FMC immediately requests the next sequential address after a read completes. The next 128-bit memory location is read and placed in the Prefetch Buffer. The speculative prefetch mechanism improves performance by reducing or even eliminating wait states when accessing sequential code and/or data.

Speculative prefetching is programmable for each bank of memory. The FMC provides invalidation control for the Prefetch Buffer.

14.7.1.3 Flash cache

Cache memory stores already executed code. This code is immediately available for repeated execution without any wait states, if needed.

The FMC provides controls for flash replacement algorithm, lock per way, and invalidation per way. The ways are numbered 0-3 and the sets are numbered 0-3. The cache supports Least Recently Used (LRU) replacement algorithm per set across all 4 ways.

The cache entries, both data and tag/valid, can be read at any time.

Software is required to maintain memory coherence when any segment of the flash cache is programmed. For example, all buffer data associated with the reprogrammed flash should be invalidated. Accordingly, cache program visible writes must occur after a programming or erase event is completed and before the new memory image is accessed.

Chapter 15
ROM Bootloader

15.1 Introduction

ROM bootloader is the boot code resident in the internal read-only memory (ROM). The ROM bootloader begins its execution when the Cortex-M33 processor is released from reset. This chapter highlights the features supported by the bootloader and describes its execution flow logic.

15.2 Boot ROM

In this device, the ROM bootloader supports automated booting from internal flash and downloading image from serial interface (LPUART, LPI2C, LPSPI).

The ROM bootloader is in the memory region starting from the address 0x1480 0000. The following diagram shows the memory map in-use during ROM execution. The first 32 KB of STCM (0x30000000 – 0x30008000) needs to be reserved for ROM bootloader execution and some ROM API execution. Please note that STCM has ECC enabled. To avoid STCM ECC error, users must always program word-aligned data to word-aligned address before reading.

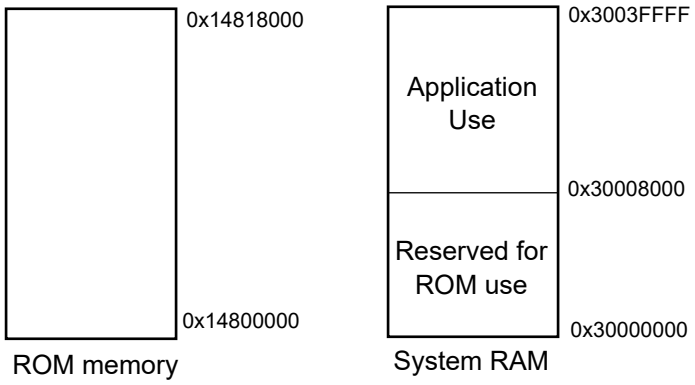


Figure 23. ROM bootloader memory usage

There are several alternate paths through the ROM bootloader:

- Normal boot path with security and TrustZone Mode (TZ-M) option.
- In-system programming (ISP) path.
- Debugger mailbox path which supports debug authentication.

The decision about which path to take depends on fuses, boot configuration in user IFR, boot pin, debug request and low power wakeup configuration. Figure below shows the top-level boot flow.

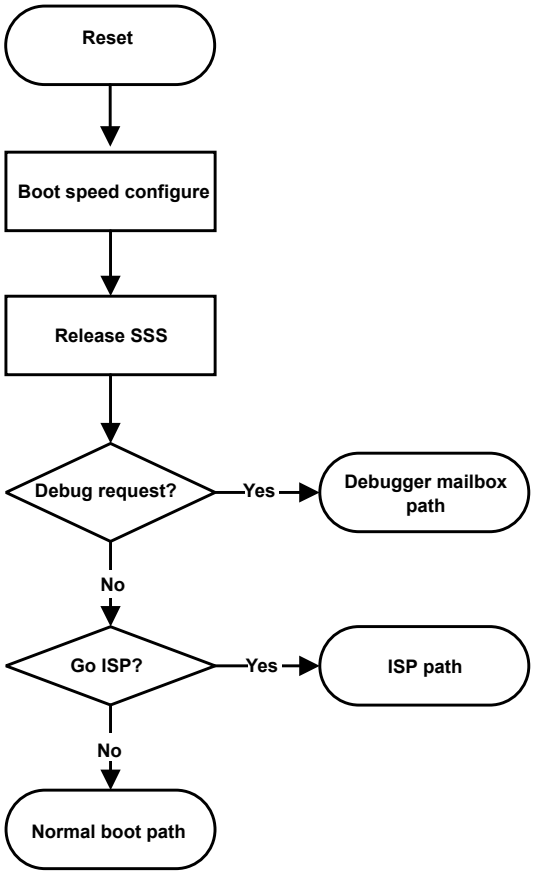

Figure 24. Top-level boot flow

15.2.1 Lifecycle and fuses

The table and diagram below describe the lifecycle states and transitions. ROM behavior is different at different lifecycle state. The lifecycle fuse needs to be programmed correctly, otherwise ROM bootloader will not boot. The NA in the table means the feature is not available.

Table 63. Lifecycle states

LIFECYCLE	Lifecycle state [0:7]	Debug authentication required to debug CM33?	Debug authentication required to debug radio core?
0000_0111	OEM Open	No	No
0000_1111	OEM Secure World Closed	Yes[1]	Yes
0001_1111	OEM Closed	Yes	Yes
1001_1111	OEM Locked	NA	NA
0011_1111	OEM Return	No	NA
11xx_xxxx	Brick	NA	NA

1. For secure world only.

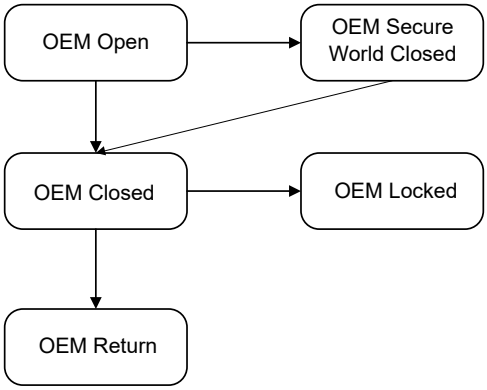

Figure 25. Lifecycle transitions

In addition to the lifecycle fuses, there are a handful of other fuse fields that will be used by the ROM bootloader during its operation. These fuse fields are shown in the table below.

Table 64. Additional fuse fields of interest

Name	Fuse index	Description
LIFECYCLE	0x0A	Lifecycle state. Corresponding product state can be determined from Table 1. Lifecycle States
DBG_EN_LOCK	0x0B	Debug Enable Lock 0b - The debug access control registers remain open when jumping to customer code. 1b - The debug access control registers are write-locked before jumping to customer code.
DBG_AUTH_DIS	0x0C	Debug Authentication Disabled 0b - Debug Authentication enabled. 1b - Debug Authentication disabled.
TZM_EN	0x0D	Trust Zone Mode Enable 0b - TZ-M is disabled by default. 1b - TZ-M is enabled.
SERIAL_DIS	0x11	Serial Download Disabled 0b - ISP path is enabled. 1b - ISP path is disabled.
WAKEUP_DIS	0x12	Wakeup Disabled 0b - Boot-ROM LP wakeup is enabled. 1b - Boot-ROM LP wakeup is disabled.

Table continues on the next page...

Table 64. Additional fuse fields of interest (continued)

Name	Fuse index	Description
CUST_PROD_OEMFW_AUTH_PUK_REVOKE[3:0]	0x13	Key revocation indicators of CUST_PROD_OEMFW_AUTH_PUK.
DBG_AUTH_VU[15:0]	0x15	These Debug Authentication Vendor Usage fuses are used by customers to restrict debug certificates.
IMG_KEY_REVOKE[15:0]	0x16	These fuses are used to revoke image signing keys separately from root keys.
SECURE_PHANTOM_CONFIG	0x18	Token configuration.
CUST_PROD_OEMFW_AUTH_PUK	0x1f	256-bit RoTKTH (customer trusted root key) typically used for CM33 main flash image authentication.
CUST_PROD_OEMFW_ENC_SK	0x20	256-bit encryption key used to protect confidentiality of OEM firmware. Typically required for firmware updates using sb3 (SB3KDK).
OEM_Enablement_Token	0x21	256-bit RoTKTH (root key hash) typically used for radio firmware authentication. (if valid token is intended to be used by programming SECURE_PHANTOM_CONFIG fuse)
DCFG_CC_SOCU_L1[8:0]	0x22	Debug authentication configuration for level 1 customer.
DCFG_CC_SOCU_L2[8:0]	0x23	Debug authentication configuration for level 2 customer.
SOC_VER_CNT	0x24	512-bits of version counter for various software components in SoC. Each software component version counter has dedicated fuse index 0x25 to 0x29.
CM33_S_VER_CNT	0x25	64-bit secure OEM CM33 firmware version counter (number of set fuse bits).
CM33_NS_VER_CNT	0x26	256-bit non-secure OEM CM33 firmware version counter (number of set fuse bits).
RADIO_VER_CNT	0x27	128-bit radio firmware version counter (number of set fuse bits).
SNT_VER_CNT	0x28	32-bit s200 loadable firmware version counter (number of set fuse bits).
CM33_BOOTLOADER_VER_CNT	0x29	Reserved for future usage of additional NXP software deliverable.
CM33_S_VER_CNT_VIRTUAL	0x2A	64-bit secure OEM CM33 firmware version counter (Integer value equivalent to number of set fuse bits).
CM33_NS_VER_CNT_VIRTUAL	0x2B	256-bit non-secure OEM CM33 firmware version counter (Integer value equivalent to number of set fuse bits).
RADIO_VER_CNT_VIRTUAL	0x2C	128-bit radio firmware version counter (Integer value equivalent to number of set fuse bits).
SNT_VER_CNT_VIRTUAL	0x2D	32-bit s200 loadable firmware version counter (Integer value equivalent to number of set fuse bits).
CM33_BOOTLOADER_VER_CNT_VIRTUAL	0x2E	Reserved for future usage of additional NXP software deliverable.
NBU_SEC_BOOT_EN	0x33	NBU secure boot enable fuse, NBU image must be authenticated successfully to boot if this fuse is set. See the Security Reference

Table continues on the next page...

Table 64. Additional fuse fields of interest (continued)

Name	Fuse index	Description
		Manual for the value of this fuse reflected in bit 12 of SMSCM [LIFECYCLE] register. 0b - NBU image doesn't need to be authenticated (default) 1b - NBU image must be authenticated to boot
OEM_SEC_BOOT_EN	0x35	Main core secure boot enable boot enable fuse, boot image must be authenticated successfully to boot if this fuse field is set to 0xA. See the Security Reference Manual for the value of this fuse reflected in bit 24-27 of SMSCM [LIFECYCLE] register. 0000b - Boot image doesn't need to be authenticated to boot (default) 1010b - Boot image must be authenticated to boot Other value - Reserved

ROM bootloader provides following ways to do the fuse reading and programming:

- nboot API (See nboot API for more details about fuse programming using nboot API),
- ISP fuse-program and fuse-read command,
- sbloader “programFuses” command in sb3.1 file

15.2.2 User IFR (IFR0) configuration

User IFR, known as IFR0 is reserved for software usage. First sector of User IFR is not able to be erased and is write-once. Other three sectors are erasable and programmable.

The allocation of User IFR pages is as follows:

Table 65. User IFR allocation

Sector	Name	Description
0	ROMCFG	ROM Bootloader configurations
1	User	Reserved for customer usage
2	CMAC table	Used to save hashes of multiple boot components.
3	OTACFG	Used for Over-the-Air update

15.2.2.1 ROM bootloader configuration

Sector 0 of User IFR is ROM and ISP configuration, which provide configuration for ROM bootloader.

Table 66. ROM Configuration fields

Offset	Size (bytes)	Configuration Field	Description

	15	Reserved	Reserved
0x0070	16	Reserved	Reserved
0x0080	64	Boot Image Base Address	Start address of Boot image, should align with 32 KB. ROM Bootloader does search from 0x80 and the first not 0xFFFFFFFF 32-bit will be the boot address. So, it's better to program from 0xB0 to 0x80, users will have 4 chances to update boot address.
0x00C0	64	Reserved	Reserved
0x0100	1	Peripherals Enable	Bit 0 – LPUART1 peripheral for ISP • 0 = LPUART1 disabled • 1 = LUPART1 enabled (default) Bit 1 – LPI2C1 peripheral for ISP • 0 = LPI2C1 disabled • 1 = LPI2C1 enabled (default) Bit 2 – LPSPI1 peripheral for ISP • 0 = LPSPI1 disabled • 1 = LPSPI1 enabled (default) Bit 3 – Reserved Bit 7:4 – Reserved
	3	Reserved	Reserved
	2	Peripheral Detection Timeout	If 0xFFFF, defaults to no timeout. If not 0xFFFF, use this value as timeout in milliseconds for active peripheral detection.
	2	Reserved	Reserved
	1	I2C Slave Address	If 0xFF, defaults to 0x10 for LPI2C slave address. If not 0xFF, use this value as the 7-bit LPI2C slave address.
	7	Reserved	Reserved
0x110	4	SSS Loadable FW Entry Address	Secure Sub-System (SSS) loadable firmware resides address
	12	Reserved	Reserved

Table continues on the next page...

Table 66. ROM Configuration fields (continued)

Offset	Size (bytes)	Configuration Field	Description
0x120	4	Secure Hash based image verification feature (for faster subsequent boot)	0xFFFFFFFF – Disabled (ECDSA based verification will be used). If 0x48534148 (“HASH”) – Enabled.
	12	Reserved	Reserved
0x130	16	Reserved	Reserved
0x140	1	Go Isp Mode Options	If enter ISP mode, the log will be recorded on the corresponding pin when this bit and go Isp mode fail alert pin are enable. Bit 0 – Reserved Bit 1– Secure boot option • 0 = Enable • 1 = 1 disable (default) Bit 7:2 – Reserved
	1	Go Isp Mode Fail Alert Pin	Set the ISP log pin Bit [4:0] – Pin Selection • 0x0~0x1F = Pin0~Pin31 Bit [7:5] – Port Selection • 0x0~0x4 = PortA ~PortE • 0x5~7 Reserved
	14	Reserved	Reserved

Restore FLW Flag and FLW Region Definitions fields are Flash Logic Window configurations used for dual image boot. When dual image boot is enabled, there are two boot images on the internal flash. ROM bootloader first tries to boot the boot image with latest version, if fails, ROM bootloader tries to boot the other boot image. To enable the dual image boot, Restore FLW Flag needs to be enabled, Boot Image Base Address field and FLW Region Definition fields need to be configured correctly. Boot Image Base Address indicates the start address of one boot image. FLW Region Definitions indicate the start address and the size of the alternative boot image. Here is the FLW Region Definition structure:

```
struct flw_region {
   uint32_t abase;
   uint32_t bcnt; };
```

The FLW region descriptors simply consist of FLW ABASE, the starting address of the alternative boot image, and, FLW BCNT, the size of the alternative boot image in 32 KB blocks.

If dual image boot is not enabled, ROM bootloader boots from Boot Image Base Address. If Boot Image Base Address is not configured, ROM bootloader will boot from the beginning of flash.

Configure NPX for Normal Boot, NPX Region Definitions fields are used for NPX feature.

Bit 0 of Boot Configuration field is used to enable ISP path for ROM bootloader. BOOT_CFG pin will be enabled if this bit is set. The pull-down on the BOOT_CFG pin is to ensure the device does not enter ISP by default. When BOOT_CFG pin is enabled and the BOOT_CFG pin is not pulled down, ROM bootloader will enter ISP path.

Boot Speed bits will be loaded by ROM bootloader to decide how to configure the power and clock. Bit 1:2 of Boot Configuration indicates the boot speed:

Table 67. Boot speed

Boot speed value in IFR0	Clock source	CPU_CLK/BUS_CLK/SLOW_CLK	DCDC & CORE_LDO voltage
11/00/01: Normal Boot (default)	FRO_192M	48/48/24 MHz	CORE_LDO : 1.0 V DCDC : 1.8 V or 1.25 V
10: Fast Boot	FRO_192M	96/96/24 MHz	CORE_LDO : 1.1 V DCDC : 1.8 V or 1.35 V

15.2.2.2 Over-the-air (OTA) update configuration

Table 68. OTA update configuration

Offset	Size (bytes)	Configuration Field	Description
0x00	4	Update available	0x746f4278u = Indicates update is available
	12	Reserved	Reserved
0x10	4	Update(sb3) dumped location	0x74784578 = sb3 is dumped in external flash
			Other values = sb3 is dumped in internal flash
0x14	4	Baud rate (in bps)	Value used to configure LPSPI NOR flash if update(sb3) is dumped in external flash.
0x18	4	Update(sb3) dump address	Start address (internal/external flash) where update(sb3) is dumped.
0x1c	4	Update(sb3) file bytes	Size of update(sb3) file in number of bytes.
0x20	4	FW update status	0x5ac3c35a = Indicates update was success 0x4412d283/0x2d61e1ac = Indicates failure to process sb3 file OR failure to erase/write update status to OTACFG page
	12	Reserved	Reserved
0x30	16	Feature unlock key	To use FW update feature offered by ROM (instead of extended bootloader) 16-byte key must be programmed. updKey[16] = {0x61, 0x63, 0x74, 0x69, 0x76, 0x61, 0x74, 0x65, 0x53, 0x65, 0x63, 0x72, 0x65, 0x74, 0x78, 0x4d};

15.2.3 Normal boot path

ROM bootloader follows this path when device goes through a WARM reset or POR if not getting a request to go to another path. The ROM bootloader validates the application code residing in the internal flash and boot when validation is successful. By default, when there is no fuse/IFR0 boot configuration programmed, the ROM bootloader does validation for boot image based on image type. It does basic SP and PC value check for raw binary application; CRC check for CRC image and ECDSA authentication for signed image. Secure boot can be enabled and enforced by setting OEM_SEC_BOOT_EN fuse. Radio image sits on radio flash is not validated by the ROM bootloader by default. NBU_SEC_BOOT_EN can be used to enable the authentication for radio image during boot time. If authentication for radio image is enabled but failed during boot time, then radio core will be locked, and it can't be released from reset.

Please note that WDOG0 is disabled during normal boot path and enabled before jumping to the boot image. Meanwhile, the WDOG0 timeout value (TOVAL) has been set to longest (0xFFFF).

Figure below shows the flow of normal boot.

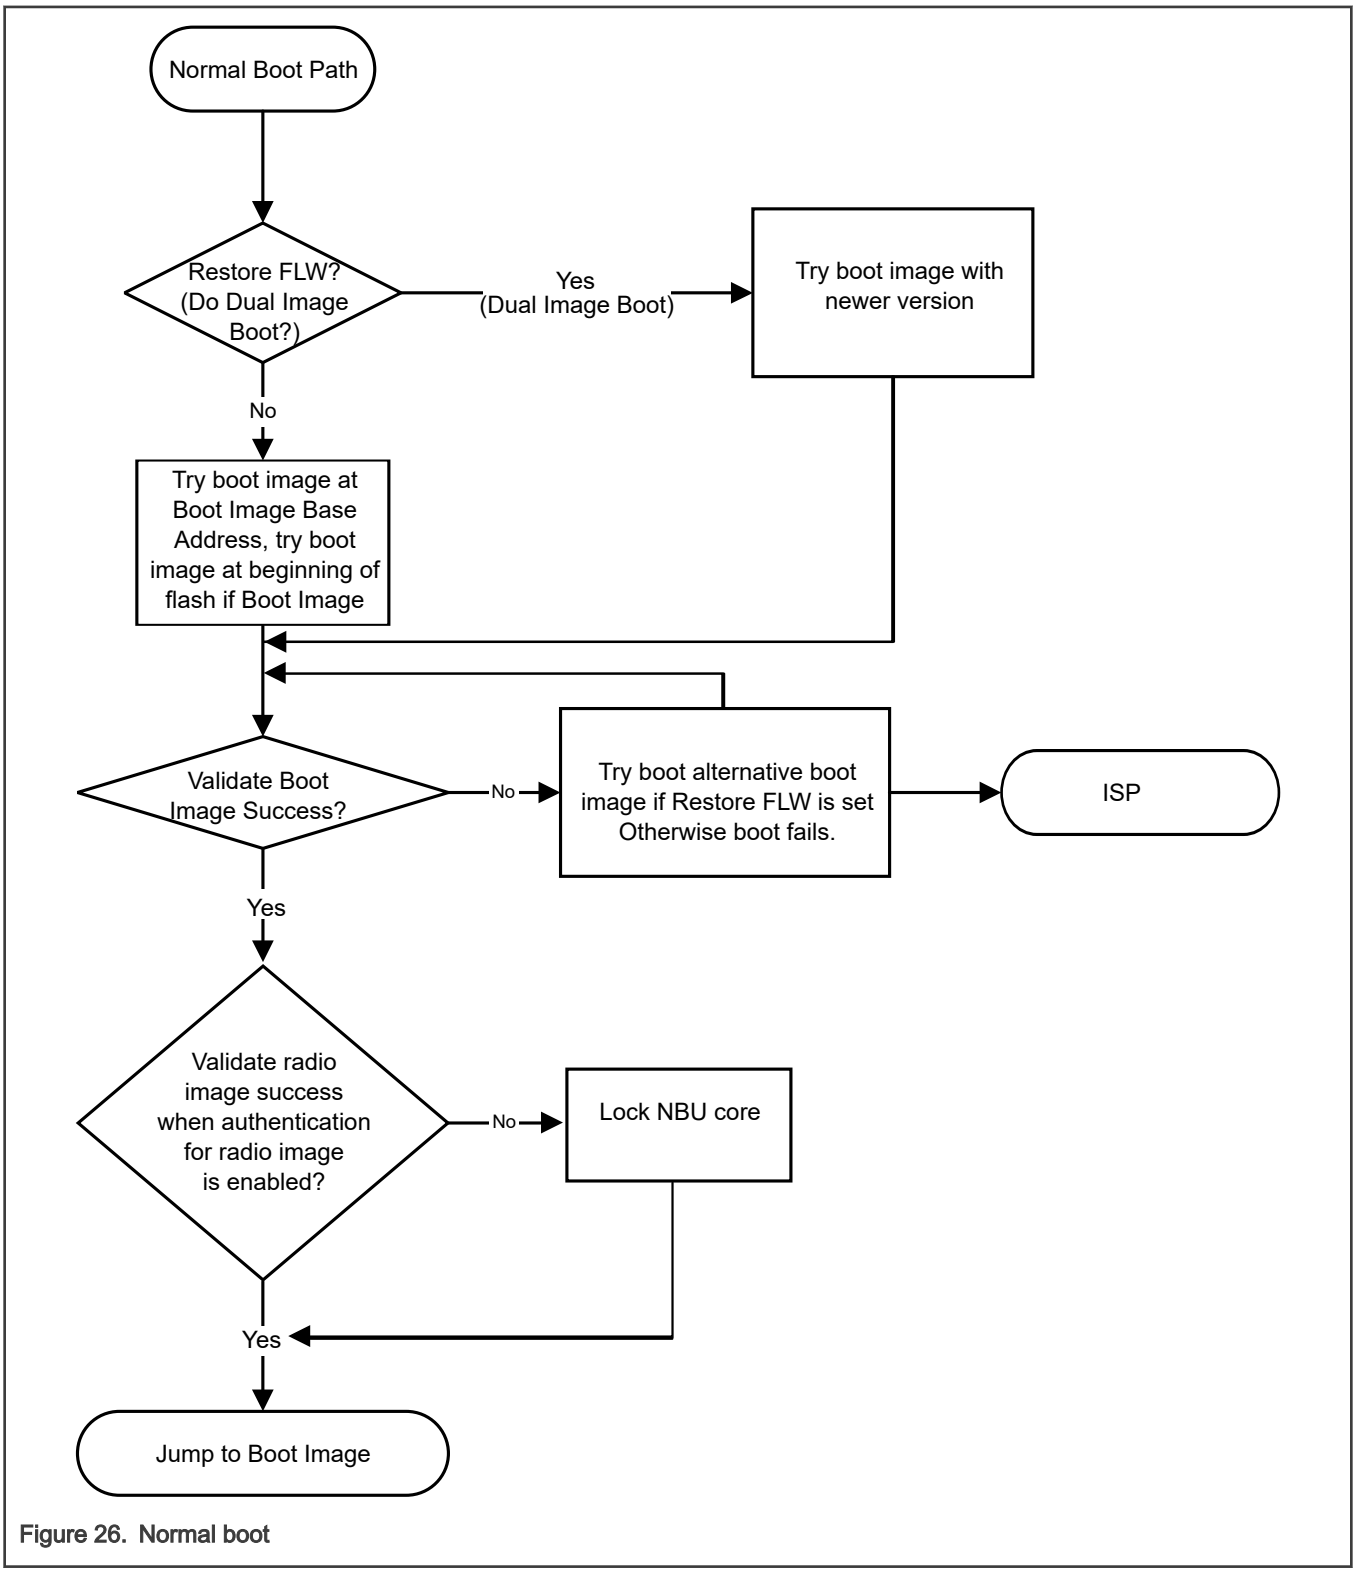

Figure 26. Normal boot

15.2.3.1 Dual image boot

Boot ROM supports dual image boot, useful in scenario where primary image fails to boot for any reason so secondary image (as a backup) can boot. This is achieved in conjunction with Flash Logical Window feature. It will allow developing for position independent code. That means same linker file can be used for creating multiple application images to be treated as primary (experimental or latest firmware image) and secondary (as a backup fallback image).

Use case example of dual boot:

1. “Restore FLW Flag” bit 0 is set to indicate ROM to use FLW feature.
2. Primary image is placed at address 0x10000 and “Boot Image Base Address” field of ROMCFG in user IFR0 is programmed accordingly.
3. Secondary image (fallback/backup) is placed at address 0x20000 and “ABASE” field in FLW region definitions of ROMCFG in user IFR0 is programmed accordingly.
4. Make sure BCNT field of FLW region definitions is set correctly to indicate image size as multiple of 32 KB block size.
5. Boot ROM will compare versions of primary and secondary image.
6. Boot ROM will try to boot latest versioned image. At the same time older versioned image base address is stored in ROM runtime context.
7. If both images have same version, then image located at address specified by “Boot Image Base Address” field of ROMCFG in user IFR0 is considered for boot.
8. For any reason (mainly authentication failure or rollback protection) latest versioned image fails to boot then boot ROM falls back to the older versioned image.

15.2.4 Faster subsequent boot

Boot ROM supports secure boot primarily using an ECDSA verification. And it can also support secure boot using hash (cmac) based image verification for faster subsequent boot.

- The user need to:
  - Program IFR0 page0 at offset 0x120 to request hash based image verification.
  - Include a sbloader command to erase IFR0 page2 for every FW update.
- The ROM handles this request with the following steps:
  - First time after resetting to boot or trying to boot using jump/execute sbloader command after successful FW update, requires ROM to compute hash of image data.
  - Boot ROM computes hash (cmac) for multiple boot components, viz., main flash image (application), radio FW. And stores it in a IFR0 page2 in structured format as described. So it can be used to achieve faster boot time from next boot attempt.
  - But for very first time post FW update, after calculating hash of image data, boot ROM will still use ECDSA based image verification mechanism to perform secure boot.
  - For all subsequent FW updates, it is user’s responsibility to erase IFR0 page2. So that boot ROM understands it needs to calculate hash for multiple bootable components and store it in a structured format.
  - If no FW update is required/performed then triggering multiple resets could utilize faster secure boot sequence.
- If hash based image authentication fails
  - Images are still expected to have signature. So boot ROM would fall back to ECDSA based verification as a primary secure boot mechanism.

IFR0 page2 (hash structure/cmac table maintenance):

This IFR0 dedicated page is used to store hash for boot images in a structured format as shown below. Note that, Buffer size of hash table to be reprogrammed must be at max. 48*4 bytes (to save flash programming time) but phrase-by-phrase programming can also be done as boot ROM progresses through various stages.

```
enum _cmac_table_index
{
kCmacIndexPrim = 0x0U,
kCmacIndexOEM = 0x1U,
kCmacIndexNBU = 0x2U,
kCmacIndexELEfirmware = 0x3U,
kCmacIndexLast = 0x4U,
};

typedef struct{
uint32_t update_needed;
uint32_t reserved0[3];
uint8_t imgHash[NBOOT_CMAC_SIZE_IN_BYTES];
}cmac_info_t;

typedef struct {
cmac_info_t components[kCmacIndexLast]; /*!< Upto 4 components: 2 images (dual), 1 radio, 1 extended
bootloader (TBD) */
}cmac_table_t;
```

Offset	Size (bytes)	Field description	Description
0x0000	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0010	16	16 byte CMAC for application image	Hash of main flash primary boot image data at 0x0 OR Hash of Image data at ABASE (if FLW is enabled)
0x0020	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0030	16	16 byte CMAC for fallback image	Hash of fallback image data (if “Image 1 Base Address” field in IFR0 page0 is not 0xFFFFFFFF)
0x0040	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0050	16	16 byte CMAC for radio image	Hash of radio (NBU) flash image data

Table continues on the next page...

Table continued from the previous page...

Offset	Size (bytes)	Field description	Description
0x0060	4	Hash update needed	0xFFFFFFFF - Yes 0x00000000 – No
	12	Reserved	Reserved
0x0070	16	16 byte CMAC for ELE's image	Hash of ELE's image data

15.2.5 Low power wakeup path

The ROM bootloader provides a fast low power wakeup mechanism that supports all low power modes, including:

- Power Down (PD) mode
- Deep Power Down (DPD) mode
- Smart Power Switch (SPS) mode

When the WAKEUP_DIS flag is cleared (WAKEUP_DIS = 0) and the sticky NPX configuration for DPD wakeup is not enabled, the ROM bootloader can execute low power wakeup path after waking up from low power mode. ROM bootloader does normal boot if low power wakeup path fails.

Figure 27 Illustrates the low power wakeup path.

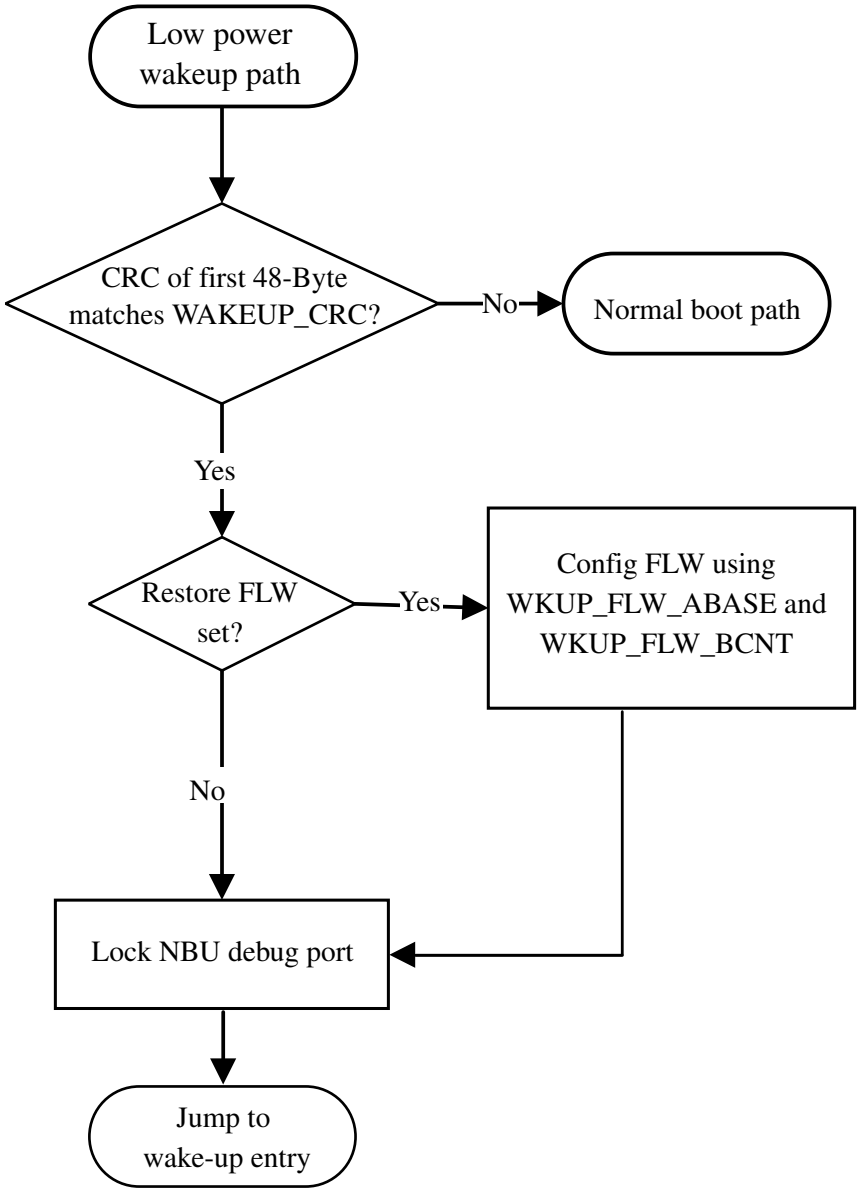

Figure 27. Low power wakeup flow

15.2.5.1 Wakeup from PD mode and DPD mode

When the wakeup path is enabled (i.e., WAKEUP_DIS = 0) and the system wakes up from Power Down (PD) or Deep Power Down (DPD) mode, the ROM bootloader enters the low power wakeup path if the WAKEUP register in SPC0 is set to a non-zero value.

If the CRC value preloaded into REG[0] of REGFILE1 matches the CRC computed over the first 48 bytes of the wakeup image, the ROM bootloader transfers control to the wakeup image at the entry point specified in the WAKEUP register in SPC0. Otherwise, the ROM bootloader exits the low power wakeup path and proceeds with the normal boot sequence.

If the Flash Logic Window (FLW) must be configured for the low power wakeup path, the following values must be correctly set. The ROM bootloader uses WAKEUP_FLW_ABASE and WAKEUP_FLW_BCNT to configure the FLW for low power wakeup path.

- FLW restore flag in IFR0
- WAKEUP_FLW_ABASE in REG[1] of REGFILE1
- WAKEUP_FLW_BCNT in REG[2] of REGFILE1 (Bit 31: Valid bit, Bit 30: Lock bit, Bits 0–14: Block count)

NOTE

If the system boots successfully via the low power wakeup path, the ROM bootloader does not modify WDOG0. In this path, the ELE remains unreleased, and the CM3 debug port remains locked.

15.2.5.2 Wakeup from Smart Power Switch (SPS) mode

Compared to PD and DPD modes, SPS mode offers significantly lower leakage power. In SPS mode, all RAM instances are automatically power-gated, resulting in complete data loss across RAM - except for the last 8 KB of RAM (TCM8), which can remain powered and retain data.

This retained memory region enables the ROM bootloader to execute a fast low power wakeup path. The last two words of TCM8 are reserved by the ROM bootloader for:

- WAKEUP Entry Point at offset 0x1FFC
- WAKEUP_CRC at offset 0x1FF8

During wakeup, if the CRC value stored in WAKEUP_CRC matches the CRC computed over the first 48 bytes of the wakeup image, the ROM bootloader transfers control to the wakeup image at the entry point specified in WAKEUP Entry. If the CRC check fails, the ROM bootloader exits the low power wakeup path and proceeds with the normal boot path.

When using the low power wakeup path from SPS mode, the FLW restore flag in IFR0 must not be configured. FLW restoration is not supported in this wakeup scenario.

15.2.6 Firmware update feature

ROM Bootloader has firmware update feature. It can be used for updating main flash (CM33) as well as radio flash firmware.

Use case example of remote radio firmware update:

1. Main flash (CM33) contains a customer's application image along with NXP delivered OTA client.
2. NXP OTA client helps in fetching image over-the-air via wireless protocol.
3. Image blocks fetched over-the-air are dumped in either internal or external flash.
4. Once the entire image is received, OTA client must indicate and provide meta data information for update to be performed in User IFR0 OTACFG page. (Refer to OTA update configuration).
5. Application is responsible of triggering a software reset upon which boot ROM uses data provided in OTACFG page to start firmware update.
6. Upon successful update, IFR0 OTACFG page is erased and “FW update status” is updated by boot ROM and reset is triggered to follow "Normal boot path".

If the external flash is used, LPSPI1 is configured to master mode and pin assignment is showed in table below.

Table 69. LPSPI1 pin assignment when external flash used and LPSPI1 configured to master mode

Pin name	Pin assignment	Alt
LPSPI1_SCK	PTB2	2
LPSPI1_SIN	PTB1	2
LPSPI1_SOUT	PTB3	2
LPSPI1_DATA2	PTB5	2
LPSPI1_DATA3	PTB4	2
LPSPI1_SS0	PTB0	2

15.2.7 ISP path

ROM bootloader provides in-system programming utility that operates over a serial connection on the MCUs. It enables quick and easy programming of MCUs through the entire product lifecycle, including application development, final product manufacturing, and beyond. Host-side command line tool is available to communicate with the bootloader. Users can utilize host tools to upload/download application code and do manufacturing via the bootloader.

When ROM bootloader enters ISP mode and it will auto-detect activity on the LPI2C/LPSPI/LPUART interface. The auto-detect looks for activity on the LPUART, LPI2C, LPSPI interface and selects the appropriate interface once a properly formed frame is received. If an invalid frame is received, the data is discarded and scanning resumes.

Users can make ROM bootloader go to ISP path by pressing the BOOT_CONFIG pin (PTA4) since BOOT_CONFIG pin is enabled by default in User IFR (IFR0). See ROM bootloader configuration for details of config BOOT_CONFIG pin. In addition, ROM bootloader will go to ISP path when no boot image is found, PC and SP are not valid and some other boot failure conditions.

15.2.7.1 Available peripherals

Table below shows the peripheral instances and pin assignments used by ISP.

Table 70. Peripheral instances and pin assignments used by ISP

Peripheral instances	Pin name	Pin assignment	Alt
LPUART1	LPUART1_TX	PTC3	3
	LPUART1_RX	PTC2	3
LPSPI1	LPSPI1_PCS0	PTB0	2
	LPSPI1_SIN	PTB1	2
	LPSPI1_SCK	PTB2	2
	LPSPI1_SOUT	PTB3	2
LPI2C1	LPI2C1_SCL	PTB5	4
	LPI2C1_SDA	PTB4	4
Boot pin	BOOT_CONFIG	PTA4	Default

15.2.7.2 Available ISP commands

ISP commands availability is controlled by lifecycle. Table below shows the ISP commands available for each lifecycle. Details of several commands can be found in sections below.

Table 71. Available ISP commands for different lifecycle

Command	Description	Before OEM Open	At OEM Open	After OEM Open
Reset	Reset the device	Available	Available	Available
get-property <tag>	Query about various properties and settings	Available	Available	Available
set-property <tag> <value>	Change properties or options in ROM Bootloader	Available	Available	Available
receive-sb-file <file>	Receive a file in Secure Binary (SB) format	Available	Available	Available
flash-erase-region	Erase one or more sectors of the flash memory	Available	With limitation for radio flash	NA

Table continues on the next page...

Table 71. Available ISP commands for different lifecycle (continued)

Command	Description	Before OEM Open	At OEM Open	After OEM Open
flash-erase-all [<memoryID>]	Erase the entire flash memory specified by memoryID	Available	With limitation for radio flash	NA
read-memory <addr> <byte_count> [<file>]	Read memory at specified address	Available	With limitation for radio flash	NA
write-memory <addr> [<file> | {{<hex-data>}}]	Write memory at specified address from a file or string of hex values Note: When write to SRAM, make sure the length of file or hex-data is 4 byte aligned	Available	With limitation for radio flash	NA
fill-memory <addr> <byte_count> <pattern> [word | short | byte]	Fill memory with pattern; pattern size can be word(default), short or byte	Available	With limitation for radio flash	NA
fuse-program <index> [<file> | {{<hex-data>}}]	Program fuse at the specified index from file or string of hex values	Available	Available	NA
fuse-read <index> <byte_count> [<file>]	Read fuse from the specified index	Available	Available	NA
Execute <address> <arg> <stackpointer>	Jumps to code at the provided address and does not return to the ROM bootloader	Available	Available	NA
trust_provisioning	Only support Operation_Prove_Genuinity, generate a string of numbers, and then spsdk to verify to determine whether it is an NXP product	Available	Available	NA

15.2.7.2.1 Available properties

Table below shows the available properties (tag) for this device.

Table 72. Supported properties in GetProperty and SetProperty

Name	Writable	Tag value	Size in Bytes	Description
CurrentVersion	no	1	4	The current bootloader version.
AvailablePeripherals	no	2	4	The set of peripherals supported on this chip.
FlashStartAddress	no	3	4	Start address of program flash.
FlashSizeInBytes	no	4	4	Program flash size in bytes.
FlashSectorSize	no	5	4	The size of one sector of program flash in bytes.
FlashBlockCount	no	6	4	The number of blocks of the on-chip flash.
AvailableCommands	no	7	4	The set of commands supported by the bootloader.
CRCCheckStatus	no	8	4	The status of the application CRC check.

Table continues on the next page...

Table 72. Supported properties in GetProperty and SetProperty (continued)

Name	Writable	Tag value	Size in Bytes	Description
VerifyErase	yes	10	4	Controls whether the bootloader verifies erase to flash. The VerifyErase feature is enabled by default: 1 = Enable 0 = Disable
MaxPacketSize	no	11	4	Maximum supported packet size for the currently active peripheral interface.
ReservedRegions	no	12	4	List of memory regions reserved by the bootloader. Returned as value pairs (<startaddress-ofregion>, <end-addressof-region>).
RAMStartAddress	no	14	4	Start address of RAM
RAMSizeInBytes	no	15	4	RAM size in bytes.
SystemDeviceId	no	16	4	System Device ID
SecurityState	no	17	4	Security status
UniqueDeviceId	no	18	16	Unique device identification
BootStatus	no	32	4	Value of Boot Status Register
LoadableFWVersion	no	33	4	SSS loadable firmware version
FuseProgramVoltage	yes	34	4	Control the System LDO VDD Regulator Voltage Level. To program fuse, System LDO VDD regulator level needs to be regulated to Over Drive Voltage (2.5 V). The default System LDD VDO Regulator Voltage Level is regulated to Normal Voltage (1.8 V). 0 = System LDO VDO Regulator Voltage Level is related to Normal Voltage (1.8 V) 1 = System LDO VDD regulator level is regulated to Over Drive Voltage (2.5 V)
TargetVersion	no	24	4	Target version

15.2.7.2.2 Fuse reading and programming

A set of fuses can be read / programmed using fuse-program and fuse-read commands. The index of fuses can be found in Lifecycle and fuses.

Please note that -- set-property 0x22 needs to be used before -- fuse-program command to ensure fuse can be programmed successfully. And -- set-property 0x22 needs to be done after all the fuse programming completes.

15.2.7.2.3 Commands with limitation

Command flash-erase-all can have memoryID as a parameter, if no ID is specified or 0 is specified, the entire Program Flash will be erased. If 2 is specified as memoryID, the entire radio Program Flash will be erased. If 3 is specified as memoryID, the entire radio User IFR (IFR0) will be erased.

15.2.7.2.4 receive-sb-file

receive-sb-file command is used to do image update on CM33 flash or radio (CM33) flash when security is enforced. It receives a secure binary (SB) file, decrypt, authenticate and program the image to the target memory. CUST_PROD_OEMFW_ENC_SK fuse needs to be programmed correctly to ensure this command can be used successfully. Please note that -- set-property 34 1 needs to be used before receive-sb-file command if the sb file contains "programFuses" command. And -- set-property 34 0 needs to be done after receive-sb-file is done.

15.2.7.3 In-System Programming protocol

This section explains the general protocol for the packet transfers between the host and the ROM Bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase.

- If the data phase is incoming (from the host to the bootloader), it is part of the original command.
- If the data phase is outgoing (from the bootloader to host), it is part of the response command.

15.2.7.3.1 Command with no data phase

The protocol for a command with no data phase contains:

- Command packet (from the host)
- Generic response command packet (to host)

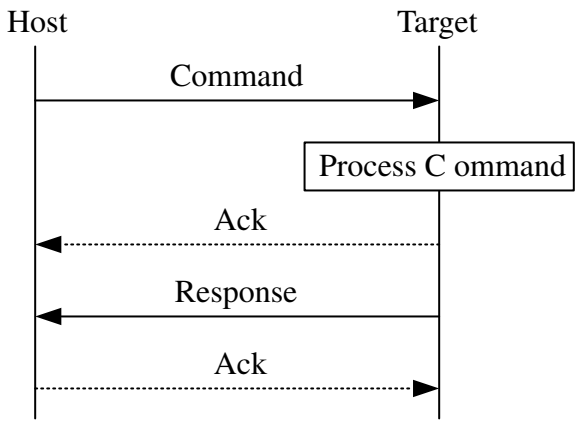

Figure 28. Command with no data phase

NOTE

In these diagrams, the ACK sent in response to a command or a data packet can arrive at any time before, during, or after the command or data packet has processed.

15.2.7.3.2 Command with incoming data phase

The protocol for a command with incoming data phase contains:

- Command packet (from host) (kCommandFlag_HasDataPhase set).
- Generic response command packet (to host).
- Incoming data packets (from the host).
- Generic response command packet.

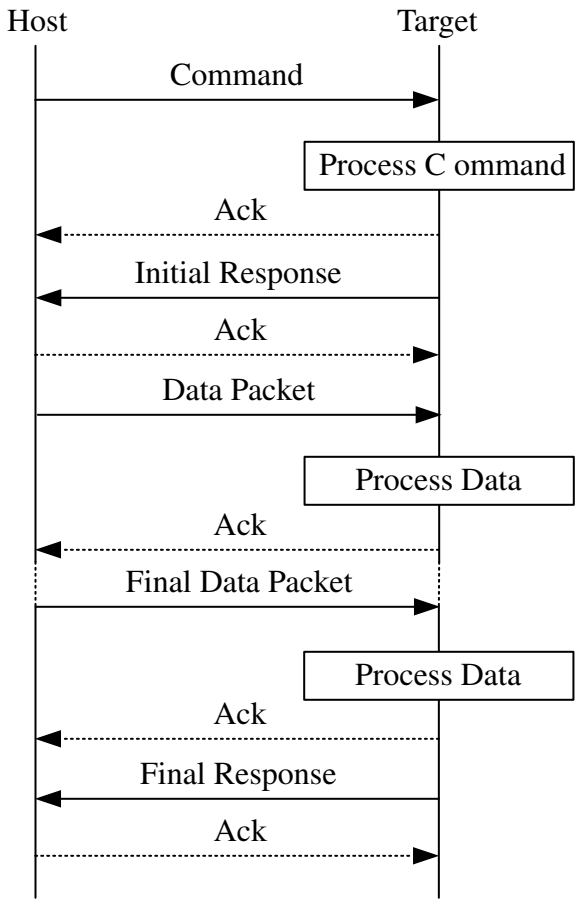

Figure 29. Command with incoming data phase

NOTE

- The host may not send any further packets while it is waiting for the response to a command.
- The data phase is aborted if the Generic Response packet prior to the start of the Data phase does not have a status of kStatus_Success.
- Data phases may be aborted by the receiving side by sending the final GenericResponse early with a status of kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

15.2.7.3.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

- Command packet (from the host).
- ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set).
- Outgoing data packets (to host).
- Generic response command packet (to host).

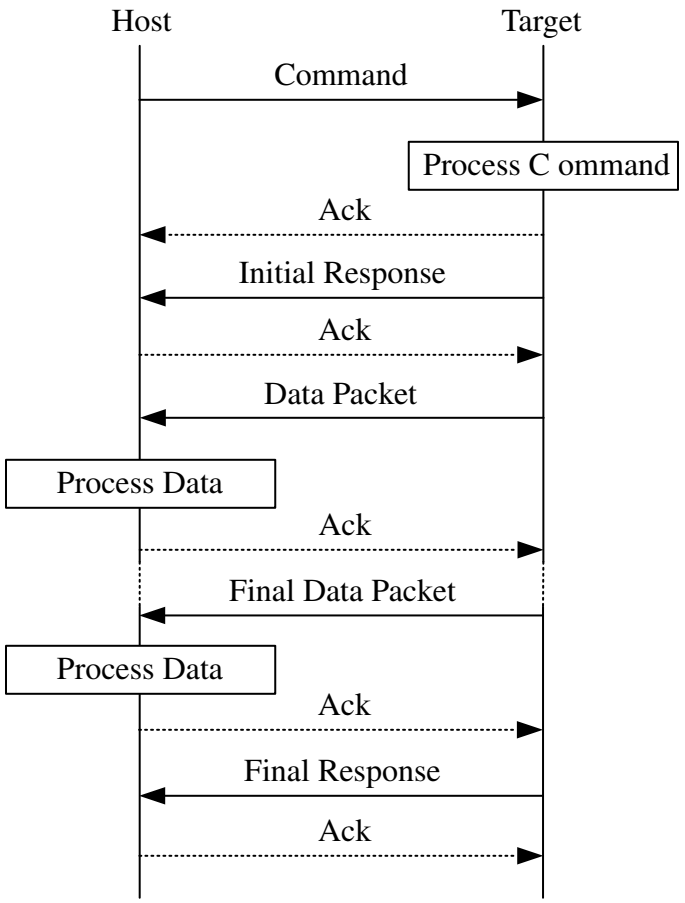

Figure 30. Command with outgoing data phase

NOTE

- The data phase is considered part of the response command for the outgoing data phase sequence. The host may not send any further packets while the host is waiting for the response to a command.
- The data phase is aborted if the ReadMemory Response command packet, prior to the start of the data phase, does not contain the kCommandFlag_HasDataPhase flag. Data phases may be aborted by the host sending the final Generic Response early with a status of kStatus_AbortDataPhase. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

15.2.7.4 ISP packet type

The bootloader device works in slave mode. All data communications are initiated by a host, which is either a PC or an embedded host. The bootloader device is the target, which receives a command or data packet. All data communications between host and target are packetized.

There are six types of packets used:

- Ping packet.
- Ping Response packet.
- Framing packet.
- Command packet.

- Data packet.
- Response packet.

All fields in the packets are in little-endian byte order.

15.2.7.4.1 Ping packet

The Ping packet is the first packet sent from a host to the target to establish a connection on the selected peripheral in order to run autobaud detection. The Ping packet can be sent from host to target at any time that the target is expecting a command packet. If the selected peripheral is LPUART, a ping packet must be sent before any other communications. For other serial peripherals, it is optional.

In response to a Ping packet, the target sends a Ping Response packet, discussed in later sections.

Table 73. Ping packet format

Byte #	Value	Name
0	0x5A	start byte
1	0xA6	ping

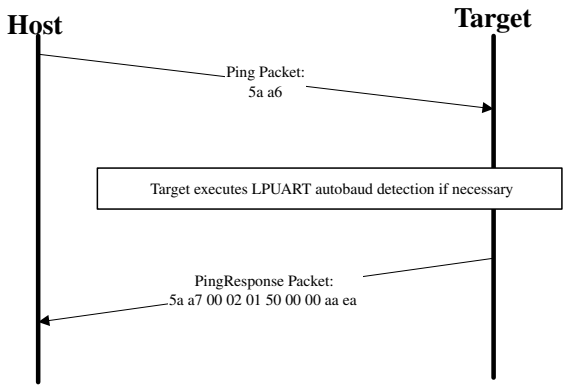

Figure 31. Ping packet protocol sequence

15.2.7.4.2 Ping response packet

The target sends a Ping Response packet back to the host after receiving a Ping packet. If communication is over an LPUART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping Response packet. Once the Ping Response packet is received by the host, the connection is established, and the host starts sending commands to the target.

Table 74. ping response packet format

Byte #	Value	Parameter
0	0x5A	Start byte
1	0xA7	Ping response code
2	0x00	Protocol bugfix
3	0x03	Protocol minor
4	0x01	Protocol major

Table continues on the next page...

Table 74. ping response packet format (continued)

Byte #	Value	Parameter
5	0x50	Protocol name = 'P' (0x50)
6	0x00	Options low
7	0x00	Options high
8	0xaa	CRC16 low
9	0xea	CRC16 high

The Ping Response packet can be sent from host to target any time the target expects a command packet. For the LPUART peripheral, it must be sent by the host when a connection is first established, in order to run outbound. For other serial peripherals, it is optional but recommended to determine the serial protocol version. The version number is in the same format as the bootloader version number returned by the GetProperty command.

15.2.7.4.3 Framing packet

The framing packet is used for flow control and error detection for the communications links that do not have such features built-in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in this section is used for serial peripherals including the LPUART, LPI2C, and LPSPI.

Table 75. Framing packet format

Byte #	Value	Parameter	Remark
0	0x5A	Start byte	
1		packetType	
2		length_low	Length is a 16-bit field that specifies the entire command or data packet size in bytes.
3		length_high	
4		crc16_low	This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See the CRC16 algorithm after this table.
5		crc16_high	
6 . . . n		Command or Data packet payload	

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

Table 76. Special framing packet format

Byte #	Value	Parameter
0	0x5A	Start byte
1	0xA*n*	packetType

The Packet Type field specifies the type of the packet from one of the defined types (below):

Table 77. packetType field

packetType	Name	Description
0xA1	kFramingPacketType_Ack	The previous packet was received successfully; the sending of more packets is allowed.
0xA2	kFramingPacketType_Nak	The previous packet was corrupted and must be re-sent.
0xA3	kFramingPacketType_AckAbort	Data phase is being aborted.
0xA4	kFramingPacketType_Command	The framing packet contains a command packet payload.
0xA5	kFramingPacketType_Data	The framing packet contains a data packet payload.
0xA6	kFramingPacketType_Ping	Sent to verify the other side is alive. Also used for LPUART autobaud.
0xA7	kFramingPacketType_PingResponse	A response to Ping; contains the framing protocol version number and options.

15.2.7.4.4 CRC16 algorithm

This section provides the CRC16 algorithm.

The CRC is computed over each byte in the framing packet header, excluding the crc16 field itself, plus all of the payload bytes. The CRC algorithm is the XMODEM variant of CRC-16.

Table 78. Characteristics of the XMODEM variant

Variant	Values
Width	16
Polynomial	0x1021
Init value	0x0000
Reflect in	False
Reflect out	False
xor out	0x0000
Check result	0x31c3

The check result is computed by running the ASCII character sequence "123456789" through the algorithm.

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
   uint32_t crc = 0;
   uint32_t j;
   for (j=0; j < lengthInBytes; ++j)
   {
        uint32_t i;
    uint32_t byte = src[j];
     crc ^= byte << 8;
```

```
      for (i = 0; i < 8; ++i)
       {
          uint32_t temp = crc << 1;
          if (crc & 0x8000)
           {
               temp ^= 0x1021;
           }
           crc = temp;
       }
    }
    return crc;
}
```

15.2.7.4.5 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Table 79. Command packet format (32 bytes)

Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param1 (32-bit)	Param2 (32-bit)	Param3 (32-bit)	Param4 (32-bit)	Param5 (32-bit)	Param6 (32-bit)	Param7 (32-bit)
Byte 0	Byte 1	Byte 2	Byte 3	-	-	-	-	-	-	-

Table 80. Command header format

Byte #	Command Header Field	Remark
0	Command or Response tag	The command header is 4 bytes long, with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only 7 parameters can fit into the command packet.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all the transfers.

Table 81. Command tags

Command Tag	Name	Remark
0x01	FlashEraseAll	The command tag specifies one of the commands supported by the bootloader. The valid command tags for the bootloader are listed here.
0x02	FlashEraseRegion	
0x03	ReadMemory	
0x04	WriteMemory	
0x05	FillMemory	
0x06	Reserved	
0x07	GetProperty	

Table continues on the next page...

Table 81. Command tags (continued)

Command Tag	Name	Remark
0x08	ReceiveSbFile	
0x09	Execute	
0x0A	Reserved	
0x0B	Reset	
0x0C	SetProperty	
0x0D	Reserved	
0x0E	Reserved	
0x0F	Reserved	
0x10	Reserved	
0x11	Reserved	
0x12	Reserved	
0x13	Reserved	
0x14	FuseProgram	
0x15	Reserved	
0x16	TrustProvisioning	
0x17	FuseRead	

Table 82. Response tags

Response Tag	Name	Remark
0xA0	GenericResponse	The response tag specifies one of the responses the bootloader (target) returns to the host. The valid response tags are listed here.
0xA7	GetPropertyResponse (used for sending responses to GetProperty command only)	
0xA3	ReadMemoryResponse (used for sending responses to ReadMemory command only)	
0xAF	FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)	
0xB5	TrustProvisioningResponse	

Flags: Each command packet contains a Flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets follow the command sequence. The number of bytes that are transferred in the data phase is determined by a command specific parameter in the parameters array.

ParameterCount: The number of parameters included in the command packet.

Parameters: The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to 7 parameters.

15.2.7.4.6 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse
- GetPropertyResponse
- ReadMemoryResponse
- FlashReadOnceResponse
- TrustProvisioningResponse

GenericResponse: After the bootloader has processed a command, the bootloader sends a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

Table 83. GenericResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The Status codes are errors encountered during the execution of a command by the target. If a command succeeds, then a kStatus_Success code is returned.
4 - 7	Command tag	The Command tag parameter identifies the response to the command sent by the host.

GetPropertyResponse: The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

Table 84. GetPropertyResponse parameters

Byte #	Parameter
0 - 3	Status code
4 - 7	Property value
. . .	. . .
	Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type.

ReadMemoryResponse: The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count set to 2 for the status code and the data byte count parameters shown below.

Table 85. ReadMemoryResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The status of the associated Read Memory command.
4 - 7	Data byte count	The number of bytes sent in the data phase.

FlashReadOnceResponse: The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a FlashReadOnceResponse tag value (0xAF), and the flags field set to 0. The parameter count is set to 2 plus the number of words requested to be read in the FlashReadOnceCommand.

Table 86. FlashReadOnceResponse parameters

Byte #	Parameter
0 – 3	Status code
4 – 7	Byte count to read
…	…
	Can be up to 20 bytes of requested read data.

TrustProvisioningResponse packet is sent by the target in response to the host sending a TrustProvisioning command. The TrustProvisioningResponse packet contains the framing packet data and the command packet data, with the command /response tag set to a TrustProvisioning tag value(0xB5), and the flag is set to 0.

15.2.7.5 Bootloader command set

All bootloader commands follow the command packet format wrapped by the framing packet as explained in previous sections.

See Available ISP commands for different lifecycle for a list of commands supported by the bootloader.

15.2.7.5.1 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

The 32-bit property tag is the only parameter required for GetProperty command.

Table 87. Parameters for GetProperty Command

Byte #	Command
0 - 3	Property tag See Available properties for more details.
4 - 7	External Memory Identifier (only applies to get property for external memory)

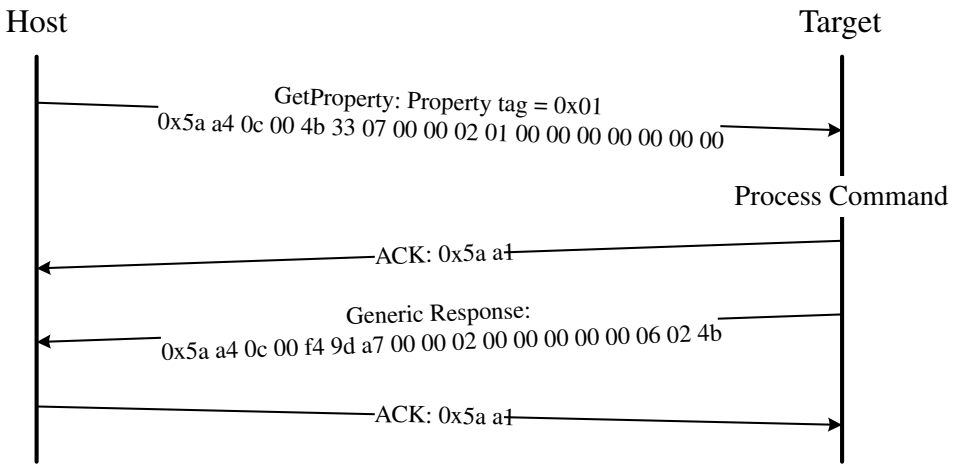

Figure 32. Protocol Sequence for GetProperty Command

Table 88. GetProperty Command Packet Format (Example)

GetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x4B 0x33
Command packet	commandTag	0x07 – GetProperty
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	propertyTag	0x00000001 - CurrentVersion
	Memory ID	0x00000000 - Internal Flash

The GetProperty command has no data phase.

Response: In response to a GetProperty command, the target sends a

GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). The next table shows an example of a GetPropertyResponse packet.

Table 89. GetProperty Response Packet Format (Example)

GetPropertyResponse	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0c 0x00 (12 bytes)
	crc16	0x07 0x7a
Command packet	responseTag	0xA7
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	status	0x00000000
	propertyValue	0x0000014b - CurrentVersion

15.2.7.5.2 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options of the bootloader. The command accepts the same property tags used with the GetProperty command. However, only some properties are writable--see Available properties. If an attempt to write a read-only property is made, an error is returned indicating the property is read-only and cannot be changed.

The property tag and the new value to set are the two parameters required for the SetProperty command.

Table 90. Parameters for SetProperty Command

Byte #	Command
0 - 3	Property tag See Available properties for more details.
4 - 7	Property value

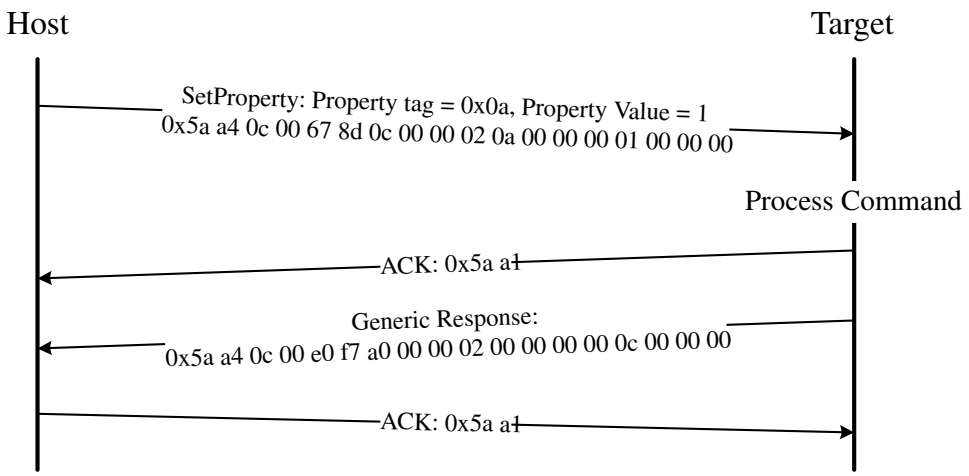

Figure 33. Parameters for SetProperty Command

Table 91. SetProperty Command Packet Format (Example)

SetProperty	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x0C 0x00
	crc16	0x67 0x8D
Command packet	commandTag	0x0C – SetProperty with property tag 10
	flags	0x00
	reserved	0x00
	parameterCount	0x02
	propertyTag	0x0000000A - VerifyWrites
	propertyValue	0x00000001

The SetProperty command has no data phase.

Response: The target returns a GenericResponse packet with one of following status codes:

Table 92. SetProperty Response Status Codes

Status Code
kStatus_Success
kStatus_ReadOnly
kStatus_UnknownProperty
kStatus_InvalidArgument

15.2.7.5.3 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory. If any flash regions are protected, then the FlashEraseAll command fails and returns an error status code. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires memory ID. If memory ID is not specified, the internal flash (memory ID =0) will be selected as default.

Table 93. Parameter for FlashEraseAll Command

Byte #	Parameter	
	Memory ID	Descriptions
0-3	0x000	Internal Flash
	0x002	Radio PFlash
	0x003	Radio User IFR

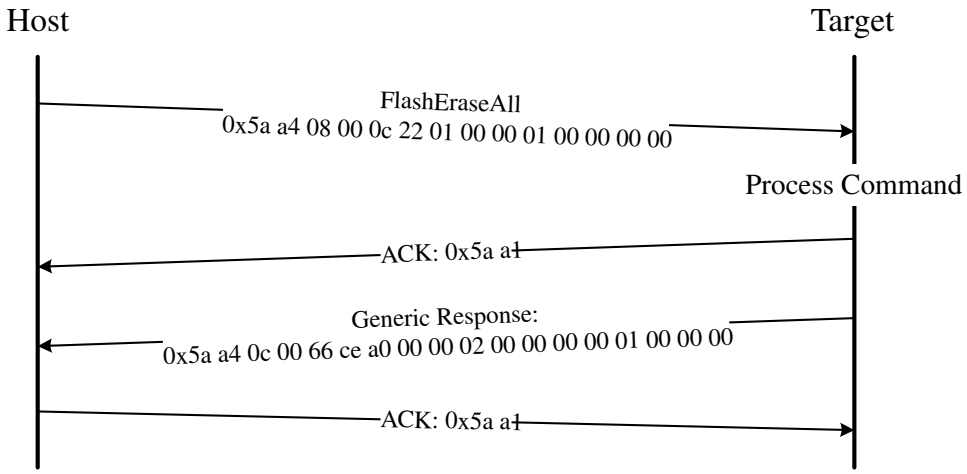

Figure 34. Protocol Sequence for FlashEraseAll Command

Table 94. FlashEraseAll Command Packet Format (Example)

FlashEraseAll	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x08 0x00
	crc16	0x0C 0x22
Command packet	commandTag	0x01 - FlashEraseAll
	flags	0x00
	reserved	0x00
	parameterCount	0x01
	Memory ID	refer to the above table

The FlashEraseAll command has no data phase.

Response: The target returns a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command or set to an appropriate error status code.

15.2.7.5.4 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory.

The start address, and number of bytes are the 2 parameters required for the FlashEraseRegion command. The start and byte count parameters must be 32-byte aligned ([3:0] = 0000), or the FlashEraseRegion command fails and returns kStatus_FlashAlignmentError (101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command fails and returns kStatus_FlashAddressError (102). If any part of the region specified is protected, the FlashEraseRegion command fails and returns kStatus_MemoryRangeInvalid (10200).

Table 95. Parameters for FlashEraseRegion Command

Byte #	Parameter
0 - 3	Start address
4 - 7	Byte count
8 - 11	Memory ID

The FlashEraseRegion command has no data phase.

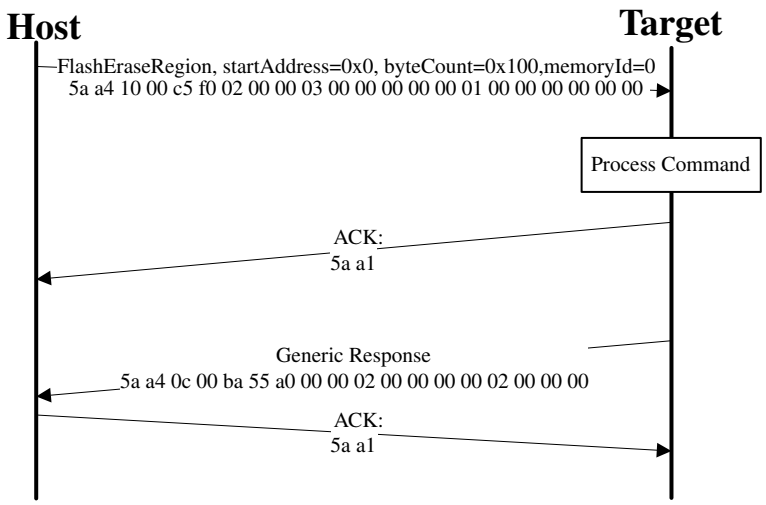

Figure 35. Protocol Sequence for FlashEraseRegion Command

Response: The target returns a GenericResponse packet with one of following error status codes.

Table 96. FlashEraseRegion Response Status Codes

Status Code
kStatus_Success (0)
kStatus_MemoryRangeInvalid (10200)
kStatus_FlashAlignmentError (101)
kStatus_FlashAddressError (102)
kStatus_FlashAccessError (103)
kStatus_FlashCommandFailure (105)

15.2.7.5.5 ReadMemory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address, and number of bytes are the two parameters required for ReadMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 97. Parameters for read memory command

Byte	Parameter	Description
0-3	Start address	Start address of memory to read from
4-7	Byte count	Number of bytes to read and return to caller
8-11	Memory ID	Internal or external memory Identifier

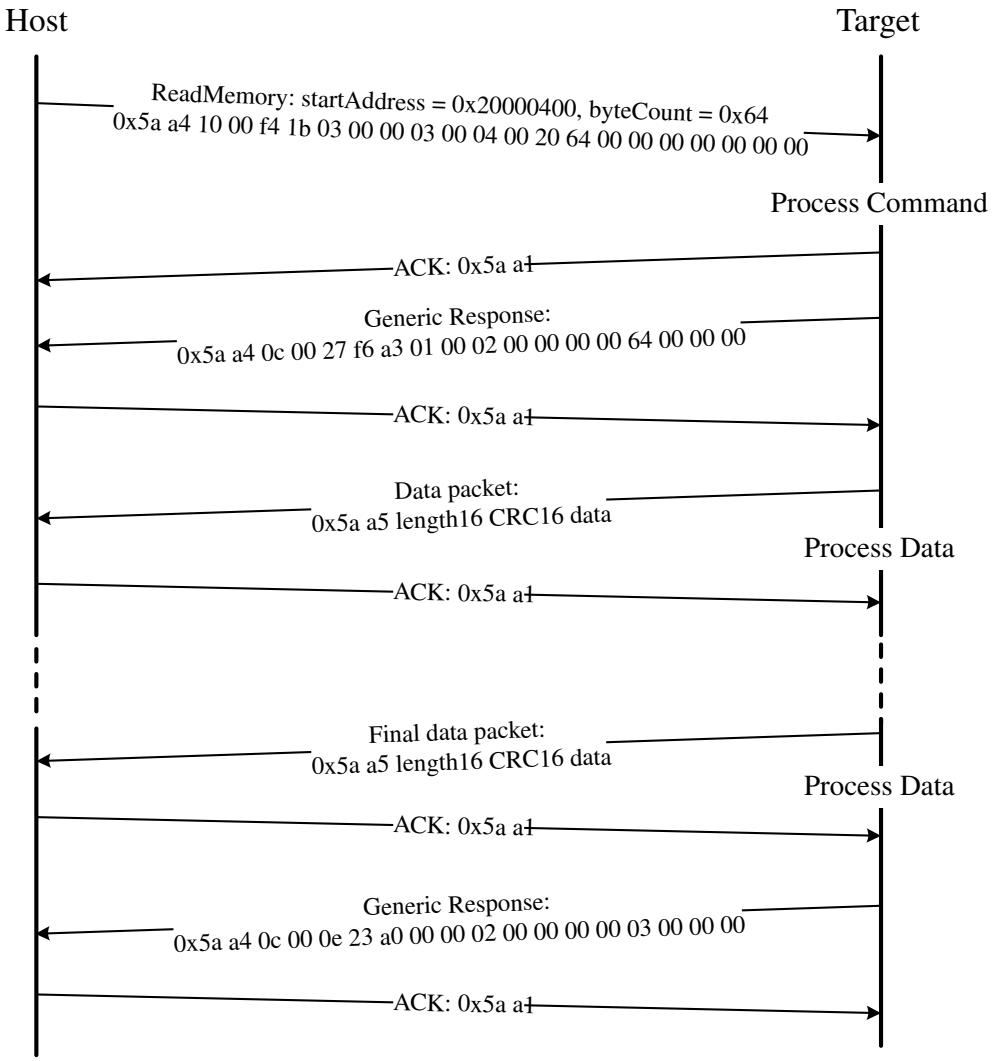

Figure 36. Command sequence for ReadMemory

Table 98. ReadMemory Command Packet Format (Example)

ReadMemory	Parameter	Value
Framing packet	Start byte	0x5A0xA4,
	packetType	kFramingPacketType_Command
	length	0x10 0x00
	crc16	0xF4 0x1B

Table continues on the next page...

Table 98. ReadMemory Command Packet Format (Example) (continued)

Command packet	commandTag	0x03 - readMemory
	flags	0x00
	reserved	0x00
	parameterCount	0x03
	startAddress	0x20000400
	byteCount	0x00000064
	memoryID	0x0

Data Phase: The ReadMemory command has a data phase. Because the target works in slave mode, the host needs to pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

Response: The target returns a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command or set to an appropriate error status code.

15.2.7.5.6 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM). However, if flash protection is enabled, then writes to protected sectors fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be 16-byte aligned ([3:0] = 0000).
- The byte count is rounded up to a multiple of 4, and trailing bytes are filled with the flash erase pattern (0xff).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

The start address and number of bytes are the 2 parameters required for WriteMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 99. Parameters for WriteMemory Command

Byte #	Command
0 - 3	Start address
4 - 7	Byte count
8 - 11	Memory ID

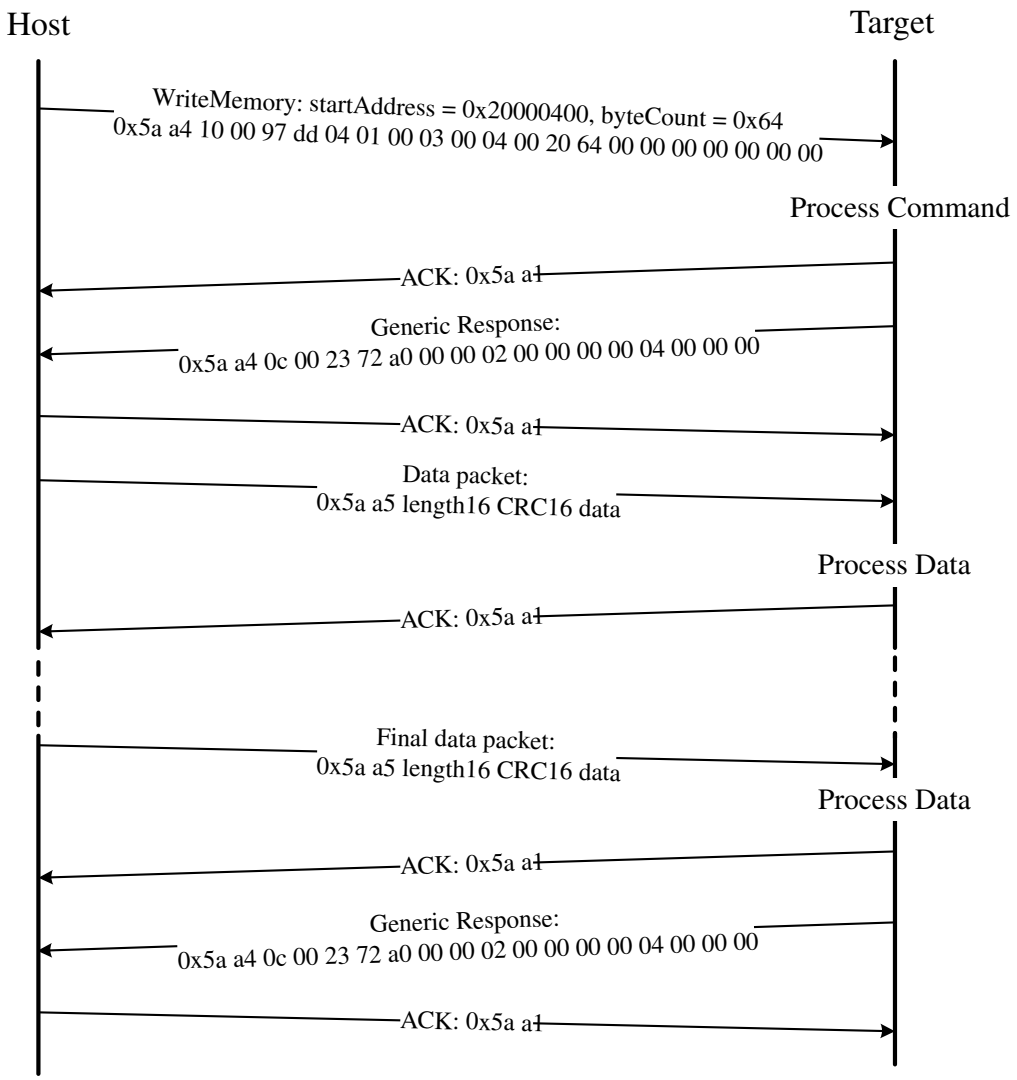

Figure 37. Protocol Sequence for WriteMemory Command

Table 100. WriteMemory Command Packet Format (Example)

WriteMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00

Table continues on the next page...

Table 100. WriteMemory Command Packet Format (Example) (continued)

	crc16	0x97 0xDD
Command packet	commandTag	0x04 - writeMemory
	flags	0x01
	reserved	0x00
	parameterCount	0x03
	startAddress	0x20000400
	byteCount	0x00000064
	memoryID	0x0

Data Phase: The WriteMemory command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to kStatus_Success upon successful execution of the command, or to an appropriate error status code.

15.2.7.5.7 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that a data pattern is included in FillMemory command parameter, and there is no data phase for the FillMemory command, while WriteMemory does have a data phase.

Table 101. Parameters for FillMemory Command

Byte #	Command
0 - 3	Start address of memory to fill
4 - 7	Number of bytes to write with the pattern • The start address should be 32-bit aligned. • The number of bytes must be evenly divisible by 4.
8 - 11	32-bit pattern

- To fill with a byte pattern (8-bit), the byte must be replicated 4 times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated 2 times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern is 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern is 0x5AFE5AFE.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be 16-byte aligned ([3:0] = 0000).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

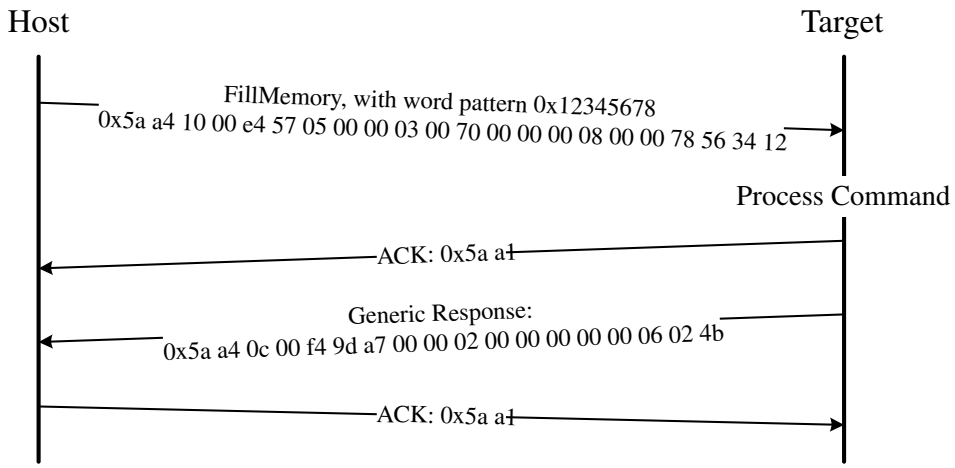

Figure 38. Protocol Sequence for FillMemory Command

Table 102. FillMemory Command Packet Format (Example)

FillMemory	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00
	crc16	0xE4 0x57
Command packet	commandTag	0x05 – FillMemory
	flags	0x00
	Reserved	0x00
	parameterCount	0x03
	startAddress	0x00007000
	byteCount	0x00000800
	patternWord	0x12345678

The FillMemory command has no data phase.

Response: upon successful execution of the command, the target (Kinetis bootloader) returns a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

15.2.7.5.8 Execute command

The execute command results in the bootloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command. If the stack pointer is set to zero, the called code is responsible for setting the processor stack pointer before using the stack.

Table 103. . Parameters for Execute Command

Byte #	Command
0 - 3	Jump address
4 - 7	Argument word
8 - 11	Stack pointer address

The Execute command has no data phase.

Response: Before executing the Execute command, the target validates the parameters and return a GenericResponse packet with a status code either set to kStatus_Success or an appropriate error status code.

15.2.7.5.9 Reset command

The Reset command results in the bootloader resetting the chip.

The Reset command requires no parameters.

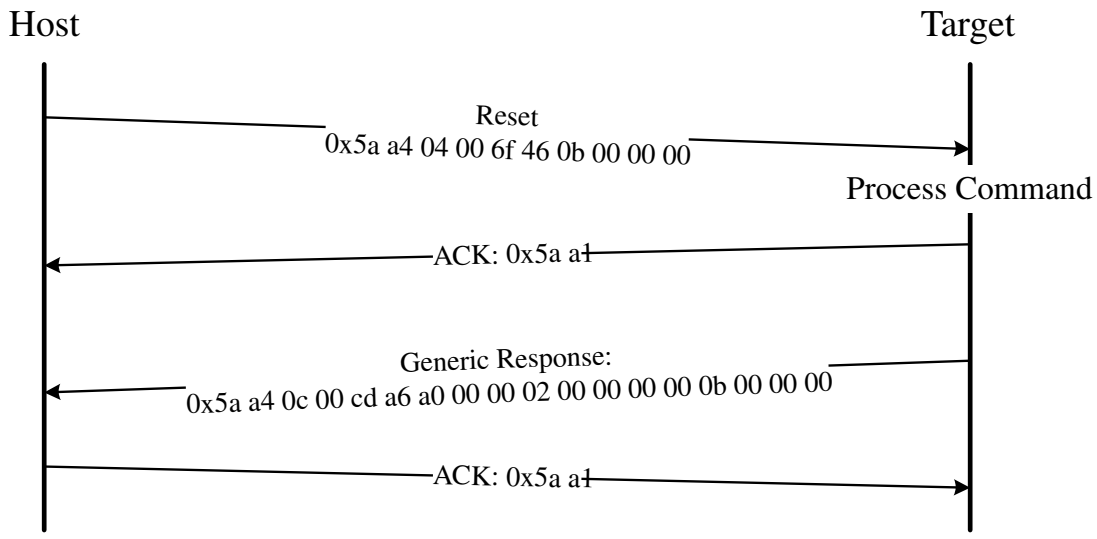

Figure 39. Protocol Sequence for Reset Command

Table 104. Reset Command Packet Format (Example)

Reset	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x04 0x00
	crc16	0x6F 0x46
Command packet	commandTag	0x0B - reset
	flags	0x00
	reserved	0x00
	parameterCount	0x00

The Reset command has no data phase.

Response: The target returns a GenericResponse packet with status code set to kStatus_Success, before resetting the chip.

The reset command can also be used to switch boot from flash after successful flash image provisioning via ROM bootloader. After issuing the reset command, allow 5 seconds for the user application to start running from Flash.

15.2.7.5.10 Receive SBFile command

The Receive SB File command (ReceiveSbFile) starts the transfer of an SB file to the target. The command only specifies the size in bytes of the SB file that is sent in the data phase. The SB file is processed as it is received by the bootloader. See the Secure boot related sections for more details about the SB file.

Table 105. . Parameters for Receive SB File Command

Byte #	Command
0 – 3	Byte count

Data Phase: The Receive SB file command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the Receive SB File command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to the kStatus_Success upon successful execution of the command or set to an appropriate error code.

15.2.7.6 LPUART ISP

The bootloader integrates an autobaud detection algorithm for the LPUART peripheral, thereby providing flexible baud rate choices.

Autobaud feature: If LPUART*n* is used to connect to the bootloader, then the LPUART*n*_RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the bootloader detects the ping packet (0x5A 0xA6) on LPUART*n*_RX, the bootloader firmware executes the autobaud sequence.

If the baudrate is successfully detected, then the bootloader sends a ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The Kinetis bootloader then enters a loop, waiting for bootloader commands via the LPUART peripheral.

NOTE

The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed LPUART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this instance, the autobaud detection state machine should be reset.

Supported baud rates: The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, 115200 and 230400.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

Packet transfer: After autobaud detection succeeds, bootloader communications can take place over the LPUART peripheral. The following flow charts show:

- How the host detects an ACK from the target
- How the host detects a ping response from the target
- How the host detects a command response from the target

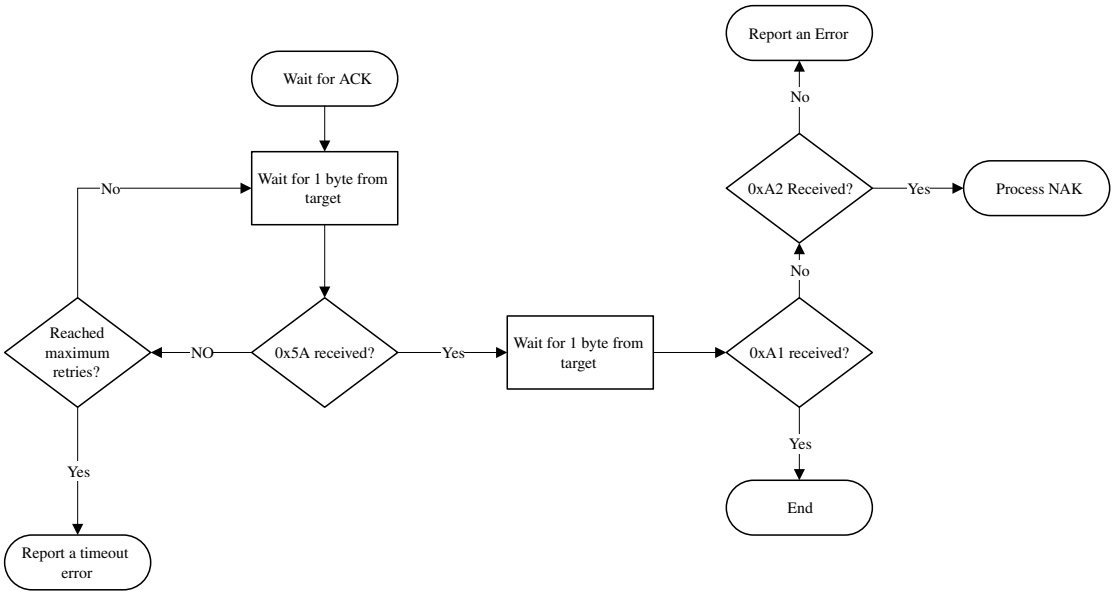

Figure 40. Host reads an ACK from target via LPUART

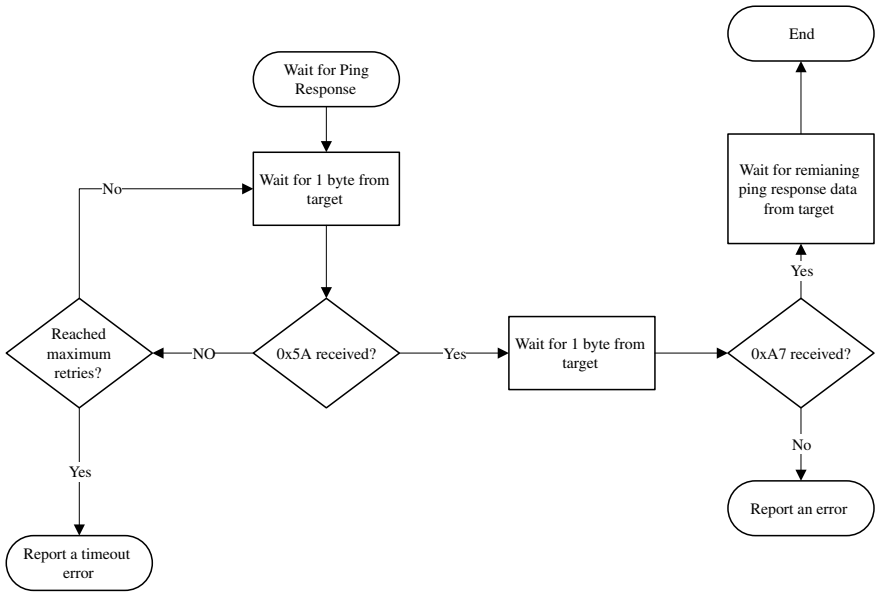

Figure 41. Host reads a ping response from target via LPUART

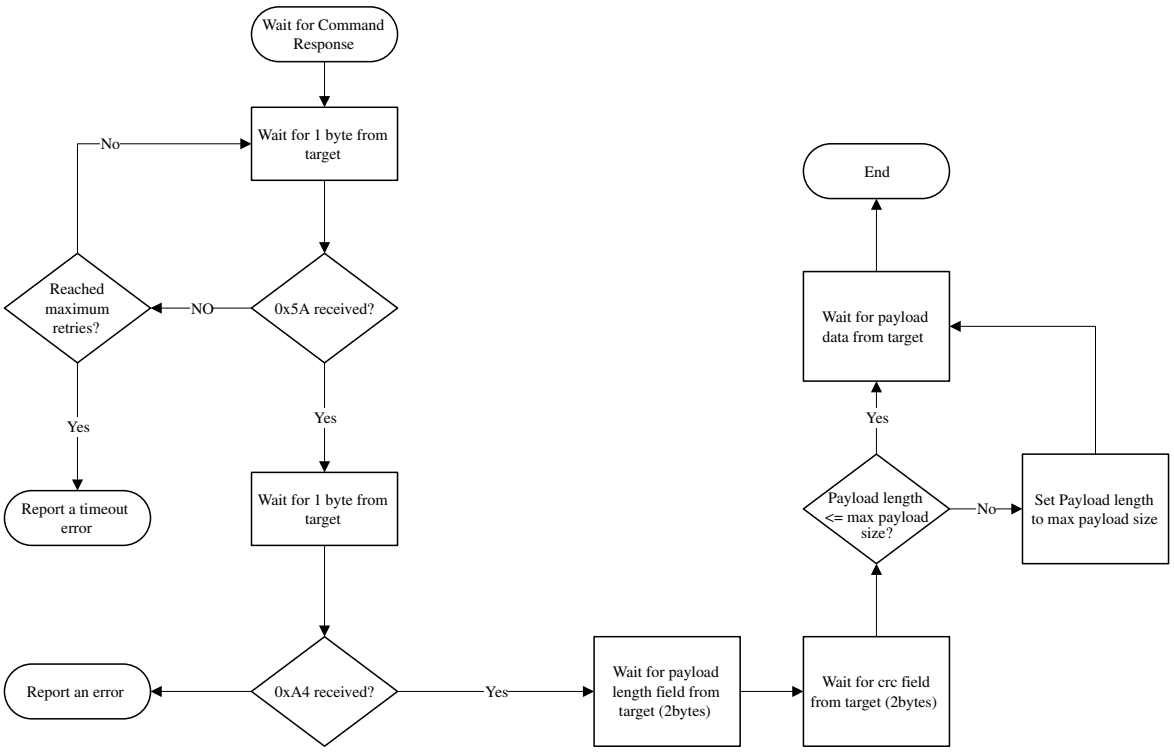

Figure 42. Host reads a command response from target via LPUART

For information on commands and formats, see ISP packet type

15.2.7.7 LPI2C ISP

The bootloader supports In-System Programming or serial boot via the LPI2C peripheral, where the LPI2C peripheral serves as the LPI2C slave. The bootloader uses 0x10 as the 7-bit LPI2C slave address and supports up to 400 kbit/s speed during transfer.

The maximum supported LPI2C baud rate depends on the core clock frequency when the bootloader is running. The typical baud rate is 400 kbit/s with factory settings.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

The LPI2C peripheral serves as an LPI2C slave device, hence each transfer should be started by the host, and each outgoing packet should be fetched by the host as well.

- An incoming packet is sent by the host with a selected LPI2C slave address and the direction bit is set to write.
- An outgoing packet is read by the host with a selected LPI2C slave address and the direction bit is set as read.
- 0x00 is sent as the response to host if the target is busy with processing or preparing data.

The following charts show the communication flow of the host reading the ACK packet and the corresponding responses from the target.

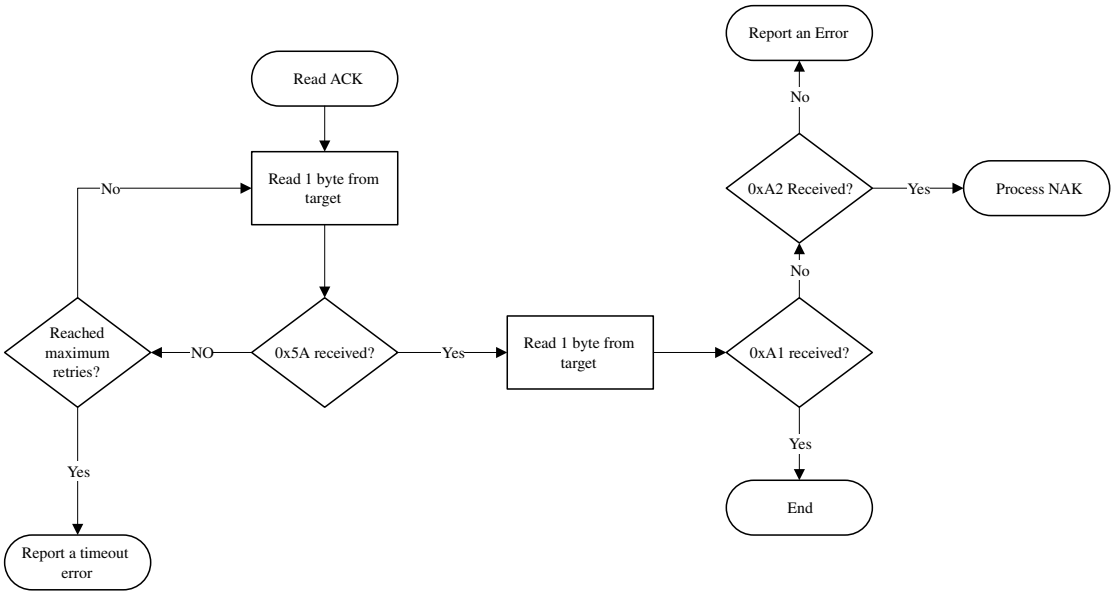

Figure 43. Host reads ACK packet from target via LPI2C

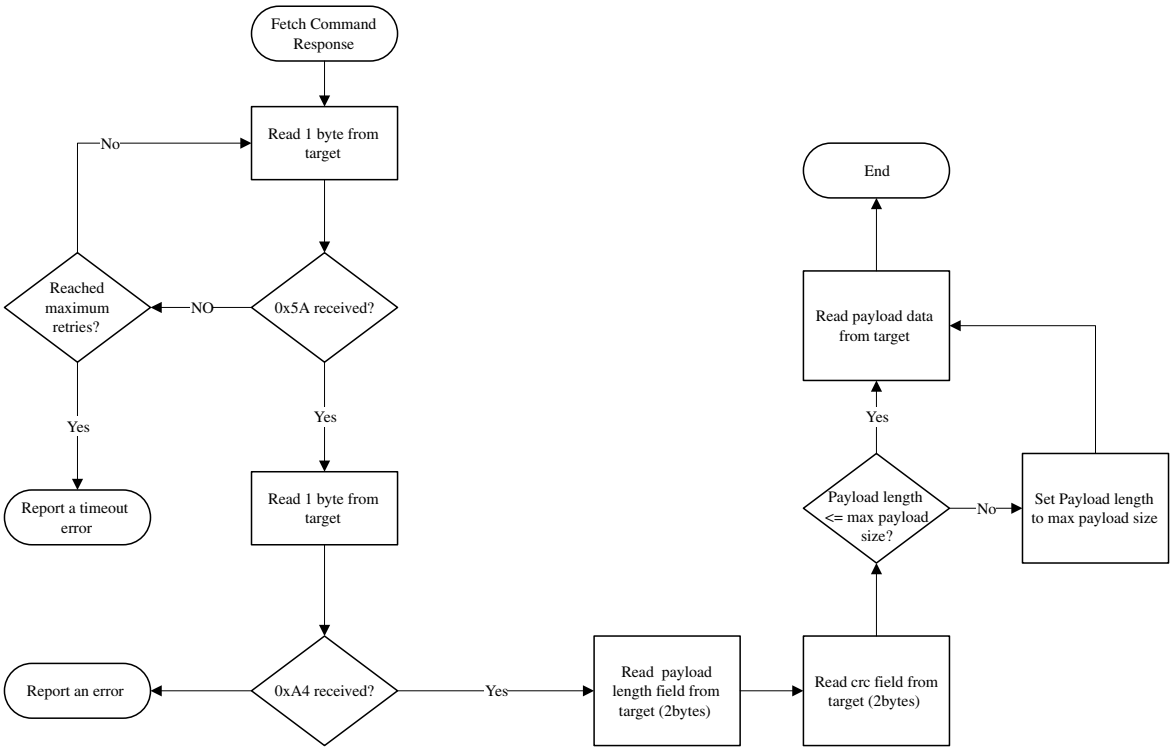

Figure 44. Host reads response from target via LPI2C

For information on commands and formats, see ISP packet type

15.2.7.8 LPSPI ISP

The bootloader supports In-System Programming or serial boot via the LPSPI peripheral.

The maximum supported baud rate of the LPSPI depends on the core clock frequency when the bootloader is running. The typical baud rate is 1 MHz with the factory settings. The actual baud rate is up to 4 MHz when the core is running at high-speed boot mode. The LPSPI peripheral in the bootloader serves as an LPSPI slave device. Each transfer, therefore, must be started by the host, and each outgoing packet should be fetched by the host as well.

NOTE

The peripheral baud rate mentioned here is just at ISP packet level, the actual download speed in ISP is lower than the baud rate because of overhead in the ISP protocol and packet handling.

Compared to LPUART and LPI2C peripherals, the transfer on LPSPI is slightly different:

- The host receives 1 byte after it sends out any byte.
- Received bytes should be ignored when the host is sending out bytes to the target
- The host starts reading bytes by sending 0x00s to target
- The byte 0x00 is sent as a response to host if the target is under the following conditions:
  - Processing incoming packet
  - Preparing outgoing data
  - Received invalid data

The following flowcharts show how the host reads a ping response, an ACK and a command response from target via LPSPI without the nIRQ pin enabled.

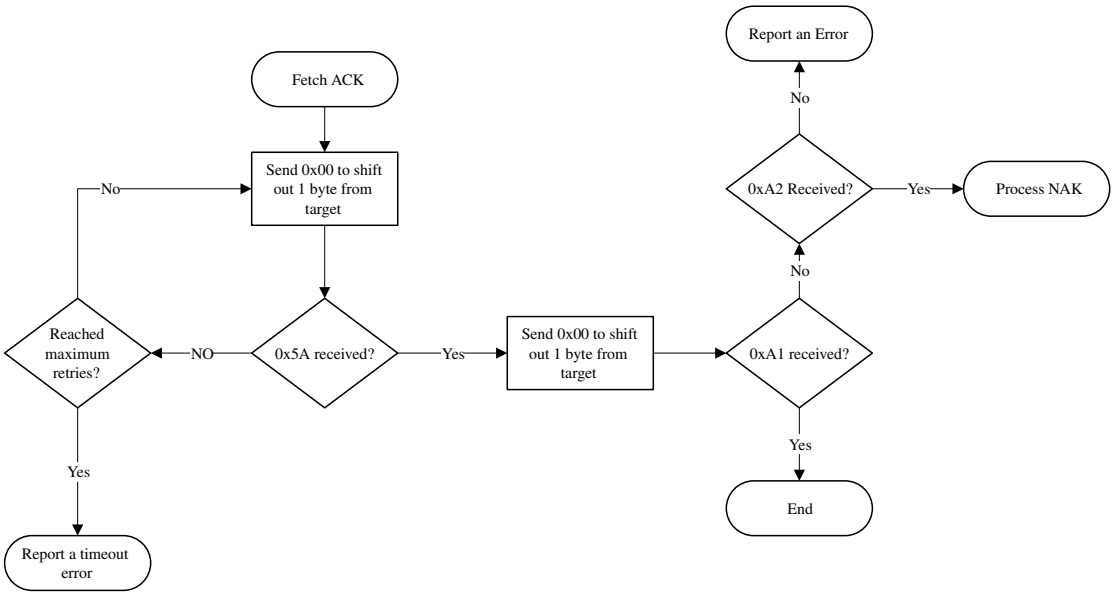

Figure 45. Host reads ACK from target via LPSPI

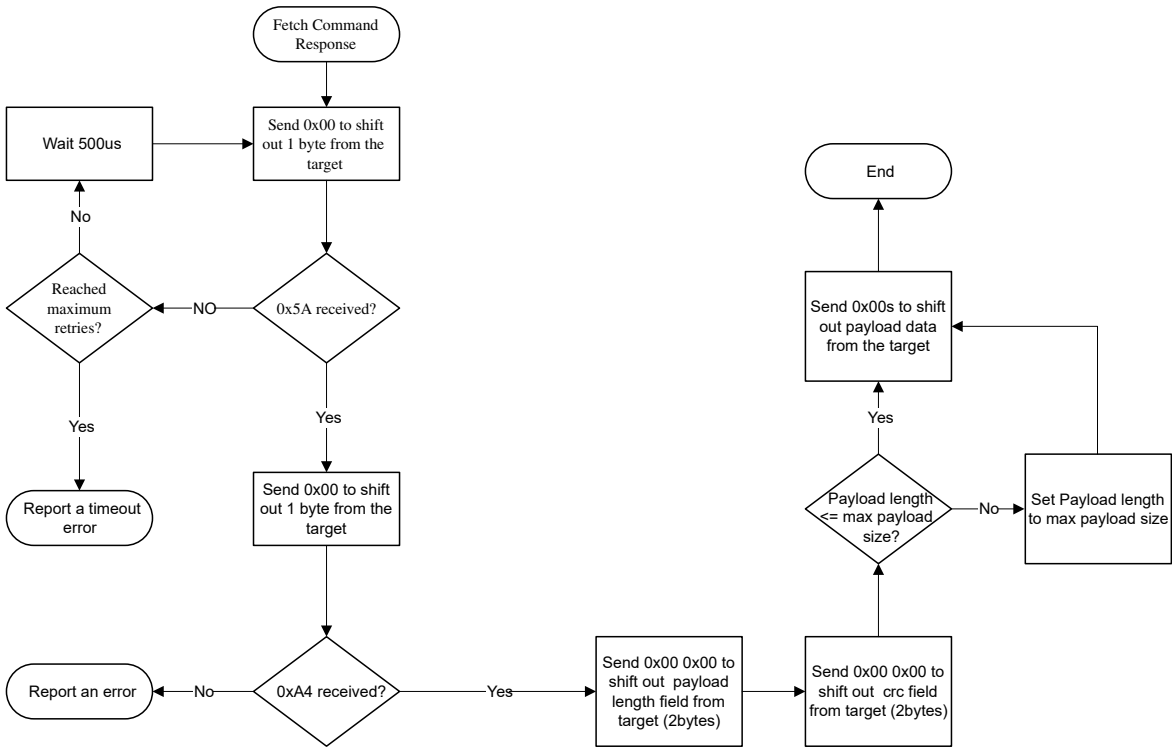

Figure 46. Host reads response from target via LPSPI

For information on commands and formats, see ISP packet type

15.2.8 Debugger mailbox path

Debugger Mailbox (DM) is a register-based mailbox operating over Serial Wire Debug Port (SWD). It can be accessed via a Debug Access port (DM-AP) which is always enabled. The external world can send and receive data to/from the ROM bootloader via Debugger Mailbox. One important feature of Debugger Mailbox is that it supports NXP Debug Authentication Protocol, which

allows users to enable debug access for CM33 and radio (CM33) when security is required. Meanwhile, users can utilize Debugger Mailbox to initiate a debugging session when there is no valid boot image.

The communication to the Debugger Mailbox is initiated by the debugger. It does so by setting a re-synchronization request and then resets the chip. ROM bootloader can observe the request and go to Debugger Mailbox Path.

15.2.8.1 Quick guide of using debugger mailbox

To make ROM bootloader enter the Debugger Mailbox, the debugger needs to select DM-AP and set the RESYNCH_REQ bit and the CHIP_RESET_REQ bit to 1 in the CSW register. Following a successful initial re-synchronization and reset, communication by the debugger to the device is achieved using 32-bit DM-AP command writes to the REQUEST register in the Debug Mailbox (DM-AP Commands are shown in table below) The debugger can read results of communications via the RETURN register. Response codes are shown in DM-AP return codes.

The example below shows how to enter debug mailbox and do the communication:

```
// Pseudo Code Syntax
// ------------------------------------------------------------------------
// WriteDP <register> <value>
// value = ReadDP <register>
// AP transactions presume the DM AP is selected
// WriteAP <register> <value>
// value = ReadAP <register> <value>
// ------------------------------------------------------------------------
// Read AP ID register to identify DM AP at index 2
WriteDP 2 0x020000F0
// The returned AP ID should be 0x002A0000
value = ReadAP 3
print "AP ID: ", value
// Select DM AP index 2
WriteDP 2 0x02000000
// Write DM RESYNC_REQ + CHIP_RESET_REQ
WriteAP 0 0x21
// Write DM-AP Command START DM-AP (1) to REQUEST register (1)
WriteAP 1 1
// Read the return code of START DM-AP command from RETURN register (2), 0x0 means success
ReadAP 2
// Write Get Lifecycle (2) to REQUEST register (1)
WriteAP 1 2
// Read the value of current lifecycle from RETURN register (2)
ReadAP 2
```

When doing debug authentication, Debug Auth Start command needs to be sent first and DAC needs to be read back. Then sending Debug Auth Response command with DAR. Pseudo code below shows how to use debug authentication commands. See Debug authentication for more details.

```
// Assume already in Debugger Mailbox
// Write Debug Auth Start (0x10) to REQUEST register (1)
WriteAP 1 0x10
// Read the data count of DAC
ReadAP 2
// Assume reading back 0x82000000, then the length of DAC is 0x200 word (4-byte)
// Send the ACK_TOKEN with the length of remaining data (word) to receive
WriteAP 1 0x0200A5A5
// Read DAC data
ReadAP 2
WriteAP 1 0x01FFA5A5
ReadAP 2
…
```

```
WriteAP 1 0x0001A5A5
ReadAP 2
// Get the whole DAC, generate DAR using DAC, assume length of DAR is 0x400 word (4-byte)
// Write Debug Auth Response (0x11) with DAR length to REQUEST register (1)
WriteAP 1 0x04000011
// Read the ACK_TOKEN from RETURN register (2), should be 0x0400A5A5
ReadAP 2
// Send DAR data, use 0x00000000 as an example of data
WriteAP 1 0x00000000
// Read the ACK_TOKEN, should be 0x03FFA5A5
ReadAP 2
// Send next DAR data
WriteAP 1 0x00000000
ReadAP 2
…
WriteAP 1 0x00000000
// Complete sending DAR when ACK_TOKEN is 0x0000A5A5
ReadAP 2
```

15.2.8.1.1 DM-AP commands

Commands for the DM-AP are listed below. These would be written to the REQUEST register. Please note that Bulk Erase/ Enter ISP Mode/ Set FA Mode can only be issued after authentication at lifecycle after OEM Open.

Table 106. DM-AP commands

Command	ID	Parameter/Response	Description
Start DM-AP	0x01	*Parameters*: None *Response*: 32-bit status	Cause the device to enter DM-AP command mode. This must be done prior to Get Lifecycle command. This command is provided for backwards compatibility and does not need to be used for most commands.
Bulk Erase	0x03	*Parameters*: None *Response*: 32-bit status	Erase the entire CM33 Program Flash (IFR0 not included).
Exit DM-AP	0x04	*Parameters*: None *Response*: 32-bit status	Cause the device to exit DM-AP command mode. The device returns to normal boot path.
Enter ISP Mode	0x05	*Parameters*: dataWordCount: 0x1 data[0]: ISP mode enum. 0xffffffff – Auto detection 0x1 - LPUART 0x2 - LPI2C 0x4 - LPSPI Others - Reserved	Enter specified ISP path.

Table continues on the next page...

Table 106. DM-AP commands (continued)

Command	ID	Parameter/Response	Description
		Response: 32-bit status	
Set FA Mode	0x06	*Parameters*: data[]: FA Request *Response*: 32-bit status	Set the part permanently in "Fault Analysis" mode to return to NXP factory. ROM erases customer sensitive assets (key codes) stored in PFR. Sets Fault Analysis (FA or RMA) mode bit in PFR field. So, that customers could ship these parts to NXP for FA/RMA testing.
Start Debug Session	0x07	*Parameters*: None *Response*: 32-bit status	This command is used to indicate ROM the intention of connecting debugger. ROM bootloader enables debug access (if no debug authentication required) and enters while(1) loop.
Debug Auth Start	0x10	*Parameters*: dataWordCount: 0x0 *Response*: data[] : DAC	Start Debug Authentication Protocol. ROM responds to debugger with *DAC (Debug Authentication Challenge)* message.
Debug Auth Response	0x11	*Parameters*: data[] : DAR *Response*: 32-bit status	Debug Authentication Response.

15.2.8.1.2 DM-AP return codes

Return codes for DM-AP commands are listed below. These commands can be read from the RETURN register. See table below.

Table 107. DM-AP return codes

Return code	Descriptions
0x0000 0000	Command succeeded.
0x0010 0001	Debug mode not entered. This is returned if other commands are sent prior to the “Enter DM-AP” command.
0x0010 0002	Command not recognized. A command was received other than the ones defined above.
0x0010 0003	Command failed.

15.2.8.2 Debugger Mailbox protocol

ROM Bootloader implements debug mailbox protocol to interact with host debug systems over the SWD interface. The protocol has following features:

- Request/response based.
- Support for relatively large command and response data.
- All commands and responses are 32-bit word aligned.
- Supports data above 32 bits by using an ACK_TOKEN that moderates the transfer in 32-bit value chunks.
- Requests and responses use the same basic structure.

15.2.8.2.1 Mailbox registers

The registers in the debug mailbox are shown in Table below. These registers are readable by the CPU and are intended primarily to allow on-chip ROM routines to implement requests from an external debugger.

Table 108. Register overview: DBGMailbox (base address = 0x58000000)

Name	Access	Offset	Description	Reset value
CSW	R/W	0x000	Command and status word	0x0
REQ	R/W	0x004	Request from the debugger to the device	0x0
RETURN	R/W	0x008	Return value from the device to the debugger	0x0
ID	RO	0x0FC	Identification register	0x002A0000

15.2.8.2.1.1 Command and Status Word Register (CSW)

The CSW register contains command and status bits to facilitate communication between the debugger and the device.

Table 109. Command and Status Word register (CSW, offset = 0x000)

Bit	Symbol	Description	Reset Value
0	RESYNCH_REQ	The debugger sets this bit to request a re-synchronization.	0x0
1	REQ_PENDING	A request is pending for the debugger: a value is waiting to be read from the REQUEST register.	0x0
2	DBG_OR_ERR	When 1, a debug overrun has occurred: a REQUEST value has been overwritten by the debugger before it was read by the device.	0x0
3	AHB_OR_ERR	When 1, an AHB overrun has occurred: a RETURN value has been overwritten by the device before it was read by the debugger.	0x0
4	SOFT_RESET	Setting this write-only bit in the CSW register of the DM-AP by an external debugger resets the DM-AP state machine and its registers. While setting RESYNCH_REQ only resets the DP and CPU handshake state machine.	0x0
5	CHIP_RESET_REQ	This write-only bit causes the device (but not the DM-AP) to be reset by generating SYSRESET_REQ.	0x0
31:6	Reserved		-

15.2.8.2.1.2 Request value register

The REQUEST register is used by a debugger to send action requests to the device.

Table 110. Request value register (REQUEST, offset = 0x004)

Bit	Symbol	Description	Reset Value
31:0	REQUEST	Request value. Reads as 0 when no new request is present. Cleared by the device. Can be read back by the debugger in order to confirm communication.	0x0

15.2.8.2.1.3 Return value register

The RETURN register provides any response from the device to the debugger.

Table 111. Return value register (RETURN, offset = 0x008)

Bit	Symbol	Description	Reset Value
31:0	RET	Return value. This is any response from the device to the debugger. If no new data is present, a debugger read will be stalled until new data is available.	0x0

15.2.8.2.1.4 Identification register

The ID register provides an identification of the DM-AP interface.

Table 112. Identification register (ID, offset = 0x0FC)

Bit	Symbol	Description	Reset Value
31:0	ID	Identification value.	0x002A0000

15.2.8.2.2 Mailbox commands

15.2.8.2.2.1 Request

The first word transmitted in a request is a header word containing the command ID and number of following data words. Following the header are the number of 32-bit words specified in the header.

Table 113. Request register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	commandID[7:0]	commandID[15:8]	dataWordCount[7:0]	dataWordCount[15:8]
1	*data...*			

The C structure definition for a request is as follows:

```
struct dm_request {
  uint16_t commandID;
  uint16_t dataWordCount;
  uint32_t data[]; };
```

15.2.8.2.2.2 Response

The first word transmitted in a response is a header word containing the command status and number of following data words.

- To support legacy command and response value, Bit_31 in header will be used to indicate that the response follows new protocol structure.

Table 114. Response register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	commandStatus[7:0]	commandStatus[15:8]	dataWordCount[7:0]	dataWordCount[14:8] new_protocol[15]
1	*data...*			

The C structure definition for a response is as follows:

```
struct dm_response {
    uint16_t commandStatus;
    uint16_t dataWordCount;
    uint32_t data[];
};
```

15.2.8.2.2.3 ACK_TOKEN

- When command has parameters the debugger should wait for ACK_TOKEN (sent through DBG_MB_RETURN register) before sending next 32-bit value.
- Similarly when response packet has data to send back to debugger, ROM will wait for debugger to send ACK_TOKEN (sent through DBG_MB_REQUEST register) before sending next 32-bit value.
- Upper 16 bits are set by receiving end with number of remaining words expected.
- Lower 16 bits are always set to 0xA5A5.

Table 115. ACK_TOKEN register byte description

Word	Byte 0	Byte 1	Byte 2	Byte 3
0	0xA5	0xA5	remainCount[7:0]	remainCount[15:8]

The C structure definition for a ACK_TOKEN is as follows:

```
struct dm_ack_token {
    uint16_t token; /* always set to 0xA5A5 */
    uint16_t remainCount; /* count of remaining word */};
```

15.2.8.2.2.4 Error handling

If an overrun occurs from either side of the communication, the appropriate error flag is set in the CSW. The state machine hardware will prevent further communication in any direction once an overrun has occurred in that direction, so if such an error occurs, the debugger will need to start with a new re-synchronization request in order to clear the error flag.

15.2.8.3 Debug authentication

The fundamental principles of debugging, which require access to the system state and system information, conflict with the principles of security, which require the restriction of access to assets. Thus, many products disable debug access completely

before deploying the product. This causes challenges for product design teams to do proper Return Material Analysis (RMA). To address these challenges, the ROM bootloader offers a debug authentication protocol as a mechanism to authenticate the debugger (an external entity) has the credentials approved by the product manufacturer before granting debug access to the device.

The debug authentication scheme is a challenge-response scheme and assures that debugger in possession of required debug credentials only can successfully authenticate over debug interface and access restricted parts of the device. This protocol is divided into steps as shown in description and figure below.

1. The debugger initiates the Debug Mailbox message exchange by setting the RESYNCH_REQ bit and CHIP_RESET_REQ bit in the CSW register of DM-AP.
2. The debugger waits (minimum 30ms) for the devices to restart and enter debug mailbox request handling loop.
3. The debugger sends Debug Authentication Start command (command code 0x10) to the device.
4. The device responds back with Debug Authentication Challenge (DAC) packet based on the debug access rights pre-configured in CMPA fields, which are collectively referred as Device Credential Constraints Configuration (DCFG_CC). The response packet also contains a 32 bytes random challenge vector.
5. The debugger responds to the challenge with a Debug Authentication Response (DAR) message by using an appropriate debug certificate, matching the device identifier in the DAC. The DAR packet contains the debug access permission certificate, also referred as Debug Credential (DC), and a cryptographic signature binding the DC and the challenge vector provided in the DAC.
6. The device on receiving the DAR, validates the contents by verifying the cryptographic signature of the message using the debugger's public key present in the embedded the Debug Credential (DC). On successful validation of DAR, the device enables access to the debug domains permitted in the DC.

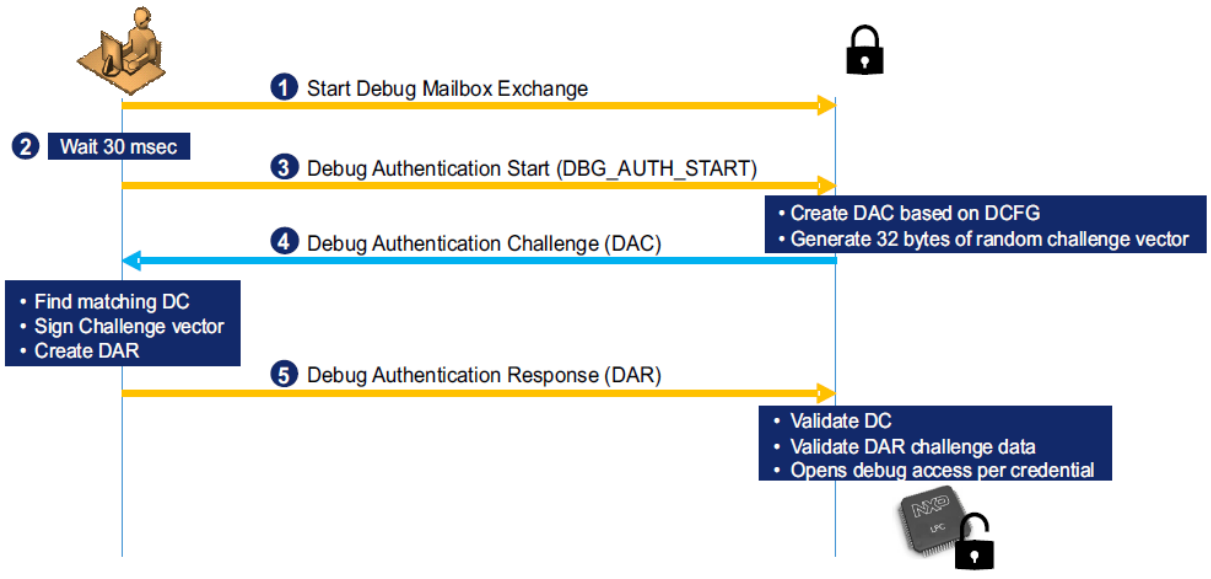

Figure 47. Debug authentication flow

15.2.8.3.1 Debug access control configuration

The ROM bootloader handles the device side of Debug authentication process. However, the debug access control rights and security policies can be configured by programming the following configuration fields which are collectively referred to as Device Configuration for Credential Constraints (DCFG_CC).

- DCFG_VER: This field controls the cryptographic primitives used during authentication.

- DCFG_ROTID: This field defines the Root of trust identifier (ROTID). The ROTID field is used to bind the devices to specific Certificate Authority (CA) keys issuing the debug credentials. These CA keys are also referred as Root of Trust (RoTK) keys.
- DCFG_UUID: Controls whether to enforce UUID check during Debug Credential (DC) validation. If this field is set only DC with matching device UUID can unlock the debug access.
- DCFG_CC_SOCU: This configuration field specifies access rights to various debug domains.
- DCFG_VENDOR_USAGE: This field can be used to define vendor specific debug policy use case such as DC revocations or department identifier. It is recommended to use field for revocation of already issued debug certificates.

15.2.8.3.1.1 Protocol Version (DCFG_VER)

This device supports Debug authentication protocol version 2.1, which are defined based on the secp384r1 curve.

NOTE

Both debug authentication certificates and image signing certificates use same Root of Trust keys (RoTK).

15.2.8.3.1.2 Root of Trust Identifier (DCFG_ROTID)

The Root of Trust Identifier used in debug authentication protocol is composed of two elements.

- A 256-bit cryptographic hash (SHA256 or leading 32 bytes of SHA384, according root certificates EC types, secp256r1->SHA256 or secp384r1->SHA384) over the Root of Trust Keys hash table.
- A 32-bit field containing revocation bits for the four Root of Trust keys in the table.

15.2.8.3.1.3 Enforce UUID checking (DCFG_UUID)

Controls whether to enforce UUID check during Debug Credential (DC) validation. If this field is set, then only DC containing a UUID attribute that is an exact match to the device can unlock the debug access.

This field can be set by programming UUID_CHECK (bit 16) in CC_SOCU.

This device-specific constraint, if enabled, is in addition to all the other constraints defined and enforced by the authentication protocol

15.2.8.3.1.4 Credential Constraints (DCFG_CC_SOCU)

The DCFG_CC_SOCU is a configuration that specifies debug access restrictions per debug domain. These access restrictions are also referred as constraint attributes in this section. The debug subsystem is sub-divided into multiple debug domains to allow finer access control. Table 117 shows debug domains and their corresponding control bit position in DCFG_CC_SOCU. Which is logically composed of two components:

- SOCU_PIN (bit 7-0 in CC_SOCU): A bitmask that specifies which debug domains are predetermined by device configuration.
- SOCU_DFLT (bit 15-8 in CC_SOCU): Provides the final access level for those bits that the SOCU_PIN field indicated are predetermined by device configuration.

The following table shows the restriction levels:

Table 116. Access restriction levels

Restriction Level	SOCU_PIN [n]	SOCU_DFLT [n]	Description
0	1	1	Access to the sub-domain is always enabled.

Table continues on the next page...

Table 116. Access restriction levels (continued)

Restriction Level	SOCU_PIN [n]	SOCU_DFLT [n]	Description
			This setting is provided for module use case scenario where DCFG_CC_SOCU_NS would be used to define further access restrictions before final deployment of the product.
1	0	0	Access to the sub-domain is disabled at start up. But the access can be enabled through debug authentication process by providing appropriate Debug Credential (DC) certificate.
2	0	1	Illegal setting. Part may lock-up if this setting is selected.
3	1	0	Access to the sub-domain is permanently disabled and cannot be reversed. This setting offers the highest level of restriction.

Debug domains supported by this device are shown in table below.

Table 117. CC_LIST_Table

Bit	Symbol	Description
0	NIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
1	DBGEN	Controls invasive debugging of TrustZone for Arm8-M defined non-secure domain of CM33.
2	SPNIDEN	Controls non-Invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
3	SPIDEN	Controls invasive debugging of TrustZone for Arm8-M defined secure domain of CM33.
4	NBU_DBGEN	Controls debugging of NBU (radio, CM33)
5	FA_CMD_EN	Controls whether DM-AP command, Set FA Mode (command code: 0x06), can be issued through after authentication.
6	ISP_CMD_EN	Controls whether ISP boot flow DM-AP command (command code: 0x05) can be issued after authentication.
7	ME_CMD_EN	Controls whether DM-AP command, Bulk Erase (command code: 0x02), can be issued through after authentication.
31:8	RSRVD	Reserved

15.2.8.3.1.5 DCFG_VENDOR_USAGE

This field can be used to define vendor specific debug policy use case such as Debug Credential (DC) certificate revocations or department identifier or model identifier. During Debug Authentication Response (DAR) processing the device checks that

the value specified in Vendor Usage field of DC matches exactly the value programmed in DCFG_VENDOR_USAGE fields of device configurations.

15.2.8.3.2 Debug Authentication Challenge (DAC)

The debug authentication protocol begins with a DEBUG_AUTH_START request, issued by the debugger to the device, which replies by Authentication Challenge (DAC) message, issued by the device to the debugger. The DAC carries information about current device state to the debugger, inputs from DAC are necessary to find existing or request generation of new Debug Credential (DC). Protocol version 2.x uses ECC for digital signatures, minor version 0 (”2.0”) points to secp256r1 and minor version 1 (“2.1”) points to secp384r1.

Structure of DAC message is shown in following Figure .

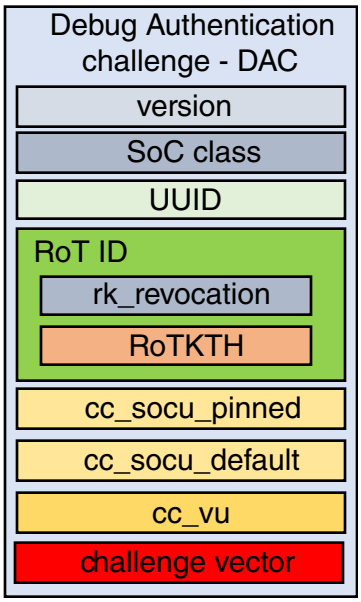

Figure 48. Debug Authentication Challenge (DAC)

- **version** – uint32_t, little endian

  Fixed to value 0x02000000u "2.0" (major =2, minor = 0) -> secp256r1 used as RoTKTH, or fixed to value 0x02000100u "2.1" (major =2, minor = 1) -> secp384r1 used as RoTKTH

- **SoC class** – uint32_t, little endian

  Fixed to 0x5u for this device, identify the device family

- **UUID** – uint32_t[4], little endian

  Unique ID of device.

- **RoT ID** – object

  Identifier of root of trust settings in device.

  — **rk_revocation** – uint32_t, little endian

  1 bit per RoTK (up to 4 RoTK can be defined for device, bit is 1 – RoTK is revoked (not usable for debug auth), bit is 0 – RoTK can be used.

  rk_revocation[bits 31:4] -> reserved for future use.

  rk_revocation[bit 3] -> bit value 0 = RoTK[3] OK / bit value 1 = RoTK[3] revoked

  rk_revocation[bit 2] -> bit value 0 = RoTK[2] OK / bit value 1 = RoTK[2] revoked

rk_revocation[bit 1] -> bit value 0 = RoTK[1] OK / bit value 1 = RoTK[1] revoked

rk_revocation[bit 0] -> bit value 0 = RoTK[0] OK / bit value 1 = RoTK[0] revoked

— **RoTKTH** – uint8_t[32]

RoTKTH (Root of Trust Key Table Hash) value is stored in device fuses. If RoTKTH size is 48 bytes (RoTKTH is SHA384 digest of the RoT Key Table), then this field value carries only leading 32 bytes of RoTKTH full value.

- **cc_socu_pinned** – uint32_t, little endian

  Actual value of CC_SOCU_PINNED in device, which is based on actual device lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses combination. For bit representation of CC_SOCU_PINNED please refer to Table 116.

- **cc_socu_default** – uint32_t, little endian

  Actual value of CC_SOCU_DEFAULT, which is based on actual device lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses combination. For bit representation please refer to Table 116.

- **cc_vu** – uint32_t, little endian

  Vendor usage value, custom value provided by vendor, stored in DBG_AUTH_VU fuse in device, value needs to be the same as value specified present later in debug certificate (DC), used for pairing of corresponding DC.

- **challenge vector** – uint8_t[32]

  Random number generated for each request to be signed in debug authentication response (DAR) to avoid reusing of DAR.

15.2.8.3.3 Debug Credential (DC)

Prior to generating debug credential, it is necessary to generate EC keypair (secp256r1 or secp384r1) for debugger known as Debug Credential Key (DCK). The public key part of DCK (DCK_{public}) is used to represent the identity of the debugger through the creation of a DC, which binds that public key to some usage attributes (UUID, CC_SOCU), and is then authorized/signed by the vendor's Roots of Trust key ($RoTK_{private}$) using ECDSA algorithm. If RoTK is based on secp256r1 then DCK also needs to be based on secp256r1. If RoTK is based on secp384r1then DCK also needs to be based on secp384r1. Combining of EC types is not allowed in DC.

The private part of DCK ($DCK_{private}$) will be used later for signing of Debug Authentication Response (DAR).

The DC structure is illustrated in the following figure.

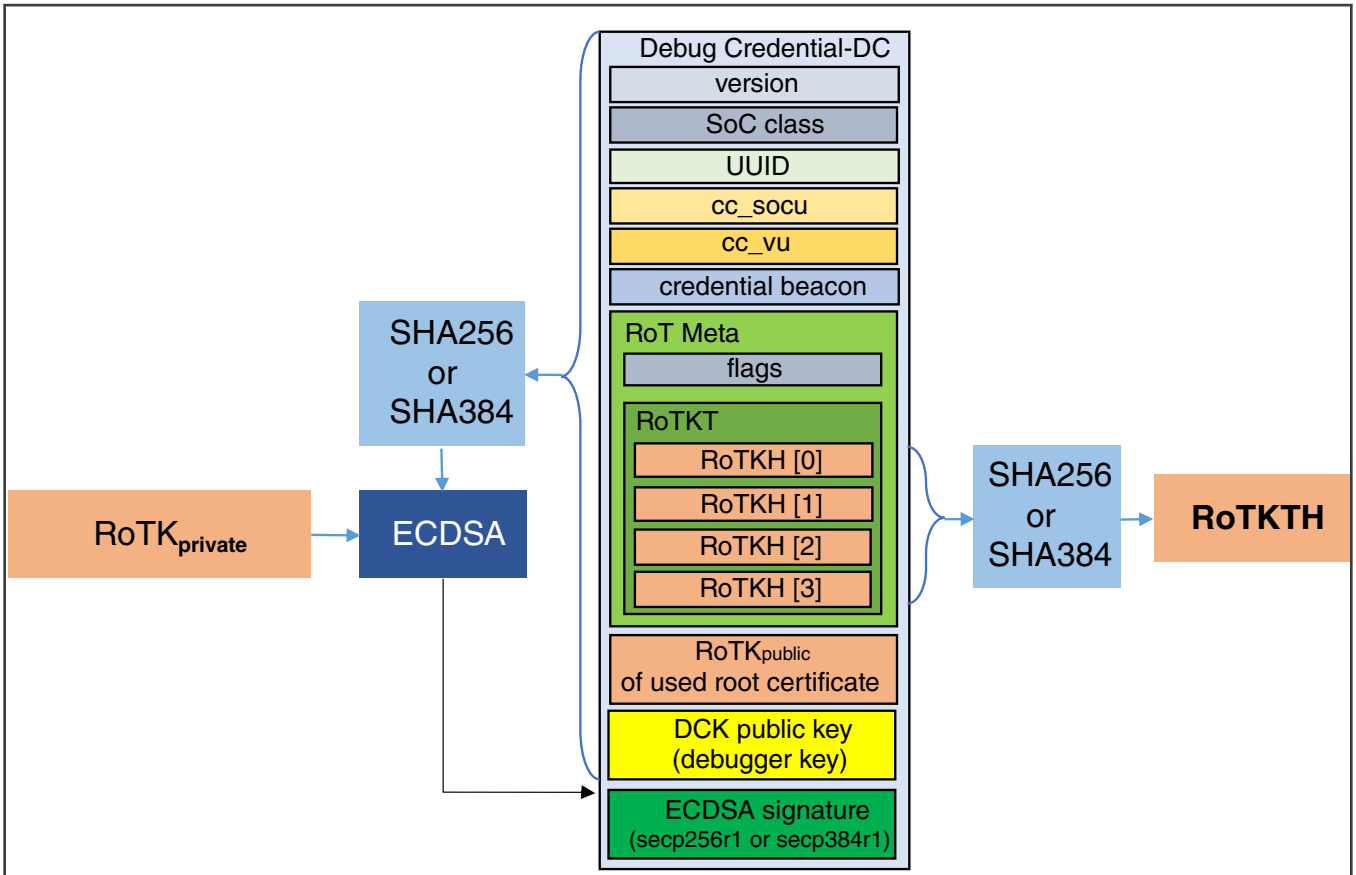

Figure 49. Debug Credential (DC)

The data structure is represented as a packed binary concatenation of its component fields as shown in the list below:

- **version** – uint32_t, little endian

  Fixed to value 0x02000000u “2.0” (major =2, minor = 0) -> secp256r1 used as RoTK or fixed to value 0x02000100u “2.1” (major =2, minor = 1) -> secp384r1 used as RoTK

- **SoC class** – uint32_t, little endian

  Fixed to 0x5u, identify the device family.

- **UUID** – uint32_t[4], little endian

  Unique ID of device. Can be set to 0 when debug credential is used for SoC class matching (one debug credential can be used to open debug ports on all devices with same CTRK and same SoC class, UUID matching in device have to be disabled – default). If UUID matching in device is enabled, then UUID value needs to correspond with UUID value of the device received in DAC.

- **cc_socu** – uint32_t, little endian

  Proposed value of SOCU, will be validated and combined on device with current lifecycle, DCFG_CC_SOCU_L1 and DCFG_CC_SOCU_L2 fuses values to have final state of debug ports, which will be applied on device. Refer to Table 116 for Bit details.

- **cc_vu** – uint32_t, little endian

  Vendor usage value need to be matched with value of DBG_AUTH_VU in device fuses (received on DAC).

- **credential beacon** – uint32_t, little endian

  Value loaded to the beacon register after successful debug authentication. Value is used by application to control debug ports. Mask 0xFFFFu is applied to the value of credential beacon and is connected with authentication beacon value from

DAR as following formula: beacon = (credentialBeacon & 0xFFFFu) | ((authenticationBeacon & 0xFFFFu) << 16). If final beacon value is non zero, debug ports are not enabled by ROM bootloader itself and debug ports configuration is delegated to booted application, which can control debug ports according final beacon value available in register (e.g. third party secondary bootloader will open debug just before jump to loaded application, debug of secondary bootloader can be enabled only by special beacon value of credential beacon).

- **RoT meta** – object

  Device root of trust meta data object.

  - **flags** – uint32_t, little endian

    Configuration details of RoT meta object, needs to be matched with RoT ID received in DAC.

    - **flags[bit 31]**: CA flag, always 1 in DC.
    - **flags[bits 30:12]**: Reserved for future use.
    - **flags[bits 11:8]**: Used root cert number [0-3] (specify RoTK used to DC signature), used only when more than 1 RoTK specified for device.
    - **flags[bits 7:4]**: Number of records in RoTKT [1-4], when equal to 1, then RoTKT not present in DC.
    - **flags[bits 3:0]**: Reserved for future use.

  - **RoTKT** – object

    Root of Trust keys Table, optional object (in case when is specified only one RoTK for device, RoTKT is not present, 1 to 4 RoTK can be specified for device), so if RoTKT is present in DC, then RoTKT table contains at least two RoTKH and maximally 4 RoTKH records.

    - **RoTKH[0-3]** – uint8_t[32] or uint8_t[48]

      Root of Trust Key Hash is SHA256 or SHA384 of RoTKpublic. Hash algorithm is selected based on RoTK EC type (secp256r1 -> SHA256 or secp384r1 -> SHA384). Same RoTKs and RoTKTH values are shared between debug authentication, SB3.1 firmware update container and signed boot image.

- **$RoTK_{public}$** – uint8_t[64] or uint8_t[96]

  X and Y coordinates of public key of selected RoTK, which will be used for signing and verification of DC, field size depends on EC type (secp256r1 or secp384r1)

- **DCK_{public}** – uint8_t[64] or uint8_t[96]

  X and Y coordinates of public key of DCK, field size depends on EC type of DCK key (secp256r1 or secp384r1). DCK and RoTKs must be defined on same EC type, combination of EC types is not allowed.

- **ECDSA signature** – uint8_t[64] or uint8_t[96]

  SHA256 or SHA384 of all Debug Credential data (as described on previous figure) used for ECDSA signature. Hash algorithm selected according to EC type of RoTK (secp256r1 -> SHA256 or secp384r1 -> SHA384). Signature coordinates (r,s) stored in big-endian.

15.2.8.3.4 Debug Authentication Response (DAR)

Debugger will find existing or request generation of new corresponding DC according to the inputs from DAC message. The $DCK_{private}$ key is used as input for calculation of ECDSA signature of the corresponding DC including device UUID and Challenge vector from received DAC (Challenge vector is not part of DAR, but it is used as last input to hash of DAR). For signature used SHA256 or SHA384 hash algorithm based on DCK EC type (secp256r1 or secp384r1), if secp256r1-> SHA256, if secp384r1->SHA384. The DAR structure and generation process is described in following figure.

Because regular debuggers usually don't offer feature for ECDSA signing, some PC tool communicating with debugger is needed. NXP offers tool nxpcertgen.exe for generation of DC and nxpdebugmbox.exe for full debug authentication process. Usage of mentioned tools is described in separate user manual related to them.

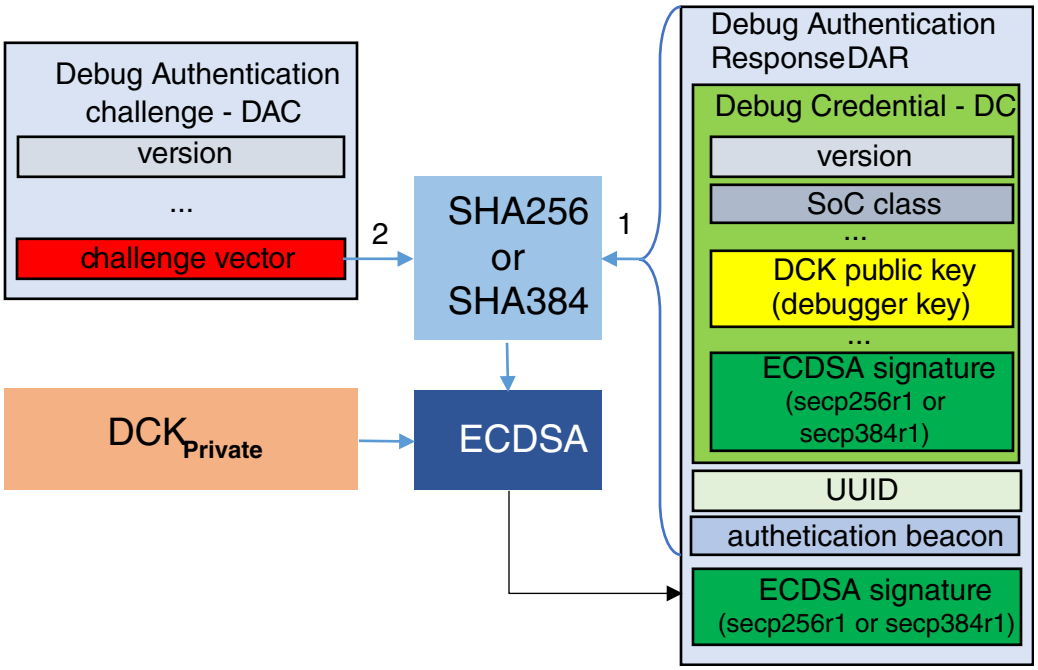

Figure 50. Debug Authentication Response (DAR)

- **Debug credential** – object

  Matched debug credential based on data received from DAC message.

- **authentication beacon** – uint32_t, little endian

  Value loaded to the beacon register after successful debug authentication. Value is used by running application to control debug ports. Mask 0xFFFFu is applied to the value and is connected with credential beacon value from DC as following formula: beacon. Beacon = (credentialBeacon & 0xFFFFu) | ((authenticationBeacon & 0xFFFFu) << 16). If final beacon value is non zero, debug ports are not enabled by ROM bootloader itself and debug ports configuration is delegated to booted application, which can control debug ports according final beacon value available in register (e.g. third party secondary bootloader will open debug just before jump to loaded application, debug of secondary bootloader can be protected by special beacon value).

- **UUID** – uint32_t[4], little endian

  Unique ID of device, must be same as UUID value provided by device in DAC message

15.2.8.3.5 Device processing the DAR

The device BootROM will process DAR received from debugger. As a part of the validation step, device will:

1. Verify DC: Validate DC version, SoC, UUID, RoT, VU, and DC signature.
2. Verify that the DAR has a valid signature that binds it to the CV from the DAC.

If all the steps are successfully completed, it can be deduced that:

- The debugger possesses the private key corresponding to the vendor/RoT-signed credential.
- The credential satisfies the constraints specified in the device configuration.
- The response of the debugger to the challenge from the device is produced and signed in response to the challenge (because of its cryptographic dependency on the challenge vector). The response is not replayed from a previous authentication where a different challenge vector is used.

After completion of processing DAR, if authentication is successful, Debug Access will be granted. If authentication fails, no special response is issued but further debug access request will be ignored, and device will enter in a failure loop (infinite loop waiting for debug attach)

15.2.8.3.6 Debug authentication use cases

15.2.8.3.6.1 Return Material Analysis (RMA) use case

The diagram below shows RMA flow using debug authentication scheme, where a debug credential certificate is issued for each field technician.

1. Vendor generates RoT key pairs and programs the device with SHA256 hash of RoT public key hashes before shipping
2. Field technician generates his own key pair and provides public key to vendor for authorization.
3. Vendor attests the field technician's public key. In the debug credential certificate, vendor assigns the access rights.
4. End customer having issues with a locked product takes it to field technician.
5. Field technician uses his credentials to authenticate with device and un-locks the product for debugging.

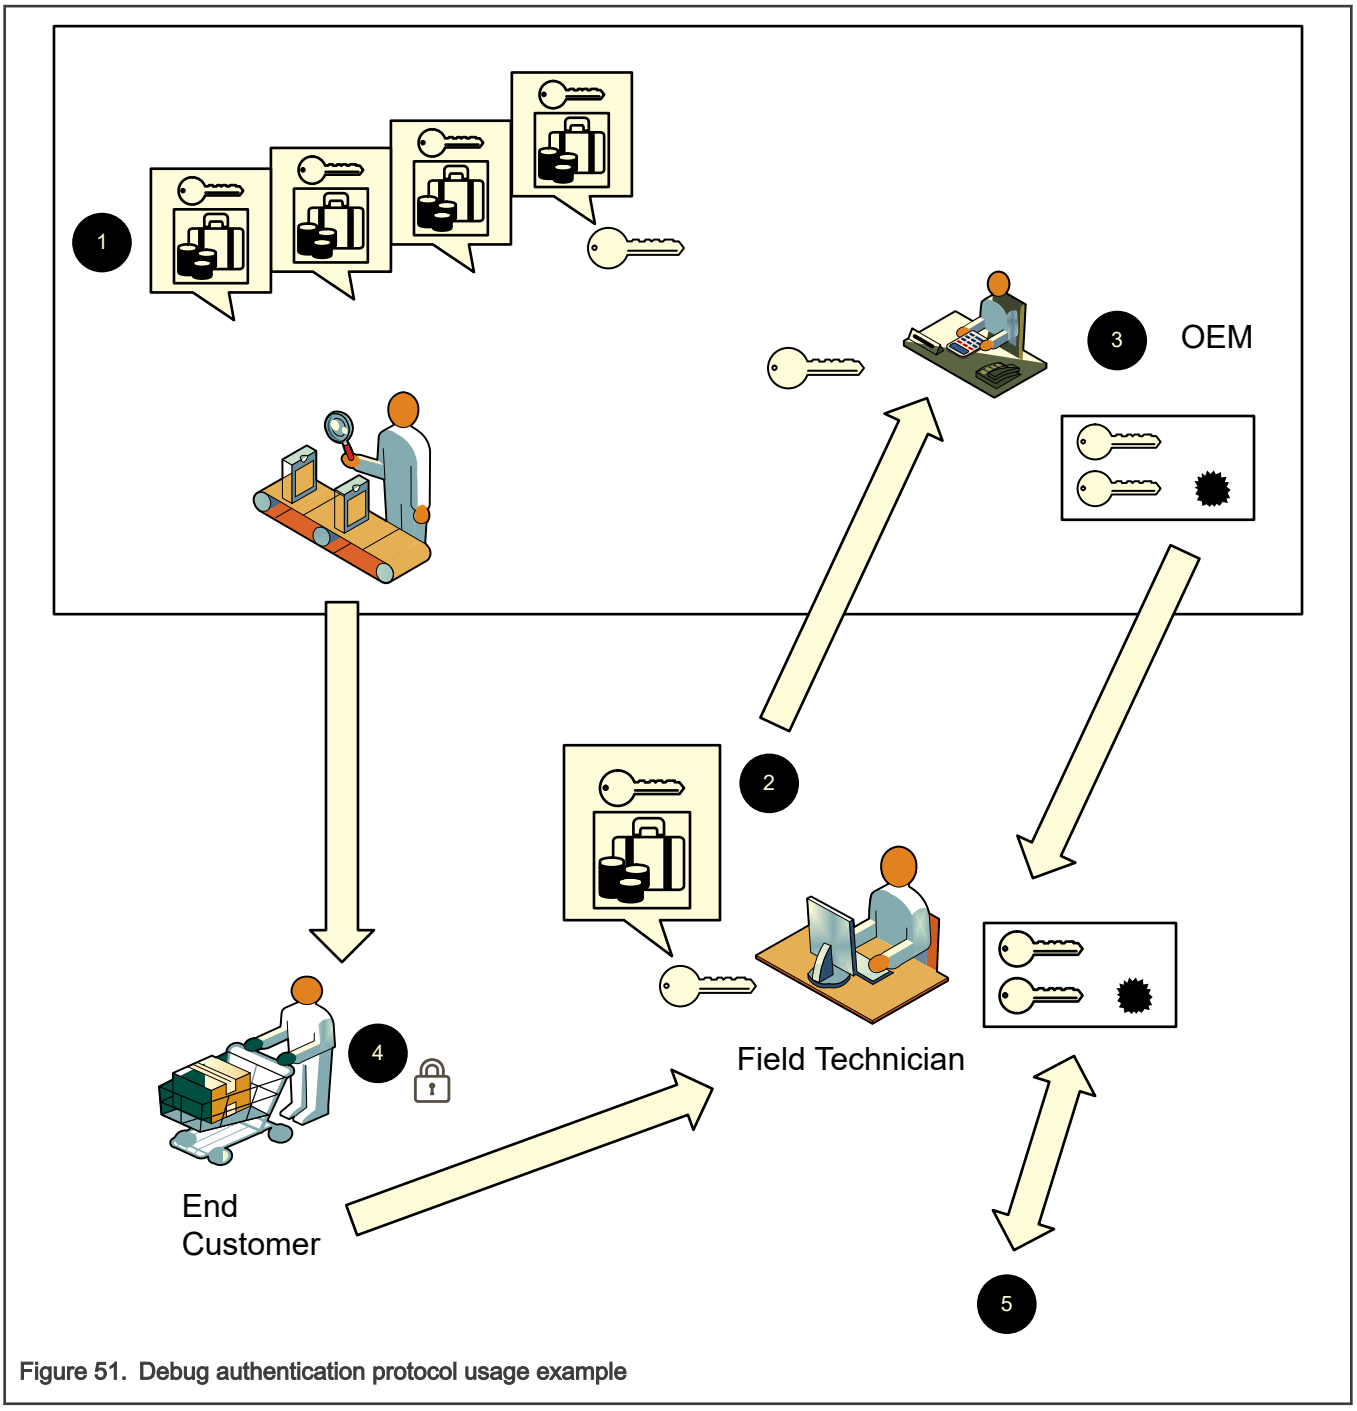

Figure 51. Debug authentication protocol usage example

15.2.8.3.6.2 Module use case with OEM tier1 and tier2 Lifecycle states

The CC_SOCU_PIN_NS & CC_SOCU_DFLT_NS is provided to allow module-maker and OEM using the module to implement tiered protection approach.

- The module maker who is referred as Tier-1 developer can develop secure code and define access rights to his module using CC_SOCU_PIN & CC_SOCU_DFLT.
- Configuration can be such that debug access to secure module is blocked but non-secure debug is always allowed.
- Once the module is ready, Tier-1 developer can release the module to OEM (a.k.a. tier-2 developer), but block debug access to secure mode and enable debug access to non-secure mode.

- Tier-2 developer can develop non-secure module and extend access rights configuration to that module using CC_SOCU_DFLT_NS and CC_SOCU_PIN_NS.

15.2.8.3.7 Fault Analysis (FA) mode

The ROM bootloader offers an FA Mode (Set FA Mode) command handler to enable to delete sensitive information (for example, Keys) before handling over the device to OEM for fault analysis. ROM allows Set FA Mode command only when corresponding flag, FA_CMD_EN, is set. Users must pass an FA request message to Set_FA_Mode command to enter FA mode.

Set FA Mode command will perform the following:

- Erase all OEM Keys in fuse
- Erase the internal flash
- Flush all temporary key registers
- Move the lifecycle to OEM Return

15.2.9 Initiate a debug session

When ROM bootloader is executing (i.e., instructions are fetched from the ROM memory address range), the debug access port (AP) of CM33 is disabled irrespective of device life-cycle state. This mechanism is referred as 'Boot-ROM protection' in this document. Thus, the method to initiate a debug session will vary depending on the device state and intended debug scenario. The scenarios described in the rest of these section are as follows:

- Flash does not contain a valid, bootable image. If the flash does not contain a valid image, the ROM bootloader will proceed to ISP mode and wait to be connected via one of its serial interfaces; in ISP mode the debug interface is disabled.
- ISP mode initiated because the ISP pin was asserted on the device at reset.
- Connection to a device running a valid application, with the intent to update flash with a new application.
- Connection to a device running a valid application in flash, with the intent to debug without updating flash (also called a "debug attach").

15.2.9.1 Debug session with invalid flash image or ISP mode

When the device boots, there may be no valid image in the boot media, at which point the ROM bootloader enters the In-System Programming (ISP) path, and debug access is disabled for security reasons. Another scenario is where the device may be placed into ISP mode because the ISP has been asserted as the device leaves reset.

To start a debug session under these scenarios, users need to enter Debugger Mailbox and send the DM-AP command Start Debug Session. Upon receiving the command, the ROM bootloader ensures any unwanted peripheral interrupts are disabled and secrets managed before enabling debug access. After configuring debug access, the ROM enters a while (1) loop. For lifecycle which does not require debug authentication, once the Start Debug Session has been successfully executed, the AP for CM33 and radio will be accessible and can used to set breakpoints, etc. as with other Cortex-M devices. For lifecycle which requires debug authentication, DM-AP commands Debug Auth Start and Debug Auth Response need to be done successfully before sending Start Debug Session command to ensure AP for CM33 or radio can be accessible.

Example below shows how a debug session is initiated at lifecycle which debug authentication is not required:

```
// Pseudo Code Syntax
// ------------------------------------------------------------------------
// WriteDP <register> <value>
// value = ReadDP <register>
// AP transactions presume the DM AP is selected
// WriteAP <register> <value>
// value = ReadAP <register> <value>
// ------------------------------------------------------------------------
// Read AP ID register to identify DM AP at index 2
WriteDP 2 0x020000F0
// The returned AP ID should be 0x002A0000
```

```
value = ReadAP 3
print "AP ID: ", value
// Select DM AP index 2
WriteDP 2 0x02000000
// Write DM RESYNC_REQ + CHIP_RESET_REQ
WriteAP 0 0x21
// Write DM START_DBG_SESSION to REQUEST register (1)
WriteAP 1 7
// Poll RETURN register (2) for zero return
value = -1
while value != 0 {
        value = (ReadAP 2 & 0xFFFF)
}
print "DEBUG_SESSION_REQ: ", value
```

15.2.9.2 Debug session with valid application in flash

In this scenario, ROM bootloader configures debug access before jumping to the application in flash. If the device is at some lifecycle debug authentication is not required and debug has not been disabled by an application already in flash, the APs of CM33 and radio are accessible, a debug session can be initialized without any other operation. If debug authentication is required, entering Debugger Mailbox, doing the debug authentication successfully and exiting Debugger Mailbox need to be done before ROM bootloader booting the application. By doing so, users can initialize a debug session after ROM bootloader jumping to the application in flash.

15.2.10 Clock

15.2.10.1 Clock gating

The heart of the clocking architecture is the System Clock Generator (SCG) module. The SCG controls multiple clock sources (FIRC/SIRC/SOSC/ROSC/CORECLK/BUSCLK/SLOWCLK) that can then be distributed to the Module Reset and Clock Control (MRCC) module. Clock gating of modules helps users to only consume power for modules that are needed for their end application. The clock to each module can be gated on or off via a programmable register.

Each peripheral has independent clock gating for both the peripheral interface clock and the peripheral functional clock. This clock gating is controlled via MRCC module. MRCC provides a clock select field, a clock disable, a divider of the selected clock source, and a peripheral reset bit that provides independent resetting of the peripheral. MRCC routes interface clocks and functional clocks for all peripherals.

The CPU_CLK, BUS_CLK, and SLOW_CLK are always enabled in the various RUN and Wait modes. If these clocks are not used in low-power stop modes, they will be disabled via the Core Mode Controller (CMC) and System Power Controller (SPC) modules.

15.2.10.2 Module/Peripheral clocking

Most peripheral clocks by default are disabled, ROM will un-gate the peripheral clocks as needed by the boot flow and also enables functional clock.

Here are some of the clocks used by ROM and their setup values:

- TRDC CPU_CLK
- CRC0 BUS_CLK
- LPSPI1 BUS_CLK
- LPUART1 BUS_CLK
- LPI2C1 BUS_CLK
- SSS CPU_CLK
- GPIO{B/C} CPU_CLK

- PORT{A/B} CPU_CLK

15.3 ROM API

ROM bootloader provides several APIs for users. Disabling the interrupts before making any ROM API call is suggested, since API code does not deal with interrupts. Flash APIs are mainly used to manage flash including read, write and erase. Similarly, SPI NOR APIs are mainly used to manage SPI NOR including read, write and erase. nboot APIs are mainly used to do security related operations including image authentication and fuse programming. kb APIs are mainly used to process SB file.

The ROM API table locates at address 0x14816800. See Figure below for the ROM API layout.

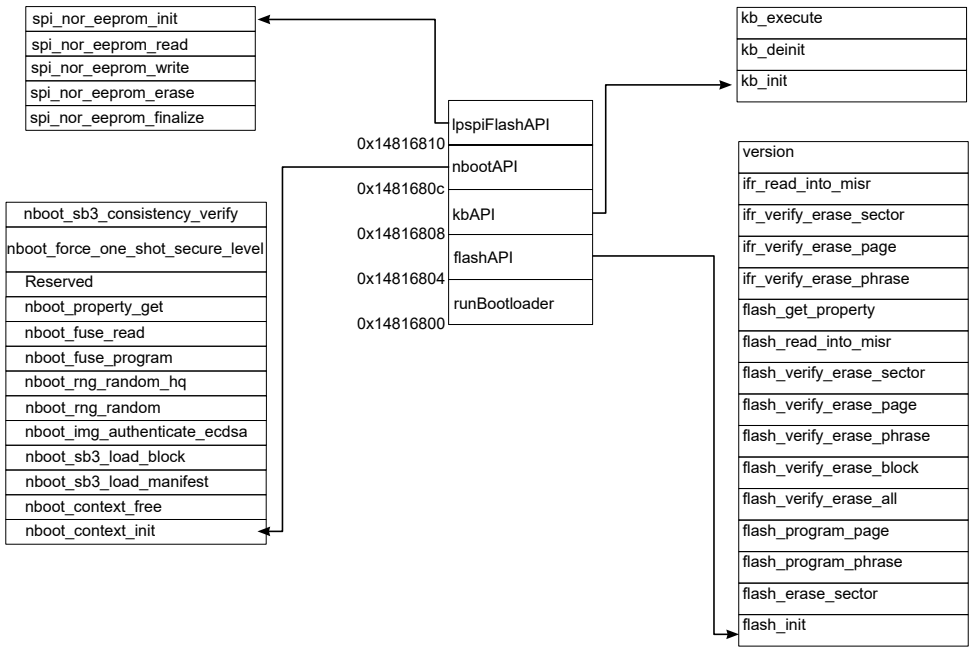

Figure 52. ROM API layout

15.3.1 Flash API

Flash APIs implement all the flash operation supported by CM33 FMU and RF-FMU1. Details of each API is described in this section.

15.3.1.1 flash_init

This API is used for initializing the flash controller and the flash_config context. It must be called before calling other flash APIs.

Prototype

```
status_t flash_init (flash_config_t *config);
```

Parameters

Table 118. flash_init parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.

flash_config_t is defined as following:

```
typedef struct _flash_mem_descriptor {
    uint32_t blockBase;
    uint32_t totalSize;
    uint32_t blockCount;
} flash_mem_desc_t;

typedef struct _flash_ifr_desc {
    uint32_t pflashIfr0Start;
    uint32_t pflashIfr0MemSize;
} flash_ifr_desc_t;

typedef struct _msf1_config {
    flash_mem_desc_t flashDesc;
    flash_ifr_desc_t ifrDesc;
} msf1_config_t;

typedef struct _flash_config {
    msf1_config_t msf1Config[2];
} flash_config_t;
```

Example:

```
typedef struct
{
    __I void (*runBootloader)(void *arg);           //!< Function to start the bootloader executing.
    __I FLASH_API_Type *flashApiBase;         //!< Internal Flash driver API.
    __I KB_API_Type *kbApiBase;               //!< Bootloader API.
__I NBOOT_API_Type *nbootApiBase;         //!< Image authentication API.
    __I SPI_FLASH_API_Type *spiflashApiBase;             //!< SPI Flash API.

} ROM_API_TYPE;
/** ROM API base address */
#define ROM_API_BASE                        (0x14816800UL)
/** ROM API base pointer */
#define ROM_API                             ((ROM_API_TYPE*) ROM_API_BASE)
/** FLASH API base pointer */
#define FLASH_API                           (ROM_API->flashApiBase)
static flash_config_t flashConfig;
FLASH_API->flash_init(&flashConfig);
```

15.3.1.2 flash_erase_sector

This API is used for erasing specified flash sector (8 KB) in flash or User IFR(IFR0). This API will erase sectors which include the start address and (start + lengthInBytes - 1) address.

Prototype

```
status_t flash_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes, uint32_t key);
```

Parameters

Table 119. flash_erase_sector parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be erased. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be erased.
Key	Key is used to validate erase operation. Must be set to "kFLASH_ApiEraseKey"

Example:

```
#define FOUR_CHAR_CODE(a, b, c, d) (((d) << 24) | ((c) << 16) | ((b) << 8) | ((a)))
#define CM33_FMU                                    ((FMU_Type *)0x40020000u)
enum _flash_driver_api_keys
{
           kFLASH_ApiEraseKey = FOUR_CHAR_CODE('l', 'f', 'e', 'k')
};
result = FLASH_API->flash_erase_sector(&flashConfig, CM33_FMU, 0x0, 4, kFLASH_ApiEraseKey);
```

15.3.1.3 flash_program_phrase

This API is used for programming phrase-aligned data to a previously erased flash or User IFR phrase.

Prototype

```
status_t flash_program_phrase (flash_config_t *config, FMU_Type *base, uint32_t start,
                          uint32_t *src, uint32_t lengthInBytes);
```

Parameters

Table 120. flash_program_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be programmed. The starting address must be phrase-aligned (4-word or 16-byte).
Src	Pointer to the source buffer of data that is to be programmed into flash.
lengthInBytes	The length, given in bytes (not words or long words) to be programmed. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

15.3.1.4 flash_program_page

This API is used for programming page aligned data to a previously erased flash or User IFR page.

Prototype

```
status_t flash_program_page (flash_config_t *config, FMU_Type *base, uint32_t start,
                        uint32_t *src, uint32_t lengthInBytes);
```

Parameters

Table 121. flash_program_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be programmed. The starting address must be page-aligned (32-word or 128-byte).
Src	Pointer to the source buffer of data that is to be programmed into flash.
lengthInBytes	The length, given in bytes (not words or long words) to be programmed. The lengthInBytes must be page-aligned (32-word or 128-byte).

15.3.1.5 flash_verify_erase_all

This API is used for checking if all flash and IFR space are in the erased state..

Prototype

```
status_t flash_verify_erase_all (FMU_Type *base);
```

Parameters:

Table 122. flash_verify_erase_all parameters

Parameter	Description
FMU base	Base pointer to FMU or RF-FMU1

15.3.1.6 flash_verify_erase_block

This API is used for checking if a flash block is in the erased state.

Prototype

```
status_t flash_verify_erase_block (flash_config_t *config, FMU_Type *base, uint32_t blockaddr);
```

Parameters

Table 123. flash_verify_erase_block parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
blockaddr	Starting address of a flash block, needs to be block-aligned

15.3.1.7 flash_verify_erase_phrase

This API is used for checking if specified flash phrases are in the erased state.

Prototype

```
status_t flash_verify_erase_phrase (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 124. flash_verify_erase_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

15.3.1.8 flash_verify_erase_page

This API is used for checking if specified flash pages are in the erased state.

Prototype

```
status_t flash_verify_erase_page (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 125. flash_verify_erase_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be page-aligned (32-word or 128-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be page-aligned (32-word or 128-byte).

15.3.1.9 flash_verify_erase_sector

This API is used for checking if specified IFR0 sectors are in the erased state.

Prototype

```
status_t flash_verify_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 126. flash_verify_erase_sector parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of required flash memory to be checked. The starting address must be sector-aligned (8192-byte).

Table continues on the next page...

Table 126. flash_verify_erase_sector parameters (continued)

Parameter	Description
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be sector-aligned (8192-byte).

15.3.1.10 flash_read_into_misr

This API is used for generating a signature based on the contents of the selected flash memory using an embedded MISR.

Prototype

```
status_t flash_read_into_misr (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t end,
uint32_t *seed, uint32_t *signature);
```

Parameters

Table 127. flash_read_into_misr parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the selected flash region . The start address must be page-aligned (32-word or 128-byte).
End	The ending address of the selected flash region. Ending address must be flash phrase aligned (4-word or 16-byte) and the last phrase in a page.
Seed	MISR seed
Signature	Pointer to buffer expecting signature after successful generation

15.3.1.11 ifr_verify_erase_phrase

This API is used for checking if specified IFR0 phrases are in the erased state.

Prototype

```
status_t ifr_verify_erase_phrase (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 128. ifr_verify_erase_phrase parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required IFR0 memory to be checked. The starting address must be phrase-aligned (4-word or 16-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be phrase-aligned (4-word or 16-byte).

15.3.1.12 ifr_verify_erase_page

This API is used for checking if specified IFR0 pages are in the erased state.

Prototype

```
status_t ifr_verify_erase_page (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 129. ifr_verify_erase_page parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be checked. The start address must be page-aligned (32-word or 128-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be page-aligned (32-word or 128-byte).

15.3.1.13 ifr_verify_erase_sector

This API is used for checking if specified IFR0 sectors are in the erased state.

Prototype

```
status_t ifr_verify_erase_sector (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t
lengthInBytes);
```

Parameters

Table 130. ifr_verify_erase_sector parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the required flash memory to be checked. The start address must be sector-aligned(8192-byte).
lengthInBytes	The length, given in bytes (not words or long words) to be checked. The lengthInBytes must be sector-aligned(8192-byte).

15.3.1.14 ifr_read_into_misr

This API is used for generating a signature based on the contents of the selected IFR0 space using an embedded MISR.

Prototype

```
status_t ifr_read_into_misr (flash_config_t *config, FMU_Type *base, uint32_t start, uint32_t end,
uint32_t *seed, uint32_t *signature);
```

Parameters

Table 131. ifr_read_into_misr parameters

Parameter	Description
Config	Pointer to flash_config_t data structure in memory to store driver runtime state.
FMU base	Base pointer to FMU or RF-FMU1
Start	The starting address of the selected flash region . The start address must be page-aligned (32-word or 128-byte).
End	The ending address of the selected flash region. Ending address must be flash phrase aligned (4-word or 16-byte) and the last phrase in a page.
Seed	MISR seed
Signature	Pointer to buffer expecting signature after successful generation

15.3.1.15 flash_get_property

This API returns the required flash property, which includes base address, block size, and other options.

NOTE

The API returns the status kStatus_FLASH_Unknown, which may appear to indicate a failure. However, this status does not mean the API has failed. The result of the operation is provided through the value parameter.

Prototype

```
status_t flash_get_property (flash_config_t *config, flash_property_tag_t whichProperty, uint32_t
*value);
```

Parameters

Table 132. flash_get_property parameters

Parameter	Description
config	Pointer to flash_config_t data structure in memory to store driver runtime state.
whichProperty	The required property from the list of properties.
Value	Property value return to value pointer

Table 133. Property definition

Property Definition	Value
FMU_SectorSize	0x00
FMU_TotalSize	0x01
FMU_BlockSize	0x02
FMU_BlockCount	0x03
FMU_BlockBaseAddr	0x04
RF-FMU1_TotalSize	0x11
RF-FMU1_BlockSize	0x12
RF-FMU1_BlockCount	0x13
RF-FMU1_BlockBaseAddr	0x14

15.3.1.16 Flash API status code

Table 134. Flash API status code

Status	Code	Description
kStatus_FLASH_Success	0	The flash operation is successful
kStatus_FLASH_InvalidArgument	4	Invalid argument detected during executing a FLASH API.
kStatus_FLASH_SizeError	100	Invalid size detected during executing a FLASH API.
kStatus_FLASH_AlignmentError	101	Alignment error detected during executing a FLASH API.
kStatus_FLASH_AddressError	102	Address error detected during executing a FLASH API.
kStatus_FLASH_AccessError	103	Access error detected during executing a FLASH API.
kStatus_FLASH_ProtectionViolation	104	Command Protection Violation Flag which indicates an attempt was made to modify a protected area of flash memory during a command operation.
kStatus_FLASH_CommandFailure	105	Command failure detected during executing a FLASH API.
kStatus_FLASH_UnknownProperty	106	Unknown property for flash_get_property API.
kStatus_FLASH_EraseKeyError	107	Incorrect EraseKey for flash_erase API.
kStatus_FLASH_CommandAborOption	121	Operation is aborted

15.3.2 nboot API

The ROM API table is located at address 0x1481680c and contains absolute ROM API function addresses which can be called using function pointers. Only secure boot related functions are described in this chapter.

The main purpose of these APIs is to provide access to functions used and implemented in ROM to authenticate the application image and processing sb3 files.

15.3.2.1 nboot_context_init

This API is used for initializing the nboot context data structure. It must be called before calling other nboot APIs which performs authentication and sb3 processing.

Prototype:

```
nboot_status_t nboot_context_init(nboot_context_t *context);
```

Parameters

Table 135. nboot_context_init parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.

15.3.2.2 nboot_context_free

This API is used to release context used by all nboot functions.

Prototype:

```
nboot_status_t nboot_context_free(nboot_context_t *context);
```

Parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory used to store runtime state.

15.3.2.3 nboot_sb3_load_manifest

This API is used to verify nboot sb3.1 manifest. It loads keys into the key store so that they can be used for subsequent operations such as nboot_sb3_load_block. NBOOT context must be initialized by the API nboot_context_init before calling this API.

Prototype:

```
nboot_status_t nboot_sb3_load_manifest(nboot_context_t *context, uint32_t *manifest);
```

Parameters

Table 136. nboot_sb3_load_manifest parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
manifest	Pointer to the input manifest buffer.

15.3.2.4 nboot_sb3_load_block

This API is used to verify and decrypt NBOOT SB3.1 block. Decryption is performed in-place. NBOOT context must be initialized by the API nboot_context_init before calling this API.

Prototype:

```
nboot_status_t nboot_sb3_load_block(nboot_context_t *context, uint32_t *block);
```

Parameters

Table 137. nboot_sb3_load_block parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
block	Pointer to the input block

15.3.2.5 nboot_img_authenticate_ecdsa

This API is used to authenticate signed image with asymmetric cryptography.

Prototype:

```
nboot_status_t nboot_img_authenticate_ecdsa(nboot_context_t *context, uint8_t imageStartAddress[],
nboot_bool_t *isSignatureVerified);
```

Parameters

Table 138. nboot_img_authenticate_ecdsa

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.

Table continues on the next page...

Table 138. nboot_img_authenticate_ecdsa (continued)

Parameter	Description
imageStartAddress	Pointer to start of the image in memory (32-bit word aligned)
isSignatureVerified	Pointer to memory holding function call result. typedef enum { kNBOOT_TRUE = 0x3C5AC33Cu, kNBOOT_TRUE256 = 0x3C5AC35Au, kNBOOT_TRUE384 = 0x3C5AC3A5u, kNBOOT_FALSE = 0x5AA55AA5u, kNBOOT_OperationAllowed = 0x3c5a33ccU, kNBOOT_OperationDisallowed = 0x5aa5cc33U, } nboot_bool_t;

15.3.2.6 nboot_rng_random

This API is used to get random number(s).

Prototype:

```
nboot_status_t nboot_rng_random(nboot_context_t *context, void *buf, size_t bufLen);
```

Parameters

Table 139. nboot_rng_random

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Buf	Pointer to buffer in memory to store random number
bufLen	Buffer length in number of bytes.

15.3.2.7 nboot_rng_random_hq

This API is used to get high quality random number(s).

Prototype:

```
nboot_status_t nboot_rng_random_hq(nboot_context_t *context, void *buf, size_t bufLen);
```

Parameters

Table 140. nboot_rng_random_hq

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Buf	Pointer to buffer in memory to store random number
bufLen	Buffer length in number of bytes.

15.3.2.8 nboot_fuse_program

This API is used to program a fuse word at a given address with new data. Before using this API, voltage must be regulated for over-drive and normalize voltage after operation is completed.

Prototype:

```
nboot_status_t nboot_fuse_program(nboot_context_t *context, uint32_t addr, uint32_t *data, uint32_t
systemClockFrequencyMHz);
```

Parameters

Table 141. nboot_fuse_program

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Addr	Fuse index
Data	Pointer to data expected to be programmed in fuse
systemClockFrequencyMHz	Boot frequency

15.3.2.9 nboot_fuse_read

This API is used to read a fuse word.

Prototype:

```
nboot_status_t nboot_fuse_read(nboot_context_t *context,
                                    uint32_t addr,
                                    uint32_t *data,
                                    uint32_t systemClockFrequencyMHz);
```

Parameters

Table 142. nboot_fuse_read

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
Addr	Fuse index
Data	Pointer to data buffer expecting fuse contents after successful read
systemClockFrequencyMHz	Boot frequency

15.3.2.10 nboot_property_get

This API is used to read property. One of the important properties that can be read is the property that last authentication of signed image container has succeeded.

Prototype:

```
nboot_status_t nboot_property_get(nboot_context_t *context,
                                  uint32_t propertyId,
```

```
                                    uint8_t *destData,
                                    size_t *dataLen);
```

Parameters

Table 143. nboot_property_get parameters

Parameter	Description
context	Pointer to nboot_context_t data structure in memory to store runtime state.
propertyId	Property ID must be supported by nboot
destData	Pointer to data buffer for storing returned contents
dataLen	Data buffer length

Property IDs supported are as follows:

Table 144. Supported property IDs

Property	ID	Description
DICE_CDI	0x10	Returns 32 bytes of CDI value.
IMAGE_HASH	0x20	Return 64 bytes (SHA-512) value containing hash of the last authenticated image.
PSA_BOOT_SEED	0x30	Returns 32 bytes boot seed.
LAST_AUTH_STATE	0x40	Returns 4 bytes status of last authentication.
SSS_ROM_VERSION	0x50	Returns 8 bytes of SSS ROM version.
SSS_FW_VERSION	0x51	If SSS FW not loaded successfully, returns 0xFFFFFFFF as 1st word. Else returns 2 words, 1st word: version, 2nd word – commit id.
DTRK_ATTEST_PUBK	0x60	Returns 64 bytes value – public part of the DTRK_ATTEST private key
UUID	0x90	Returns UUID to serve as device unique identifier.

15.3.2.11 nboot API status code

The following table lists the nboot API status code.

Table 145. nboot API status code

Status	Code
kStatus_NBOOT_Success	0x5a5a5a5a
kStatus_NBOOT_Fail	0x5a5aa5a5
kStatus_NBOOT_InvalidArgument	0x5a5aa501
kStatus_NBOOT_RequestTimeout	0x5a5aa502
kStatus_NBOOT_ResourceBusy	0x5a5aa503
kStatus_NBOOT_OperationNotAvaialable	0x5a5aa5e5
kStatus_NBOOT_MemcpyFail	0x5a5a845a

15.3.3 kb API

This set of APIs provides an interface to bootloader functions. The primary purpose of these APIs is to expose ROM-level functionality for processing Secure Binary (SB) files.

NOTE

These APIs are functional when TRDC (Trusted Resource Domain Controller) is disabled. If TRDC is enabled with different configurations, the APIs may encounter issues when attempting to erase or program internal flash memory when using addresses where bit 28 is set to 1.

15.3.3.1 kb_init

This API is used to initialize bootloader and nboot context necessary to process sb3 file format.

Prototype:

```
status_t kb_init(kb_session_ref_t **session_out, const kb_options_t *options)
```

This API is expected to return kStatus_Success (0) on success and kStatus_Fail (1) on failure.

15.3.3.2 kb_deinit

This API is used to release nboot context and finalize sb3 file processing.

Prototype:

```
status_t kb_deinit(kb_session_ref_t *session)
```

15.3.3.3 kb_execute

This API is used to decrypt sb3 file and store signed image contents specified by loader command supported while generating sb3 image through Json configuration. If sb3 file to be processed includes sblaoder command “programFuses” then voltage must be regulated for over-drive and normalize voltage once operation is completed.

Prototype:

```
status_t kb_execute(kb_session_ref_t *session, const uint8_t *data, uint32_t dataLength)
```

Parameters

Table 146. kb_execute parameters

Parameter	Description
data	session pointer obtained from kb_init function
dataLength	sb file data length in bytes
isUpdateExt	Indicator for update(sb) file start address is in internal or external flash. 0x74784578u = External flash Other values = Internal flash

15.3.3.4 kb API status code

Table 147. Flash API status code

Status	Code	Description
kStatus_Success	0	API succesfully finished its operation
kStatus_Fail	1	API failed and it could not finish its operation
kStatus_InvalidArgument	4	API cannot proceed because the input argument value is invalid
kStatus_RomLdrDataUnderrun	10109	API needs to be called again with more data (next data chunk)
kStatus_RomLdrJumpReturned	10110	API finished its execution but the jump to user code returned
kStatus_RomLdrRollbackBlocked	10115	New firmware version is lesser than the present one
kStatus_RomLdrPendingJumpCommand	10119	Returned by kb_execute; Call of kb_finish is needed to do the requested jump
kStatus_RomApiBufferSizeNotEnough	10802	API cannot proceed because the provided buffer (via call of kb_init in options argument) is not large enough
kStatus_RomApiInvalidBuffer	10803	API cannot proceed because the provided buffer pointer is NULL or buffer size is 0

15.3.4 SPI Flash API

15.3.4.1 spi_eeprom_init

This API is used to initialize SPI Flash with requested baud rate and reads JEDEC ID as sanity check.

Prototype:

```
status_t spi_nor_eeprom_init(uint32_t baudRate)
```

Parameters

Table 148. spi_eeprom_init parameters

Parameter	Description
baudRate	Value used to configure SPI NOR flash for subsequent operations.

15.3.4.2 spi_eeprom_read

This API is used to read SPI Flash memory contents.

Prototype:

```
status_t spi_eeprom_read(uint8_t *dest, uint32_t NoOfBytes, uint32_t address, bool
requestFastRead);
```

Parameters

Table 149. spi_eeprom_read parameters

Parameter	Description
dest	Pointer to destination buffer to store memory contents read from SPI flash.
NoOfBytes	Number of bytes to read.
address	Absolute start address of SPI Flash from which read operation should be prformed.
requestFastRead	true = Uses FAST READ (0Bh) false = Uses simple read READ (03h) • User must check AC chacracteristics of Flash memory model and should know SPI functional clock before requesting requestFastRead. Otherwise requestFastRead option can cause a bootleneck in data transaction speed as command buffer involves dummy byte.

15.3.4.3 spi_eeprom_write

This API is used to program data to SPI flash.

Prototype:

```
status_t spi_eeprom_write(uint8_t *data, uint32_t NoOfBytes, uint32_t address);
```

Parameters

Table 150. spi_eeprom_write parameter

Parameter	Description
data	Pointer to the buffer of data that is to be programmed into SPI flash.
NoOfBytes	Number of bytes to be programmed.
Address	Start address of the SPI Flash memory to be programmed.

15.3.4.4 spi_eeprom_erase

This API is used to erase SPI flash contents with specific erase size.

Prototype:

```
status_t spi_eeprom_erase(uint32_t address, eraseOptions_t option);
```

Parameters

Table 151. spi_eeprom_erase parameters

Parameter	Description
address	Start address of the SPI Flash memory to be erased.

option	Following are the options supported for erase operation:
	`typedef enum`
	`{`
	`  kSize_ErasePage = 0x1,`
	`  kSize_Erase4K = 0x2,`

Table continues on the next page...

Table 151. spi_eeprom_erase parameters (continued)

Parameter	Description
	kSize_Erase32K = 0x3, kSize_Erase64K = 0x4, kSize_EraseAll = 0x5, } eraseOptions_t; **NOTE** kSize_ErasePage option is not supported for all memory models. Example: Adesto flash can support page erase commands but not Micron.

15.3.4.5 spi_eeprom_finalize

This API is used de-initialize IOMUX and clock settings used for SPI Flash operations and resets all LPSPI logic and control registers.

Prototype:

```
void spi_eeprom_finalize(void);
```

15.3.4.6 SPI Flash API status code

The following table lists the SPI Flash API status code.

Table 152. SPI Flash API status code

Status	Code
kStatus_Success	0
kStatus_Fail	1

15.3.5 runBootloader API

This API allows to enter the bootloader from the application within the ROM API.

Prototype

```
void (*runBootloader)(uint32_t *arg);
```

Table 153. runBootloader parameter

Parameter	Description
arg	arg Pointer to structure user_app_boot_invoke_option_t

The input argument to the function is a pointer to a 32-bit value which controls how to enter the bootloader:

Table 154. runBootloader API arg fields

Field	Offset	Description
Tag	[31:24]	Fixed value: EBh (enter boot)
Boot mode	[23:20]	• 0: Boot from flash

Table continues on the next page...

Table 154. runBootloader API arg fields (continued)

Field	Offset	Description
		• 1: ISP Mode
Interface	[19:16]	For ISP mode, following interface can be selected • 0: UART • 1: I2C • 2: SPI • 3: CAN • 15: Autodetect
Reserved	[15:0]	-

The function stores the value of the input argument into POR clear register CMC[BSR1] and resets the device, which causes bootloader to run. Bootloader examines the argument value stored in the register and decides what to do:

- ISP Boot mode causes ISP path to be entered like the ISP pin was asserted.
- Master boot mode causes booting the boot image on flash.

Chapter 16
Flash Memory Unit (FMU)

16.1 Chip-specific FMU information

Table 155. Reference links to related information

Topic	Related module	Reference
Full description	FMU	FMU
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

For the SoC 32 KB IFR0, the first 8 KB is program once and never allows to be erased.

16.1.1 Module instances

This device has two instances of the FMU module, FMU0 and FMU1.

16.1.2 IFR map

For this device, refer to Table 65 for Table 187.

16.1.3 FCTRL[RWSC]

The configuration of Read Wait-State Control (RWSC) filed of Flash Control Register (FCTRL) is shown in below table.

Table 156. Configuration in different run modes and speed

Mode	Typical Frequency (MHz)	FCTRL[RWSC]
SD - 1.1V	96	0010b
SD - 1.1V	64	0001b
SD - 1.1V	48	0001b
SD - 1.1V	32	0000b
MD - 1.0V	48	0001b
MD - 1.0V	32	0001b
MD - 1.0V	24	0000b

16.1.4 FSTAT[PEWEN]

NOTE

This bit is only writable by accessing it through the test interface.

16.2 Overview

The flash module includes the following accessible memory regions:

- Program flash memory for vector space and code store
- Separate flash memory for parameter store

Flash memory is ideal for single-supply applications, permitting in-the-field erase and reprogramming operations without the need for any external high voltage power sources.

The flash module includes a command controller that executes commands to modify flash memory contents. An erased bit reads '1' and a programmed bit reads '0'. The programming operation is unidirectional; it can only move bits from the '1' state (erased) to the '0' state (programmed). Only the erase operation restores bits from '0' to '1'; bits cannot be programmed from a '0' to a '1'.

CAUTION

A flash memory location must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a flash phrase or page is not allowed. Re-programming of existing 0s to 0 is not allowed as this overstresses the device.

The standard shipping condition for flash memory is erased. Data loss over time may occur due to degradation of the erased ('1') states and/or programmed ('0') states. Therefore, it is recommended that flash memory be re-erased immediately prior to factory programming to ensure that the full data retention capability is achieved.

16.2.1 Block diagram

The block diagram of the flash module is shown in the following figure.

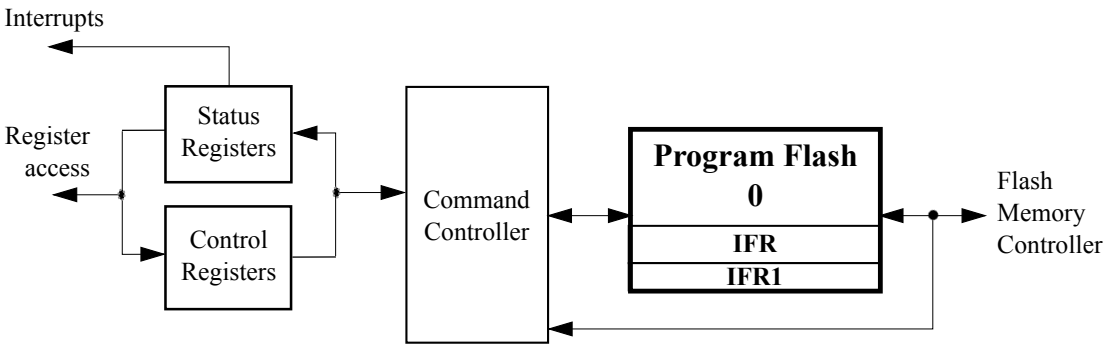

Figure 53. Flash block diagram

16.2.2 Features

The flash memory module provides the following features:

- Sector size of 8 Kbytes
- Single-bit error correction and double-bit error detection for each flash or IFR phrase
- Signature generation for flash contents
- Command-based flash program, erase, and verify operations
- Internal high-voltage supply generator for flash program and erase operations
- Optional interrupt generation upon flash command completion
- Optional interrupt generation upon double-bit error detection during flash reads from the FMC

NOTE

See the chip configuration details for the exact amount of flash memory available.

16.3 Functional description

The following sections describe functional details of the flash module.

16.3.1 Operations

Operations are typically used to modify flash memory contents. The next sections describe:

- Command write sequence used to set flash command parameters and launch execution
- Available flash commands
- Commands impacted by Block Checker and FMC access protection

16.3.1.1 Command write sequence

Flash commands are accomplished using a command write sequence illustrated in Figure 54. The command controller monitors the transaction protection level on writes during the command write sequence, performs various checks on the command (FCCOB) content, and continues with command execution if all requirements are fulfilled.

Before launching a command, the ACCERR, PVIOL, and CMDABT flags in the FSTAT register must be zero and the CCIF flag must be one to verify that any previous command has completed. The FAIL flag in the FSTAT register is cleared by the command controller when a command is launched unless the FAIL flag was set during initialization due to FMU parameters not being loaded from IFR1. If CCIF is clear, the previous command execution is still active, a new command write sequence cannot be started, and all writes to the FCCOB registers are ignored.

16.3.1.1.1 Load the FCCOB Registers

The user must load the FCCOB registers with all parameters required by the specific flash command. The contents of any FCCOB register not used by the specific flash command are ignored except for FCCOB1 (command options) where undefined bits should be cleared. The individual registers that make up the FCCOB data set can be written in any order. All writes to the FCCOB registers in a command write sequence must occur at the same transaction protection level. Any write to the FCCOB registers that violates this rule will be ignored.

Addresses loaded into FCCOB registers assume the flash and IFR spaces start at 0000_0000h.

16.3.1.1.2 Launch the Command by Clearing CCIF

Once all relevant command parameters have been loaded, the user launches the command by clearing the FSTAT[CCIF] bit by writing a '1' to it. The write to clear CCIF must occur at the same transaction protection level as the writes used to load the FCCOB registers. Any write to clear CCIF that violates this rule will be ignored. The CCIF flag remains clear until the flash command completes.

The FSTAT register contains a blocking mechanism which prevents a new flash command from launching (unable to clear CCIF) if the previous command resulted in the setting of an access error (ACCERR), protection violation (PVIOL), or active command abort flag (CMDABT). In error scenarios, two writes to FSTAT are required to initiate the next command: the first write to clear these flags, the second write to clear CCIF. The write to clear these flags can occur at any transaction protection level.

16.3.1.1.3 Command Execution and Error Reporting

Flash command processing contains the following steps:

1. The command controller performs a series of parameter checks, if applicable, which are unique to each command. If the parameter check fails, the FSTAT[ACCERR] flag is set. ACCERR reports invalid instruction codes or options, out of bounds or misaligned addresses, or missing FMU parameters. In the case FMU parameters were not loaded from IFR1 during initialization, the ACCERR flag sets and the FSTAT[FAIL] flag remains set. Command processing never proceeds to execution when the parameter check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag. Note that for program and erase operations, PEWEN will not set if FMU parameters were not loaded and PERDY will not set if program or erase related writes to flash or IFR space violate command requirements.
2. If necessary, the command controller performs a protection check to see if the command is allowed to execute on the requested memory space. If the protection check fails, the FSTAT[PVIOL] flag is set. Command processing never

proceeds to execution when the protection check fails. Instead, command processing is terminated after setting the FSTAT[CCIF] flag.

3. If the parameter and protection checks pass, the command proceeds to execution. Run-time errors, such as failure to verify, may occur during the execution phase and are reported in the FAIL flag. A flash command may have access errors, protection violations, and run-time errors, but the run-time errors are not seen until all access errors and protection violations have been corrected.
4. If FCTRL[ABTREQ] sets during command execution, the operation will abort with the FSTAT[CMDABT] flag set.
5. Command execution results, if applicable, are reported back to the user via the FCCOB registers.
6. The command controller sets FSTAT[CCIF] signifying that the command has completed.

CAUTION

If the FAIL flag is set along with ACCERR, FMU parameters were not loaded from IFR1 during initialization. In this case, it is recommended that the flash module be reinitialized. If the issue persists, flash commands will continue to set the ACCERR and FAIL flags.

The flow for a generic command write sequence is illustrated in the following figure.

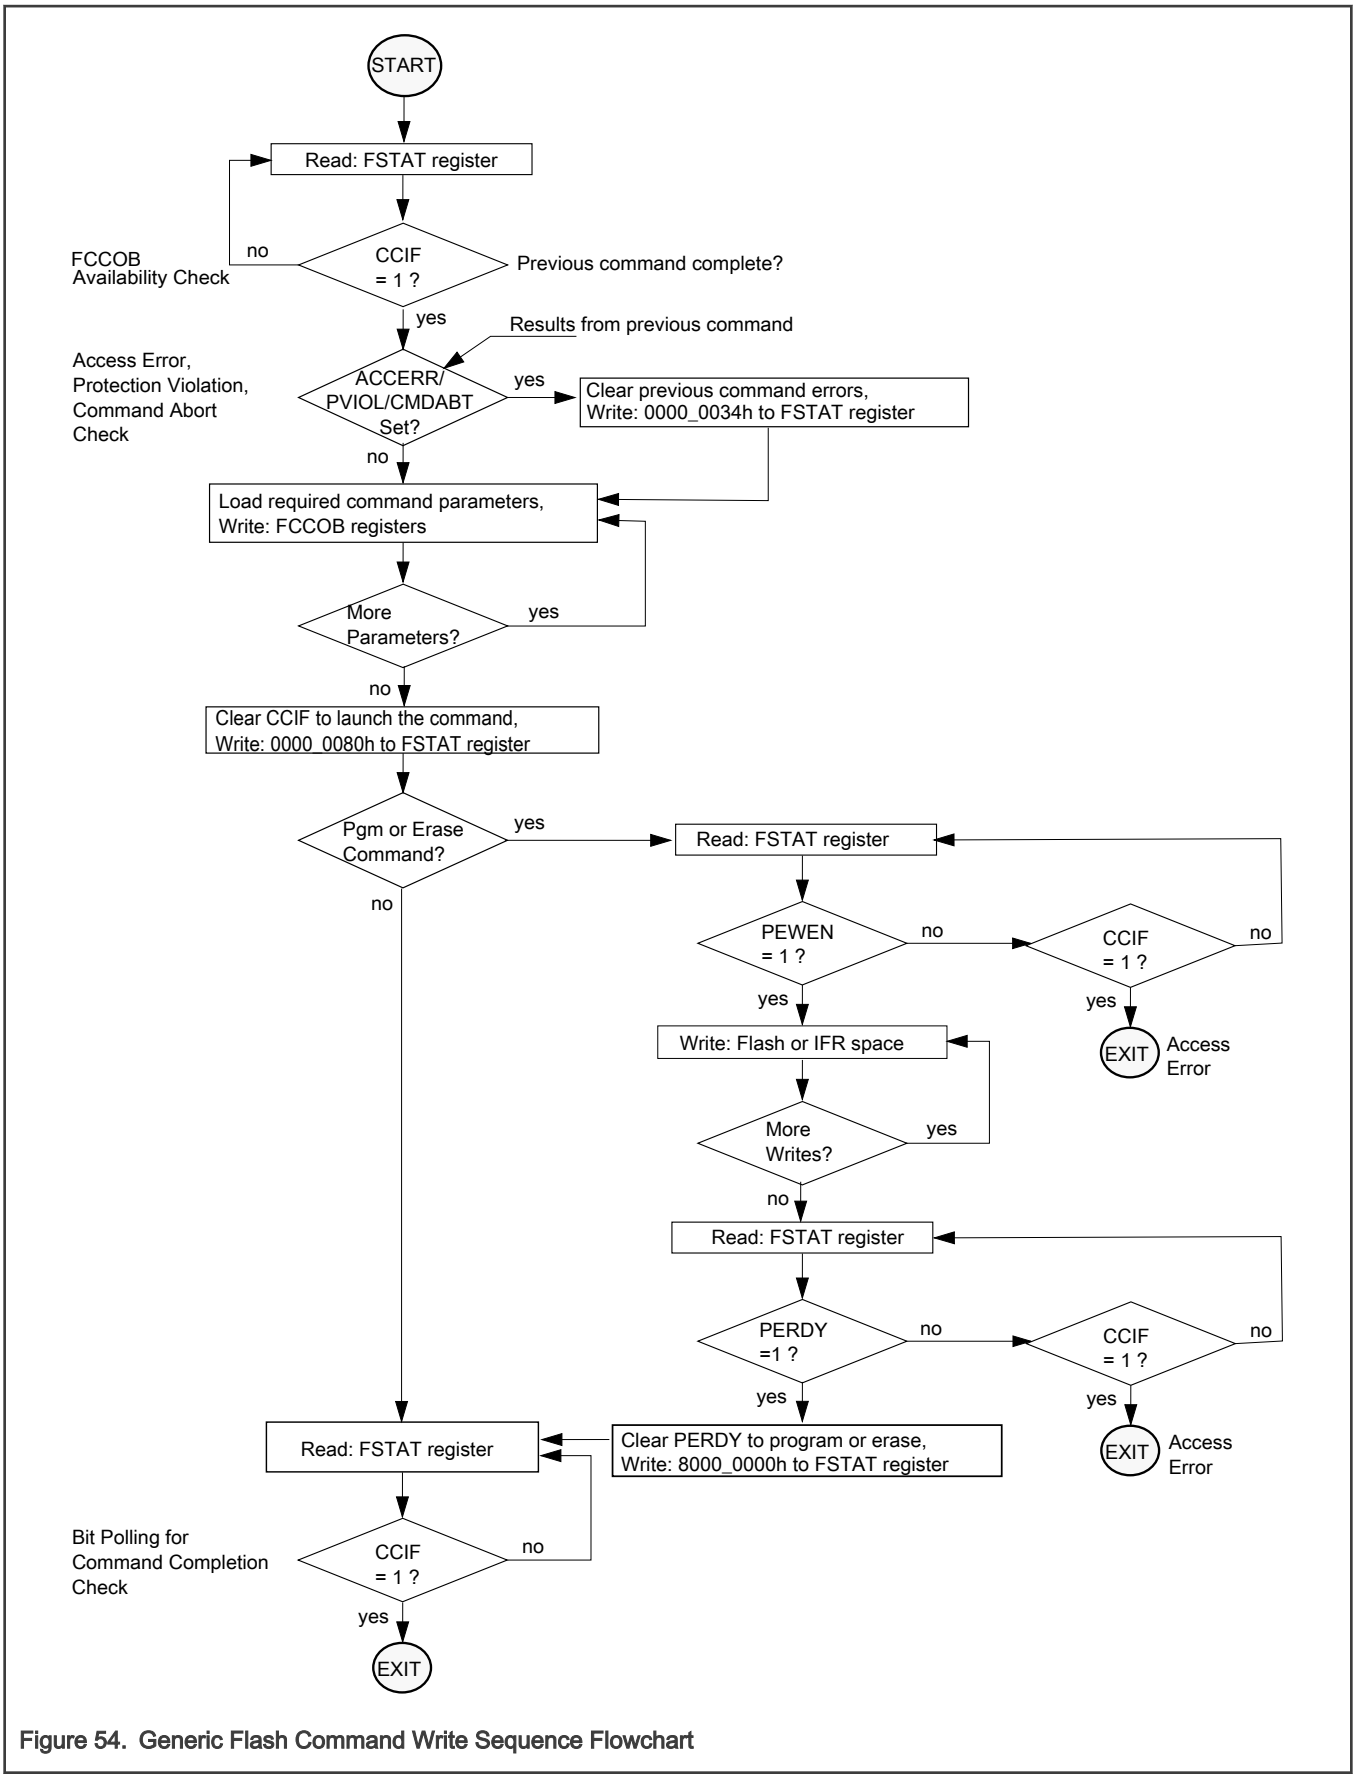

Figure 54. Generic Flash Command Write Sequence Flowchart

16.3.1.1.4 Aborting a Command Write Sequence or Command Operation

FSTAT[CMDP] sets at the start of a command write sequence, typically by writing to one of the FCCOB registers. With CMDP set, setting the FCTRL[ABTREQ] bit allows a user to abort a command write sequence and take control over a new command write sequence. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and at the same or higher security/privilege protection level when compared to FSTAT[CMDPRT], the current owner of the command write sequence. While ABTREQ is set, CCIF cannot be cleared to launch a command.

If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically.

If CCIF is low when ABTREQ is set, the command controller will abort execution of the current command operation, set FSTAT[CMDABT], and set CCIF. The CMDPRT field will be updated based on the write transaction that set the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CMDABT is set, CCIF cannot be cleared to launch a command. Aborting a program or erase operation may leave the flash or IFR space being modified in an indeterminate state.

NOTE

Aborting certain flash commands may take longer to abort than to execute. See the device data sheet for flash command timing specifications.

16.3.1.2 Flash commands

The following table summarizes the function of all flash commands. If any column is marked with an 'X', the flash command is relevant to that particular memory resource.

FCMD	Command	Program flash 0	IFR	Function
00h	Read 1s All (RD1ALL)	x	x	Verify that all flash and IFR space is erased
01h	Read 1s Block (RD1BLK)	x		Verify that a flash block is erased
02h	Read 1s Sector (RD1SCR)	x		Verify that a flash sector is erased
03h	Read 1s Page (RD1PG)	x		Verify that a flash page is erased
04h	Read 1s Phrase (RD1PHR)	x		Verify that a flash phrase is erased
05h	Read into MISR (RDMISR)	x		Generate MISR signature for range of flash pages
12h	Read 1s IFR Sector (RD1ISCR)		x	Verify that an IFR sector is erased
13h	Read 1s IFR Page (RD1IPG)		x	Verify that an IFR page is erased
14h	Read 1s IFR Phrase (RD1IPHR)		x	Verify that an IFR phrase is erased
15h	Read IFR into MISR (RDIMISR)		x	Generate MISR signature for range of IFR pages

Table continues on the next page...

Table continued from the previous page...

FCMD	Command	Program flash 0	IFR	Function
23h	Program Page (PGMPG)	x	x	Program data to a flash or IFR page
24h	Program Phrase (PGMPHR)	x	x	Program data to a flash or IFR phrase
40h	Erase All (ERSALL)	x	x	Erase all flash and IFR space if enabled
42h	Erase Sector (ERSSCR)	x	x	Erase a flash sector

16.3.1.3 Flash commands impacted by Block Checker and FMC access protection

The following flash commands are impacted by Block Checker and FMC access protection:

- Program Phrase (PGMPHR)
- Program Page (PGMPG)
- Erase Sector (ERSSCR)

During execution of these flash commands, a sequence of AHB writes to flash or IFR space are required with validity checked by the Block Checker or FMC. When writes are enabled by the FMU, violations detected by the FMC are reported as an access error in the FMU. The other violations are handled by the Block Checker or FMC.

Table 157. Flash Write Access Checks

Flash Write Violation Condition	Block Checker	FMC	FMU
Flash or IFR address out-of-range	X		
Flash or IFR write permission check fails	X		
Write to IFR1 space		X	
Write width not 32-bit		X	
Writes not enabled by FSTAT[PEWEN]		X	
First write in sequence not properly aligned per FSTAT[PEWEN]			X
Non-sequential write after first aligned write in sequence			X
Bus permissions for the AHB write do not match the bus permissions of the APB write that launched the flash command			X

16.3.2 Flash command descriptions

This section describes all flash commands that can be launched by a valid command write sequence. The flash module sets the FSTAT[ACCERR] bit and aborts the command execution if any of the following illegal conditions occur:

- There is an unrecognized command code in the FCCOB FCMD field.
- There is an error in an FCCOB field for the specific command. Refer to the error handling table provided for each command.

The ACCERR, PVIOL, and CMDABT flags in the FSTAT register should be cleared prior to starting a command write sequence. As described in Launch the Command by Clearing CCIF, a new command cannot be launched while these flags are set.

Do not attempt to read a flash block while a flash command is running (CCIF = 0) on that same block. The flash module may return a transfer error to the FMC resulting in a bus fault. The exception to this rule is during program operations where the flash block is still readable after the command is launched up until the time the FSTAT[PERDY] flag is cleared.

CAUTION

Flash data must be in the erased state before being programmed. Cumulative programming of bits (adding more zeros) is not allowed.

16.3.2.1 Read 1s All Command

The Read 1s All command checks if all flash and IFR space are in the erased state.

Table 158. Read 1s All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	00h (RD1ALL)

Upon clearing CCIF to launch the Read 1s All command, the command controller:

- verifies that all flash and IFR space are in the erased state

If all flash and IFR space are not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s All operation completes.

Table 159. Read 1s All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.2 Read 1s Block Command

The Read 1s Block command checks if a flash block is in the erased state.

Table 160. Read 1s Block Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	01h (RD1BLK)
2	Block address

Upon clearing CCIF to launch the Read 1s Block command, the command controller:

- verifies that the selected flash block is in the erased state

If the selected flash block is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Block operation completes.

Table 161. Read 1s Block Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]

Table continues on the next page...

Table 161. Read 1s Block Command Error Handling (continued)

Error Condition	Error Bit
Address is not valid	FSTAT[ACCERR]
Address is not block aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.3 Read 1s Sector Command

The Read 1s Sector command checks if a flash sector is in the erased state.

Table 162. Read 1s Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	02h (RD1SCR)
2	Sector address

Upon clearing CCIF to launch the Read 1s Sector command, the command controller:

- verifies that the selected flash sector is in the erased state

If the selected flash sector is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Sector operation completes.

Table 163. Read 1s Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not sector aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.4 Read 1s Page Command

The Read 1s Page command checks if a flash page is in the erased state.

Table 164. Read 1s Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	03h (RD1PG)
2	Page address

Upon clearing CCIF to launch the Read 1s Page command, the command controller:

- verifies that the selected flash page is in the erased state

If the selected flash page is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Page operation completes.

Table 165. Read 1s Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not page aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.5 Read 1s Phrase Command

The Read 1s Phrase command checks if a flash phrase is in the erased state.

Table 166. Read 1s Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	04h (RD1PHR)
2	Phrase address

Upon clearing CCIF to launch the Read 1s Phrase command, the command controller:

- verifies that the selected flash phrase is in the erased state

If the selected flash phrase is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s Phrase operation completes.

Table 167. Read 1s Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.6 Read into MISR command

The Read into MISR operation generates a signature based on the contents of the selected flash memory using an embedded MISR.

Table 168. Read into MISR Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	05h (RDMISR) [7:0]
2	Starting flash page address
3	Ending flash phrase address
4	Word 0 of MISR seed
5	Word 1 of MISR seed
6	Word 2 of MISR seed
7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes flash data starting with the starting flash page address provided
3. continues until the ending flash phrase address has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 169. Read into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not flash page aligned	FSTAT[ACCERR]
Ending address is not flash phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Requested range crosses a flash block boundary	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Uncorrectable ECC error is detected	FSTAT[FAIL]

16.3.2.7 Read 1s IFR Sector Command

The Read 1s IFR Sector command checks if an IFR sector is in the erased state.

Table 170. Read 1s IFR Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	12h (RD1ISCR)
2	IFR sector address

Upon clearing CCIF to launch the Read 1s IFR Sector command, the command controller:

- verifies that the selected IFR sector is in the erased state

If the selected IFR sector is not in the erased state, the FSTAT[FAIL] flag is set. The CCIF flag sets after the Read 1s IFR Sector operation completes.

Table 171. Read 1s IFR Sector Command Error Handling

Error Condition	Error Bit

7	Word 3 of MISR seed
Returned values	
4	Word 0 of MISR signature
5	Word 1 of MISR signature
6	Word 2 of MISR signature
7	Word 3 of MISR signature

Upon clearing CCIF to launch the Read IFR into MISR command, the command controller:

1. initializes the MISR with the seed provided
2. processes IFR data starting with the starting IFR page address provided
3. continues until the ending IFR phrase has been processed (must be the last phrase in a page)
4. returns the resulting signature into the FCCOB register bank unless an uncorrectable ECC fault is detected

The CCIF flag sets after the Read IFR into MISR operation completes. If the operation is aborted by setting FCTRL[ABTREQ], a signature will not be returned if the abort occurs prior to the operation writing the signature.

MISR polynomial is $X^{128} + X^{126} + X^{101} + X^{99} + 1$.

Table 177. Read IFR into MISR Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Address is not valid	FSTAT[ACCERR]
Starting address is not IFR page aligned	FSTAT[ACCERR]
Ending address is not IFR phrase aligned	FSTAT[ACCERR]
Ending address is not the last phrase in a page	FSTAT[ACCERR]
Starting address is larger than the ending address	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Uncorrectable ECC error is detected	FSTAT[FAIL]

16.3.2.11 Program Page command

The Program Page operation programs 32 words of data to a previously erased flash or IFR page.

CAUTION

The page must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a page is not allowed.

Table 178. Program Page Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	23h (PGMPG) [7:0]

Upon clearing CCIF to launch the Program Page command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 32 consecutive words to the flash or IFR space with the first write being page aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted page written to in step 2
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Page operation completes. The Program Page operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Program Page command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted page. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 179. Program Page Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Initial address is not page aligned and subsequent addresses phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.11.1 Page programming

The standard process of programming one or more flash or IFR pages is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Page command to enable writes to the flash space.
3. After the command controller sets FSTAT[PEWEN], write 32 consecutive words to the flash space with the first word page aligned. The data written to the flash space is not readable until the program operation has successfully completed.
4. After the flash page has been written, the command controller will stall and set FSTAT[PERDY].
5. Clear PERDY allowing the command controller to resume and program the 32 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR pages in previously erased flash memory, repeat steps 2 through 6.

16.3.2.12 Program Phrase command

The Program Phrase operation programs 4 words of data to a previously erased flash or IFR phrase.

CAUTION

The phrase must be in the erased state before being programmed. Cumulative programming of bits (back-to-back program operations without an intervening erase) within a phrase is not allowed.

Table 180. Program Phrase Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	24h (PGMPHR) [7:0]

Upon clearing CCIF to launch the Program Phrase command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]
5. waits for the user to clear FSTAT[PERDY]
6. programs the data into the targeted phrase written to in step 2.
7. verifies bits to be programmed are programmed to the program verify level

The CCIF flag sets after the Program Phrase operation completes. The Program Phrase operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set and the CMDABT flag is cleared, the Program Phrase command may be repeated (same addresses, same data) to complete the program operation without erasing the sector containing the targeted phrase. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 181. Program Phrase Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not phrase aligned	FSTAT[ACCERR]
Number of writes to flash or IFR space is more than expected	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.12.1 Phrase programming

The standard process of programming one or more flash or IFR phrases is as follows:

1. If required, launch the Erase Sector command to erase the flash or IFR sector to be programmed (repeat for additional sectors).
2. Launch the Program Phrase command to enable writes to the flash and IFR space.
3. After the command controller sets FSTAT[PEWEN], write 4 consecutive words to the flash or IFR space with the first word phrase aligned. The data written to the flash or IFR space is not readable until the program operation has successfully completed.
4. After the flash or IFR phrase has been written, the command controller will stall the operation and set FSTAT[PERDY].

5. Clear PERDY allowing the command controller to resume and program the 4 words into the flash or IFR space written to in step 3.
6. Wait for CCIF to set indicating the program operation has completed.
7. To program additional flash or IFR phrases in previously erased flash memory, repeat steps 2 through 6.

16.3.2.13 Erase All command

The Erase All operation erases all flash and IFR space if enabled by the MCU.

Table 182. Erase All Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	40h (ERSALL) [7:0]

Upon clearing CCIF to launch the Erase All command, the command controller:

1. erases flash block 0 sector-by-sector
2. verifies flash block 0 is erased; if not, skips IFR space in block 0
3. erases IFR space in block 0 sector-by-sector
4. verifies IFR space in block 0 is erased
5. clears FSTAT[CMDP] flag

The CCIF flag sets after the Erase All operation completes. If either the flash or IFR space is not in the erased state, FSTAT[FAIL] sets.

Table 183. Erase All Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Command is disabled by the MCU	FSTAT[PVIOL]
Operation is aborted	FSTAT[CMDABT]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.2.14 Erase Sector command

The Erase Sector operation erases the IFR sector to prepare the sector for programming.

Table 184. Erase Sector Command FCCOB Requirements

FCCOB Number	FCCOB Contents
0	42h (ERSSCR) [7:0]

Upon clearing CCIF to launch the Erase Sector command, the command controller:

1. sets FSTAT[PEWEN] to enable writes to the flash and IFR space in the system memory map
2. waits for the user to write 4 consecutive words to the flash or IFR space with the first write being phrase (or sector) aligned
3. clears FSTAT[PEWEN] field
4. sets FSTAT[PERDY]

5. waits for the user to clear FSTAT[PERDY]
6. erases the selected flash or IFR sector
7. verifies the selected flash or IFR sector is erased

If the selected flash or IFR sector is not in the erased state, FSTAT[FAIL] is set. The CCIF flag sets after the Erase Sector operation completes. The Erase Sector operation can be aborted by setting FCTRL[ABTREQ]. If the operation is aborted, the operation terminates with the FSTAT[CMDABT] flag set. Once CCIF is set, the Erase Sector command may be repeated to complete the erase operation. Invalid writes to flash or IFR space based on Block Checker or FMC access protection are trapped outside of the flash module.

Table 185. Erase Sector Command Error Handling

Error Condition	Error Bit
FMU parameters not loaded from IFR1 during initialization	FSTAT[ACCERR]
Protection level of the writes to flash or IFR space do not match the protection level of the command write sequence	FSTAT[ACCERR]
Address is not flash or IFR phrase aligned	FSTAT[ACCERR]
Operation is aborted	FSTAT[CMDABT]
IFR Sector is protected (see FCNFG register)	FSTAT[PVIOL]
FMU parameters not loaded from IFR1 during initialization	FSTAT[FAIL]
Verify fails	FSTAT[FAIL]

16.3.3 Mass Erase

If enabled by the MCU, MCU resources can be used to launch a mass erase operation without accessing the flash registers.

To know how to enable/disable mass erase for your device, refer the chip-specific section.

The status of the mass erase request is reflected in the FCNFG[ERSREQ] bit. When launched, the mass erase operation occurs regardless of the state of the CMDP, ACCERR, PVIOL, or CMDABT flags in the FSTAT register but requires FSTAT[CCIF] to be set and the MCU to enable mass erase. When mass erase is launched with CCIF set, the CMDP, CCIF, CWSABT, PVIOL, and CMDABT flags in the FSTAT register clear. The ACCERR and FAIL flags also clear unless the FMU parameters were not loaded from IFR1 during initialization in which case the mass erase operation terminates without performing any erase of flash memory.

Upon successful launch of the mass erase operation, the command controller (same steps as the Erase All command):

1. erases flash block 0 sector-by-sector
2. verifies flash block 0 is erased; if not, skips IFR space in block 0
3. erases IFR space in block 0 sector-by-sector
4. verifies IFR space in block 0 is erased

The CCIF flag sets and the ERSREQ bit clears once the operation completes and the FSTAT[FAIL] flag sets if any verify step fails during the mass erase operation. This method of erasing the flash memory cannot be aborted by setting FCTRL[ABTREQ].

16.3.4 Modes

16.3.4.1 Sleep mode

If the CPU enters sleep mode while a flash command is executing, the flash module can wake the CPU via the command complete interrupt (see Interrupts).

16.3.4.2 Non-Active Power mode

If a flash command is active (CCIF = 0) when the MCU requests a non-active power mode, the command execution completes before the MCU is allowed to enter the non-active power mode.

16.3.5 Clocking

This module has no clocking considerations.

16.3.6 Interrupts

The flash module can generate interrupt requests to the MCU upon the occurrence of various flash module events. These interrupt events and their associated status and control bits are shown in the following table.

Table 186. Flash Module Interrupt Sources

Flash Event	Readable Status Bit	Interrupt Enable Bit
Flash Command Complete	FSTAT[CCIF]	FCNFG[CCIE]
Flash ECC Fault Detected	FSTAT[DFDIF]	FCNFG[DFDIE]

NOTE

Vector addresses and their relative interrupt priority are determined at the MCU level.

16.4 External signals

The flash module contains no signals that connect off-chip.

16.5 Initialization

On each reset, the command controller initializes the following based on IFR1 content:

1. FCTRL[RWSC]
2. FMU Parameters (FMUPARM)

The FSTAT[CCIF] flag is cleared throughout the initialization flow. The flash module also holds off all access to flash registers and flash memory during initialization. Completion of the initialization flow is marked by setting FSTAT[CCIF]. If an uncorrectable ECC error is detected during initialization, the FSTAT[FAIL] flag sets. The FAIL flag also sets if FMU parameters are not loaded from IFR1 during initialization. In this case, attempts to launch a flash command terminate with the ACCERR and FAIL flags set. The recommendation is to refrain from launching flash commands if the FAIL flag sets after initialization.

If a reset occurs while any flash command is in progress, that command is immediately aborted. The state of the flash memory or IFR space being programmed or erased is not guaranteed. Command operations do not automatically resume after exiting reset.

16.6 Memory map and registers

This section describes the flash memory map for IFR/IFR1 space and registers. See the MCU system memory map for the location of all flash memory space and registers. Data read from unimplemented memory space in the flash module is undefined.

16.6.1 IFR description

Each flash block contains IFR space separate from the main flash memory. IFR space is memory mapped (see the MCU system memory map). IFR space is divided into IFR pages programmable using the Program Page command. IFR pages are further divided into IFR phrases programmable using the Program Phrase command. Once programmed, IFR phrases can be

reprogrammed after a successful erase using the Erase Sector command operation unless the IFR sector is protected by the FCNFG register.

Table 187. IFR map

Offset Byte Address	IFR Field Size (Bytes)
Block 0 IFR Sector 0	
0000h-1FFFh	8,192
Block 0 IFR Sector 1	
2000h-3FFFh	8,192
Block 0 IFR Sector 2	
4000h-5FFFh	8,192
Block 0 IFR Sector 3	
6000h-7FFFh	8,192

Each flash block also contains IFR1 space separate from the main flash memory. IFR1 space in program flash block 0 is memory mapped for read-only access (see the MCU system memory map). IFR1 space cannot be erased or programmed by the user.

Table 188. IFR1 map

Offset Byte Address	IFR1 Field Size (Bytes)
Block 0 IFR1 Sector	
0000h-15FFh	5,632
1600h-16FFh	256
1700h-1FFFh	2,304

16.6.2 Register descriptions

The flash module contains a set of memory-mapped control and status registers.

NOTE

While a command is running (FSTAT[CCIF]=0), register writes are allowed to FSTAT[PERDY,DFDIF,CWSABT], FCNFG, and FCTRL[ABTREQ,FDFD,RWSC].

16.6.2.1 Flash register descriptions

16.6.2.1.1 Flash memory map

16.6.2.1.2 Flash Status Register (FSTAT)

Offset

Register	Offset
FSTAT	0h

Function

The FSTAT register reports the operational status of the flash module.

NOTE

When set, ACCERR, PVIOL, and CMDABT flags prevent the launch of any more commands until the flag is cleared (by writing a one to it).

CAUTION

When clearing the DFDIF flag, be careful not to use read-modify-write on the entire FSTAT register and inadvertently clear CCIF to launch a command.

Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	u

Fields

Field	Function
31 PERDY	Program-Erase Ready Control/Status Flag The PERDY flag is set by the command controller when a program or sector erase command operation has successfully completed the write phase. The command controller will stall the command operation until the user clears the PERDY flag by writing a 1 to PERDY. Failure to clear PERDY will leave the command controller stalled but the flash or IFR space targeted by the command operation will remain readable by the FMC. If FCTRL[ABTREQ] is set while the PERDY flag is set, the command controller will clear PERDY, abort the command operation, and set both CCIF and CMDABT. 0b - Program or sector erase command operation not stalled 1b - Program or sector erase command operation ready to execute
30-26 —	Reserved
25-24 PEWEN	Program-Erase Write Enable Control During program or sector erase command operations, writes are enabled to flash or IFR space in the system memory map. For phrase programming or sector erase, writes are enabled for 4 consecutive words (16 bytes) with address phrase aligned. For page programming, writes are enabled for 8 consecutive phrases (128 bytes) with address page aligned. For programming, data written to erased flash or IFR space for program commands is not available until the program operation has successfully completed. PEWEN will not assert if FMU parameters were not loaded from IFR1 during initialization. 00b - Writes are not enabled 01b - Writes are enabled for one flash or IFR phrase (phrase programming, sector erase) 10b - Writes are enabled for one flash or IFR page (page programming) 11b - Reserved
23-18 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
17 SALV_USED	Salvage Used for Erase operation This flag indicates salvage was used during the last Erase Sector, Erase All, or Mass Erase operation and is valid at the end of the operation. Salvage involves using ECC to pass erase verify allowing single-bit faults per phrase verified. This flag remains valid until any flash command or Mass Erase operation launches at which time the flag clears. Use of salvage does not guarantee that the erase operation succeeds but only that salvage was used on at least one phrase. 0b - Salvage not used during last operation 1b - Salvage used during the last erase operation
16 DFDIF	Double Bit Fault Detect Interrupt Flag The DFDIF flag indicates an uncorrectable ECC fault was detected during a valid flash read access from the FMC. The DFDIF flag is cleared by writing a 1 to DFDIF. Writing a 0 to DFDIF has no effect. 0b - Double bit fault not detected during a valid flash read access 1b - Double bit fault detected (or FCTRL[FDFD] is set) during a valid flash read access
15-12 CMDDID	Command domain ID While the CMDP flag is set, the CMDDID bits reflect the domain ID of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an FCCOB register, clear CCIF, or clear PERDY must have the same domain ID as the write transaction that started the command write sequence. The CMDDID bits persist after the CMDP flag clears until the CMDP flag sets again at the start of a new command write sequence. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDDID bits.
11 CMDP	Command protection status flag The CMDP flag sets when a command write sequence starts with a write to load an existing FCCOB register or clear CCIF while ACCERR, PVIOL, and CMDABT are clear. Clearing the CWSABT, ACCERR, PVIOL, or CMDABT flags as part of a command write sequence will not set the CMDP flag. While the CMDP flag is set, the protection level of any subsequent write transaction to load an FCCOB register, clear CCIF, or clear PERDY must match the CMDPRT bits and the domain ID must match the CMDDID bits. The CMDP flag remains set until cleared when CCIF is set after a command operation or Power Down recovery completes unless the CMDABT flag is set. The CMDP flag is cleared even if the operation ends with ACCERR or PVIOL set. When the CMDP flag is cleared, the CMDPRT and CMDDID bits remain unchanged. The CMDP flag is also cleared by a mass erase request with CCIF set. 0b - Command protection level and domain ID are stale 1b - Command protection level (CMDPRT) and domain ID (CMDDID) are set
10 —	Reserved
9-8 CMDPRT	Command protection level

Table continues on the next page...

Table continued from the previous page...

Field	Function
	While the CMDP flag is set, the CMDPRT bits reflect the secure/privilege protection level of the write transaction controlling a command write sequence or aborting a command operation. Writes to load an existing FCCOB register, clear CCIF, or clear PERDY must occur with the same protection level as indicated by the CMDPRT bits. Writes to clear the CWSABT, ACCERR, PVIOL, or CMDABT flags are not influenced by the state of the CMDPRT bits. If FCTRL[ABTREQ] is set while CCIF is high or low, the CMDPRT bits will change to reflect the security/ privilege protection level of the write transaction that set the ABTREQ bit. 00b - Secure, normal access 01b - Secure, privileged access 10b - Nonsecure, normal access 11b - Nonsecure, privileged access
7 CCIF	Command Complete Interrupt Flag The CCIF flag indicates that a flash command has completed. The CCIF flag is cleared by writing a 1 to CCIF to launch a flash command. The CCIF flag stays low until the command completes. The CCIF flag is cleared by a mass erase request with CCIF set. The CCIF flag is also cleared upon entry into Deep Sleep, Power Down, and Deep Power Down modes and stays low until the end of recovery from these non-active power modes. The CCIF flag is reset to 0 but is set to 1 at the end of flash initialization. 0b - Flash command, initialization, or power mode recovery in progress 1b - Flash command, initialization, or power mode recovery has completed
6 CWSABT	Command Write Sequence Abort Flag The CWSABT flag indicates whether a request to abort a command write sequence prior to command launch has been granted. If FCTRL[ABTREQ] is set while CCIF is high, the CWSABT flag will get set. Once CWSABT is set, ABTREQ will get cleared. While the CWSABT flag is set, ABTREQ cannot be set. The CWSABT flag is cleared by writing a 1 to CWSABT while CCIF is set or clear and ABTREQ is clear. Writing a 0 to the CWSABT flag has no effect. The CWSABT flag is cleared by a mass erase request with CCIF set. 0b - Command write sequence not aborted 1b - Command write sequence aborted
5 ACCERR	Command Access Error Flag The ACCERR flag indicates an illegal attempt was made to launch a flash command due to a violation of the command write sequence or by providing invalid command parameters. The ACCERR flag also sets during command execution if FMU parameters were not loaded from IFR1 during initialization. While the ACCERR flag is set, the CCIF flag cannot be cleared to launch a command. The ACCERR flag is cleared by writing a 1 to ACCERR while CCIF is set. Writing a 0 to the ACCERR flag has no effect. The ACCERR flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No access error detected 1b - Access error detected
4 PVIOL	Command Protection Violation Flag The PVIOL flag indicates an attempt was made to modify a protected area of flash memory during a command operation. While the PVIOL flag is set, the CCIF flag cannot be cleared to launch a command. The PVIOL flag is cleared by writing a 1 to PVIOL while CCIF is set. Writing a 0 to the PVIOL flag has no effect. The PVIOL flag is cleared by a mass erase request with CCIF set but is not cleared during Power Down recovery. 0b - No protection violation detected 1b - Protection violation detected
3 —	Reserved
2 CMDABT	Command Abort Flag The CMDABT flag indicates FCTRL[ABTREQ] was set during a command operation while CCIF was clear. This event will result in the termination of the operation unless it occurs during the exit routine of the operation. Once CMDABT is set, ABTREQ will get cleared. While the CMDABT flag is set, ABTREQ cannot be set and the CCIF flag cannot be cleared to launch a command. The CMDABT flag is cleared by writing a 1 to CMDABT while CCIF is set and ABTREQ is clear. Writing a 0 to the CMDABT flag has no effect. The CMDABT flag is cleared by a mass erase request with CCIF set. 0b - No command abort detected 1b - Command abort detected
1 —	Reserved
0 FAIL	Command Fail Flag The FAIL flag is set if an error is detected during execution of a flash command, mass erase operation, or flash initialization. If the FAIL flag sets along with ACCERR after launching a flash command or mass erase operation, FMU parameters were not loaded from IFR1 during initialization and a clean POR where FMU parameters are successfully loaded is required to clear the FAIL flag. As a status flag, this bit cannot (and need not) be cleared by the user like some of the other flags in this register. The value of the FAIL flag for "command-N" is valid only at the end of the "command-N" execution when CCIF=1 and before the next command has been launched. At some point during the execution of "command-N+1," the FAIL flag is cleared unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is cleared by a mass erase request with CCIF set unless FMU parameters were not loaded from IFR1 during initialization. The FAIL flag is not cleared during Power Down recovery.

Field	Function
	0b - Error not detected 1b - Error detected

16.6.2.1.3 Flash Configuration Register (FCNFG)

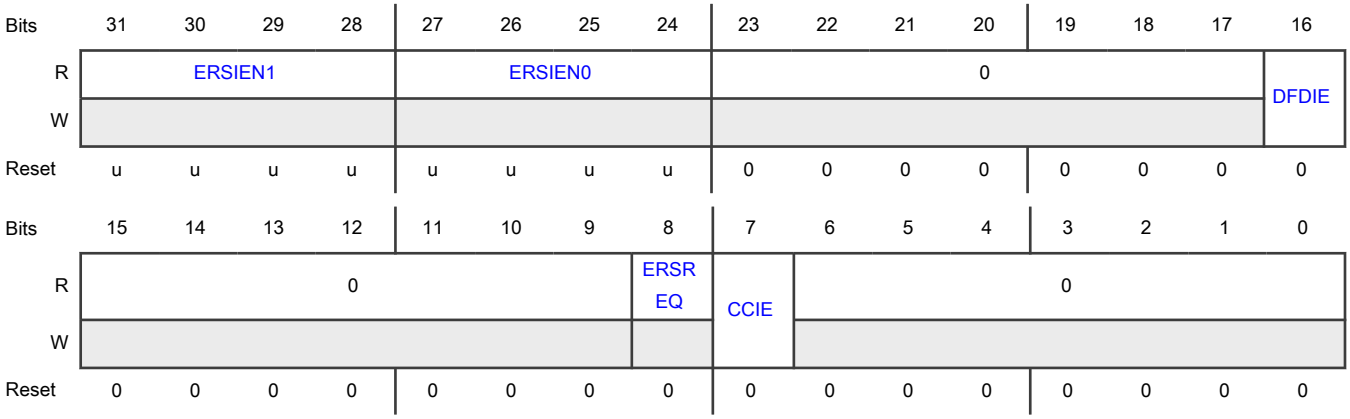
Offset

Register	Offset
FCNFG	4h

Function

This register provides information on the current functional state of the flash module.

Diagram



Fields

Field	Function
31-28 ERSIEN1	Erase IFR Sector Enable - Block 1 (for dual block configs) This field controls the ability to erase the IFR sectors in block 1 using the ERSSCR command. These bits are loaded from sideband signals during initialization and at launch of ERSSCR command. Note: These bits have no effect on single block configurations. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 1 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 1 IFR Sector X is not protected from erase by ERSSCR command
27-24	Erase IFR Sector Enable - Block 0

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERSIEN0	This field controls the ability to erase the IFR sectors in block 0 using the ERSSCR command. These bits are loaded from sideband signals during initialization and at launch of ERSSCR command. Note: The ERSALL command and MCU mass erase request do not adhere to these restrictions. X equals 0, 1, 2, or 3. Any and all bits in the field are independently configured. 0000b - Block 0 IFR Sector X is protected from erase by ERSSCR command 0001b - Block 0 IFR Sector X is not protected from erase by ERSSCR command
23-17 —	Reserved
16 DFDIE	Double Bit Fault Detect Interrupt Enable The DFDIE bit controls interrupt generation when an uncorrectable ECC fault is detected during a valid flash read access from the platform flash controller. 0b - Double bit fault detect interrupt disabled 1b - Double bit fault detect interrupt enabled. An interrupt request is generated whenever the FSTAT[DFDIF] flag is set.
15-9 —	Reserved
8 ERSREQ	Mass Erase Request This bit indicates whether a sideband request has been received by the command controller to execute the Mass Erase operation. ERSREQ is not directly writable but sets when a Mass Erase request is received by the flash module while CCIF is set. ERSREQ is cleared by the command controller when the operation completes. 0b - No request or request complete 1b - Request to run the Mass Erase operation
7 CCIE	Command Complete Interrupt Enable The CCIE bit controls interrupt generation when a flash command completes. 0b - Command complete interrupt disabled 1b - Command complete interrupt enabled. An interrupt request is generated whenever the FSTAT[CCIF] flag is set.
6-0 —	Reserved

16.6.2.1.4 Flash Control Register (FCTRL)

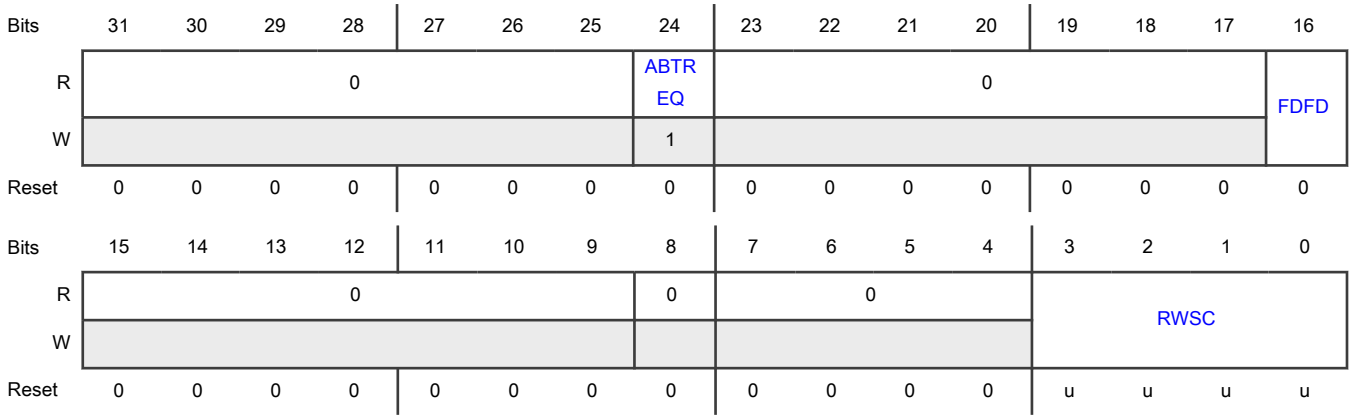
Offset

Register	Offset
FCTRL	8h

Function

The flash control register controls activity associated with flash memory reads and command operations.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ABTREQ	Abort Request With FSTAT[CMDP] set, setting the ABTREQ bit allows a user to abort a command write sequence or command operation. The ABTREQ bit can only be set by a user with the same domain ID as indicated by FSTAT[CMDDID] and the same or higher security/privilege protection level than is indicated by FSTAT[CMDPRT]. While ABTREQ is set, CCIF cannot be cleared to launch a command. If FSTAT[CCIF] is high when ABTREQ is set, the command write sequence will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CWSABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. If FSTAT[CCIF] is low when ABTREQ is set, the command operation will abort and ownership transferred to the user setting the ABTREQ bit. The FSTAT[CMDABT] flag will set and the CMDPRT field will be updated based on the write transaction that sets the ABTREQ bit. The ABTREQ bit will then be cleared automatically. While CWSABT or CMDABT are high, writes to ABTREQ will be ignored. 0b - No request to abort a command write sequence

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Request to abort a command write sequence
23-17 —	Reserved
16 FDFD	Force Double Bit Fault Detect The FDFD bit enables the user to emulate the setting of the FSTAT[DFDIF] flag to check the associated interrupt routine. The FDFD bit is cleared by writing a 0 to FDFD. 0b - FSTAT[DFDIF] sets only if a double bit fault is detected during a valid flash read access from the platform flash controller 1b - FSTAT[DFDIF] sets during any valid flash read access from the platform flash controller. An interrupt request is generated if the DFDIE bit is set.
15-9 —	Reserved
8 —	Reserved
7-4 —	Reserved
3-0 RWSC	Read Wait-State Control These bits control the number of wait-states added to account for the ratio of system clock period to flash access time during full speed power mode. Ratios greater than one require non-zero settings for the RWSC field for proper flash accesses. The required settings are documented in the device data sheet. 0h - no additional wait-states are added (single cycle access) 1h - 1 additional wait-state is added 2h - 2 additional wait-states are added ... Fh - 15 additional wait-states are added These bits are loaded from IFR1 during initialization. **NOTE** The default FCTRL[RWSC] is set to a value appropriate for the chip's max operating frequency. Refer to the chip-specific section for the default value.

16.6.2.1.5 Flash Common Command Object Registers (FCCOB0 - FCCOB7)

Offset

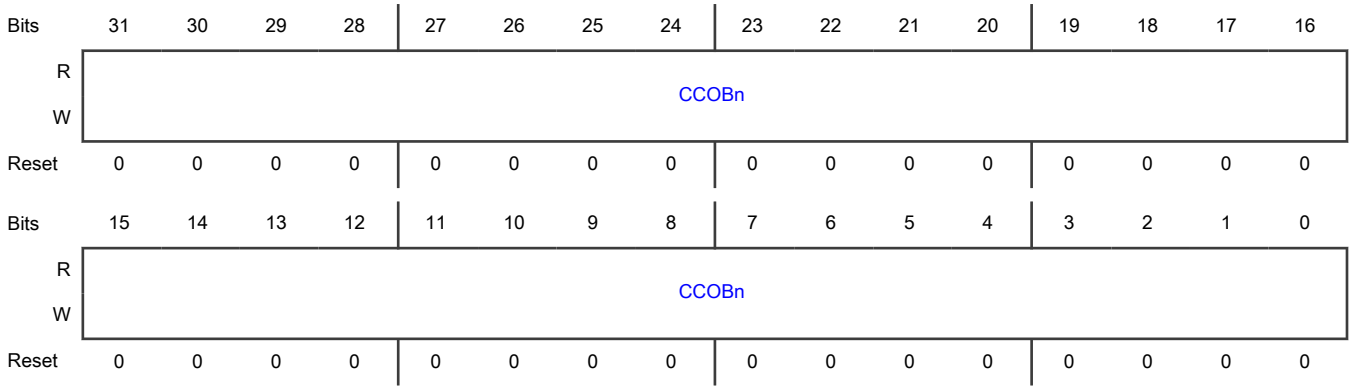
For a = 0 to 7:

Register	Offset
FCCOBa	10h + (a × 4h)

Function

The FCCOB register group provides fields for command codes and parameters. The individual words within the set append a 0-7 hex identifier to the FCCOB register name: FCCOB0, FCCOB1, ..., FCCOB7.

Diagram



Fields

Field	Function
31-0 CCOBn	CCOBn The FCCOB register group provides a command code and relevant parameters to the command controller. The individual registers that compose the FCCOB data set can be written in any order, but you must provide all needed values, which vary from command to command. First, set up all required FCCOB fields and then initiate the command execution by writing a 1 to the FSTAT[CCIF] bit. This clears the CCIF bit, which locks all FCCOB parameter fields and they cannot be changed by the user until the command completes (CCIF returns to 1). No command buffering or queueing is provided; the next command can be loaded only after the current command completes. Some commands return information to the FCCOB registers. Any values returned to FCCOB are available for reading after the FSTAT[CCIF] flag returns to 1. The following table shows a generic flash command format. The first FCCOB register, FCCOB0, always contains the command code. This 8-bit value defines the command to be executed. The command code is followed by the parameters required for this specific flash command, typically an address and/or data values.

NOTE

The command parameter table is written in terms of FCCOB Number (which is equivalent to the word number). This number is a reference to the FCCOB register name and is not the register address.

FCCOB Number[1]	Typical Command Parameter Contents [31:0]
0	FCMD [7:0] (flash command code, bits [31:8] are not writable)

Field	Function	
	FCCOB Number[1]	Typical Command Parameter Contents [31:0]
	1	FCMDOPT [7:0] (flash command options, bits [31:8] are not writable)
	2	Flash address 1 (start)
	3	Flash address 2 (end)
	4	Data Word 0
	5	Data Word 1
	6	Data Word 2
	7	Data Word 3
	1. Refers to FCCOB register name, not register address	

16.7 Glossary

Block Checker — MCU IP that provides a mechanism to set access rights to the flash memory for read and write operations.

Command write sequence — A series of MCU writes to the Flash FCCOB register group and FSTAT[CCIF] that initiates and controls the execution of flash algorithms that are built into the flash module.

Endurance — The number of times that an aligned flash or IFR phrase can be erased and reprogrammed.

FCCOB (Flash Common Command Object Block) — A group of flash registers that are used to pass command, address, data, and any associated parameters to the command controller.

Flash block — A macro within the flash module which provides the nonvolatile memory storage with an aligned block address being the first address in the block.

Flash module — All flash blocks plus a flash management unit providing command control and an interface to MCU buses.

Flash page — 128 bytes of flash main memory with an aligned page having byte-address[6:0] = 00h; represents the largest portion of the flash memory that can be programmed in one operation.

Flash phrase — 16 bytes of flash main memory with an aligned phrase having byte-address[3:0] = 0000b; represents the smallest portion of the flash memory that can be programmed in one operation.

Flash sector — 8 Kbytes of flash main memory with an aligned sector having byte-address[12:0] = 0000h; represents the smallest portion of the flash memory that can be erased in one operation.

FLW — The Flash Logical Window module allows a specific logical address range to access a programmable physical address range in the flash memory with programmable FLW default settings stored in IFR space.

FMC — Flash Memory Controller module manages flash memory reads and writes.

IFR — Information flash region separate from the main flash memory array. Each flash block has 32 Kbytes of user IFR space. Sometimes referred to as IFR0.

IFR1 — Information flash region separate from the main memory array reserved for array trim, MCU trim, and test. Each flash array has 8 Kbytes of IFR1 space.

IFR page — 128 bytes of IFR or IFR1 space with an aligned IFR page having byte-address[6:0] = 00h; represents the largest portion of IFR space that can be programmed.

IFR phrase — 16 bytes of IFR or IFR1 space with an aligned IFR phrase having byte-address[3:0] = 0000b; represents the smallest portion of IFR space that can be programmed in one operation.

IFR sector — 8 Kbytes of IFR or IFR1 space with an aligned IFR sector having byte-address[12:0] = 0000h; represents the smallest portion IFR space that can be erased.

MISR — Multiple-input signature register used to generate a signature based on flash memory contents read.

MSF — Microcontroller Secure Flash.

NVM — Nonvolatile memory. The flash block is an NVM using NOR-type flash memory technology.

Program flash — Program flash memory provides nonvolatile storage for vectors and code store.

Retention — The length of time that data (erased or programmed) can be kept in the NVM without experiencing errors upon readout.

Security/Privilege protection levels — The Flash module supports 4 levels of security/privilege protection for flash commands:

1. Secure (Trusted) / Privileged
2. Secure (Trusted) / User
3. Non-secure (Non-Trusted) / Privileged
4. Non-secure (Non-Trusted) / User

Chapter 17
System Register File (REGFILE)

17.1 Chip-specific REGFILE information

Table 189. Reference links to related information

Topic	Related module	Reference
Full description	REGFILE	REGFILE
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

17.1.1 Module instances

This device has two instances of the REGFILE module, REGFILE0, and REGFILE1. REGFILE0 has no WAR or RAR registers while REGFILE1 has WAR and RAR registers.

17.1.2 Module reset

REGFILE0 retains its contents during low-voltage detect (LVD) events and is only reset during a power-on reset. REGFILE1 can be reset by every reset except wakeup from Power Down and Deep Power Down.

17.1.3 Low-power wakeup booth path

This device embeds a ROM bootloader code resident in the ROM area. Low-power wakeup boot flow requires the usage of REGFILE1 REG0 to store WAKEUP CRC data to verify the ROM wakeup word, therefore, REGFILE1 REG0 should not be used to store application data when low-power wakeup boot is enabled, but it should contain the valid WAKEUP CRC parameter to ensure proper boot sequence. See the Low_power wakeup path for more information about REGFILE1 REG0 usage during low-power boot flow.

17.2 Overview

The REGFILE module is used to store data, which is written to the Register File Registers, to be persistent.

17.3 Memory Map and Registers

17.3.1 REGFILE register descriptions

17.3.1.1 REGFILE memory map

REGFILE0 base address: 4002_1000h

REGFILE1 base address: 4002_2000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 1Ch	Register File Register a (REG0 - REG7)	32	RW	0000_0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
100h	Write Access Register (WAR)	32	RW	0000_00FFh
104h	Read Access Register (RAR)	32	RW	0000_00FFh

17.3.1.2 Register File Register a (REG0 - REG7)

Offset

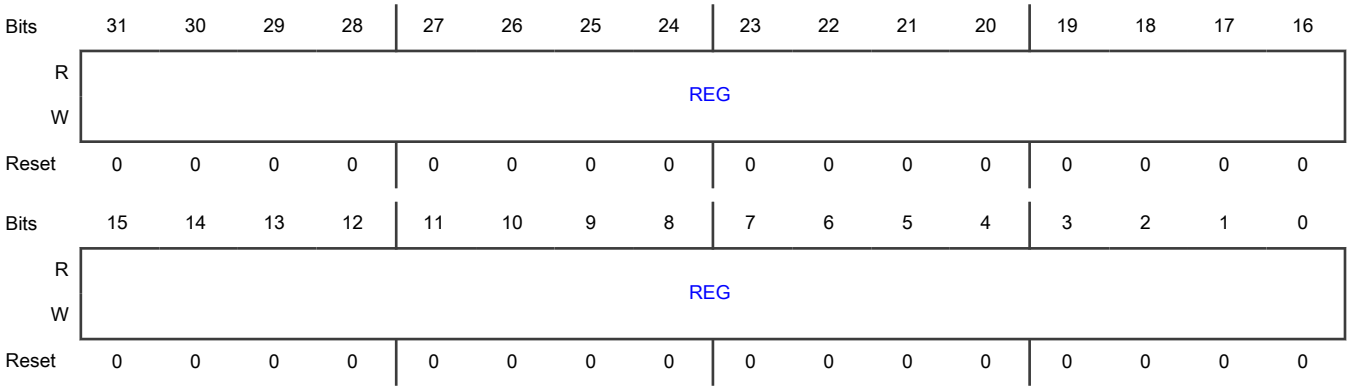
For a = 0 to 7:

Register	Offset
REGa	0h + (a × 4h)

Function

Each register can be accessed as 8-, 16-, or 32-bit.

Diagram



Fields

Field	Function
31-0 REG	Register File

17.3.1.3 Write Access Register (WAR)

Offset

Register	Offset
WAR	100h

Function

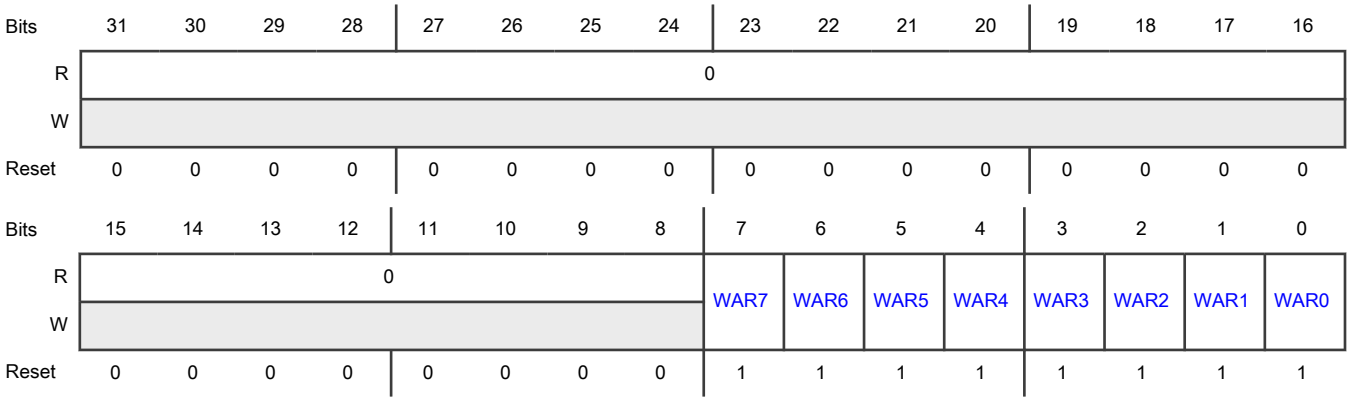
This register controls write access to the REG registers

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
REGFILE0	—	WAR
REGFILE1	WAR	—

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 WARn	REGn Register Write Access 0b - Not allow to write to the REGn register and WARn field until next reset. 1b - Allow to write to the REGn register and WAR0 field.

17.3.1.4 Read Access Register (RAR)

Offset

Register	Offset
RAR	104h

Function

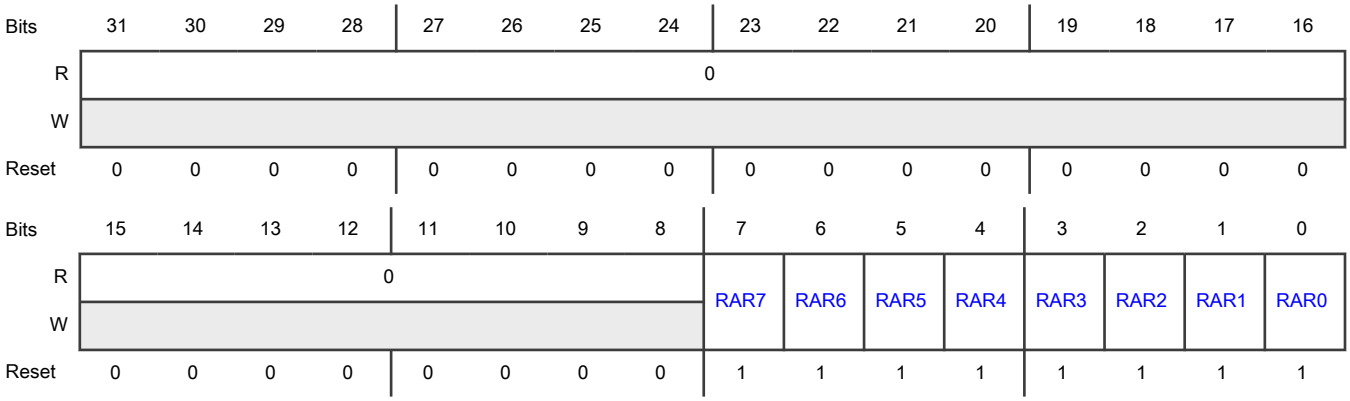
This register controls read access to the REG registers

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
REGFILE0	—	RAR
REGFILE1	RAR	—

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 RARn	REGn Register Read Access 0b - Not allow to read the REGn register until next reset. Reading corresponding REGn register returns all 0. 1b - Allow to read the REGn register.

17.4 Functional description

REGFILE can be used to store data that must be persistent across the low power modes. Write the information into the Register File Registers and read the information back.

If a REGFILE instance supports Write Access Register (WAR) and Read Access Register (RAR), they can lock write and read operations on the Register File Registers until the next reset is performed.

NOTE

Not all the instances support WAR and RAR registers, refer to WAR and RAR registers for instances that support them.

17.4.1 Power mode

The REGFILE module is powered in all power modes unless it is in the VDD_SWITCH domain. In VDD_SWITCH domain, the REGFILE module is only powered down to Deep Power Down mode.

17.4.2 Reset

See chip-specific section for the reset of REGFILE module.

Chapter 18
Signal Muxing and Pinout

18.1 Introduction

To optimize functionality in small packages, pins have several functions available via signal multiplexing. This chapter illustrates which of this device's signals are multiplexed on which external pin.

18.2 Package pinout

Table 191. Reference links to related information

Topic	Related module	Reference
Full description	PORT	PORT
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

19.1.1 Module instances

This device has four instances of the port module, PORTA, PORTB, PORTC, and PORTD.

19.1.2 Port B EFT detect clear (EDCR)

Port B and Port C pins share the same EFT detector clear control from PORTC_EDCR register. Any write to the PORTB_EDCR does not take effect.

19.1.3 Port voltage range (CONFIG[RANGE])

PORTA_CONFIG[RANGE] controls the voltage ranges of Port A, B, and C. Reading or writing PORTB_CONFIG[RANGE] and PORTC_CONFIG[RANGE] does not take effect.

19.2 Overview

PORT provides support for pad control functions. You can configure most functions independently for each pin, in the 32-bit port, and affect the pin regardless of its pin multiplexing state.

There exists a single instance of the PORT module for each port, and not all pins within each port are implemented on a specific chip.

19.2.1 Block diagram

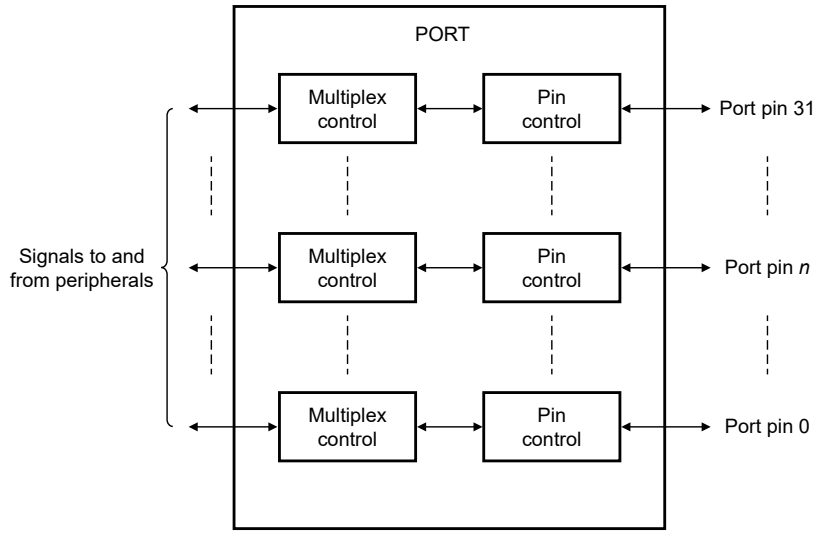

Figure 56. Block diagram

19.2.2 Features

- Individual pull control fields with pullup, pulldown, and pull-disable support

- Individual drive strength fields supporting high and low drive strengths
- Individual slew rate fields supporting fast and slow slew rates
- Individual PCR*n*[PFE] fields that enable and disable individual input passive filters on selected pins
- Individual PCR*n*[ODE] fields that enable and disable individual open drain outputs
- Digital input inversion to optionally invert the digital input
- Individual electrical fast transient (EFT) detect with an EFT detect flag and associated interrupt
- Individual mux control fields supporting analog or pin disabled, GPIO, and up to 10 chip-specific digital functions

19.3 Functional description

19.3.1 Pin control

Each port pin has a corresponding Pin Control Register (PCR) associated with it that helps you configure the following functions for each pin within the 32-bit port:

- Pullup or pulldown enable
- Drive strength configuration
- Slew rate configuration
- Open drain enable
- Passive input filter enable on selected pins
- Digital input inversion
- EFT detection
- Software configuration lock
- Pin multiplexing mode

These functions apply across all digital pin multiplexing modes, and individual peripherals do not override the configuration in PCR*n* unless otherwise noted. For example, if an I^2C function is enabled on a pin, it does not override the pullup or open drain configuration for that pin.

PCR*n*[LK] allows the configuration for each pin to be locked until the next system reset. When locked, writes to the lower half of that PCR*n* are ignored, although a bus error is not generated on an attempted write to a locked register.

The configuration of each PCR*n* is retained when the PORT module is disabled.

When you configure a pin in a digital pin multiplexing mode, the input buffer for that pin is enabled, allowing the pin state to be read via the corresponding GPIO.PDIR or allowing a pin interrupt or DMA request to be generated. If a pin is always floating when its input buffer is enabled, it can cause an increase in power consumption. This situation must be avoided. A pin can be floating because of an input pin that is not connected or an output pin that is tristated (output buffer is disabled).

Enabling the internal pull resistor (or implementing an external pull resistor) ensures that a pin does not float when its input buffer is enabled. The internal pull resistor is automatically disabled whenever the output buffer is enabled, allowing PCR*n*[PE] to remain 1. Configuring Pin Multiplexing mode to disabled or analog (PCR*n*[MUX] = 0) disables the pin's input buffer and results in lowest power consumption.

19.3.2 Global pin control

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) allow a single register write to update the lower 16 bits of PCR*n* for up to 16 pins, all with the same value. You cannot write to locked registers by using Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR).

Global Pin Control Low (GPCLR) and Global Pin Control High (GPCHR) enable you to quickly configure multiple pins within the same port and with the same peripheral function. These are write-only registers that always read as 0.

19.3.3 EFT detection

The EFT detect circuit is active whenever PORT is powered and EDCR[EDLC] and EDCR[EDHC] are 0.

The EFT high detect circuit for each pin is reset whenever EDCR[EDHC] = 1. Likewise, the EFT low detect circuit for each pin is reset whenever EDCR[EDLC] = 1 and that pin's EFT high detect is not asserted.

19.3.4 Clocking

This module has no clocking considerations.

19.3.5 Interrupt

When EFT on a pin is detected, an interrupt request is generated to indicate the detection of EFT on that pin. This interrupt is enabled when EDIER[EDIE*n*] = 1. Writing 0 to these fields clears the interrupt request but does not affect EFT detection on the corresponding pin (EDFR[EDF*n*]).

19.4 Initialization

To initialize PORT, perform the following procedure:

1. Initialize the pin functions:
   - Initialize single pin functions by writing appropriate values to PCR*n*.
   - Initialize multiple pins (up to 16) with the same configuration by writing appropriate values to Global Pin Control Low (GPCLR) or Global Pin Control High (GPCHR).
2. Lock the configuration for a given pin, by writing 1 to PCR*n*[LK], so that it cannot be changed until the next reset.

19.5 Application information

19.5.1 Determine polarity of an asserted EFT detection

You can determine the polarity of an asserted EFT detect by performing this procedure:

1. Read EFT Detect Flag (EDFR).
2. Write 1 and then write 0 to EDCR[EDLC].
3. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT low detector only (no EFT high detector triggering).
4. Write 1 and then write 0 to EDCR[EDHC].
5. Read EFT Detect Flag (EDFR) again. Any field that has now become 0 indicates triggering of the EFT high detector. Any field that did not become 0 indicates triggering of both the EFT high and EFT low detectors.
6. Write 1 and then write 0 to both EDCR[EDLC] and EDCR[EDHC] to ensure that all detectors are reset.

19.6 Memory map and register definition

Any read or write access to the PORT memory space, outside the valid memory map, results in a bus error. All register accesses complete with zero wait states.

19.6.1 PORT register descriptions

Configures the multiplexing slots on each pin.
Not all pins support all pin multiplexing slots. Unimplemented pin multiplexing slots are reserved.
Unimplemented pin multiplexing slots can result in different behaviors, if the unimplemented slot is phantomed (because the module is phantomed on that die) versus unimplemented on the die.
The corresponding pin is configured according to the following pin multiplexing slots:

Chapter 20
General-purpose Input and Output (GPIO)

20.1 Chip-specific GPIO information

Table 193. Reference links to related information

Topic	Related module	Reference
Full description	GPIO	GPIO
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

20.1.1 Module instances

This device has four instances of the GPIO module, GPIOA, GPIOB, GPIOC, and GPIOD.

20.1.2 GPIO interrupts

For each GPIO module, two interrupt channels have been assigned. Refer to Interrupt channel assignments for more details.

20.2 Overview

GPIO communicates to the processor core via a zero wait-state interface for maximum pin performance.

20.2.1 Block diagram

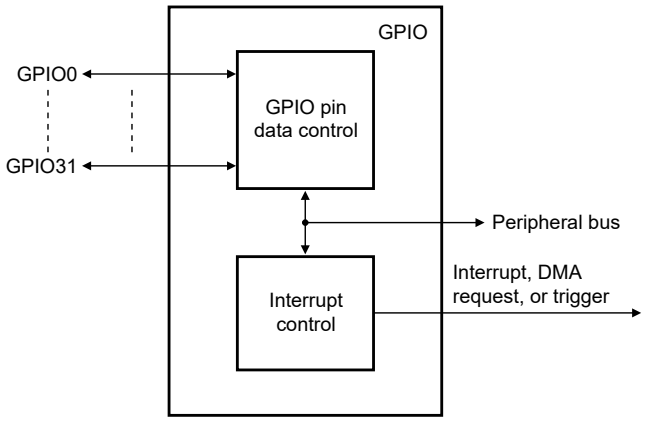

Figure 57. Block diagram

20.2.2 Features

- Port Data Input (PDIR) displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt modules for that pin are enabled.
- Port Data Output (PDOR), with corresponding set, clear, and toggle registers, controls the output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) controls the direction of each pin when the pin is configured for the GPIO function.

- Port Input Disable (PIDR) controls disabling of the input for each general-purpose pin.
- Pin interrupts:
  - Interrupt flags and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt, peripheral trigger, or DMA request is configured for each pin.
  - Support for edge-sensitive (rising, falling, or both) or level-sensitive (low, high) interrupts is configured for each pin.
  - Asynchronous wake-up in Low-Power mode.
  - GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, output trigger, or DMA request.
- Protection registers:
  - Each pin is configured for secure or nonsecure and privileged or nonprivileged access.
  - Each interrupt, trigger, and DMA request domain is configured for secure or nonsecure and privileged or nonprivileged access.

20.3 Functional description

20.3.1 Low-Power mode

You can configure GPIO to exit Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

20.3.2 Debug mode

GPIO remains functional in Debug mode.

20.3.3 General-purpose input

The logic state of each pin is available via Port Data Input (PDIR) if:

- The corresponding field in Port Input Disable (PIDR) is 0.
- The pin is configured for a digital function.

20.3.4 General-purpose output

The logic state of each pin is controlled via Port Data Output (PDOR) and Port Data Direction (PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input or output.

Table 194. General-purpose output

If	Then
A pin is configured for the GPIO function and the corresponding PDDR field is 0	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR field is 1	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR field.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allow one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

20.3.5 Clocking

GPIO receives a single clock, which is used for register access and synchronization with external pin inputs. There are no special considerations.

20.3.6 Reset

GPIO receives a single reset, which resets the peripheral. There are no special considerations.

20.3.7 External interrupts

The external interrupt capability of GPIO is available in all digital pin muxing modes.

GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests. You can configure each pin individually for interrupt, output trigger, or DMA requests:

- Each output implements a separate interrupt status flag (ISF) register for that domain.
- Each output generates a single interrupt.
- Each output generates a single DMA request.
- Each output generates a single peripheral trigger output.

You can configure each pin individually for any of the external interrupt modes shown in the following table.

Table 195. Available pin configurations for external interrupts

Signal conditions	Software polling using flags	Peripheral triggers	Interrupts	DMA requests
Rising-edge	Yes	—	Yes	Yes
Falling-edge	Yes	—	Yes	Yes
Rising- and falling-edge	Yes	—	Yes	Yes
High-level	—	Yes	Yes	—
Low-level	—	Yes	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless GPIO is in Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

GPIO generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to either ISFR0[ISF*n*] or ICR0[ISF].

GPIO generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit Low-Power mode.

GPIO generates a peripheral trigger output that asserts if any pin configured for the active-high trigger is logic 1, or any pin triggered for the active-low trigger is logic 0. The peripheral trigger output asynchronously updates from the value on the configured pins.

20.3.8 Global interrupt control

The two global interrupt control registers (Global Interrupt Control Low (GICLR) and Global Interrupt Control High (GICHR)) allow a single register write to update the upper 16 bits of Interrupt Control a (ICR0 - ICR31) for up to 16 pins, all with the same value.

These global interrupt control registers allow you to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read 0.

20.3.9 DMA

GPIO generates 2 requests. For each pin, you can configure DMA requests to assert for either rising, falling, or both edge detection. See External interrupts for more information.

20.3.10 Access protection

GPIO implements access protection registers (PCNS and PCNP) for each pin, as shown in Table 196.

Table 196. PCNS and PCNP register access protection implementation

Access	Description
Secure	You can write to or read the pins configured for secure access only in the Secure state.
Nonsecure	You can write to or read the pins configured for nonsecure access only in the Nonsecure state.
Privilege	You can write to the pins configured for privilege access only in the Privilege state.
Nonprivilege	You can write to the pins configured for nonprivilege access in both the Privilege and Nonprivilege states.

GPIO implements access protection registers (ICNS and ICNP) for each interrupt, trigger output, and DMA request as shown in Table 197.

Table 197. ICNS and ICNP register access protection implementation

Access	Description
Secure	You can configure the outputs programmed for secure access only in the Secure state.
Nonsecure	You can configure the outputs programmed for nonsecure access only in the Nonsecure state.
Privilege	You can configure the outputs programmed for privilege access only in the Privilege state.
Nonprivilege	You can configure the outputs programmed for nonprivilege access in both the Privilege and Nonprivilege states.

You can write to the access protection registers (PCNS, PCNP, ICNS, and ICNP) only in the Secure-Privilege state; you can optionally lock these registers until the next reset.

Configuring a pin interrupt, trigger output, or DMA request requires the following access permissions:

- Access permission to configure the pin.
- Access permission to either configure to the desired interrupt, trigger output, or DMA request, or writing 0 to ICR*n*[IRQC].
- Access permission to either configure with the existing interrupt, trigger output, or DMA request, or if the current value of ICR*n*[IRQC] is 0.
- The interrupt configuration is not locked.

20.4 External signals

Table 198. External signals

Signal	Description		Direction
GPIO31–GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	

Table continues on the next page...

Table 198. External signals (continued)

Signal	Description		Direction
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each chip. See the "Signal Multiplexing" chapter for the number of GPIO pins within each port available on this chip.

20.5 Initialization

To initialize GPIO:

1. Initialize the GPIO pins for the output function:
   a. Configure the output logic value for each pin by using Port Data Output (PDOR).
   b. Configure the direction for each pin by using Port Data Direction (PDDR).
2. Initialize the interrupt function by writing to Interrupt Control a (ICR0 - ICR31) for the corresponding pins and desired configuration. If the pin is previously used for a different function, first write 0100_0000h to Interrupt Control a (ICR0 - ICR31) to disable the previous function and clear the flag.

20.6 Application information

GPIO includes the following applications:

- Reading the state of a single pin by performing a byte read of Pin Data (P0DR - P31DR).
- Updating the state of a single pin by performing a byte write to Pin Data (P0DR - P31DR).
- Reading the state of multiple pins by reading Port Data Input (PDIR).
- Updating the state of multiple pins by using the following ways:
  - Writing to Port Data Output (PDOR).
  - Writing to Port Set Output (PSOR) to write 1 to Port Data Output (PDOR).
  - Writing to Port Clear Output (PCOR) to write 0 to Port Data Output (PDOR).
  - Writing to Port Toggle Output (PTOR) to toggle Port Data Output (PDOR).

20.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the "Signal Multiplexing" chapter for the exact control bits of each port.

20.7.1 GPIO register descriptions

20.7.1.2 Version ID (VERID)

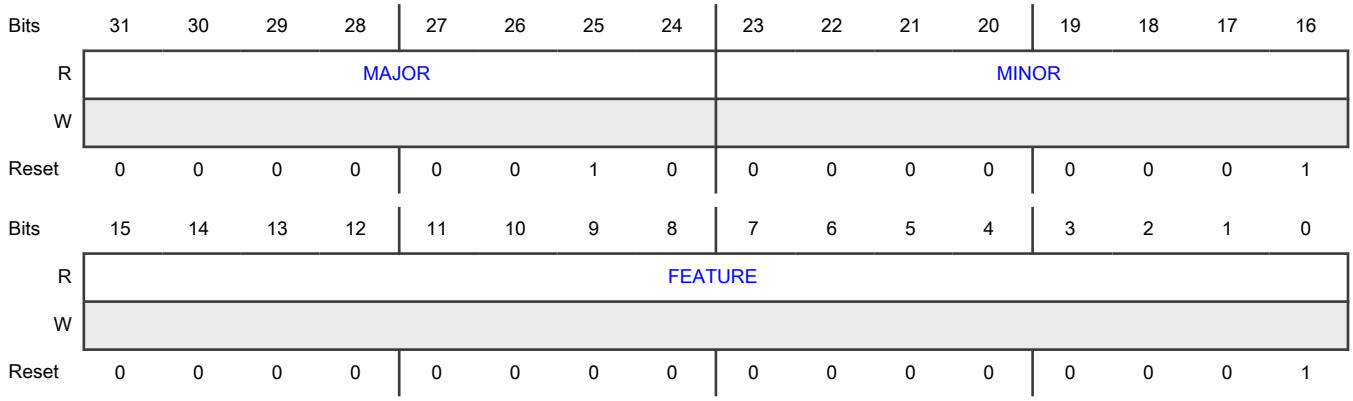
Offset

Register	Offset
VERID	0h

Function

Indicates the version ID number of each GPIO.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the specification.
15-0 FEATURE	Feature Specification Number Indicates the feature set number. 0000_0000_0000_0000b - Basic implementation 0000_0000_0000_0001b - Protection registers implemented

20.7.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Indicates the interrupt number of each GPIO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3 ICNP	Lock ICNP Locks Interrupt Control Nonprivilege (ICNP). If this field is 0, you can write to ICNP in the Secure-Privilege state. If this field is 1, you cannot write to ICNP until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
2 PCNP	Lock PCNP Locks Pin Control Nonprivilege (PCNP). If this field is 0, you can write to PCNP in the Secure-Privilege state. If this field is 1, you cannot write to PCNP until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
1 ICNS	Lock ICNS Locks Interrupt Control Nonsecure (ICNS). If this field is 0, you can write to ICNS in the Secure-Privilege state. If this field is 1, you cannot write to ICNS until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
0 PCNS	Lock PCNS Locks Pin Control Nonsecure (PCNS). If this field is 0, you can write to PCNS in the Secure-Privilege state. If this field is 1, you cannot write to PCNS until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset

20.7.1.5 Pin Control Nonsecure (PCNS)

Offset

Register	Offset
PCNS	10h

Function

Configures secure or nonsecure access protection for each pin. You can write to this register only in the Secure-Privilege state if it is not locked (LOCK[PCNS] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each pin. If this field is 0, the pin is configured for secure access. You can read or write to the corresponding pin's registers and fields only in the Secure state. When you access the corresponding pin's registers in the Nonsecure state, all fields in the registers related to that pin are read zero (with writes ignored). If this field is 1, the pin is configured for nonsecure access. You can read or write to the corresponding pin's registers and fields only in the Nonsecure state. When you access the corresponding pin's registers in the Secure state, all fields in the registers related to that pin are read zero (with writes ignored). 0b - Secure access 1b - Nonsecure access

20.7.1.6 Interrupt Control Nonsecure (ICNS)

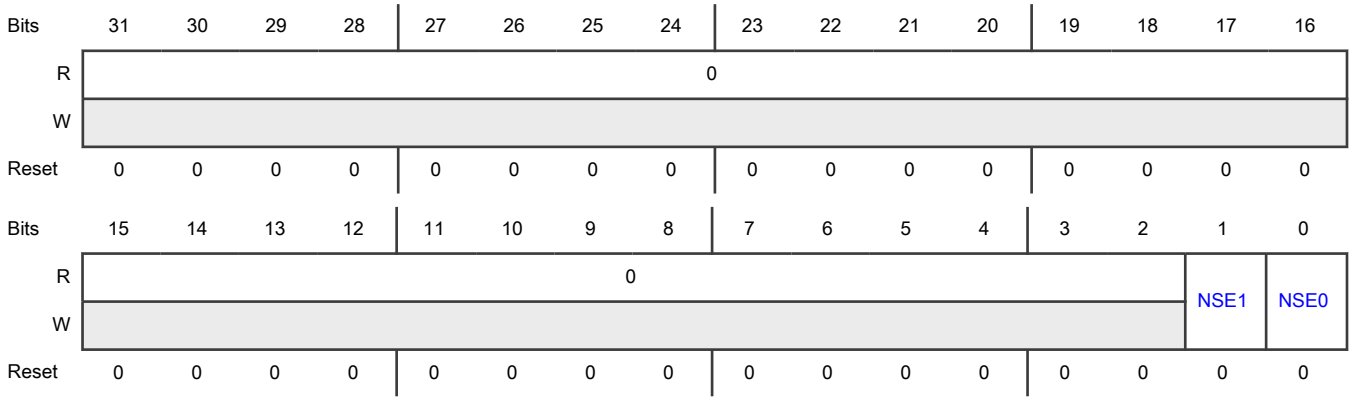
Offset

Register	Offset
ICNS	14h

Function

Configures secure and nonsecure access protection for each interrupt, output trigger, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNS] = 0).

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each interrupt, output trigger, or DMA request. If this field is 0, the interrupt, output trigger, or DMA request is configured for secure access. You can configure a pin to use the corresponding interrupt, output trigger, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, output trigger, or DMA request only in the Secure state. If this field is 1, the interrupt, output trigger, or DMA request is configured for nonsecure access. You can configure a pin to use the corresponding interrupt, output trigger, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, output trigger, or DMA request only in the Nonsecure state. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Secure access 1b - Nonsecure access

20.7.1.7 Pin Control Nonprivilege (PCNP)

Offset

Register	Offset
PCNP	18h

Function

Configures access protection on each pin either for privilege or for both privilege and nonprivilege accesses. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[PCNP] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each pin. If this field is 0, the pin is configured for privilege access. Write access to the corresponding pin's registers and fields is allowed only in the Privilege state. When you access the corresponding pin's registers and fields in the Nonprivilege state, all fields related to that pin in this GPIO are readable (with writes ignored). If this field is 1, the pin is configured for nonprivilege access; read or write access to the corresponding pin's registers is allowed in both Privilege and Nonprivilege states. 0b - Privilege access 1b - Nonprivilege access

20.7.1.8 Interrupt Control Nonprivilege (ICNP)

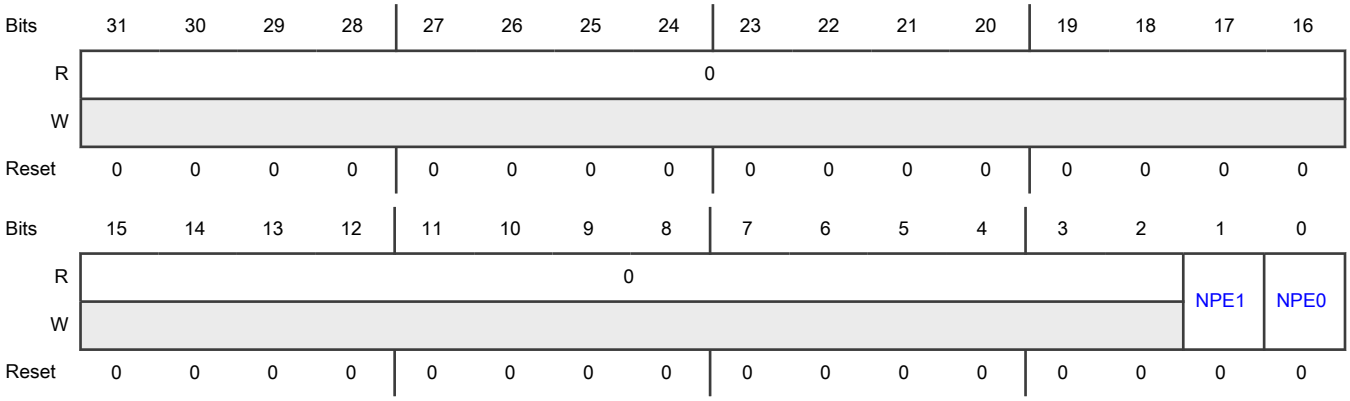
Offset

Register	Offset
ICNP	1Ch

Function

Configures privilege and nonprivilege access protection for each interrupt, trigger output, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNP] = 0).

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each interrupt, trigger output, or DMA request. If this field is 0, the pin is configured for privilege access. You can configure a pin to use the corresponding interrupt, trigger output, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, trigger output, or DMA request only in the Privilege state. If this field is 1, the pin is configured for nonprivilege access. In either Privilege or Nonprivilege state, you can configure a pin to use the corresponding interrupt, trigger output, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, trigger output, or DMA request. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Privilege access 1b - Nonprivilege access

20.7.1.9 Port Data Output (PDOR)

Offset

Register	Offset
PDOR	40h

Function

Configures the logic levels that are driven on each general-purpose output pin.

NOTE

Do not modify the pin configuration registers associated with pins that are not available in your selected package. By default, these unbonded pins are set to the Disable state for lowest power consumption.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PIDn	Port Input Disable Disables a pin for general-purpose input. If this field is 0, the pin is configured for general-purpose input, provided the pin is configured for a digital function. If this field is 1, the pin is disabled for general-purpose input. 0b - Configured for general-purpose input 1b - Disabled for general-purpose input

20.7.1.16 Pin Data (P0DR - P31DR)

Offset

For a = 0 to 31:

Register	Offset
PaDR	60h + (a × 1h)

Function

Configures the data feature of a pin. Pins that are unimplemented or not configured for a digital function read zero.

NOTE

You must not modify Pin Data (P0DR - P31DR) associated with the pins that are not available in your selected package. These unbonded pins are, by default, set to the Disable state for lowest power consumption.

Diagram

Bits	7	6	5	4	3	2	1	0
R	0							PD
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-1 —	Reserved
0 PD	Pin Data (I/O) Specifies the pin logic level. This field updates the corresponding field in Port Data Output (PDOR); reading this field returns the value in the corresponding field of Port Data Input (PDIR). If this field is 0, the pin logic level is logic zero or not configured for use by a digital function. If this field is 1, the pin logic level is logic one. 0b - Logic zero 1b - Logic one

20.7.1.17 Interrupt Control a (ICR0 - ICR31)

Offset

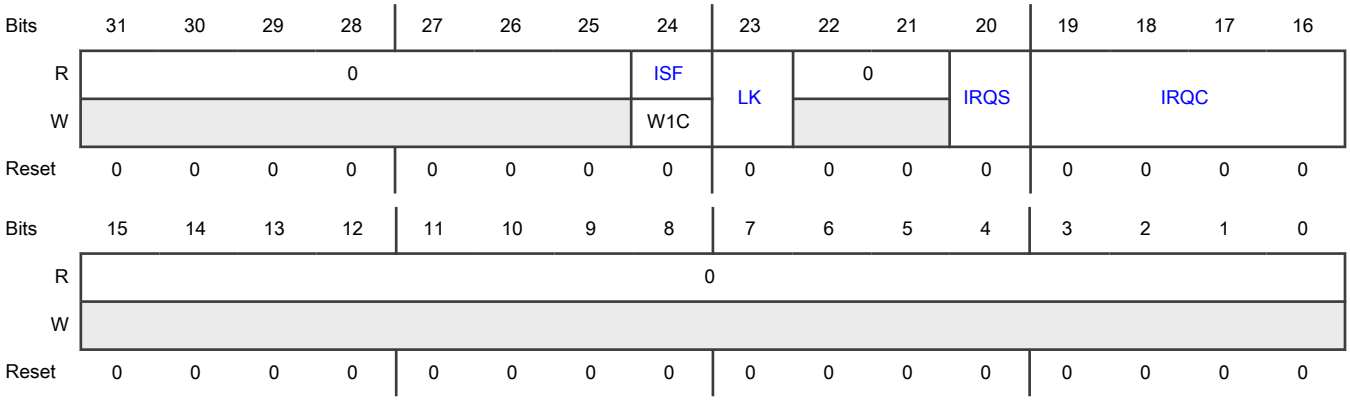
For a = 0 to 31:

Register	Offset
ICRa	80h + (a × 4h)

Function

Configures interrupt features on each pin.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 ISF	Interrupt Status Flag Indicates whether the configured interrupt is detected. The pin interrupt configuration is valid in all digital pin muxing modes. The fields in Interrupt Status Flag (ISFR0 - ISFR1) have the same function. ISF can be cleared with either register field. If the pin is configured to generate a DMA request, then the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level-sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
23 LK	Lock

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Locks ICR[23:0], and you cannot update the locked field until the next system reset. If this field is 0, interrupt configuration by ICR[23:0] is not locked and can be updated. If this field is 1, interrupt configuration by ICR[23:0] is locked and cannot be updated until the next system reset. 0b - Not locked 1b - Locked
22-21 —	Reserved
20 IRQS	Interrupt Select Configures the selected interrupt, trigger output, or DMA request. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Interrupt, trigger output, or DMA request 0 1b - Interrupt, trigger output, or DMA request 1
19-16 IRQC	Interrupt Configuration Specifies the ISF and DMA request configuration. The pin interrupt configuration is valid in all digital pin muxing modes. When changing the interrupt configuration, it is recommended to first disable ISF and then write the new configuration. The corresponding pin is configured to generate interrupt, trigger, or DMA request. **NOTE** See the GPIO chip-specific information to determine the GPIO instances that support interrupt, DMA request, or trigger capabilities. 0000b - ISF is disabled 0001b - ISF and DMA request on rising edge 0010b - ISF and DMA request on falling edge 0011b - ISF and DMA request on either edge 0100b - Reserved 0101b - ISF sets on rising edge 0110b - ISF sets on falling edge 0111b - ISF sets on either edge 1000b - ISF and interrupt when logic 0 1001b - ISF and interrupt on rising edge 1010b - ISF and interrupt on falling edge 1011b - ISF and Interrupt on either edge

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1100b - ISF and interrupt when logic 1 1101b - Enable active-high trigger output; ISF on rising edge (pin state is ORed with other enabled triggers to generate the output trigger for use by other peripherals) 1110b - Enable active-low trigger output; ISF on falling edge (pin state is inverted and ORed with other enabled triggers to generate the output trigger for use by other peripherals) 1111b - Reserved
15-0 —	Reserved

20.7.1.18 Global Interrupt Control Low (GICLR)

Offset

Register	Offset
GICLR	100h

Function

Updates any combination of the lower 16 Interrupt Control registers with the same value. This register supports only 32-bit writes and ignores any 16-bit or 8-bit writes.

Diagram

Fields

Field	Function
31-16 GIWD	Global Interrupt Write Data

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the write value that is written to the upper 16 bits of Interrupt Control a (ICR0 - ICR31), selected by GIWE.
15-0 GIWEn	Global Interrupt Write Enable Indicates whether the upper 16 bits of the corresponding Interrupt Control a (ICR0 - ICR31) are updated with the value in GIWD. 0b - Not updated 1b - Updated

20.7.1.19 Global Interrupt Control High (GICHR)

Offset

Register	Offset
GICHR	104h

Function

Updates any combination of the upper 16 Interrupt Control registers with the same value. This register supports only 32-bit writes and ignores any 16-bit or 8-bit writes.

Field	Function
15-0 GIWEn	Global Interrupt Write Enable Indicates whether the upper 16 bits of the corresponding Interrupt Control a (ICR0 - ICR31) are updated with the value in GIWD. 0b - Not updated. 1b - Updated

20.7.1.20 Interrupt Status Flag (ISFR0 - ISFR1)

Offset

Register	Offset
ISFR0	120h
ISFR1	124h

Function

Indicates whether the related configured interrupt is detected on each pin. The pin interrupt configuration is valid in all digital pin muxing modes. The ISF for each pin is also visible in the corresponding Interrupt Control register, and each flag can be cleared in either location.

There is a separate ISF register for each interrupt, trigger, or DMA request domain. Each status flag is only visible in the register that corresponds to that flag's domain, as configured in ICR*n*[IRQS].

Fields

Field	Function
31-0 ISFn	Interrupt Status Flag

Table continues on the next page...

Field	Function
	Indicates the detection of the configured interrupt on each pin of the same number. If this field is 0, the configured interrupt is not detected on the pin of the same number. If this field is 1, the configured interrupt is detected on the pin of the same number. If the pin is configured to generate a DMA request, then the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level-sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag

Chapter 21
Debug

21.1 Introduction

This chapter describes the debug architecture of this device.

Features:

- The Arm CoreSight™ Architecture is adapted for software trace and debug.
- Serial wire debug (SWD) and Debug Access Port (DAP) to support debugger tools.
- Instrumentation Trace Macrocell (ITM) is supported for the Cortex-M33 core and Radio Cortex-M33 core.
- Data Watchpoint and Trace (DWT) and breakpoint unit (BPU) are supported for the Cortex-M33 and Radio Cortex-M33 core subsystem.
- 1-bit SWO trace port for efficiently accessing Cortex-M33 trace information from the system.

The following figure shows the system level debug architecture.

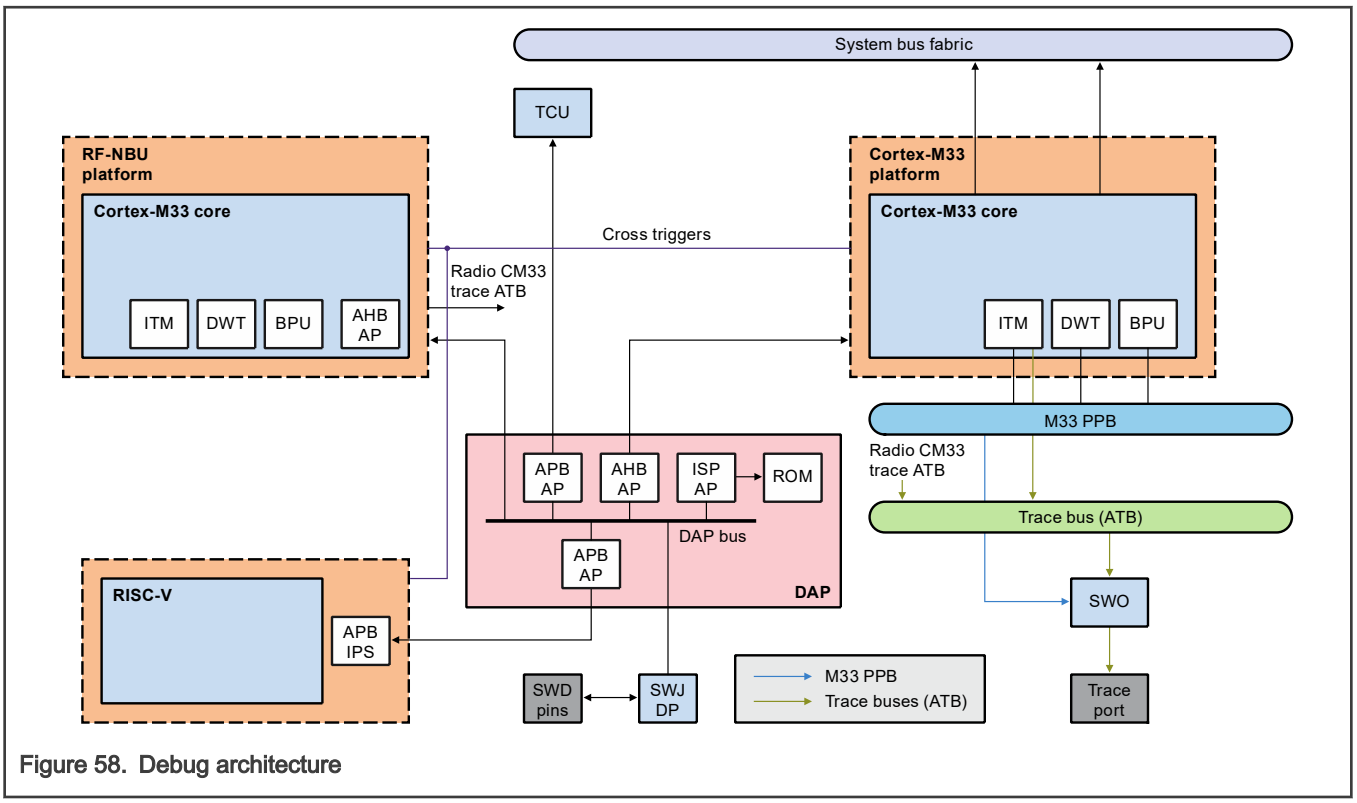

Figure 58. Debug architecture

21.2 Trace component reset sources

The following table show the trace component reset sources.

Table 199. Trace component reset sources

Core	TRACE component	Reset source
CM33	TPIU, Funnel CM33	POR reset or debug reset

Table continues on the next page...

Table 199. Trace component reset sources (continued)

Core	TRACE component	Reset source
	ITM/DWT/CTI/BPU	Only CM33 POR reset
CM3	CTI CM3	POR reset or debug reset
	ITM/DWT/FPB	Only CM3 POR reset

21.3 Test and debug port connectivity

The following figure shows the connectivity of test and debug port on this device.

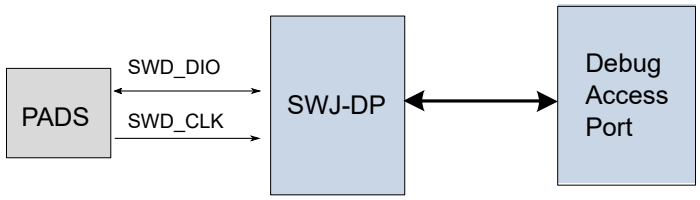

Figure 59. Debug port connectivity

The SWD signals are summarized in the following table.

Table 200. SWD signals summary

Pin Name	SWD		Internal pull up/down
	Type	Description	
SWD_DIO	I/O	Data	Pull-up
SWD_CLK	I	Clock	Pull-down

21.3.1 Serial wire debug (SWD)

The serial wire debug is a 2-pin electrical interface with a clock (SWD_CLK) and a single bi-directional data pin (SWD_DIO) to provide debug and test functionality.

21.3.2 Debug access port

Debug Access Port (DAP) is a standard Arm CoreSight component. The DAP provides multiple master driving ports, all of which are accessible and controlled through a single external interface port to provide system-wide debug. The DAP Instruction Register codes are listed in the following table.

Table 201. DAP IR Codes

Code	DAP IR
4’b1000	ABORT
4’b1010	DPACC
4’b1011	APACC
4’b1110	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to allow to extend the access ports as per the system requirement. For more information on DAP TAP, refer to Arm Debug Interface v5 Architecture specification on arm.com.

The exported DAP bus is used to host AHB AP, APB AP, MDM AP and ISP AP. The APB-AP implements registers which are used for Test mode control on the device. The MDM-AP hosts system level debug status and control registers (refer to Debug Status and Control Registers) which can be used for low power and other miscellaneous control and status. The ISP AP supports software debug feature at platform level. The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of SWJ-DP.

The following figure shows the configuration of the DAP on this device.

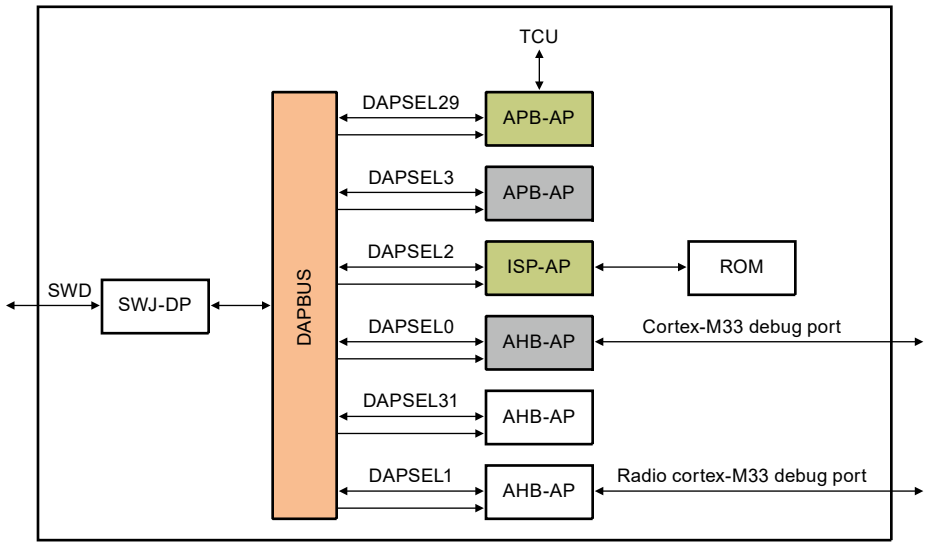

Figure 60. Debug Access Port configuration

21.4 Cortex M33 debug

This section covers the debug mechanisms associated with the CM33 processor.

21.4.1 CM33 software debug and trace

The following figure shows the data flow of software debug and trace information for the Cortex-M33 core on this device.

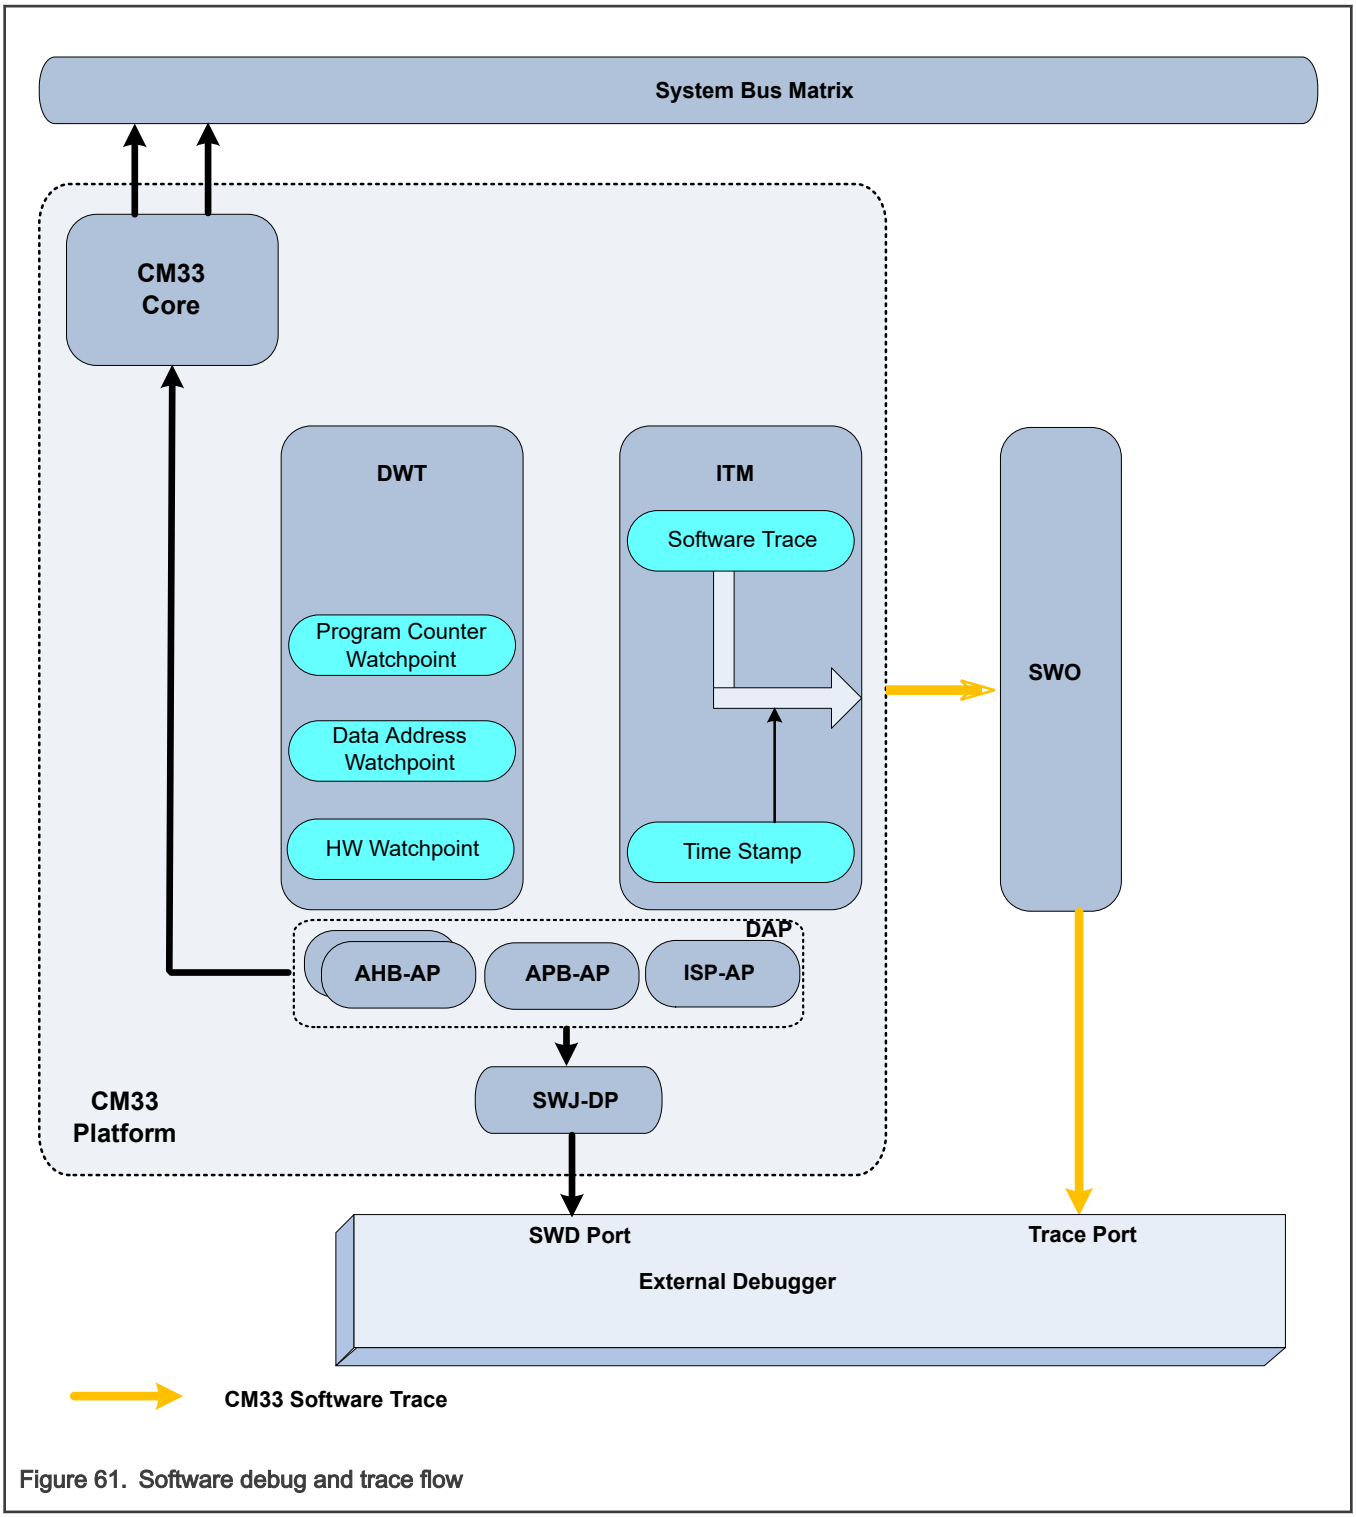

Figure 61. Software debug and trace flow

21.4.2 Data Watchpoint and Trace

The CM33 Data Watchpoint and Trace (DWT) module generates trace information in the core. It has 4 independent watchpoints which can be programmed to compare data, address, or to function as a hardware watchpoint. The DWT can be configured to generate PC samples at defined intervals and to generate interrupt event information. The CM33 DWT also provides periodic requests for protocol synchronization to the ITM and the SWO.

21.4.3 Breakpoint Unit

The CM33 Breakpoint Unit (BPU) module comprises up to 8 instruction address comparators. It provides breakpoint functionality on all instructions fetched across the entire address range in which code can be located.

21.4.4 Instrumentation Trace Macrocell (ITM)

The ITM generates trace information as packets. There are multiple sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The sources in decreasing order of priority are:

- Software Trace: Application software can write console messages directly to ITM stimulus ports, and output them to the host as trace packets.
- Hardware trace: The DWT generates these packets, and the ITM outputs them.
- Timestamping: ITM can generate timestamp packets that are inserted in to the trace stream, to help the host debugger to find out the timing of events. Timestamps are generated relative to packets. The ITM contains a 21-bit counter to generate the timestamp.

Trace data from ITM will be forwarded to SWO and streamed out via the trace port.

21.5 Cross Trigger Interface (CTI)

Table 202. CTI input triggers

Trigger Bit	Source Signal	Source Module	Description
3	Reserved	Reserved	Reserved
2	Interrupt request	RF Processor core	Acknowledged by writing to the CTIINTACK register in ISR
1	Processor restarted	RF Processor core	Processor core's output indicating that it has restarted.
0	HALTED	RF Processor core	Processor core's output indicating that it has entered the debug mode.

Here the "Source Signal" is the output port of the "Source Module". They are connected to the input triggers of the CTI.

Table 203. CTI output triggers

Trigger Bit	Destination Signal	Destination Module	Description
3	Reserved	Reserved	Reserved
2	cti_irq	NVIC	CTI interrupt
1	Processor Restarted	RF Processor core	Processor core's output indicating that it has restarted.
0	EDBGRQ	Processor core	External request Processor core to enter the debug mode

Here the "Destination Signal" is the input port of the "Destination Module". The output triggers of the CTI are connected to the input port of the destination modules.

21.6 Low power debug

Low power debug is controlled by DBGCTL[SOD] field in the CMC. When set, the debugger is disabled (debug power up acknowledge negates) when the CM33 sleeps and the device fully enters the low power mode. When clear, the clocks to the CM33 remain enabled when the CM33 sleeps and debug is attached (debug power up request is asserted) to maintain the debug connection, and the low power mode is not completely entered. Software can modify DBGCTL[SOD] before each low power entry. There are two modes supported:

- Clock gated mode
- Power gated mode

21.6.1 Clock gated modes

- If the DAP CXXXPWRUPREQ is high and the system attempts to enter STOP mode, the DAP clock and the Core clock continue to run to support core register access and trace, in this case the debug module will have access to core registers but not to modules which are clock gated.
- If the device is in STOP mode (core clock gated), the debugger can assert EDBGRQ (CM33 EDBGRQ) in dap_ctrl_halt_req register, this will wake up the core and will move it into a halted state.

21.6.2 Power gated modes

During power gated modes, the debugger will loose connection and it cannot gather any data in the duration when device stays in low power mode. If the device is expected to go into low power mode and it is desired to gain control of device when it exits low power modes.

Chapter 22
Reset

22.1 Introduction

The following reset sources exist in this device:

Table 204. Reset sources

Reset type	Source
Power	• System Power-On Reset (POR) • System Low-Voltage Detect (LVD) • System High-Voltage Detect (HVD)
External	• External Pin Reset (RESET_b) • Wake-Up Unit (WUU)
Internal	• Watchdog (WDOG) timer • Software (SW) • System Clock Generator (SCG) • Reset Acknowledge timeout (RSTACK) • Low Power Acknowledge (LPACK) • Lockup (LOCKUP) • Debug Access Port (DAP) • EdgeLock Secure Enclave (ELE) • Tamper

Each system reset source has a corresponding bit that is maintained in the System Reset Status register through reset. This information can be used to take appropriate action when coming out of a reset.

22.2 Power reset sources

To ensure predictable operation of the device, the supply voltages must remain in their specified ranges during execution. Because this is not possible during power-up and power-down, the device implements multiple voltage monitors to detect when the supply is outside an acceptable range. When this occurs, the voltage monitor asserts a reset to halt execution and prevent unexpected behavior. The voltage monitors detect power-on events as well as low and high voltage events.

22.2.1 Power-on reset (POR)

The POR voltage monitor is used to ensure that the voltage applied to the system is high enough for other analog modules such as the bias circuits and low voltage monitors to operate correctly. When voltage is initially applied to the device or when the supply voltage drops below the POR falling threshold, the POR monitor triggers the POR reset condition to the device.

The POR reset condition asserts POR reset to all power domains. A POR reset sets the appropriate bits in the CMC registers so that software can determine that a POR reset has occurred.

22.2.2 Low-voltage detect (LVD)

The LVD monitors are used to ensure that the voltage supplies to the device are high enough for the logic and memories to operate correctly. When voltage is initially applied to the device, the POR voltage monitor holds the LVD monitors in reset until the voltages are high enough. The LVD monitors continue to hold the device in reset until all monitoring voltages have risen above the respective default LVD Low thresholds (VLVDL). The LVD monitors are enabled by default.

When enabled, the LVD monitor generates a reset when the voltage drops below the V_{LVD} threshold. The voltage threshold at which the LVD reset asserts is programmable. This ensures that the device halts operation and remains in reset while the monitored voltage is not within the desired range.

The reset sources triggered by individual LVD monitors are combined into a single LVD reset. The LVD reset condition asserts a POR reset in all power domains with only the POR/LVD/HVD detection logic remaining operational. An LVD reset sets the appropriate bits in the CMC registers so that software can determine that an LVD reset has occurred.

22.2.3 High-voltage detect (HVD)

The HVD monitors are used to ensure that the voltage supplies to the device are within operation range for the logic and memories using those power supplies. The HVD monitors are disabled by default, but when an HVD circuit is enabled, the HVD monitor generates a reset when the voltage rises above the V_{HVD} threshold. This ensures that the device halts operation and remains in reset while the monitored voltage is not within the desired range.

The reset source triggered by individual HVD monitors are combined into a single HVD reset. The HVD reset condition asserts a reset to all power domains with only the POR/LVD/HVD detection logic remaining operational. An HVD reset sets the appropriate bits in the CMC registers so that software can determine that an HVD reset has occurred.

22.3 External reset sources

External resets are provided so that the device can be reset or awakened from very low power states. This allows the device to start at the correct time from a known state.

22.3.1 External pin reset (RESET_b)

The RESET_b pin is a bi-directional open-drain pin with internal pull-up resistor. The RESET_b pin is functional in two modes:

- During active and low power modes, the RESET_b pin can be asserted externally to force the device into Pin reset condition.
- During reset, the RESET_b drives low until the device has completed hardware initialization, at which point the RESET_b pin is released. If the RESET_b pin is asserted externally, then the device will remain in reset until the RESET_b input is pulled high.

The RESET_b pin implements a digital filter that software can configure to filter out glitches on the RESET_b pin that are less than 1-32 CMC clock cycles. The filter is bypassed in low power modes if the CMC clock is disabled. The CMC reset filter clock source is the SLOW_CLK.

The RESET_b is multiplexed on PTD0 pin on this device. RESET_b is the default function of this GPIO pin. Asserting RESET_b wakes the device from any mode.

The PIN reset condition triggers the CMC to assert a WARM reset to all power domains. A PIN reset sets the appropriate fields in the CMC registers so that software can determine that a PIN reset has occurred.

22.3.2 Wake-up unit (WAKEUP)

The Wake-Up Unit (WUU) provides for a number of external pins and on-chip peripherals to wake the device from Power Down or Deep Power Down modes. See the WUU chapter for a list of external and internal reset sources connected to the WUU.

On a wakeup from Power Down or Deep Power Down modes, the power management logic triggers a WAKEUP reset in the power domains that had been powered off.

The WAKEUP reset condition triggers the CMC to assert a POR reset to the power domains that were powered down. The system voltage domain is not affected by a WAKEUP reset. A WAKEUP reset sets the appropriate fields in the CMC registers so that software can determine that a WAKEUP reset has occurred.

22.4 Internal reset sources

Internal resets are provided so that the device can be reset when certain erroneous conditions are detected. This allows the device to recover from the erroneous conditions and restart from a known state.

22.4.1 Watchdog (WDOG) timer

The WDOG reset is generated by one of the WDOG modules.

The WDOG monitors the operation of the system by receiving periodic communication from software, known as servicing or refreshing the WDOG. If this periodic servicing does not occur, then the Watchdog triggers a WDOG reset condition.

The WDOG reset condition triggers the CMC to assert a WARM reset to all power domains. A WDOG reset sets the appropriate fields in the CMC registers so that software can determine that a WDOG reset has occurred.

22.4.2 Software (SW)

During execution, if the software detects erroneous operation, the software can initiate a reset to restart the device from a known state.

The SW reset condition triggers the CMC to assert a WARM reset to all power domains. A SW reset sets the appropriate fields in the CMC registers so that software can determine that a SW reset has occurred.

22.4.3 System Clock Generation (SCG)

The SCG module contains a clock monitor, which, if enabled, detects a loss of the external clock. A loss of external clock triggers the SCG reset condition.

The SCG reset condition will assert a WARM reset in all power domains. The CMC_SRS[SCG] and CMC_SRS[WARM] status bits are set on a SCG reset condition.

For details on enabling the clock monitor, see the SCG chapter. To prevent unexpected reset events, clock monitors must be disabled before entering any low-power modes that the external clocks are not present.

22.4.4 Reset Acknowledge timeout (RSTACK)

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing, this will trigger the RSTACK reset condition.

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing. This triggers the RSTACK reset condition. The RSTACK reset condition asserts a warm reset in all power domains. SRS[RSTACK], SRS[FATAL], and SRS[WARM] become 1 on an RSTACK reset condition.

The RSTACK reset condition triggers the CMC to assert a WARM reset to all power domains. An RSTACK reset sets the appropriate fields in the CMC registers so that software can determine that an RSTACK reset has occurred.

22.4.5 Low Power Acknowledge timeout (LPACK)

The low power entry state machine includes a timeout counter that is triggered if a module does not acknowledge entry into a low power mode, this will trigger the LPACK reset condition.

The low-power entry state machine includes a timeout counter that triggers if a module does not acknowledge entry into low-power mode. This triggers the LPACK reset condition. The LPACK reset condition asserts a warm reset in all power domains. SRS[LPACK] and SRS[WARM] become 1 on an LPACK reset condition.

The LPACK reset condition triggers the CMC to assert a WARM reset to all power domains. An LPACK reset sets the appropriate fields in the CMC registers so that software can determine that an LPACK reset has occurred.

22.4.6 Lock up (LOCKUP)

The Cortex-M33 core will enter the lockup state as a result of certain illegal operations, this will trigger the LOCKUP reset condition.

The LOCKUP reset condition triggers the CMC to assert a WARM reset to all power domains. A LOCKUP reset sets the appropriate fields in the CMC registers so that software can determine that a LOCKUP reset has occurred.

22.4.7 Debug Port (DAP)

Any debug access port that can initiate a reset request from a connected debugger triggers the DAP reset condition.

The DAP reset condition triggers the CMC to assert a WARM reset to all power domains. A DAP reset sets the appropriate fields in the CMC registers so that software can determine that a DAP reset has occurred.

22.4.8 EdgeLock secure enclave (ELE)

Internal EdgeLock enclave resets are provided so that the security module can be reset when security violation or certain erroneous conditions are detected. This allows security module to recover from the erroneous conditions. The reset sources in the security module available in this device are as follows.

- Security violation
- Security Watchdog timer
- Security software
- Security CPU lockup
- Security debug
- eFuse loading error

Whenever the security module detects a security violation or an erroneous condition, this will trigger the EdgeLock enclave reset condition.

The EdgeLock enclave reset condition will trigger the Core Mode Controller (CMC) to assert a WARM reset to all power domains. An EdgeLock enclave reset will set the appropriate bits in the CMC registers so that software can determine that an EdgeLock enclave reset has occurred.

22.4.9 Tamper detect (TAMPER)

Whenever a tamper detection module detects a tamper event, this will trigger the TAMPER reset condition.

The TAMPER reset condition triggers the CMC to assert a WARM reset to all power domains. A TAMPER reset sets the appropriate fields in the CMC registers so that software can determine that a TAMPER reset has occurred.

22.4.10 Radio reset request

Radio reset request could happen when NBU CM33 meet timeout or NBU system hang. It should be configured in advance to decide reset Radio subsystem or whole chip.

Radio reset can be triggered for system hang using the WDOG timer or radio AHB timeout interrupt.

22.5 Reset type

This section describes the different resets that can be generated on this device and their respective reset sequences. Reset conditions on this device are categorized into two types, POR and WARM resets.

The VBAT is only reset on the VDD_SWITCH domain POR, this is independent from the rest of the device.

The RTC, CCM32K, PORTD, GPIOD are only reset on POR (VDD_SYS).

The LPTMR are reset on POR/LVD/HVD.

The WUU is reset on any reset except wakeup from PD/DPD.

Peripherals generally reset both on POR and WARM reset but here are exceptions please refer to the peripheral section. For example CAN interrupt mask bits in CTRL1, and they are only reset by the global hard reset.

An LVD will reset the regulators to their default setting (voltage level, etc). Most of the SPC is reset on POR/LVD/HVD, there are few registers that reset on the VDD_SYS POR only (mainly voltage monitors).

22.5.1 POR reset

Each power domain generates a POR that is used to reset the entire device, including debug logic and mode control logic. The POR for each power domain can assert as a result of the following events.

- Initial power-up of MCU
- Low or High Voltage Detect
- Power domain wakeup from Power Down or Deep Power Down (varies per domain)

A POR does not guarantee the contents of on-chip SRAM, except for a Power Down wakeup and then only for the SRAM that is configured to retain state.

22.5.1.1 POR reset sequence

The following steps are performed as part of the POR (or LVD/HVD) sequence:

1. RESET_b pin is driven low and internal reset signals assert.
2. POR and LVD signals negate and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

When the device wakes up from Deep Power Down or Power Down mode, the reset sequence is slightly different from the POR reset sequence. They are described in the subsequent sections.

22.5.1.2 Deep Power Down (DPD) reset sequence

The following steps are performed as part of the Deep Power Down wakeup sequence:

1. Internal reset signals assert.
2. Wakeup signal negates and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded.
7. Internal reset signals negate.
8. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

The RESET_b pin is not driven low by a Deep Power Down reset sequence unless the RESET_b pin was used as the wake up source.

A wakeup from Deep Power Down via the RESET_b pin will follow the warm reset sequence.

22.5.1.3 Power Down (PD) reset sequence

The following steps are performed as part of the Power Down wakeup sequence:

1. Internal reset signals assert.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal trim registers are loaded.
5. Internal reset signals negate.
6. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

The RESET_b pin is not driven low by a Power Down reset sequence unless the RESET_b pin was used as the wake up source.

A wakeup from Power Down via the RESET_b pin will follow the warm reset sequence.

22.5.2 Warm reset

A WARM reset re-initializes the device to a known state once it has already been running for a period of time.

A WARM reset resets most of the logic in each power domain. Warm resets are divided into fatal reset sources and non-fatal reset sources. See the CMC chapter for which reset sources are fatal resets.

Non-fatal reset sources can be configured to generate an interrupt instead of the WARM reset. If software can clear the non-fatal reset source (including status flag) then the WARM reset is averted. Non-fatal resets retain the contents of on-chip SRAM.

Fatal reset sources cannot be configured to generate an interrupt, and do not guarantee the contents of on-chip SRAM.

The following steps are performed as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals assert.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 15 clock cycles.
4. Internal reset to Flash and Fuse controller negate and their initialization sequences commence.
5. Initialization sequences for Flash and Fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
8. Internal reset signals negate.
9. Core exits reset and fetches the initial program counter and stack pointer from Boot ROM.

Chapter 23
Clocking

23.1 Introduction

The heart of the clocking architecture is the System Clock Generator (SCG) module. The SCG controls multiple clock sources that are distributed to the main CPU platform, the memory modules and the peripheral modules. The peripheral modules have an *interface* clock that is used by the CPU/DMA to interface with each module's registers. When applicable, modules may also have *functional* clocks to provide the main timing function of the module's application. For example, functional clocks can be used to source the baud rate for a serial communications peripheral or to clock the counter of a timer peripheral.

Each module's interface clock comes directly from the SCG. The SCG provides functional clock options via the Module Reset and Clock Control (MRCC) module. Software configures the MRCC module to select a module's functional clock. The MRCC module also provides functional clock dividers as needed.

The following diagram shows the clock sources and clock trees.

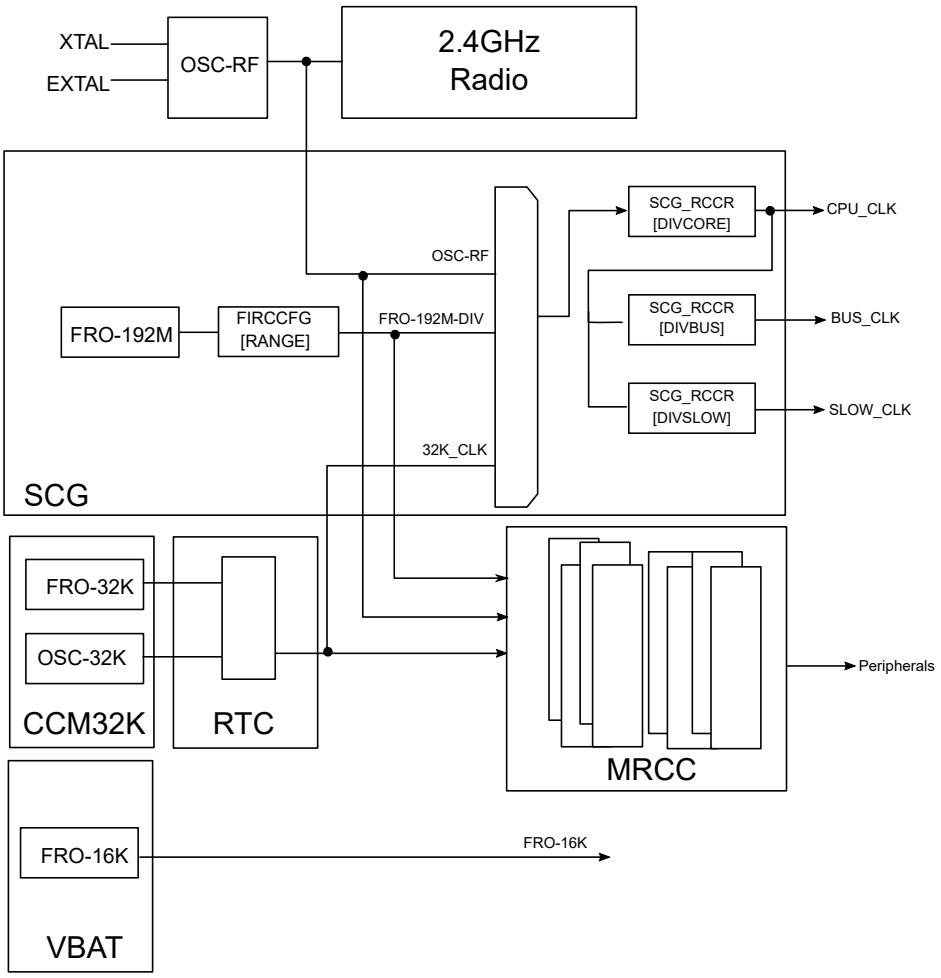

Figure 62. Device clock sources and trees

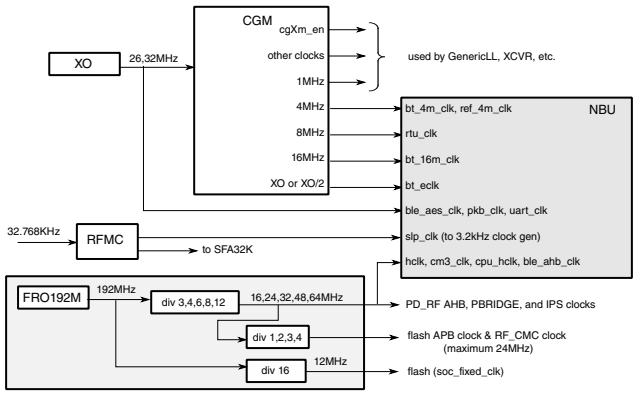

Figure 63. Radio clocking

The CPU_CLK can be sourced directly from the following:

- FRO-192M-DIV (96 MHz) – general default
- 32K_CLK
- OSC-RF

Each of the above clock sources can be divided via the SCG_RCCR[DIVCORE] divider to avoid clocking above the max CPU frequency or to reduce the CPU frequency for lower power consumption.

Other major clock trees are fed from the CPU_CLK for the on-chip peripheral and memory interfaces that are required to be either equal to the CPU_CLK frequency or an integer divide or multiple of the CPU_CLK.

The BUS_CLK and the SLOW_CLK are both sourced from the CPU_CLK. Each of this clock tree has its own independent clock divider to provide frequencies that are an integer divide of the CPU_CLK.

Modules that are required to function at a faster frequency than the CPU_CLK obtain a functional clock via the MRCC.

23.2 Clock definitions

The following table describes the clocks in the device.

Table 205. Clock definitions

Clock name	Description
CPU_CLK[1]	The main CPU clock. The CPU_CLK can be provided by one of the clock sources within the SCG, and also from the clock sources not specifically configured by the SCG. The selected clock source is fed through the DIVCORE divider stage prior to clocking the CPU. The CPU_CLK can be gated off, while other clock trees are allowed to function.
BUS_CLK[1]	The BUS_CLK provides synchronization between the CPU and the peripherals. The BUS_CLK is an integer divide or equal to the CPU_CLK. It is fed via the SCG_RCCR[DIVBUS] divider stage. The BUS_CLK can be gated off, while other clock trees are allowed to function.
SLOW_CLK	The SLOW_CLK provides synchronization between the CPU and peripherals that operate at lower frequencies. The SLOW_CLK is an integer divide of the CPU_CLK. The SLOW_CLK is fed from the CPU_CLK via the SCG_RCCR[DIVSLOW] divider stage. The SLOW_CLK can be gated off, while other clock trees are allowed to function.
OSC-32K	Oscillator with external crystal resonator of 32 kHz

Table continues on the next page...

Table 205. Clock definitions (continued)

Clock name	Description
OSC-RF	External crystal oscillator (26 MHz or 32 MHz) used by the Radio Frequency modules
FRO-32K	32 kHz Free Running Oscillator clock reference
32K_CLK	32 kHz clock source from either OSC-32K or FRO-32K
FRO-192M-DIV	192 MHz Free Running Oscillator clock source with dividers that can be used for high speed operation

1. The maximum frequency of this clock is different depending on VDD_CORE, see data sheet for details.

23.3 MRCC clock outputs

The SCG provides output clock trees for peripheral modules that require functional clocks. Functional clocks are used as the fundamental timing for applications of a module, providing asynchronous clocking from the CPU main clock. This allows modules to operate at different rates compared to the CPU platform. Examples of how functional clocks are used include:

- Clocking the reference counter of a timer module
- Sourcing the baud rate for the external communication of a serial communications peripheral

Each module that needs functional clocking has its own MRCC register that provides a clock select field, a clock disable, a divider of the selected clock source, and a peripheral reset bit that provides independent resetting of the peripheral.

23.4 Clock gating

Clock gating of modules helps consume power only for modules needed for their end application. The clock to each module can be gated on or off via a programmable register.

Each peripheral has independent clock gating for both the peripheral interface clock and the peripheral functional clock. This clock gating is controlled via the peripheral's MRCC register. Clearing MRCC[CC] disables both the interface clock and functional clock of a peripheral.

The CPU_CLK, BUS_CLK, and SLOW_CLK are always enabled in the Active modes. If these clocks are not used in low-power modes, they are disabled via the CMC and SPC modules.

23.5 Module/Peripheral clocking

The following tables detail the various clocks associated with a specific module/peripheral.

Table 206. Module/Peripheral clocking options

Chapter 24
System Clock Generator (SCG)

24.1 Chip-specific SCG information

Table 208. Reference links to related information

Topic	Related module	Reference
Full description	SCG	SCG
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

24.1.1 Module instances

This device has one instance of the SCG module, SCG0.

24.1.2 Clock naming

Each device that has an SCG module generally has a few differences from SCG modules in different devices. This section describes those differences.

Signal name differences

Table 209. Device signal names = SCG signal names

Device signal		SCG chapter signal	
Free-Running Oscillator – 192 MHz	FRO_192M	FIRC	Fast internal reference clock
Free-Running Oscillator – 6 MHz	FRO_6M	SIRC	Slow internal reference clock
FRO-32K or OSC-32K is selected to become the 32K_CLK (See note below)	32K_CLK	ROSC	Real-time clock oscillator clock
OSC-RF	OSC_RF	RFOSC, SOSC	External RF clock, system oscillator clock
Not available		LPFLL	Low power FLL clock

NOTE

Separate Power Domain: The FRO-32K and the OSC-32K clocks are generated in a separate module CCM32K (32 kHz Clock Control Module) within a different power domain. The different power domain can be powered independently, allowing the RTC module (also in this separate power domain) to be clocked by one of these clock sources (FRO-32K or OSC-32K). The input to the SCG from this separate power domain is called 32K_CLK. The OSC-RF is generated in the RF module within a different power domain. The input to the SCG from this power domain is called OSC-RF.

24.1.3 SCG clock section CLKOUTCNFG[CLKOUTSEL]

The SCG can select the system clock from the following source by CLKOUTCNFG[CLKOUTSEL]:

- 0001b - System OSC (SOSC_CLK)

- 0010b - Slow IRC (SIRC_CLK)
- 0011b - Fast IRC (FIRC_CLK)
- 0100b - RTC OSC (ROSC_CLK)

NOTE

The SCG slow clock cannot be selected as SCG system clock.

24.2 Introduction

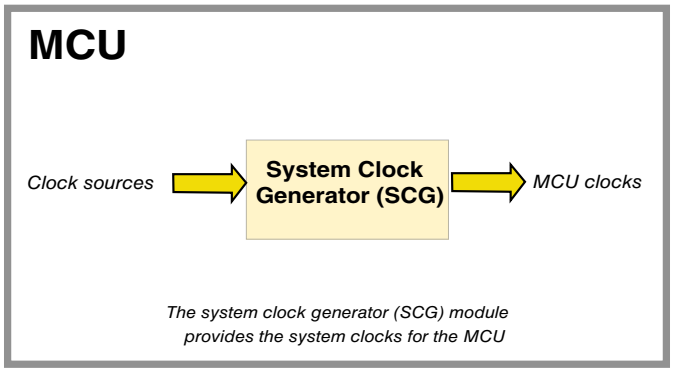

Figure 64. System Clock Generator (SCG) in MCU

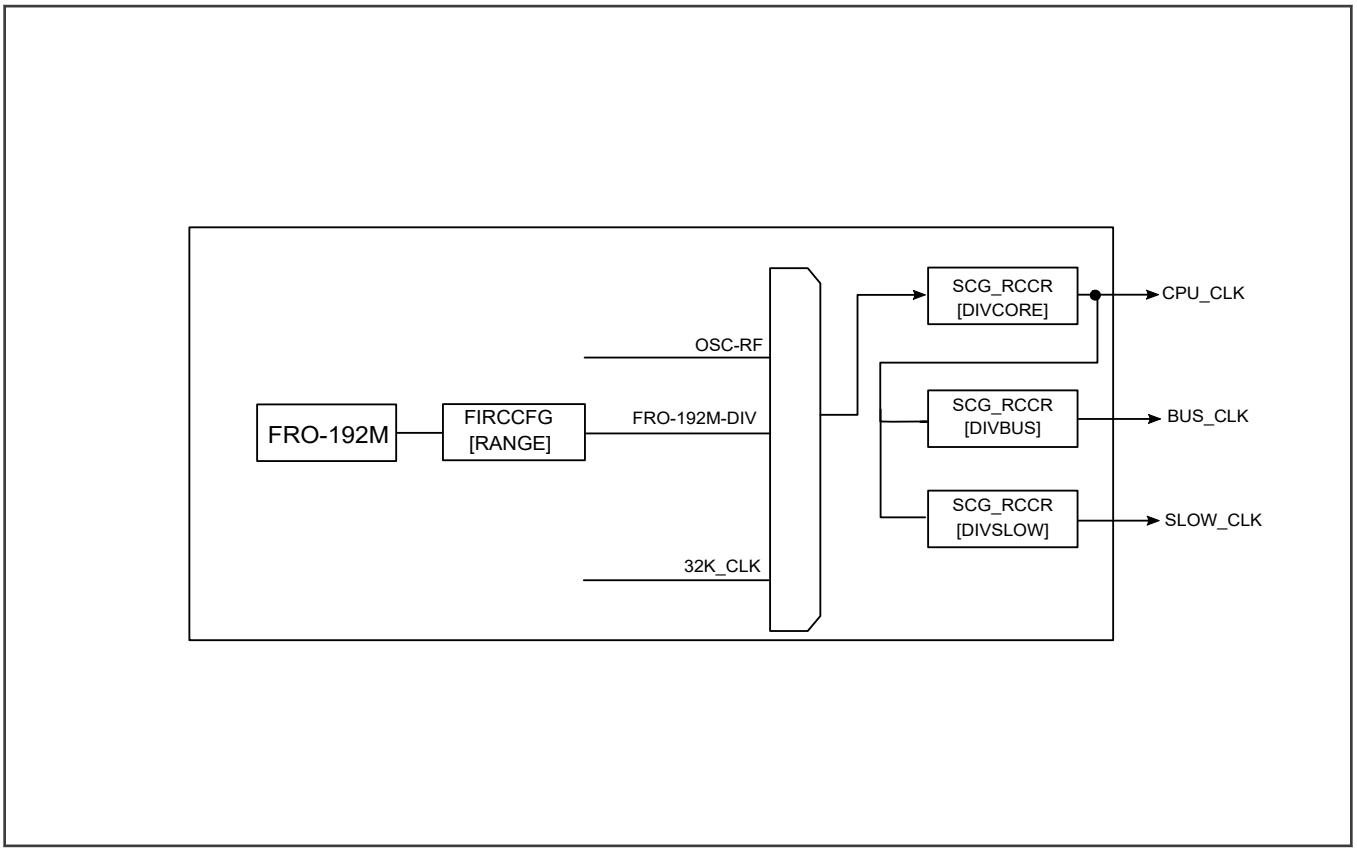
The system clock generator (SCG) module provides the system clocks for the MCU. The SCG takes clock inputs from a variety of sources and generates the types of clocks that the MCU requires.

- Available clock source inputs for the SCG include:
  - System oscillator clock (SOSC)
  - Slow internal reference clock (SIRC)
  - Fast internal reference clock (FIRC)
  - Real-Time Oscillator (ROSC)

Clock dividers are available for:

- core clock (DIVCORE)
- peripheral interface clock (DIVSLOW)
- bus clock (DIVBUS)

24.2.1 Block diagram



NOTE

To identify the oscillators used in your specific device, see the chip-specific SCG information or clocking chapters.

24.2.2 Features

Key features of the SCG module are:

- 2 Internal reference clock (IRC) generators:
  - High frequency free-running oscillator (FRO_192M) with trim capability
  - Free-running oscillator FRO_192M can be selected as the clock source for the system clocks
  - The external clock source (RFOSC) can also be used as a source clock for the systems clocks.
- System Crystal Oscillator:
  - Can be selected as the clock source for the system clocks
- Real Time Oscillator Clock (ROSC):
  - Can be selected as the clock source for the device. See the chip specific sections to ascertain which signal the RTC input maps to.
- Clock monitor with reset and interrupt request capability for SOSC, ROSC clocks

24.3 Functional description

24.3.1 SCG Clock Mode Transitions

The following figure shows the valid clock mode transitions supported by SCG.

Slow IRC (SIRC) boot mode is not supported on this device.

Figure 65. SCG Valid Mode Transitions

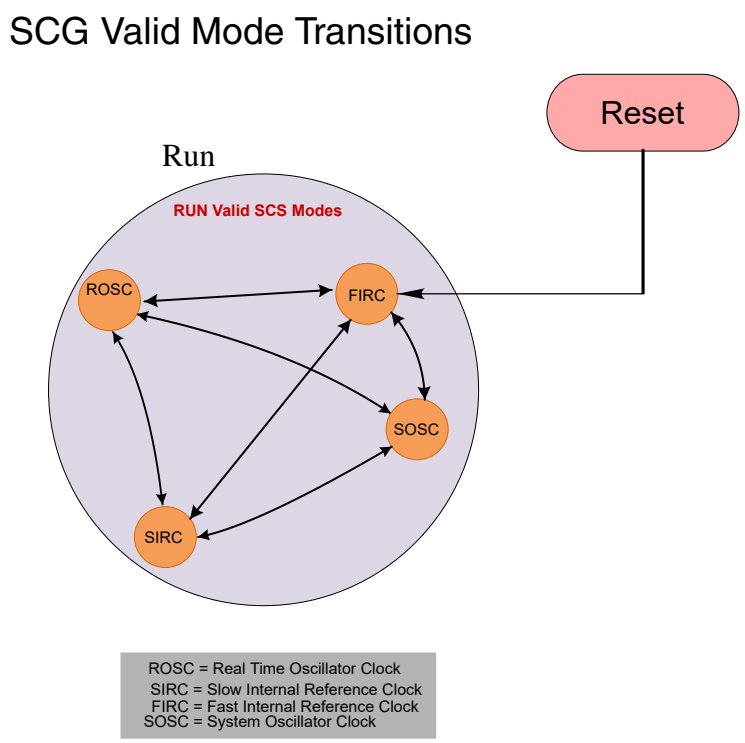


Figure 66. SCG Valid Mode Transitions

The SCG will restrict programming into invalid clock modes and writes to System Clock Source (SCS) bits will be ignored. When a transition between run modes or a transition into wait mode occurs, the SCG completes the switch to the clock mode as defined in the Run Clock Control Register (RCCR). When completed, the system switches to the selected run/wait mode.

The modes of operation listed in the following table are the valid modes for this implementation of the SCG.

Table 210. SCG modes of operation

Mode	Description
System Oscillator Clock (SOSC)	System Oscillator Clock (SOSC) mode is entered when all the following conditions occur: • RUN MODE: — 0001 is written to RCCR[SCS] • SOSCEN = 1 • SOSCVLD = 1 In SOSC mode, SCSCLKOUT and system clocks are derived from the external System Oscillator Clock (SOSC).

Table continues on the next page...

Table 210. SCG modes of operation (continued)

Mode	Description
Slow Internal Reference Clock (SIRC)	Slow Internal Reference Clock (SIRC) mode is entered when all the following conditions occur: • RUN MODE: — 0010 is written to RCCR[SCS] • SIRCVLD = 1 In SIRC mode, SCSCLKOUT and system clocks are derived from the slow internal reference clock.
Fast Internal Reference Clock (FIRC)	Fast Internal Reference Clock (FIRC) mode is the default clock mode of operation and is entered when all the following conditions occur: • RUN MODE: — 0011 is written to RCCR[SCS] • FIRCEN = 1 • FIRCVLD = 1 In FIRC mode, SCSCLKOUT and system clocks are derived from the fast internal reference clock. Two frequency range settings are available for FIRC clock as described in the FIRC[RANGE] register definition. Changes to FIRC range settings will be ignored when FIRC clock is enabled.
Real Time Clock Oscillator (RTCOSC)	Real Time Clock Oscillator (RTCOSC) mode is entered when all the following conditions occur: • RUN MODE: — 0100 is written to RCCR[SCS] • ROSCVLD = 1 In RTCOSC mode, SCSCLKOUT and systems clocks are derived from the external RTC Oscillator Clock (RTCOSC).
Stop	Entered whenever the MCU enters a Stop state. The power modes are chip-specific. For power mode assignments, see the chapter that describes how modules are configured and SCG behaviour during Stop recovery. Entering Stop mode, all SCG clock signals are static, including SCG system clocks (DIVCORE, DIVBUS, DIVSLOW). There are exceptions; the following clocks can continue to run and stay enabled in the following cases: SIRC is available in SLEEP mode when all the following conditions become true: • SIRCCSR[SIRCSTEN] = 1 FIRC is available in SLEEP mode when all the following conditions become true: • FIRCCSR[FIRCEN] = 1 • FIRCCSR[FIRCSTEN] = 1 SOSC is available in SLEEP mode when all the below conditions are true. • SOSCCSR[SOSCEN] = 1 • SOSCCSR[SOSCSTEN] = 1

24.3.2 Clocks

The following table describes the clocks of SCG.

Table 211. Clocks and their description

Clock	Type	Description
Slow Bus Clock	Input	SCG register read/write clock source.
System Oscillating Clock (SOSC)	Input	Reference clock used to generate system clocks when RCCR[SCS]=0001.
Slow Internal Reference Clock (SIRC)	Output	Reference clock used to generate system clocks when RCCR[SCS]=0010.
Fast Internal Reference Clock (FIRC)	Output	Reference clock used to generate system clocks when RCCR[SCS]=0011.
Real Time Clock Oscillator (RTCOSC)	Input	Reference clock used to generate system clocks when RCCR[SCS]=0100.

24.3.3 Interrupts/Resets

SCG includes several sources for interrupt requests. The following table summarizes these sources.

Each of these sources includes a mask control field (such as SOSCCSR[SOSCCMRE], ROSCCSR[ROSCCMRE],

Table 212. Interrupts

Flag	Functionality	Can generate interrupt?	Can generate reset?
SOSCCSR[SOSCERR]	Indicates whether SOSC source clock error has been detected either because of a loss of clock or clock has gone invalid.	Yes, if SOSCCSR[SOSCCMRE] = 0	Yes, if SOSCCSR[SOSCCMRE] = 1
ROSCCSR[ROSCCMRE]	Indicates whether ROSC source clock error has been detected either because of a loss of clock or clock has gone invalid.	Yes, if ROSCCSR[ROSCCMRE] = 0	Yes, if ROSCCSR[ROSCCMRE] = 1

24.4 External signals

SCG has no external signals.

24.5 Initialization

SCG is enabled by default and its default clock mode will be FIRC clock mode. SCG Modes of operation table describes how to configure SCG into a different clocking mode.

24.6 Memory Map/Register Definition

This section includes the memory map and register definition.

The SCG registers can only be written when in supervisor mode. Write accesses when in user mode will result in a bus transfer error. Read accesses may be performed in both supervisor and user mode.

24.6.1 SCG register descriptions

- For any writeable SCG registers, only 32-bit writes are allowed. 8-bit or 16-bit writes will result in transfer errors.

24.6.1.1 SCG memory map

24.6.1.5 Run Clock Control Register (RCCR)

Offset

Register	Offset
RCCR	14h

Function

This register controls the system clock source and the system clock dividers for the core, platform, external and bus clock domains when in Run mode only. This register can only be written using a 32-bit write. Selecting a different clock source when in RUN requires that clock source to be enabled first and be valid before system clocks switch to that clock source. If system clock divide ratios also change when selecting a different clock mode when in RUN, new system clock divide ratios will not take affect until a new clock source is valid.

NOTE

Switching to new system clock source and system clock dividers must be done after previous RCCR changes have been completed and the Clock Status Register has updated to match the present RCCR setting.

25.2 Introduction

The Module Reset and Clock Control (MRCC) module provides reset control and clock configuration for on-chip modules. Each module has its own configuration register.

25.3 Features

Per individual module, the MRCC module enables software to:

- Gate all clocks to the module
- Select the source of the functional clock
- Divide the functional clock
- Hold the module in reset

Below is a block diagram of the MRCC module:

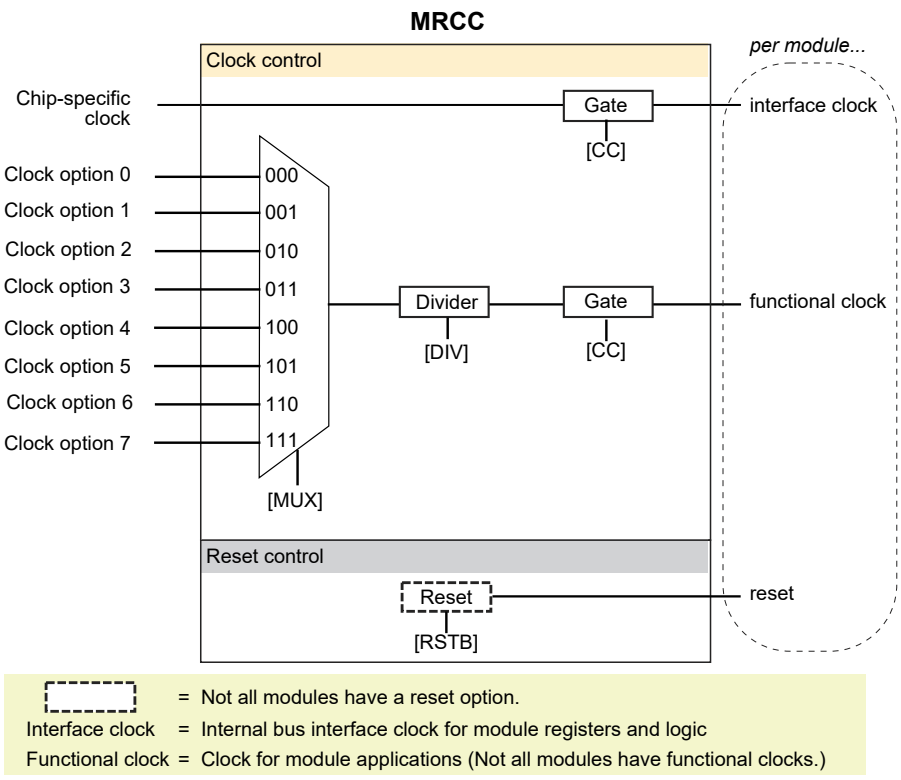

Figure 67. MRCC Block Diagram

25.4 Functional description

The MRCC module provides on-chip modules their own dedicated MRCC registers for clock gating, reset control and configuration options. Generally, each module's MRCC register contains a clock configuration (CC) field for the module's clocks.

NOTE

Before a module can be used, its clocks must be enabled (CC does not equal 00) and it must be released from reset (RSTB = 1). If a module is *not* released from reset (RSTB = 0), an attempt to access a register within that module is terminated with a bus error.

If a module has a functional clock, its MRCC register may provide options for the clock source, selected by programming the mux select (MUX) field. The selected functional clock source can then be divided by programming the divider (DIV) field.The divider factor is given by DIV+1.

NOTE

Before configuring a functional clock, the module's clocks must be disabled (CC = 00).

25.5 Memory map and register definition

Each module has its own dedicated MRCC register. See each module's MRCC register for details.

NOTE

1. To configure the clocking options available to a given module or to modify an existing configuration, first disable the module's clocks by writing 00 to its CC field. 2. For any clock which selected 32k as clock source, it should wait at least 4 clk cycle (4*1/32kHz=125us) to let the CC bit be synced by 32k clk to enable clk out. In this period do not configure MRCC.

26.2 Overview

The Signal Frequency Analyser (SFA) provides functionality to perform measurements of clock frequency, clock period, and time between triggers.

26.2.1 Block Diagram

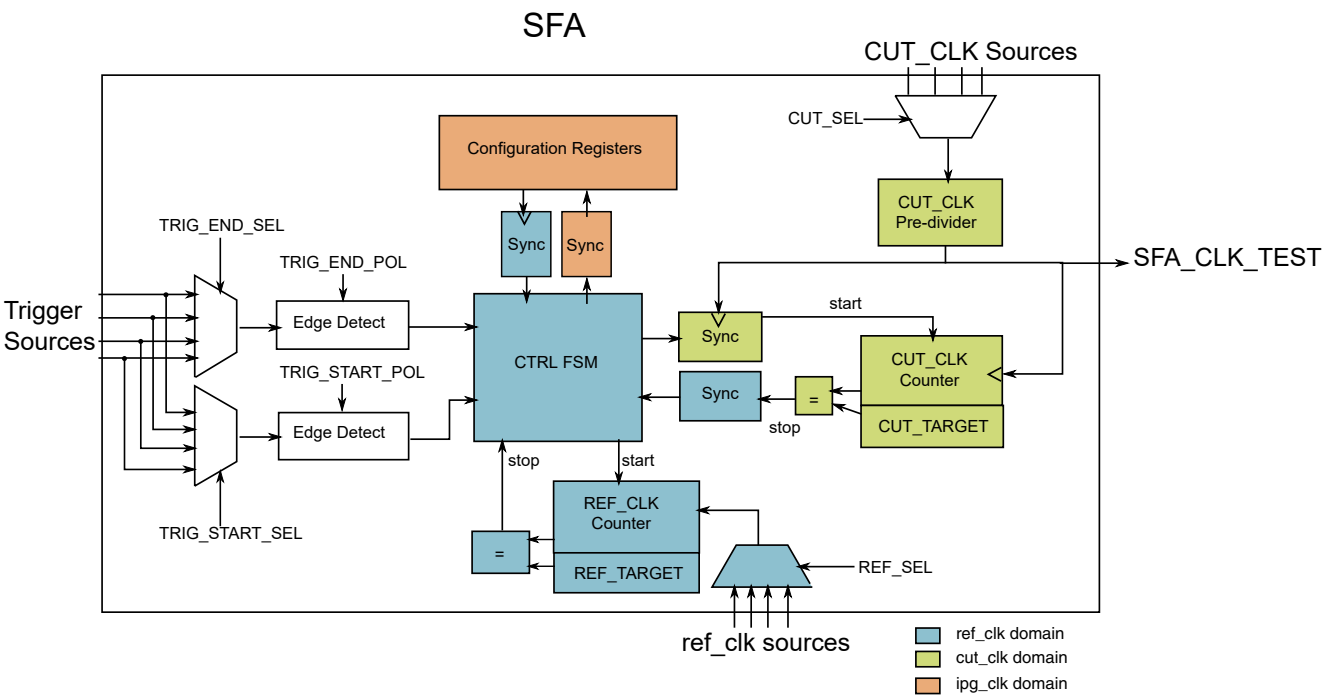

Figure 68. Signal Frequency Analyser Block Diagram

26.2.2 Features

The Signal Frequency Analyser includes the following features.

- Two 32-bit counters, one connected to the bus clock (REF clock), which serves as a reference, and the other connected to the clock under test (CUT).
- An 8-bit predivider is provided to divide down the CUT clock.
- A target count register for both the REF clock and CUT clock are provided to stop the counters.

- Trigger measurement mode to analyse the time between 2 edges (with configurable polarity) of either the same or different triggers. Note, the trigger pulse width must be at least 2 ref_clk cycles long to be properly registered.
- Selectable measurement modes to optimize test time by analysing either the frequency (for fast clocks), or the period (for slow clocks) of the CUT clock.
- Selectable sources for reference clock and CUT clock
- Support interrupt for CUT clk freq exceed setting freq limit

26.3 Functional Description

The Signal Frequency Analyser can be used to measure frequencies, periods, and time between events. The following use cases demonstrate how these capabilities can be used.

26.3.1 Frequency Measurements

The Signal Frequency Analyser can be used to measure the frequency of CUT CLK. The use cases below demonstrate how these capabilities can be used.

In general, either of the following methods may then be used to measure clock frequencies. To measure in frequency mode, register bit CTRL[MODE] must be set to 0x0 or 0x1.

Method 1 (when CUT frequency < REF frequency)(CTRL[MODE] == 0x0):

1. Set CUT and REF count targets
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it cleared
4. The next step can be completed using 2 different methods depending on the value of CTRL[SFA_TRIG_MEAS_EN]:
    a. SFA_TRIG_MEAS_EN = 0b0

       Perform a dummy write to the CUT counter. This triggers:

        i. REF counter starts counting immediately
        ii. CUT counter starts counting after a ~2 CUT cycle sync delay

    b. SFA_TRIG_MEAS_EN = 0b1

       The SFA will stall processing until the trigger edge selected by CTRL[TRIG_START_SEL] and CTRL[TRIG_START_POL] has been received. Once the trigger has been received, the following sequence will occur:

        i. REF counter starts counting immediately
        ii. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When CUT counter reaches 1, MEAS_STARTED bit asserts after a ~2 REF cycle sync delay
6. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (a saved version of the current REF counter, which keeps running) will be written.
7. When CUT counter reaches target, CUT_STOPPED bit asserts after a ~2 REF cycle sync delay
8. Upon assertion of CUT_STOPPED, the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written.
9. The measurement is considered complete once the REF_STOPPED and CUT_STOPPED bits have been asserted in the CUT_CNT register. The user can either poll the REF_STOPPED and CUT_STOPPED bits or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when the measurement is complete.
10. Calculate CUT frequency by using the difference in the REF_COUNT_END_SAVED and REF_COUNT_ST_SAVED in comparison to the CUT target

11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

The following two figures represent two possible cases for frequency measurement with CTRL[MODE] = 0x0. The first image illustrates a complete frequency measurement. Note, it is assumed that the user has started the measurement some time before this waveform snapshot was taken. Therefore, the register writes to CUT counter and REF counter are omitted. In this example the CUT target of 0x0000_FFFF is reached before the REF target count is reached. The two significant measurement events occur when MEAS_STARTED is asserted and REF_CNT_STOPPED is asserted.

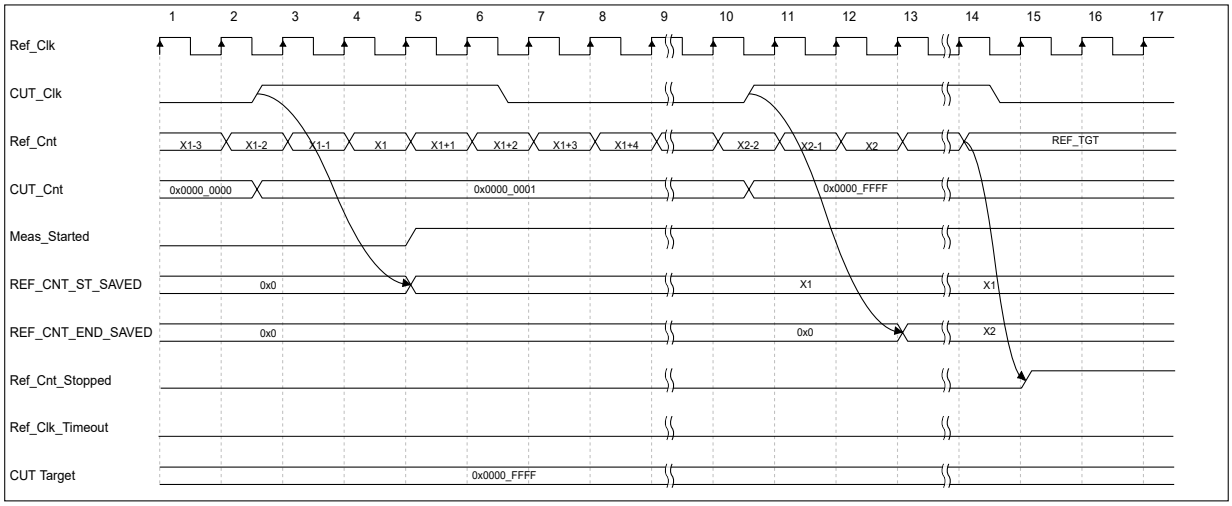

Figure 69. CUT Frequency Measurement with CUT Freq less than REF Freq

The next image illustrates the case when the frequency measurement is unable to be completed before REF_CNT_STOPPED is asserted. This is known as a reference clock timeout. In this example the CUT Target is set to 0x0000_FFFF; however, this value is never reached before REF_CNT = REF_CNT_STOPPED.

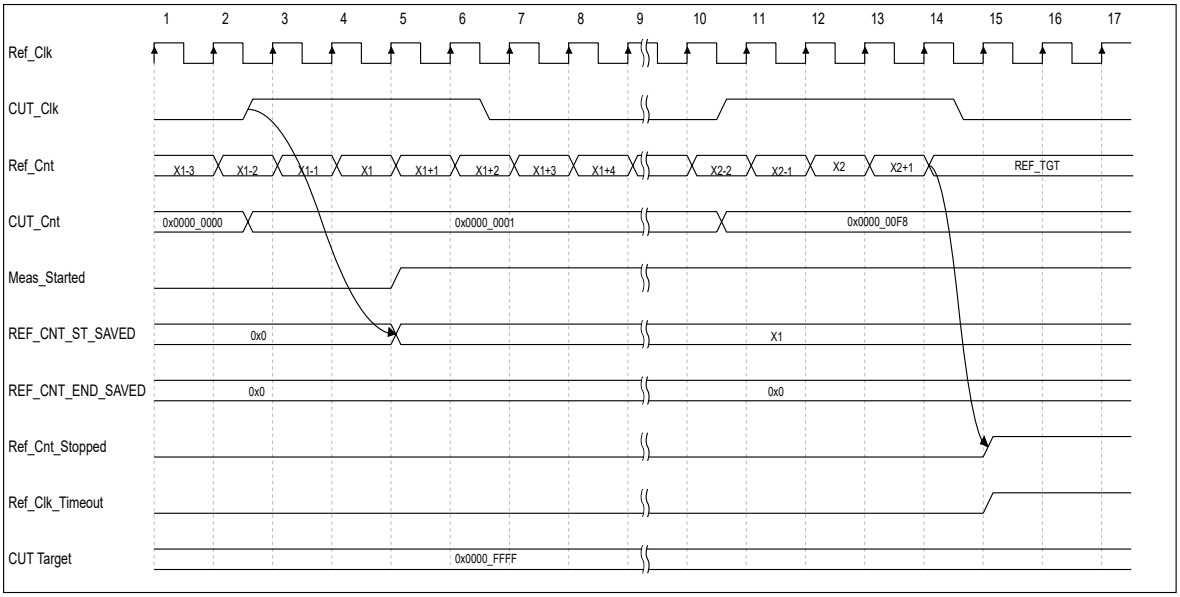

Figure 70. CUT Frequency Measurement Timeout with CUT Freq less than REF Freq

Method 2 (when CUT frequency > REF frequency)(CTRL[MODE] == 0x1):

1. Set CUT and REF count targets (Note: recommend CUT target be set to 0xFFFF_FFFF. There is no CUT_CNT_TIMEOUT flag.)
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it is clear
4. The next step can be completed using 2 different methods depending on the value of CTRL[SFA_TRIG_MEAS_EN]:
    a. SFA_TRIG_MEAS_EN = 0b0

       Perform a dummy write to the CUT counter. This triggers:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay

    b. SFA_TRIG_MEAS_EN = 0b1

       The SFA will stall processing until the trigger edge selected by CTRL[TRIG_START_SEL] and CTRL[TRIG_START_POL] has been received. Once the trigger has been received, the following sequence will occur:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When REF_COUNT reaches target, the CUT counter stops after a ~2 CUT cycle sync delay, and the CUT_STOPPED bit then sets after a ~2 REF cycle sync delay
6. Calculate CUT frequency by using the CUT_COUNT and REF target
7. To determine when the measurement has been completed, the user can either poll the CUT_STOPPED bit or enable SFA_IRQ_EN. An interrupt will be issued, if SFA_IRQ_EN is asserted and when both CUT_STOPPED and REF_STOPPED are asserted.

8. If the value CUT_CNT is greater than the value setting in CUT_HIGH_LIMIT_CNT , it means the measured cut clk frequency or trigger period is greater than maximum limit. If FREQ_GT_MAX interrupt flag is set, FREQ_GT_MAX IRQ will be generated.
9. If the value CUT_CNT less than the value setting in CUT_LOW_LIMIT_CNT , it means the measured cut clk frequency or trigger period is less than minimum limit, if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated

The following image represents an example frequency measurement with CTRL[MODE] = 0x1. In this case, the CUT frequency should be greater than the REF frequency. This measurement is used to count the number of CUT_CLK cycles that occur in REF_TARGET REF clk cycles. Note that registers REF_CNT_*_SAVED should not be read during this mode. It can be implied that REF_CNT_END_SAVED - REF_CNT_ST_SAVED = REF_TARGET.

When performing a CTRL[MODE] = 0x1 measurement, the CUT_TARGET should be set to the max value to prevent a CUT_TARGET timeout. The measurement will end when REF_CNT reaches the value stored in REF_TARGET. If CUT_TARGET is reached before REF_TARGET is reached, this will indicate an error condition. There is no flag to indicate a CUT_TARGET timeout. This is why CUT_TARGET should be set to the maximum value. The CUT_CNT timeout occurs when CUT_CNT is equal to CUT_TARGET. To detect that the CUT_CNT timeout did not occur, the CUT_CNT register should be less than CUT_TARGET at the end of a CTRL[MODE] = 0x1 measurement. When CUT_CNT is less than CUT_TARGET, the measurement stops when REF_TARGET is met.

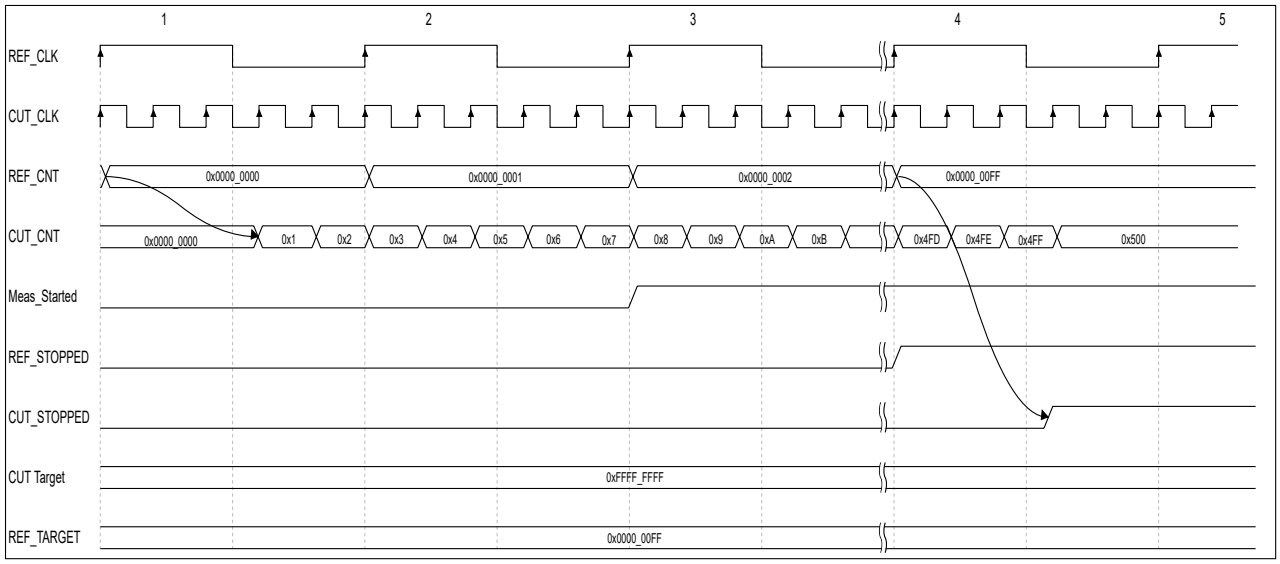

Figure 71. REF Frequency Measurement: CUT Freq greater than REF Freq

Continuous Mode (CTRL[MONITOR_EN] == 0x1):

1. Set CTRL[MONITOR_EN] will enable the continuous mode, this mode only take affect when in frequency mode (CTRL[MODE]= 2'b00 or 2'b01,CTRL[SFA_TRIG_MEAS_EN] = 1'b0)
2. Measurement will keep going on until clock frequency under test exceed the region we set (FREQ_GT_MAX_IRQ/ FREQ_LT_MIN_IRQ is asserted)

26.3.2 Clock Period Measurements

The signal frequency analyser has the capability to measure the period of CUT clock. To operate in clock period mode, the register CTRL[MODE] must be set to 0x2. This mode is used to count the number of REF CLK periods which occur during one period of CUT CLK.

Clock Period Measurement (CTRL[MODE] == 0x2). This mode is used to measure the period of CUT clock. It is assumed that CUT frequency < < REF frequency:

1. Select the source of CUT clock with CTRL[CUT_SEL], and configure any CUT pre-divide with CTRL[CUT_PREDIV].
2. Select a value for REF_TARGET. This value acts as a time-out function. The test will always end when REF_CNT == REF_TARGET.
3. Perform a dummy write to the REF counter. This triggers:
    a. REF counter starts counting immediately
    b. All previous counters will be cleared.
4. The MEAS_STARTED bit will indicate when the measurement sequence has begun.
5. The MEAS_STARTED bit is asserted on the first rising edge of the CUT after the dummy write to the REF counter. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current REF_CNT value.
6. The REF_STOPPED bit will indicate when the measurement sequence has been completed.
7. Upon completion of one full period measurement (performed from one rising edge to the next rising edge), the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current value of REF_CNT.
8. Note that REF_STOPPED may be set before the measurement has been completed. This may indicate the REF_CNT reached REF_TARGET before receiving a full period of CUT CLK. In this case, the CNT_STAT[REF_CNT_TIMEOUT] will be set to 0b1 to indicate that a time-out occurred.
9. Calculate the period width by using the difference between the values of REF_CNT_END_SAVED and REF_COUNT_ST_SAVED.
10. To determine when the measurement has been completed, the user can either poll the REF_STOPPED bit or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when REF_STOPPED is asserted.
11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

Figure 72 illustrates a CUT Clk period measurement cycle. It is assumed this timing diagram occurs sometime after beginning the measurement (dummy write to REF counter) with CTRL[MODE] == 0x2. In addition, it is assumed that SFA_IRQ_EN is asserted. In Figure 72 , the REF_TARGET register was set sufficiently high to receive a full period of CUT before REF_CNT timeout.

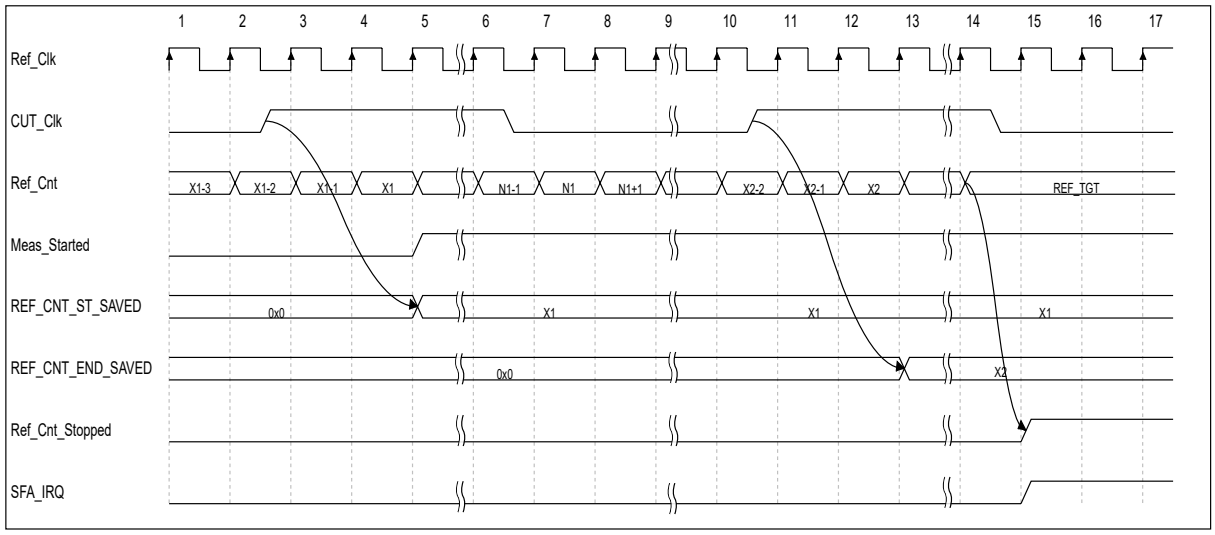

Figure 72. CUT Clk Period Measurement

Figure 73 illustrates what happens when REF_CNT reaches REF_TARGET before the SFA receives a full period of CUT Clk. The result will be an incomplete measurement, and REF_CNT_TIMEOUT will be asserted along with REF_STOPPED.

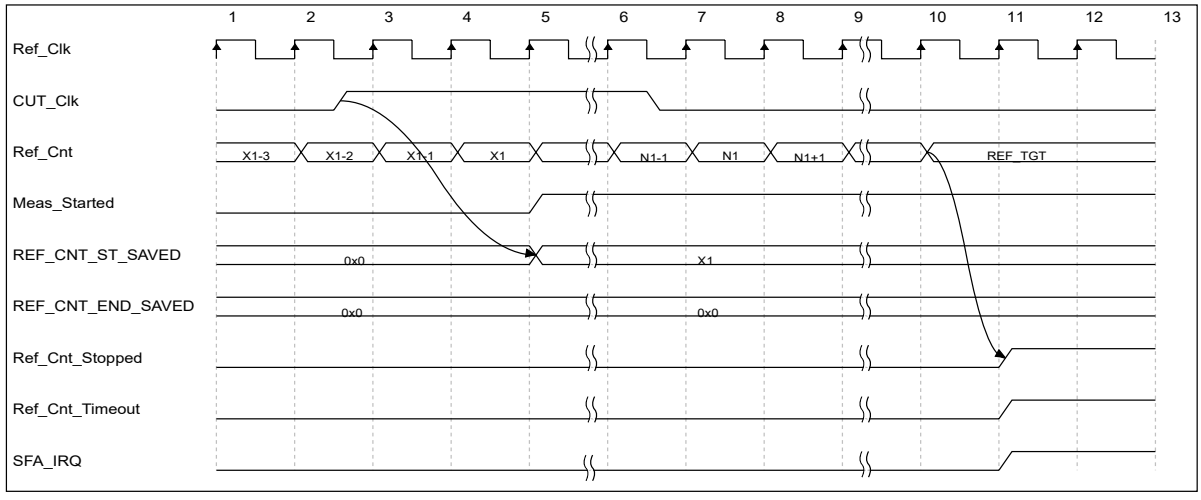

Figure 73. CUT Clk Period Timeout

26.3.3 Trigger Based Measurements

Triggered Measurement (CTRL[MODE] == 0x3). This mode is used to measure the time between two signal events. This measurement will count the number of REF clock periods between two triggers. Both the start trigger and end trigger can be selected from a bus interface. To select the start and end triggers, program the CTRL[TRIG_END_SEL] and CTRL[TRIG_START_SEL] fields. In addition, the polarity of each trigger can be selected to begin on rising or falling edge by programming CTRL[TRIG_END_POL] and CTRL[TRIG_START_POL]. It is assumed that the time between edges will be > > REF clock period:

1. Select the signal source which will begin the measurement with CTRL[TRIG_START_SEL].
2. Select a the polarity for TRIG_START_SEL by programming CTRL[TRIG_START_POL]. This will determine if the sequence begins on a rising or falling edge of TRIG_START_SEL.
3. Select both the signal source and edge polarity that will end the measurement, with CTRL[TRIG_END_SEL] and CTRL[TRIG_END_POL].
4. Select a value for REF_TARGET. This value will act as a time-out feature for the current measurement. The measurement will end when REF_CNT = REF_CNT_TARGET.
5. Perform a dummy write to the REF counter. This triggers:
    a. REF counter starts counting immediately
    b. All previous counters will be cleared.
6. The MEAS_STARTED bit will indicate when the selected TRIG_START_SEL edge has been triggered.
7. Upon assertion of MEAS_STARTED, REF_COUNT_ST_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written.
8. The REF_STOPPED bit will indicate when the selected EDGE_COUNT_END edge has been triggered.
9. Upon assertion of REF_STOPPED, REF_CNT_END_SAVED (which is a saved version of the actual REF counter) will be written.
10. Note that REF_STOPPED may be set before the measurement has been completed. This may indicate the REF_TARGET is too low for the required measurement time. In this case, the CNT_STAT[REF_CNT_TIMEOUT] will be set to 0b1 to indicate that either TRIG_END_SEL or TRIG_START_SEL was never received.
11. Calculate the edge to edge time using the difference between the values of REF_COUNT_END_SAVED and REF_CNT_ST_SAVED.
12. To determine when the measurement has been completed, the user can either poll the REF_STOPPED bit or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when REF_STOPPED is asserted.
13. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured trigger period is greater than maximum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
14. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured trigger period is less than minimum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

The following two waveforms illustrate two possible cases for trigger based measurements. Note that it is assumed that the user completed the above steps 1 through 5 before these waveforms begin. In addition, it is assumed that SFA_IRQ_EN is asserted. The first waveform shows a completed trigger based measurement. The second waveform illustrates a ref counter timeout when attempting to complete a trigger based measurement. Notice the assertion of Ref_Cnt_Timeout upon completing the measurement cycle.

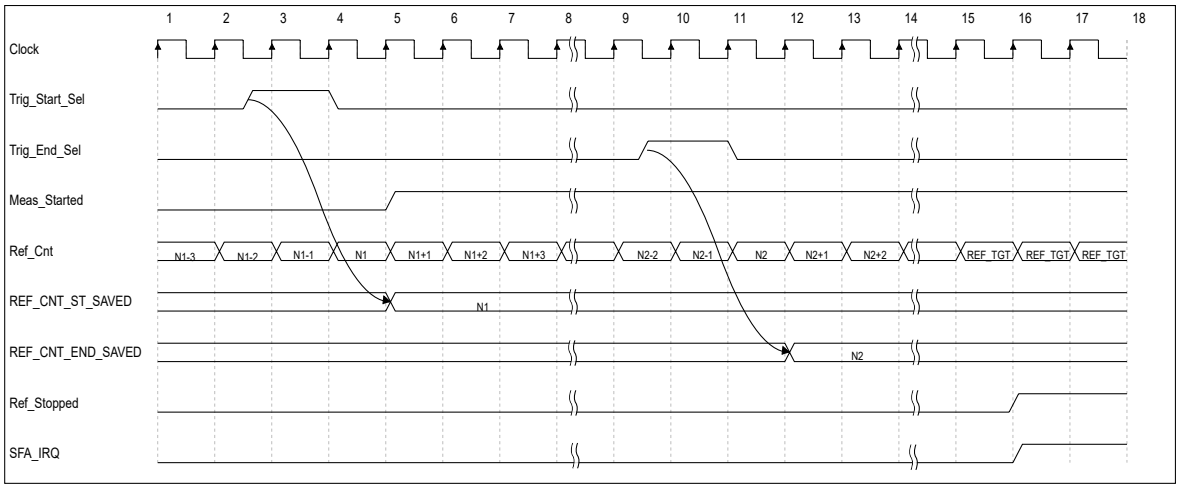

Figure 74. Trigger Based Measurement

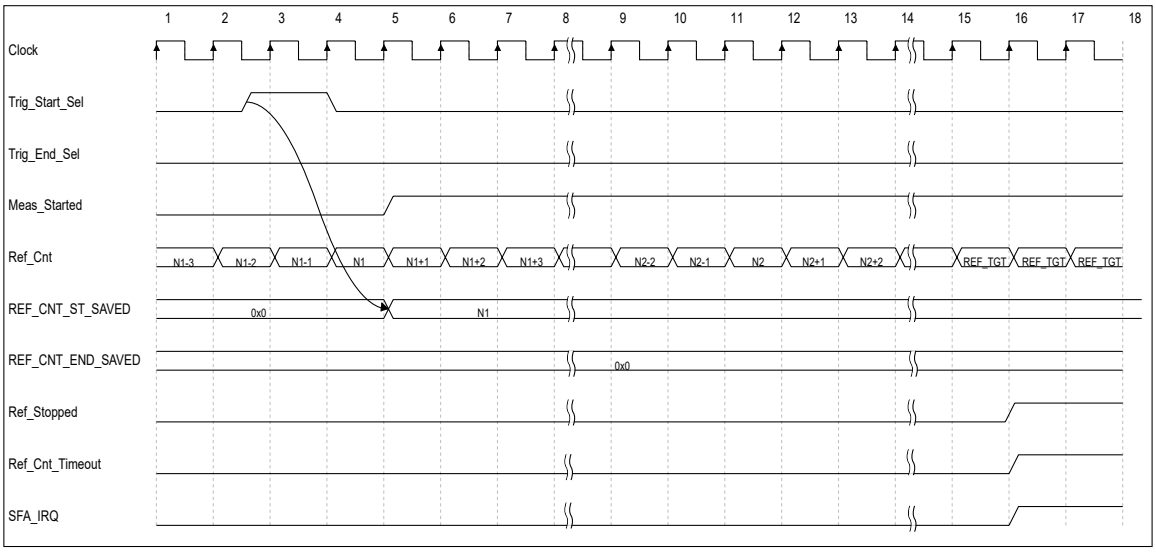

Figure 75. Trigger Based Measurement Timeout

26.3.4 Clocking

The SFA has several clock sources, for internal behaviour, register access, and for frequency measurement. Their role during the frequency measurement is covered in the Functional Description chapter. They are listed in the table below:

Table 221. SFA Clocks

Input	Description
ipg_clk	IPS System Bus Clock
ipg_clk_s	IPS System Bus Clock for pmodel
ipt_clk	High Speed TestClock
sfa_clk_inputs	Clocks under Test
sfa_ref_clk_inputs	Clocks for Reference Clock choices

26.3.5 Interrupts

This module has single interrupt: ipi_init. This interrupt is asserted when:

- CNT_STAT[4] is set and CTRL [5] is enabled
- CNT_STAT[5] is set and CTRL2[16] is enabled
- CNT_STAT[6] is set and CTRL2[17] is enabled

26.4.1.2 Signal Frequency Analyser (SFA) Control (CTRL)

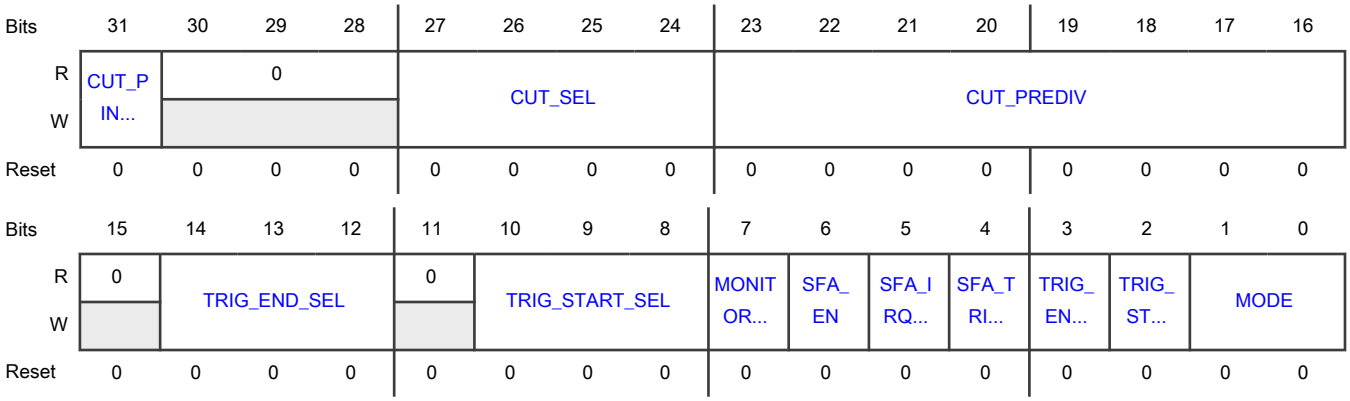
Offset

Register	Offset
CTRL	0h

Function

The SFA Control register contains fields to select both the type of measurement and the signal sources to be measured. The measurement mode will determine whether the SFA performs a frequency, period, or trigger based measurement.

Diagram



Fields

Field	Function
31 CUT_PIN_EN	CUT_PIN_EN This register field controls the connection of the clock under test to an external pin.
30-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 CUT_SEL	CUT_SEL These bits control which SoC clock is connected to the clock under test counter.
23-16 CUT_PREDIV	CUT_PREDIV The CUT_PREDIV 8-bit field provides an integer division of the input CUT signal prior to the CUT counter. Only integer values are implemented and the least significant bit is ignored. 0000_0000b - No Divide 0000_0001b - No Divide 0000_0010b - Divide by 2 0000_0011b - Divide by 2 0000_0100b - Divide by 4 0000_0101b - Divide by 4 0000_0110b - Divide by 6 0000_0111b - Divide by 6 0000_1000b - Divide by 8 0000_1001b - Divide by 8 0000_1010b-1111_1101b - Divide by CUT_PREDIV - CUT_PREDIV%2 1111_1110b - Divide by 254 1111_1111b - Divide by 254
15 —	Reserved
14-12 TRIG_END_SEL	Signal MUX For Trigger Based Measurement End This bit selects which signal will be used to commence a trigger based measurement. An edge of this signal will act as a trigger to end the measurement sequence. Either rising edge or falling edge can be selected by programming TRIG_END_POL.
11 —	Reserved
10-8 TRIG_START_SEL	Signal MUX For Trigger Based Measurement Start This bit selects which signal will be used to start an edge to edge measurement. An edge of this signal will act as a trigger to begin the measurement sequence. Either rising edge or falling edge can be selected by programming EDGE_START_POL.
7 MONITOR_EN	Monitor Enable This bit is used to enable Monitor mode. When in Monitor mode, measure will continue until the measured clk frequency has exceed the target frequency range. This bit ONLY takes affect in Frequecy Measurements(MODE = 00 or MODE=01)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not in monitor mode . 1b - In monitor mode.
6 SFA_EN	SFA Enable This bit is the general SFA Enable signal. To run any measurement, this signal must be set to 0b1. This signal must be set to 0b0 when modifying any clock inputs, clock divider values, or trigger selects. For example, prior to writing TRIG_END_POL, TRIG_START_POL, TRIG_START_SEL, TRIG_END_SEL, CUT_PREDIV, or CUT_SEL make sure that this bit is set to 0b0. 0b - The SFA is disabled. 1b - The SFA is enabled.
5 SFA_IRQ_EN	SFA Interrupt Enable This signal determines if interrupts are enabled for the SFA. When enabled, an interrupt will be issued upon completion of a measurement. 0b - Interrupts are disabled. 1b - Interrupts are enabled.
4 SFA_TRIG_MEAS_EN	SFA Triggered Measurement Enable The SFA can be triggered to start a new frequency measurement when operating with either MODE = 0x0 or MODE = 0x1. This register field will be inactive if MODE > 0x1. The start trigger will be selected with TRIG_START_SEL and the measurement will begin when the first edge is received with polarity TRIG_START_POL. Note, SFA_EN bit must be set prior to beginning any measurements. The startup process requires a dummy write to the REF_CNT register to enable trigger detection followed by a trigger from the selected source. Refer to section Frequency Measurements for more information. 0b - The measurement will start by default with a dummy write to the REF and CUT counters. 1b - The measurement will start after receiving a dummy write to the REF_CNT followed by receiving the trigger edge selected by TRIG_START_SEL and TRIG_START_POL.
3 TRIG_END_POL	Trigger End Polarity This signal determines the polarity of the trigger signal which will end a trigger based measurement. 0b - Rising edge of TRIGER[TRIG_END_SEL] will end the measurement sequence. 1b - Falling edge of TRIGGER[TRIG_END_SEL] will end the measurement sequence.
2 TRIG_START_POL	Trigger Start Polarity This signal determines the polarity of the start signal when measuring in trigger mode. 0b - Rising edge of TRIGGER[TRIG_START_SEL] will begin the measurement sequence. 1b - Falling edge of TRIGGER[TRIG_START_SEL] will begin the measurement sequence.
1-0 MODE	MEASUREMENT MODE Measurement mode determines which type of timing measurement is performed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Frequency measurement performed with REF frequency > CUT Frequency. 01b - Frequency measurement performed with REF frequency < CUT Frequency. 10b - CUT period measurement performed. 11b - Trigger based measurement performed. Note, each trigger pulse must be held for at least 2 ref_clk cycles.

26.4.1.3 Signal Frequency Analyser (SFA) Control Extended (CTRL_EXT)

Offset

Register	Offset
CTRL_EXT	4h

Function

The SFA CTRL_EXT register contains fields to select

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

R	CUT_CLK_EN															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 CUT_CLK_EN	CUT_CLK_EN This register field provides an enable signal for each CUT_CLK source. Each bit corresponds to a single CUT_CLK. Bit 0 corresponds to CUT_CLK0, bit 1 corresponds to CUT_CLK1, and so on. Enabling each bit will enable corresponding CUT_CLK.

26.4.1.4 Signal Frequency Analyser Count Status Register (CNT_STAT)

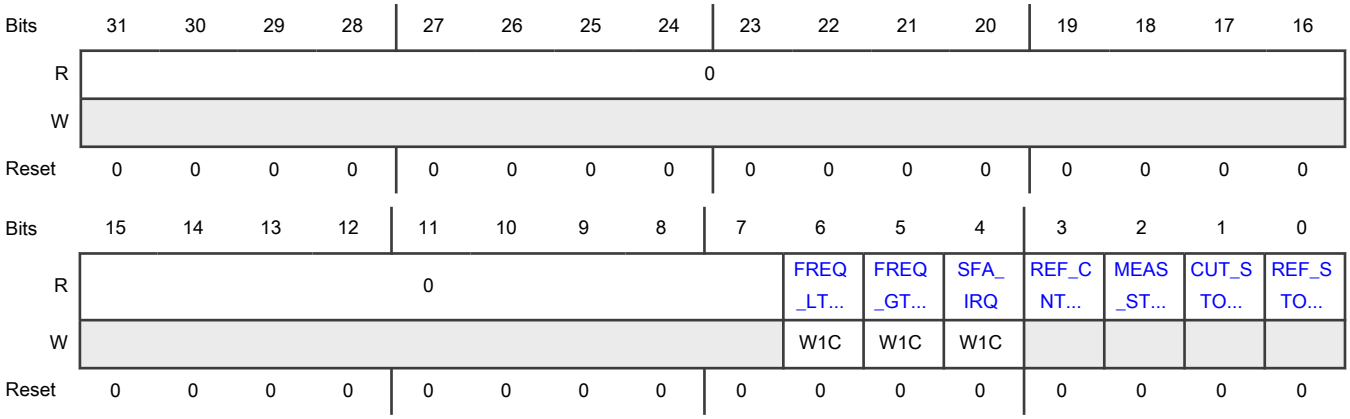
Offset

Register	Offset
CNT_STAT	8h

Function

This register returns status flags to indicate the current state of the REF and CUT counters

Diagram



Fields

Field	Function
31-7 —	Reserved
6 FREQ_LT_MIN_IRQ	FREQ_LT_MIN interrupt flag FREQ_LT_MIN interrupt flag, it means the cut clk frequency is lower than minimum setting,or trigger measurement period is greater than maximum setting
5 FREQ_GT_MAX_IRQ	FREQ_GT_MAX interrupt flag FREQ_GT_MAX interrupt flag, it means the cut clk frequency is greater than maximum setting,or trigger measurement period is less than minimum setting
4 SFA_IRQ	SFA Interrupt Request This flag indicates that REF_CNT has reached REF_TARGET. More generally, this flag indicates that a measurement has been completed and an interrupt has been issued. Writing a 0x1 to this bit position will clear the interrupt request.
3 REF_CNT_TIMEOUT	Reference Counter Time Out This flag indicates the REF counter reached REF_TARGET before the desired measurement was completed. Every test will commence when REF_CNT == REF_TARGET. For measurement accuracy,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	this bit should be equal to 0b0 when REF_STOPPED == 0b1. This bit will be cleared on any write to REF_CNT when not performing a measurement.
2 MEAS_STARTED	Measurement Started Flag In frequency measurement mode, this flag indicates when the CUT counter has started counting. Set when CUT counter increments to 1. In period measurement mode, this flag indicates that the first edge of the CUT has been received for period measurement. In edge to edge signal measurement mode, this flag will indicate when TRIGGER[TRIG_START_SEL] has been received for measurement. This event will also push the REF_CNT to the REF_CNT_ST_SAVED register. This flag is only active during CTRL[MODE] == 0x0, 0x2 or 0x3. Cleared on any write to REF_CNT when not performing a measurement.
1 CUT_STOPPED	CUT_STOPPED This flag indicates the CUT counter has stopped counting. Set when either REF or CUT counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement.
0 REF_STOPPED	REF_STOPPED This flag indicates the REF counter has stopped counting. Set when REF counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement. This bit can be polled to indicate when a measurement is complete.

26.4.1.5 Signal Frequency Analyser Clock Under Test Counter (CUT_CNT)

Offset

Register	Offset
CUT_CNT	Ch

Function

This register contains the current count of the clock under test. Writes to this register will start the clock under test and reference counters. Counting will stop when either the count matches the contents of the clock under test target count register or when reference counter matches the reference target count register. Note, attempts to read this register before the CUT_STOPPED flag has set will return 0x0000_0000

Diagram

Fields

Field	Function
31-0 CUT_CNT	CUT_CNT Current clock under test count. Writes to this register will start the clock under test and reference counters.

26.4.1.6 Signal Frequency Analyser Reference Clock Counter (REF_CNT)

Offset

Register	Offset
REF_CNT	10h

Function

This 32-bit register contains the current count of the reference clock. Writes to this register will clear the clock under test and reference counters. Counting will stop if the count matches the contents of the reference clock target count register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 REF_CNT	REF_CNT Current reference clock count. Writing to this register with any value will clear the clock under test and reference clock count and status flags registers.

26.4.1.7 Signal Frequency Analyser Clock Under Test Target Count (CUT_TARGET)

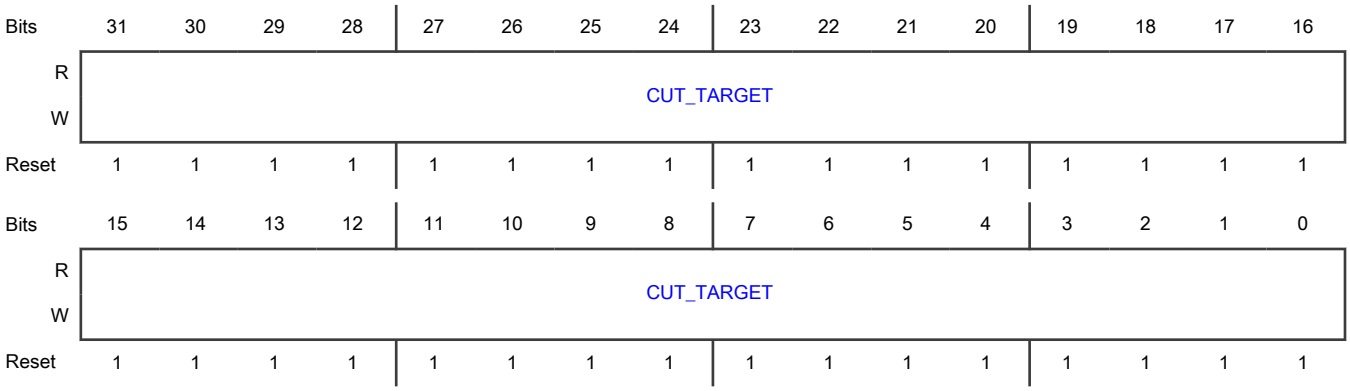
Offset

Register	Offset
CUT_TARGET	14h

Function

This register contains the target count for the clock under test. Both the reference and clock under test count will stop if the clock under test count matches the contents of this register.

Diagram



Fields

Field	Function
31-0 CUT_TARGET	CUT_TARGET Target count for the clock under test. Note, a measurement of type MODE = 0x0 or 0x1 is not valid if CUT_TARGET = 0x00000000. This value must be set to an integer > 0x0 to perform a valid measurement.

26.4.1.8 Signal Frequency Analyser Reference Clock Target Count (REF_TARGET)

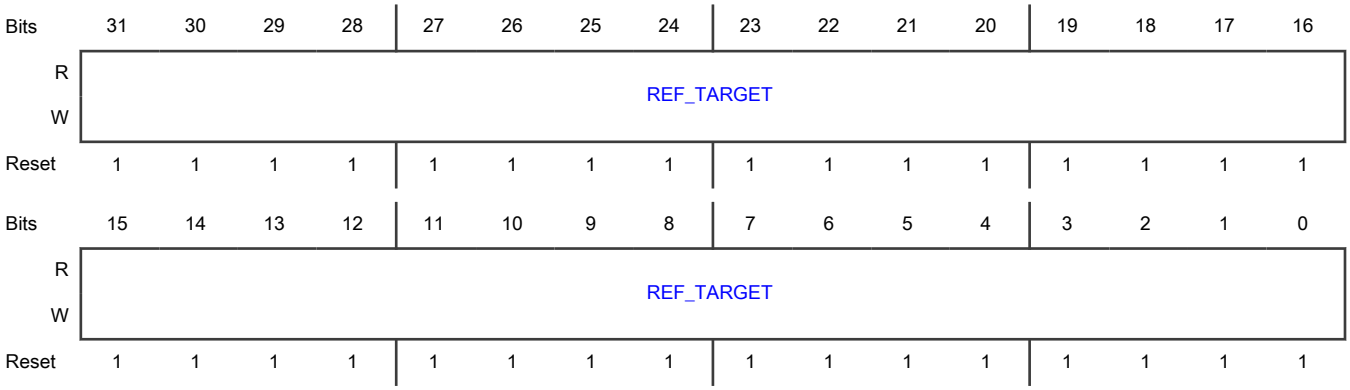
Offset

Register	Offset
REF_TARGET	18h

Function

This register contains the target count for the reference clock. Both the reference and clock under test count will stop if the reference clock count matches the contents of this register.

Diagram



Fields

Field	Function
31-0 REF_TARGET	REF_TARGET Target count for the reference clock. Note, a measurement is not valid if REF_TARGET = 0x00000000. This value must be set to an integer > 0x0 to perform a valid measurement.

26.4.1.9 Signal Frequency Analyser Reference Clock Count Start Saved Register (REF_CNT_ST_SAVED)

Offset

Register	Offset
REF_CNT_ST_SAVED	1Ch

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 REF_CNT_END_SAVED	REF_CNT_END_SAVED Saved reference clock counter. This register is loaded with the current value of REF_CNT on assertion of either the CUT_STOPPED or REF_STOPPED flags. Note, during frequency measurements with CTRL[MODE] = 0x1, this register will be unused. It is assumed that the REF_CNT_END will be equal to REF_TARGET. Cleared on any write to REF_CNT when not performing a measurement.

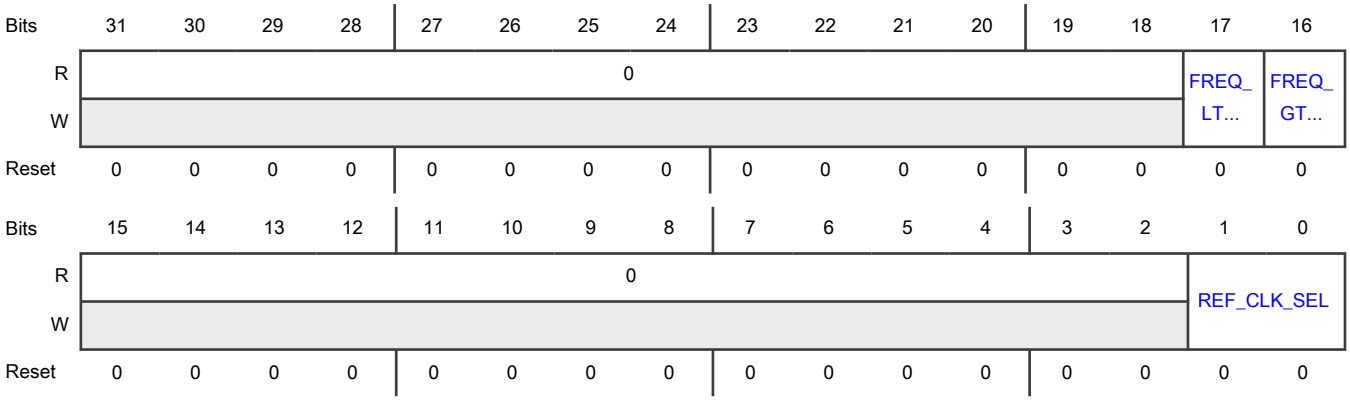
26.4.1.11 Extended control register for SFA (CTRL2)

Offset

Register	Offset
CTRL2	24h

Function
This register an extended control register for SFA

Diagram



Fields

Signal multiplexing	Port control	Signal multiplexing

27.1.1 Module instances

This device has one instance of the CCM32K module.

27.1.2 Reset

The CCM32K module supports only the POR.

27.2 Overview

The 32 kHz Clock Control Module (CCM32K) provides the 32 kHz clock to the device. This module includes the free running oscillator (FRO) and Crystal Oscillator (OSC) which serve as the clock generators of 32 kHz clock. The module has an internal clock validation mechanism to ensure the clock from OSC is stable; and manually switch from the FRO to OSC when clock from OSC is stable or switch back to FRO clock if software disables the OSC. There is also an internal monitor inside OSC to detect whether it is available, and CCM32K can automatically switch back from OSC to FRO immediately if OSC is unavailable.

27.2.1 Block diagram

The following figure shows a block diagram for the CCM32K module.

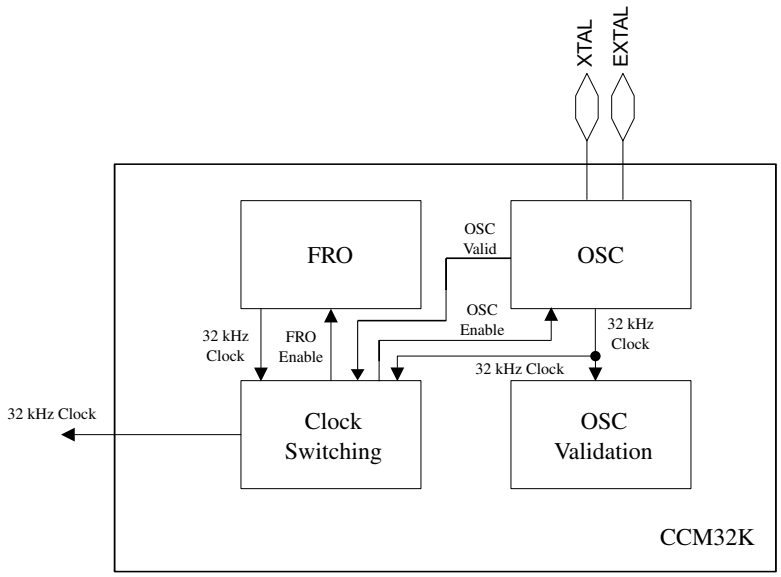

Figure 76. High level block diagram

27.2.2 Features

The CCM32K module has the following features:

- 32-kHz Free Running Oscillator (FRO) that is enabled after POR to provide clock to the device. The FRO can be disabled by software if needed.
- FRO and OSC trim values are loaded from IFR which can be overriden by software if needed.
- 32-kHz Crystal Oscillator (OSC) that is kept disabled after POR. The OSC can be enabled by software when needed. And the OSC has an internal monitor to detect whether it is available.
- Clock validation logic that checks for the quality of clock from OSC and indicates if the clock from the OSC is stable.
- Clock switching logic that switches to OSC clock when it is stable and manually switches back to FRO clock when software disables the OSC.
- Clock automatic switching logic that automatically switches back to FRO clock if OSC internal monitor detect it is unavailable.
- Locking mechanism for all registers for OSC and FRO. Once locked, the registers cannot be unlocked until the next POR. This prevents unwanted modifications to the registers.
- The loss of clock (LOC) monitoring for the quality of external 32-khz crystal oscillator with internal 32-khz FRO as reference clock.

27.3 Functional description

The following sections describe functional details of the CCM32K module.

27.3.1 OSC clock validation

The clock from the external crystal oscillator is not stable immediately after enabling it and takes certain time before it becomes stable and can be used. The clock validation mechanism ensures that sufficient amount of clock cycles have passed before enabling the clock to other modules on the device that require 32 kHz clock. When STATUS[OSC32K_ACTIVE] and STATUS[OSC32K_RDY] are asserted, 32 kHz oscillator clock can be used by other modules.

27.3.2 Clock switching

Clock switching between OSC32K and FRO32K

- Switch FRO32K to OSC32K by configuring CGC32K[CLK_SEL_32K] to 1b if OSC32K clock is available.
- Switch OSC32K to FRO32K by configuring CGC32K[CLK_SEL_32K] to 0b if FRO32K clock is available.
- No clock source active if CGC32K[CLK_SEL_32K] is high and OSC32K is disabled.
- No clock source active if CGC32K[CLK_SEL_32K] is low and FRO32K is disabled.

Clock switching can switch clock source automatically from FRO32K to OSC32K provided OSC32K is as the clock source and FRO32k is available. This logic use the valid flag indicating if the clock of OSC is available, which generated by OSC internal monitor after setting OSC32K_CTRL[OSC_CLKMON_EN] to 1. Enable this function by configuring CLKMON_CTRL[AUTO_SWITCH_EN] to 1b after OSC32K is as clock source.

27.3.3 Clock monitor

CCM32K has two clock monitors. One uses FRO_ 32K as its clock source. The other uses OSC_32K as its clock source. Each monitor checks a divided version of the other clock at the same frequency but divided by 16. The monitor expects a clock edge every 8 cycles, and you can trim the monitor to assert after 10, 12, 14, or 16 cycles with no edge.

Changing the trim makes the clock monitor more sensitive and reduces the latency, but also makes it more susceptible to variation in the duty cycle. The accuracy and latency of the monitor can vary by a cycle due to synchronization differences, so for each trim point:

- At 2 cycles after the expected edge the monitor asserts between 12.5% and 37.5% frequency variation with a maximum latency of 11 cycles
- At 4 cycles after the expected edge the monitor asserts between 37.5% and 62.5% frequency variation with a maximum latency of 13 cycles
- At 6 cycles after the expected edge the monitor asserts between 62.5% and 87.5% frequency variation with a maximum latency of 15 cycles
- At 8 cycles after the expected edge the monitor asserts between 87.5% and 112.5% frequency variation with a maximum latency of 17 cycles

The frequency of the clock monitor can also be trimmed to either 1 kHz or 64 Hz. Configuring to a slower clock increases the detector's latency but reduces power consumption.

NOTE

You must enable both the FR032k and OSC32k and OSC_RDY sets before enabling the clock monitor.

27.3.4 Clock automaitc switching

This section describes the automatic switching function of CCM32K. When selecting OSC32K as clock source, CCM32k will detect the valid signal from OSC32K constantly after setting OSC32K_CTRL[OSC_CLKMON_EN] and CLKMON_CTRL[AUTO_SWITCH_EN] to 1b. This valid signal derives from OSCK32 internal monitor that is used to detect the period of high and low level of the clock. when the frequency is below about 20khz, OSCK32 will de-assert the valid signal and then CCM32K dynamically switch the clock source to FRO32K immediately.

STATUS[AUTO_SWITCH] is 1b to identify clock source has been switched to FRO32K. Software must follow the steps below to further select OSC32K to the clock source again if need.

1. Clear CGC32K[CLK_SEL_32K] to be 0b to select FRO32K as clock source.
2. Wait until the STATUS[FRO32K_ACTIVE] is 1b to identify FRO32K is as clock source.
3. Clear CLKMON_CTRL[AUTO_SWITCH_EN] to 0b to disable clock automatic switching logic.
4. Clear OSC32K_CTRL[OSC_EN] and OSC32K_CTRL[SOX_EN] as 0b to disable OSC32K.
5. Enable OSC32K and configure it as clock source. Refer to initialization section.

27.4 External signals

This table describes the CCM32K signals that are SoC level pins.

Signal	I/O	Description
EXTAL32K	I/O	32-kHz Crystal pin
XTAL32K	I/O	32-kHz Crystal pin

27.5 Initialization

This section describes the initialization of the CCM32K module.

The CCM32K module powers up, loads the default trims from flash and starts up the FRO after Power-On-Reset (POR) is complete. The trim values get loaded after POR into their respective registers. Software must follow the steps below to further configure the module.

- FRO32K as clock source
  1. Enable the FRO32K by setting FRO32K_CTRL[FRO_EN] as 1b. The FRO32K_CTRL[FRO_EN] is reset to 1b by default.
  2. Wait until the STATUS[FRO32K_ACTIVE] is 1b to identify FRO32K available.
  3. Clear CGC32K[CLK_SEL_32K] to be 0b to select FRO32K as clock source. The CGC32K[CLK_SEL_32K] is reset to 0b by default.
- OSC32K as clock source
  1. Set OSC32K_CTRL[OSC_EN] and OSC32K_CTRL[SOX_EN] as 1b.
  2. Set OSC32K_CTRL[OSC_CLKMON_EN] as 1b if need to use automatic switching function.
  3. Select internal capacitance bank value through OSC32K_CTRL[XTAL_CAP_SEL] and OSC32K_CTRL[EXTAL_CAP_SEL] if internal capacitance back is enabled (OSC32K_CTRL[CAP_SEL_EN]).
  4. Wait until theSTATUS[OSC32K_RDY] is 1b to identify OSC32K available.
  5. Set CGC32K[CLK_SEL_32K] as 1b to select OSC32K as clock source.
  6. Wait until the STATUS[OSC32K_ACTIVE] is 1b to identify OSC32K is as clock source.
  7. Set CLKMON_CTRL[AUTO_SWITCH_EN] to 1b optionally to enable clock automatic switching logic.
- OSC32K bypass clock as clock source
  1. Set OSC32K_CTRL[OSC_EN] and OSC32K_CTRL[OSC_BYP_EN] high.
  2. Wait until theSTATUS[OSC32K_RDY] is 1b to identify OSC32K available.
  3. Set CGC32K[CLK_SEL_32K] high , then OSC32K bypass clock is selected as clock source. This clock is treated as same clock on EXTAL32 pad.

NOTE

OSC32K_ACTIVE or FRO32_ACTIVE will be asserted only when related oscillator is selected as clock source and CGC32K[CLK_OE_32K] is not all 0.

27.6 Memory Map and register definition

This section includes the CCM32K module memory map and detailed descriptions of all registers.

27.6.1 CCM32K register descriptions

27.6.1.1 CCM32K memory map

CCM32K base address: 4001_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL)	32	RW	0088_0001h
4h	Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM)	32	RW	0000_0400h
8h	32 kHz OSC Control Register (OSC32K_CTRL)	32	RW	0000_0000h
Ch	Status Register (STATUS)	32	R	0000_0010h
14h	Clock Monitor Control Register (CLKMON_CTRL)	32	RW	0000_0000h
18h	Clock Monitor Test Register (CLKMON_TST)	32	RW	0000_0000h
1Ch	32 kHz Clock Gate Control Register (CGC32K)	32	RW	0000_001Fh

27.6.1.2 Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL)

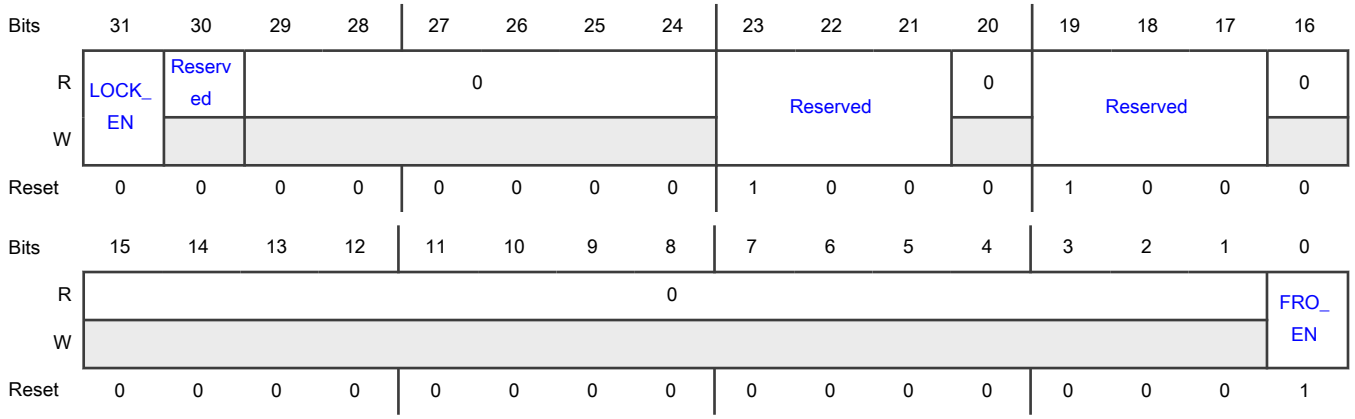
Offset

Register	Offset
FRO32K_CTRL	0h

Function

The Free Running 32 kHz Oscillator Control Register (FRO32K_CTRL) provides control fields for the 32 kHz Free Running Oscillator.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock When set to '1', this field locks all further write accesses to this register until a POR occurs. Writing '0' after setting this field to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30 —	Reserved bits. Reads only zeros.
29-24 —	Reserved bits. Reads only zeros.
23-21 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
20 —	Reserved bits. Reads only zeros.
19-17 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
16-1 —	Reserved bits. Reads only zeros.
0 FRO_EN	FRO Enable This field enables the FRO analog oscillator. There is a 120 µs typical start-up time before clocks are output from the FRO. 0b - FRO is disabled 1b - FRO is enabled

27.6.1.3 Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM)

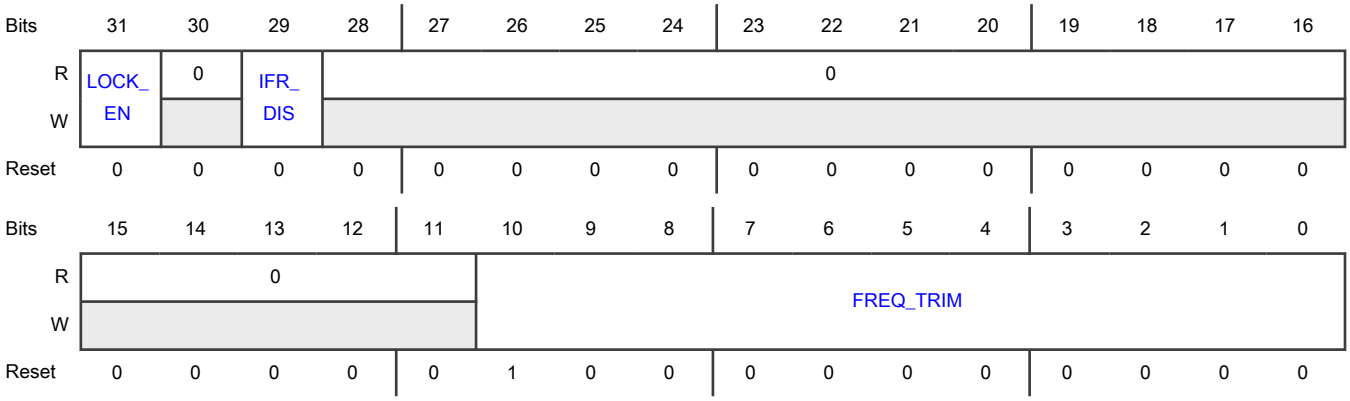
Offset

Register	Offset
FRO32K_TRIM	4h

Function

The Free Running 32 kHz Oscillator Trim Register (FRO32K_TRIM) provides frequency trim configuration for the 32 kHz Free Running Oscillator.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock When set to '1', this field locks all further write accesses to this register until a POR occurs. Writing '0' after setting this field to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30 —	Reserved
29 IFR_DIS	IFR Loading Disable Control This field controls whether the FREQ_TRIM field gets overwritten when IFR value gets loaded in the SoC. Setting this field to '1' blocks the FREQ_TRIM field from being loaded again. If LOCK_EN bit is set to '1', this field is ignored and no IFR values get loaded. 0b - IFR loading is enabled 1b - IFR loading is disabled
28-11 —	Reserved
10-0 FREQ_TRIM	Frequency Trim These field controls the frequncy of the FRO. The frequency is decreased monotonically when this field is changed progressively from 00000000000b to 11111111111b. This field is set from the IFR (Flash) but can be overridden by software. This field can be changed only when the FRO32K_CTRL[FRO_EN] field is '0'. **NOTE** To ensure monotonic change in frequency in a closed loop mode, the bit 0 of this field should always be kept '0'. The IFR_DIS and LOCK_EN fields control how this field gets loaded. If IFR_DIS is '1', this field will not be loaded with IFR value. If LOCK_EN bit is '1', this field will be locked for both IFR load and software writes. 100_0000_0000b - Default trim value

27.6.1.4 32 kHz OSC Control Register (OSC32K_CTRL)

Offset

Register	Offset
OSC32K_CTRL	8h

Function

The 32 kHz OSC Control Register (OSC32K_CTRL) controls the 32 kHz Crystal Oscillator.

11-8 EXTAL_CAP_SEL	Crystal load capacitance selection bits Selects the internal capacitance for the EXTAL pin from the capacitor bank. The final load capacitance can be calculated as $C_L = ((C_{extal} \cdot C_{xtal})/(C_{extal} + C_{xtal})) + C_{shunt}$ where: • C_{extal} is the selected capacitance on EXTAL pin • C_{xtal} is the selected capacitance on XTAL pin • C_{shunt} is the internal shunt capacitance whose value can be determined from the device's datasheet The selected capacitance value is shown below. 0000b - 0 pF 0001b - 2 pF 0010b - 4 pF 0011b - 6 pF 0100b - 8 pF 0101b - 10 pF 0110b - 12 pF 0111b - 14 pF 1000b - 16 pF 1001b - 18 pF 1010b - 20 pF 1011b - 22 pF 1100b - 24 pF 1101b - 26 pF 1110b - 28 pF 1111b - 30 pF

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 CAP_SEL_EN	Crystal Load Capacitance Selection Enable Enables the internal capacitor banks on the EXTAL and XTAL pins that vary the load capacitance on these pins. 0b - Internal capacitance bank is not enabled 1b - Internal capacitance bank is enabled
6-5 CAP_TRIM	SOX Capacitor Trim Delay selection (area) for SOX mode.
4-3 —	Reserved bits. Reads only zeros. Writes have no effect but it is preferred that these bits are not written to.
2 OSC_CLKMON_EN	Crystal Oscillator Internal Clock Monitor Enable This field enables the crystal oscillator internal clock monitor when set to '1'. The oscillator internal monitor will start detecting the frequency of clock. 0b - Oscillator internal clock monitor is disabled 1b - Oscillator internal clock monitor is enabled
1 OSC_BYP_EN	Crystal Oscillator Bypass Enable When this field is set to 1b, the crystal oscillator will be bypassed, and the output of the crystal oscillator is the same as that of the external oscillator from the EXTAL pin. Both OSC_EN and this bit must be set together to 1b to enable the bypass mode of the oscillator. To exit bypass mode, both OSC_EN and OSC_BYP_EN bits must be set to '0'. User must not move the OSC from bypass mode directly to normal mode. 0b - Crystal oscillator is not bypassed 1b - Crystal oscillator is bypassed
0 OSC_EN	Crystal Oscillator Enable This field enables the crystal oscillator when set to '1'. The oscillator will start giving the clock output but the clock is not available to the device until the STATUS[OSC_RDY] and STATUS[OSC_ACTIVE] fields are asserted. 0b - Oscillator is disabled 1b - Oscillator is enabled

27.6.1.5 Status Register (STATUS)

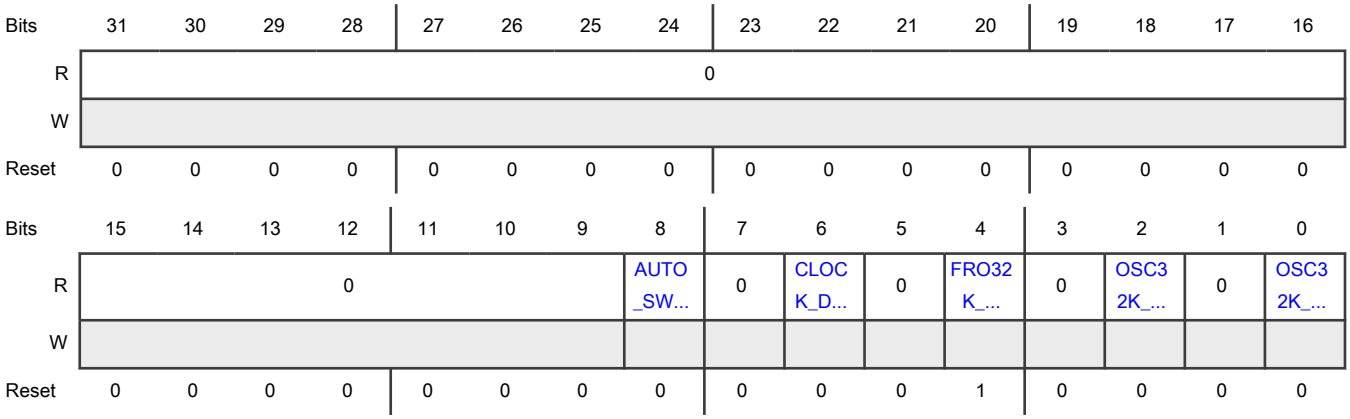
Offset

Register	Offset
STATUS	Ch

Function

This register provides status bits for the CCM32K module.

Diagram



Fields

Field	Function
31-9 —	Reserved bits. Reads only zeros.
8 AUTO_SWITCH	Clock Source Auto switch Switch back from OSC to FRO automatically if OSC is as clock source but unavailable. 0b - Clock source do not switch 1b - Clock source switch back to FRO
7 —	Reserved bits. Reads only zeros.
6 CLOCK_DET	Clock Detect The Clock monitor has detected an error. 0b - Clock error is not detected 1b - Clock error is detected
5 —	Reserved bits. Reads only zeros.
4 FRO32K_ACTIVE	32 kHz FRO active bit Indicates whether the 32 kHz free running oscillator is active and in use as the clock source or not. 0b - FRO32K is not the active clock source 1b - FRO32K is the active clock source
3	Reserved bits. Reads only zeros.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
2 OSC32K_ACTIVE	32 kHz Oscillator active bit Indicates whether the 32 kHz crystal oscillator is active and in use as the clock source or not. 0b - OSC32K is not the active clock source 1b - OSC32K is the active clock source
1 —	Reserved bits. Reads only zeros.
0 OSC32K_RDY	32 kHz Oscillator ready bit. A '1' on this bit indicates that clock output from the crystal oscillator is stable. The software can decide to switch to the OSC32K clock when this bit is set. However, this bit does not clear when due to any reason the OSC32K stops providing a clock. Other on-chip tamper detection methods might indicate if clock has stopped due to removal of crystal or other reasons. This bit de-asserts during a POR event OR if the OSC32K_CTRL[OSC_EN] bit set to 0. 0b - Clock output from crystal oscillator is not stable. 1b - Clock output from crystal oscillator is stable.

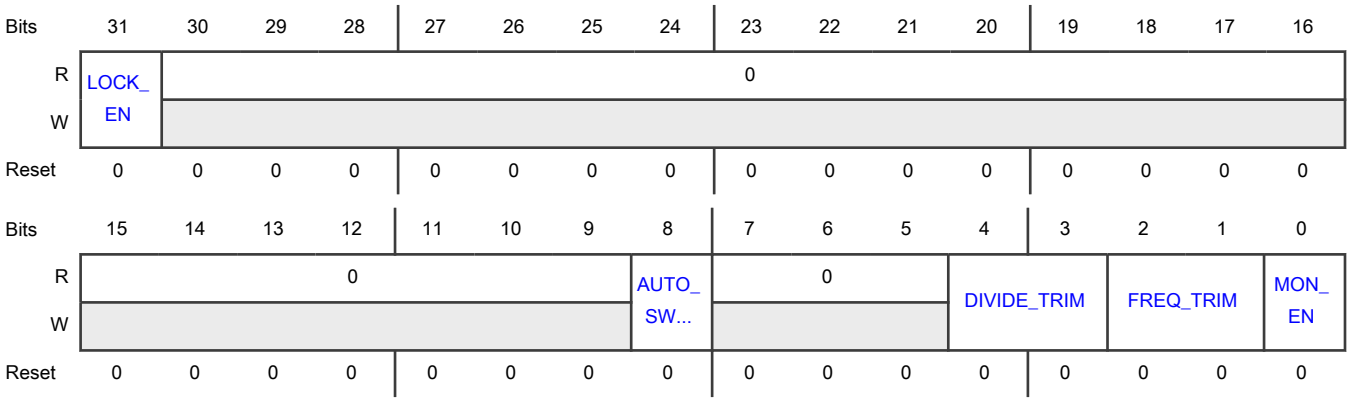
27.6.1.6 Clock Monitor Control Register (CLKMON_CTRL)

Offset

Register	Offset
CLKMON_CTRL	14h

Function
Provides control bits for clock monitor.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock bit When set to '1', this bit will lock all further write accesses to this register until a POR occurs. Writing '0' after setting this bit to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30-9 —	Reserved bits. Reads only zeros.
8 AUTO_SWITCH_EN	Automatic Switch Enable Bit When OSC32K_CTRL[OSC_CLKMON_EN] and this bit set to '1', this bit will enable the automatic switch provided OSC32K is as the clock source and FRO32k is available. 0b - Automatic switch is disable 1b - Automatic switch is enable
7-5 —	Reserved bits. Reads only zeros.
4-3 DIVIDE_TRIM	Divide Trim Clock monitor divide trim 00b - Clock monitor operates at 1 kHz for both FRO32K and OSC32K 01b - Clock monitor operates at 64 Hz for FRO32K and clock monitor operates at 1 kHz for OSC32K (Reserved) 10b - Clock monitor operates at 1 kHz for FRO32K and clock monitor operates at 64 Hz for OSC32K (Reserved) 11b - Clock monitor operates at 64 Hz for both FRO32K and OSC32K
2-1 FREQ_TRIM	Frequency trim bits Clock monitor frequency trim 00b - Clock monitor asserts 2 cycle after expected edge (assert after 10 cycles with no edge) 01b - Clock monitor asserts 4 cycles after expected edge (assert after 12 cycles with no edge) 10b - Clock monitor asserts 6 cycles after expected edge (assert after 14 cycles with no edge) 11b - Clock monitor asserts 8 cycles after expected edge (assert after 16 cycles with no edge)
0 MON_EN	CLKMON Enable Enables the CLKMON when set to '1'. 0b - CLKMON is disabled 1b - CLKMON is enabled

27.6.1.7 Clock Monitor Test Register (CLKMON_TST)

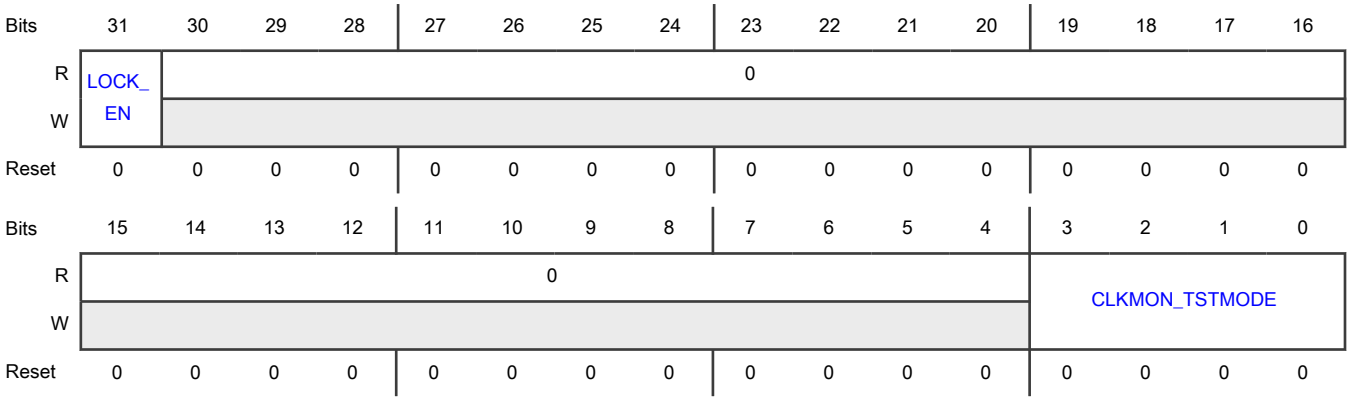
Offset

Register	Offset
CLKMON_TST	18h

Function

Provides control bits for clock monitor test.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock bit When set to '1', this bit will lock all further write accesses to this register until a POR occurs. Writing '0' after setting this bit to '1' has no effect. 0b - Register write access is unlocked 1b - Register write access is locked
30-4 —	Reserved bits. Reads only zeros.
3-0 CLKMON_TSTMODE	Test Mode Configure the CLKMON test mode. Fields '0' and '1' indicate the reference clock and enable signal respectively after entering test mode. Moreover, fields '2' and '3' are for monitored clock part. When set to '0000' following '0101' after resetting CLKMON_CTRL [MON_EN], these fields can completely turn off clock monitor.

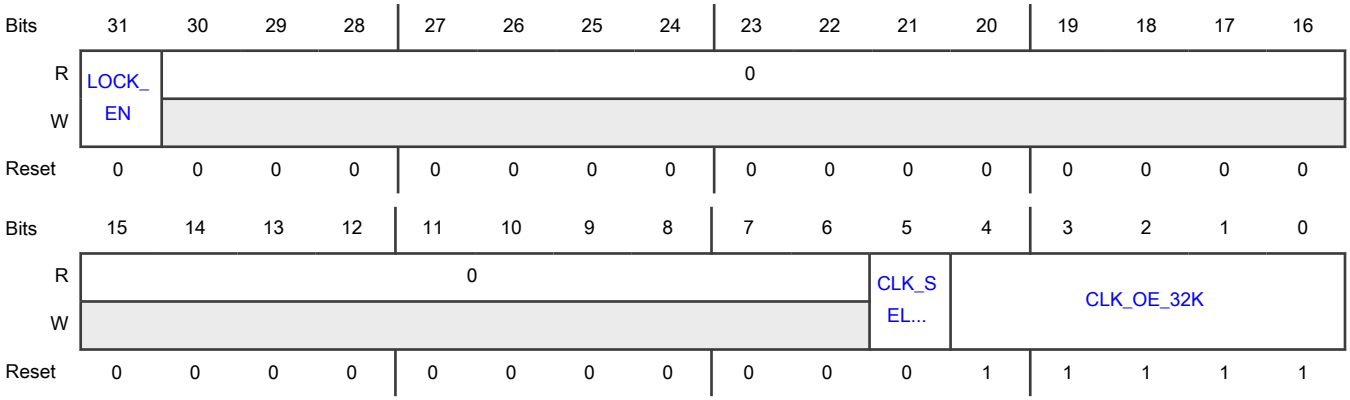
27.6.1.8 32 kHz Clock Gate Control Register (CGC32K)

Offset

Register	Offset
CGC32K	1Ch

Function
Provides 32 kHz clock output gate control bits for peripherals.

Diagram



Fields

	• CLK_OE_32K [1]: RFMC • CLK_OE_32K [2]: NBU • CLK_OE_32K [3]: WUU/RMC/PORTD • CLK_OE_32K [4]: Other modules 0_0000b - Clock output is disabled 0_0001b - Clock output is enabled

27.6.1.9 32 kHz OSC Internal Monitor Trim Register (OSC32K_MON_TRIM)

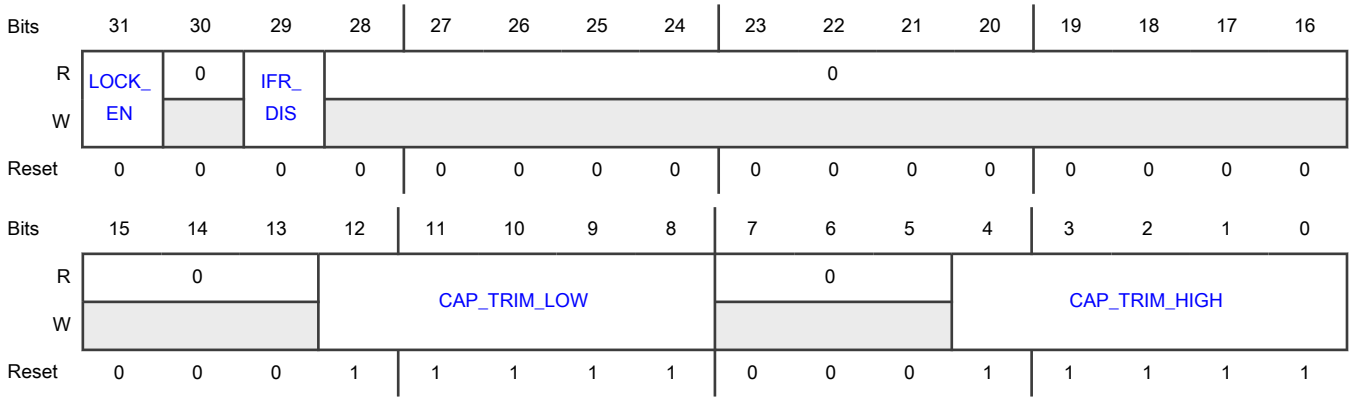
Offset

Register	Offset
OSC32K_MON_TRIM	24h

Function

The 32 kHz OSC Internal Monitor Trim Register (OSC32K_MON_TRIM) provides capacitance trim configuration for the 32 kHz OSC internal monitor.

Diagram



Fields

Field	Function
31 LOCK_EN	Write Access Lock When set to '1', this field locks all further write accesses to this register until a POR occurs. Writing '0' after setting this field to '1' has no effect. 0b - Register write access is unlocked

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Register write access is locked
30 —	Reserved
29 IFR_DIS	IFR Loading Disable Control This field controls whether the CAP_TRIM_HIGH and CAP_TRIM_LOW field gets overwritten when IFR value gets loaded in the SoC. Setting this field to '1' blocks the CAP_TRIM_HIGH and CAP_TRIM_LOW field from being loaded again. If LOCK_EN bit is set to '1', this field is ignored and no IFR values get loaded. 0b - IFR loading is enabled 1b - IFR loading is disabled
28-13 —	Reserved
12-8 CAP_TRIM_LOW	OSC32K Internal Monitor Capacitance Trim for Clock Low Level These field controls the detection of clock low level. The larger trim value indicates to the greater threshold of the clock low level period. This field is set from the IFR (Flash) but can be overridden by software. This field can be changed only when the OSC32K_CTRL[OSC_EN] field is '0'. The IFR_DIS and LOCK_EN fields control how this field gets loaded. If IFR_DIS is '1', this field will not be loaded with IFR value. If LOCK_EN bit is '1', this field will be locked for both IFR load and software writes. 1_1111b - Default trim value
7-5 —	Reserved
4-0 CAP_TRIM_HIGH	OSC32K Internal Monitor Capacitance Trim for Clock High Level Refer to CAP_TRIM_LOW. 1_1111b - Default trim value

Chapter 28
Power Management

28.1 Introduction

This chapter describes the power modes supported with this device. It also describes the power domains and the voltage supply options connected to these power domains.

NOTE

Refer to Radio low power mode for power management of radio sub-system.

28.2 Power domains

A power domain is a collection of circuits that can be powered off even when a voltage source is still supplied. This section shows the power domains within the device and the modules belong to these domains.

NOTE

If a module belongs to several power domains, the module will be powered off when any of the power domain is powered off.

1. Core main is a subdomain from the core domain.
2. These subdomains belong to the core domain. These subdomain includes optional voltage scaling options associated the voltage supply of each domain for deep sleep and power down modes. See system power control chapter for more information. Core domain is supplied by VDD_CORE voltage supply in the chip package.
3. Core wake is a subdomain from the core domain.
4. Core radio is a subdomain from the core domain.

NOTE

VDD_CORE_MAIN, VDD_CORE_WAKE and VDD_CORE_2.4G are connected to the VDD_CORE voltage supply in the chip package with optional voltage scaling options in deep sleep and power down modes.

28.3 Power modes

The device supports Active, Sleep, Deep Sleep, Power Down, and Deep Power Down modes. Any reset brings the chip back to the Active mode.

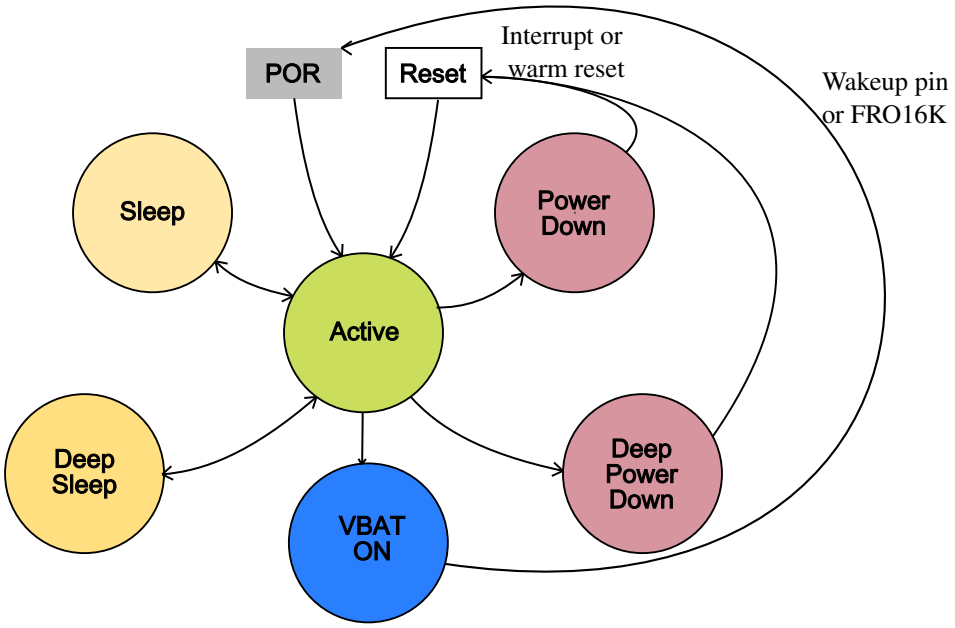

Figure 78. Power modes

28.3.1 Active mode

In Active mode, CPU execution is possible.

To achieve the performance requirements of a given system application while minimizing power consumption, Active mode permits the following power-saving options when possible:

- Configure the VDD_CORE subdomains voltage level to balance power and performance.
- Individually configure SRAM as active/shutdown by software.
- Gate the clocks to unused modules.
- Configure the unused VDD_CORE subdomains to state retention mode.
- Power-gate the unused VDD_CORE subdomains.

28.3.2 Sleep mode

In Sleep mode, CPU execution is halted. The core clock is gated off. The system clock as well as the bus clocks, if enabled, continue to operate.

Sleep mode supports the following behaviors based on different clock configurations:

- CPU clock is OFF. The system clock and bus clock remain ON. Most modules can remain operational.
- CPU clock, system clock and bus clock are all OFF. Some modules can remain operational with low power asynchronous clock sources and serve as wake-up sources.

Wake from Sleep mode is triggered by an interrupt or a wakeup event.

Sleep mode also supports a partial wake-up where a bus master other than the CPU (eg. DMA) is recovered by a wakeup event. The device automatically re-enters sleep mode after this module finishes its task.

To achieve the performance requirements of a given system application while minimizing power consumption, Sleep mode permits the following power-saving options when possible:

- Configure the VDD_CORE subdomains voltage level to balance power and performance.

- Individually configure SRAM as active / deep sleep / shutdown by software.
- Gate the clocks to unused modules.
- Configure the unused VDD_CORE subdomains to state retention mode.
- Power-gate the unused VDD_CORE subdomains.

28.3.3 Deep Sleep mode

Deep Sleep mode places most of the chip into a static state. It is the lowest power mode that can retain all registers.

The device wakes from Deep Sleep mode through the interrupt routine or wake-up event.

The core clock, system clock and the bus clock are gated off.

In Deep Sleep mode, the whole VDD_CORE_MAIN subdomain is put into state retention mode.

In Deep Sleep mode, the peripherals inside the VDD_CORE_WAKE subdomain can remain operational using an asynchronous clock and can wake the device.

Refer to Low Power Mode Controllers for peripherals in the VDD_CORE_2.4G.

External signals via GPIO or VDD_SYS domain peripherals can wake the device.

Subdomains can choose VDD_CORE or IVS scaled voltage to match the required performance or leakage.

SRAM can also be individually configured as deep sleep or shutdown by software.

28.3.4 Power Down mode

Power Down mode places the chip in power off state.

The device wakes from Power Down mode through the reset routine.

In Power Down mode, the whole VDD_CORE_MAIN subdomain is power gated.

In Power Down mode, the peripherals inside the VDD_CORE_WAKE subdomain can optionally remain operational using an asynchronous clock and can wake the device.

Refer to Low Power Mode Controllers for peripherals in the VDD_CORE_2.4G.

External signals via GPIO, VDD_SYS domain peripherals, or the RTC power domain peripherals can wake the device.

SRAM can also be individually configured as retention or off by software.

28.3.5 Vbat on

For VBAT ON, refer to Smart power switch.

28.3.6 Deep Power Down mode

Deep Power Down mode permits the lowest power level.

The device wakes from Deep Power Down mode through the Reset routine.

In Deep Power Down mode, the whole VDD_CORE domain (including all subdomains) is power gated.

In Deep Power Down mode, the on-chip regulator for VDD_CORE is powered off. The VDD_SYS on-chip regulator is powered on , and the VDD_SYS power domain is enabled. The external power supply to any of the on-chip regulators that are disabled should be turned off to avoid extra leakage.

External reset or the VDD_SYS domain peripherals can wake the device.

SRAMs without RAM LDO supplied cannot be retained in Deep Power Down mode.

28.4 Module operation in low power modes

The following table shows module functionality in low power modes.

Table 224. Cortex M33 core module operation in low power modes

VDD_CORE_2P4G_SRAM [2]	ACT/RET/OFF	ACT/RET/OFF	ACT/RET/OFF	ACT/RET/OFF	OFF
VDD_SYS	ACT	ACT	ACT	ACT	ACT

1. System SRAM is partitioned and each part is individually configurable by CMC.
2. Radio SRAM is partitioned into Tx/Rx RAM and each part is individually configurable by Radio.

Since VDD_CORE_MAIN, VDD_CORE_WAKE and VDD_CORE_2P4G are independent power domain, there are various low-power mode combinations among them. The SPC will do the arbitration on their low-power requests and select the highest low-power mode as system power mode.

From system point of view, it has several scenarios:

1. MCU in low-power mode, Radio switch between run and low-power mode (typical case for Bluetooth LE event without CPU involved)
2. Radio wakeup MCU to deal with connectivity upper layer software like Bluetooth LE Host or applications
3. MCU switch between run and low-power mode for general application, Radio in low-power mode (Radio is not enabled)

28.5 Power supply configurations

This section shows some of the most common power supply configurations.

28.5.1 Recommended configuration for tradeoff between cost and power efficiency

The following figure shows a power efficient configuration of the device power supplies.

In this configuration:

- External 3.3 V for DCDC, VDD_IO_D, VDD_IO_ABC, LDO-SYS
- LDO-CORE, VDD_RF come from DCDC output
- Generate VPA_2P4GHZ internally from VDD_RF

NOTE

VPA_2P4GHZ voltage depends on Tx power level. It can be powered internally or externally. When internal supply is used, VDD_RF voltage must be equal to or exceed VPA + 275 mV.

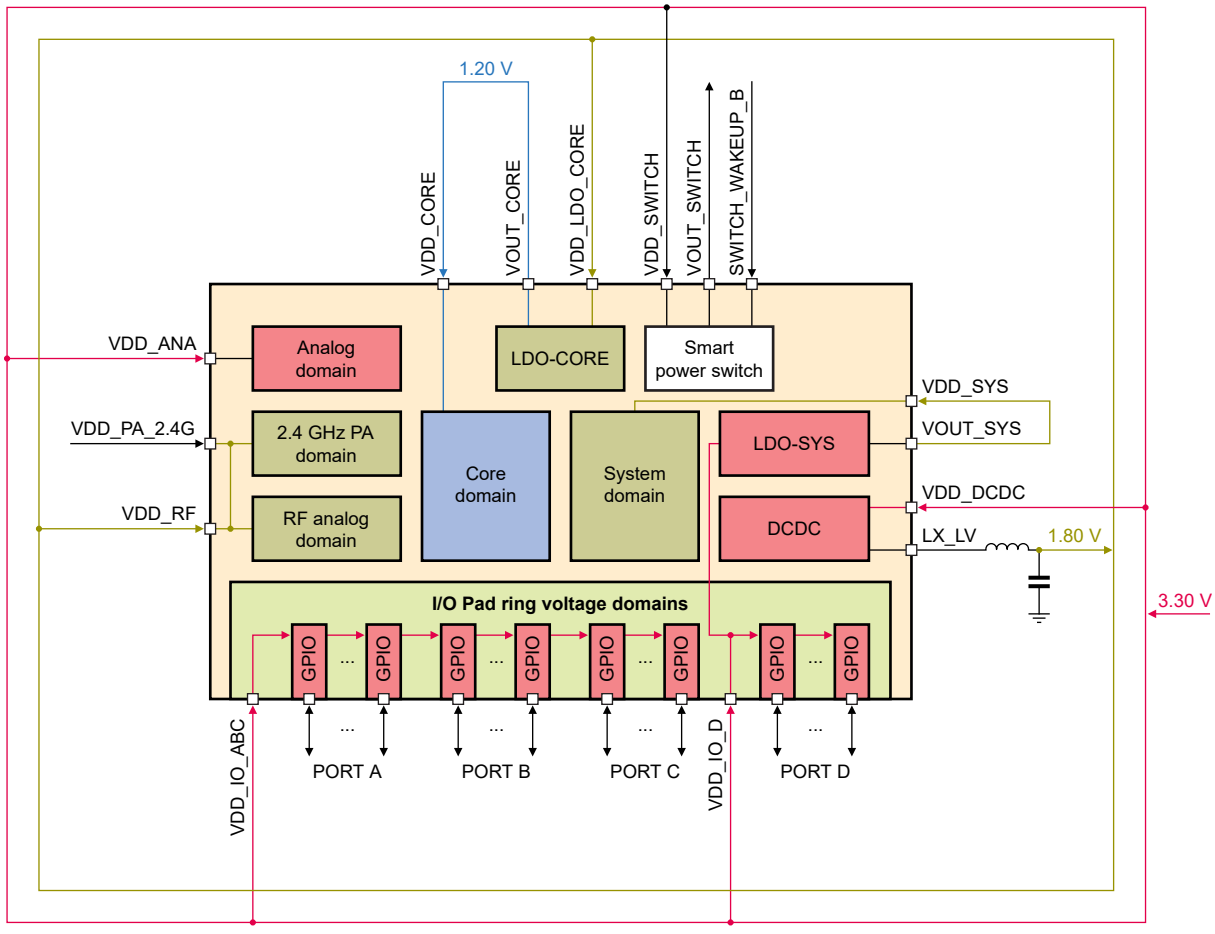

Figure 79. Power efficient schematic

28.5.2 Low cost supply configuration

The following figure shows a low cost configuration of the device power supplies.

In this configuration:

- Bypass DCDC
- External 3.3 V (range: 1.71 – 3.6 V) for LDO-CORE, LDO-SYS, VDD_IO_D, VDD_IO_ABC and VDD_RF
- Generate VPA_2PGHZ internally from VDD_RF

NOTE

VPA_2P4GHZ voltage depends on Tx power level. It can be powered internally or externally. When internal supply is used, VDD_RF voltage must be equal to or exceed VPA + 275 mV.

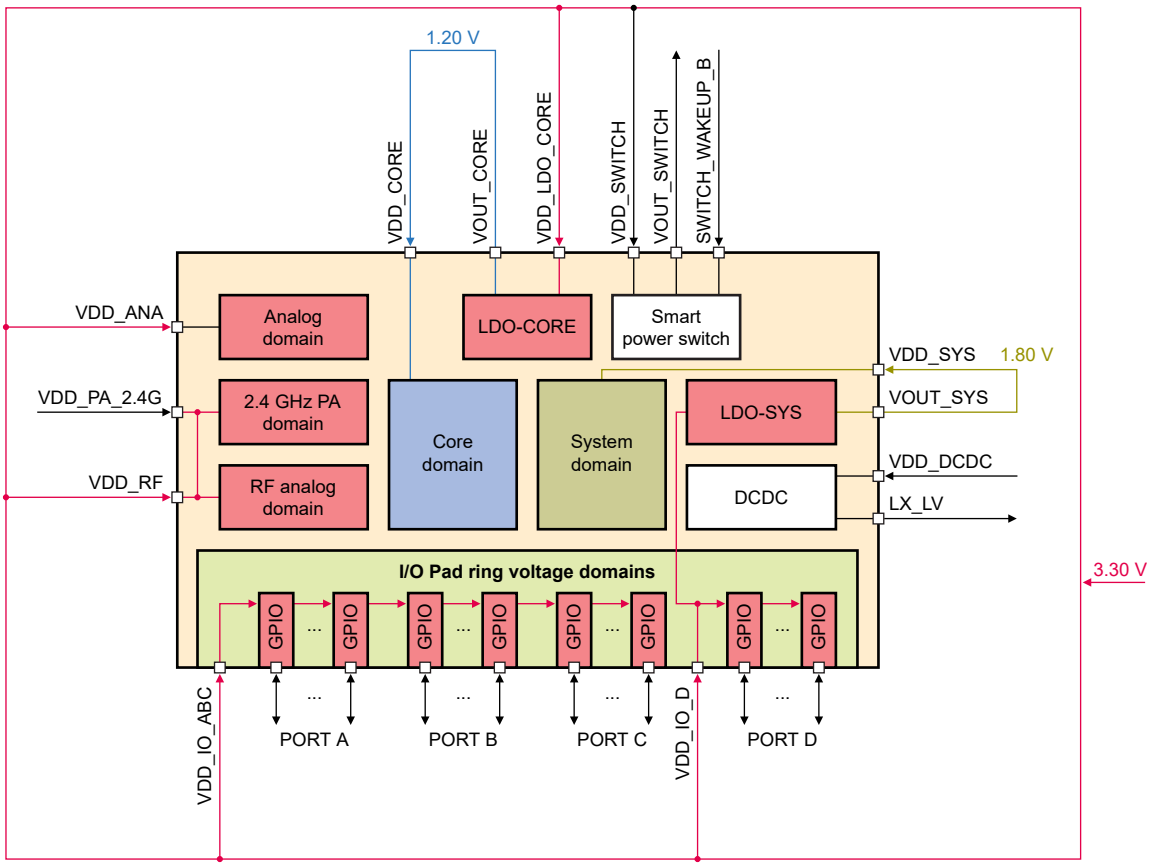

Figure 80. Low cost schematic

28.6 Power optimization

28.6.1 VDD_CORE voltage scaling

This device supports VDD_CORE voltage scaling for different performance and power consumption.

This device supports the following VDD_CORE voltage scaling methods:

- By adjusting VDD_CORE power supply input level directly with internal IVS disabled. This method is available for all power modes. The user must configure VDD_CORE voltage level through SPC registers when VDD_CORE is supplied by on-chip regulators (LDO-CORE). The device power consumption can benefit from the regulator high efficiency when DCDC is used as VDD_CORE source. However, the VDD_CORE voltage needs time to reach new levels for charging or discharging the VDD_CORE pin capacitor.

- By internal IVS (internal voltage scaling) module. This method will apply only to Deep Sleep and Power Down modes. The user should configure the target IVS output voltage level before entering low power modes. The VDD_CORE input voltage will remain unchanged. The IVS manipulates the internal supply voltage directly. The voltage will reach the new target value much faster.

Subdomains can choose VDD_CORE or IVS scaled voltage to match the required performance or leakage.

28.6.2 SRAM Configuration

The SRAM is partitioned, allowing the mode of each SRAM partition to be independently configured:

SRAM power mode	Description
Active	SRAM can be accessed normally.
Deep Sleep	SRAM cannot be accessed, but the data is retained.
Shutdown	SRAM cannot be accessed, and the data is not retained.

Depending on the requirements of the system application, software can optionally configure an individual SRAM partition to be in a lower, power-saving mode relative to the overall device power mode:

When the overall device power mode is...	An SRAM partition may be configured into this mode...
Active	Active or Shutdown
Sleep	Active or Deep Sleep or Shutdown
Deep Sleep or Power Down	Deep Sleep or Shutdown

NOTE

All SRAM partitions are forced into Shutdown mode after the device enters Deep Power Down mode.

28.6.3 Flash low power options

To balance power usage versus performance requirements, the flash module can be configured independent of the overall device power mode:

Flash power mode	Description
Full power	Supports full speed read, program and erase.
Low speed active	Supports reduced frequency read, program, and erase.

The flash module supports low-power feature by configuring CMC_FLASHCR registers. It can configure Flash in low-power mode when MCU is in Active mode or CM33 CORE is sleeping. In parallel, it provide option to automatic wakeup Flash from low-power mode when any flash access.

NOTE

To avoid unexpected access latencies, take care when configuring the flash module to a low power mode when the overall device is in Active mode. The flash module needs time to recover full-speed functionality after entering a low power mode.

28.6.4 Peripheral clock gating

To conserve power, the clocks to modules can be turned off or divided by configuring the MRCC module registers.

28.6.5 Voltage monitor optimization

Depending on the requirements of the system application, software can disable individual voltage monitors (LVD and/or HVD) within the different power domains to save power.

28.6.6 Wake-up time consideration

This device supports different low power modes for power consumption level and wake-up time balance.

The wake-up time from Sleep/Deep Sleep mode is the accumulation of following time:

- VDD_CORE power source recovery time
- The longer of the following:
  - Clock recovery time
  - Flash recovery time
- Interrupt Latency

The wake-up time from Power Down mode is the accumulation of following time:

- VDD_CORE power source recovery time
- The longer of the following:
  - Clock recovery time
  - Flash recovery time
- System Reset Latency

The wake-up time from Deep Power Down mode is:

- The boot-up time required after device released by POR. This includes everything included in a cold power-up, including the Boot ROM latency.

The clock recovery time can be affected by following factors:

- The system clock source status in low power modes. There will be no recovery time needed if the clock remains ON in low power mode.
- The system clock source before entering low power mode.

The flash recovery time depends on the flash status in low power mode.

The VDD_CORE power source recovery time can be affected by following factors:

- The regulator type used. On-chip linear regulator starts up faster than on-chip DCDC.
- The regulator status in low power modes. There will be no recovery time needed if the regulator remains in full-power regulation in low power mode.
- Whether VDD_CORE voltage scaling is enabled before and after entering low power modes
- The VDD_CORE domain voltage scaling method used. Voltage scaling by internal IVS recovers faster.
- The external capacitor on VDD_CORE pin will affect recovery time if scaling is achieved by adjusting VDD_CORE voltage directly.

28.7 Smart power switch

The smart power switch supports two major use-cases:

- It can be used to switch off all or part of MCU power supply to get lower power consumption than deep power down mode. See Figure 81 as an example.

- It can be used to power external device. For example, sensor device will be power off most of time and can keep power when measurement. Figure 79 is the example with the VOUT_SWITCH powering an external sensor, and Figure 82 is another example to power an external sensor and an I/O rail.

It has several ways to turn on power switch

- The POR of power switch input supply
- external SWITCH_WAKEUP_B pin. Once driven low, it can turn on power switch;
- internal wakeup logic from SPC if VSYS is powered ON;
- internal timer using internal FRO16K

NOTE

To support standby RAM LDO and RAM power switch, smart power switch input supply (VDD_SWITCH) is required to be powered permanently.

In Figure 81:

- External 3.3 V supply to Smart Power Switch
- Power switch output connected to DCDC, LDO-SYS, VDD_ANA, VDD_IO_D and VDD_IO_ABC
- DCDC output connected to LDO-CORE, VDD_RF

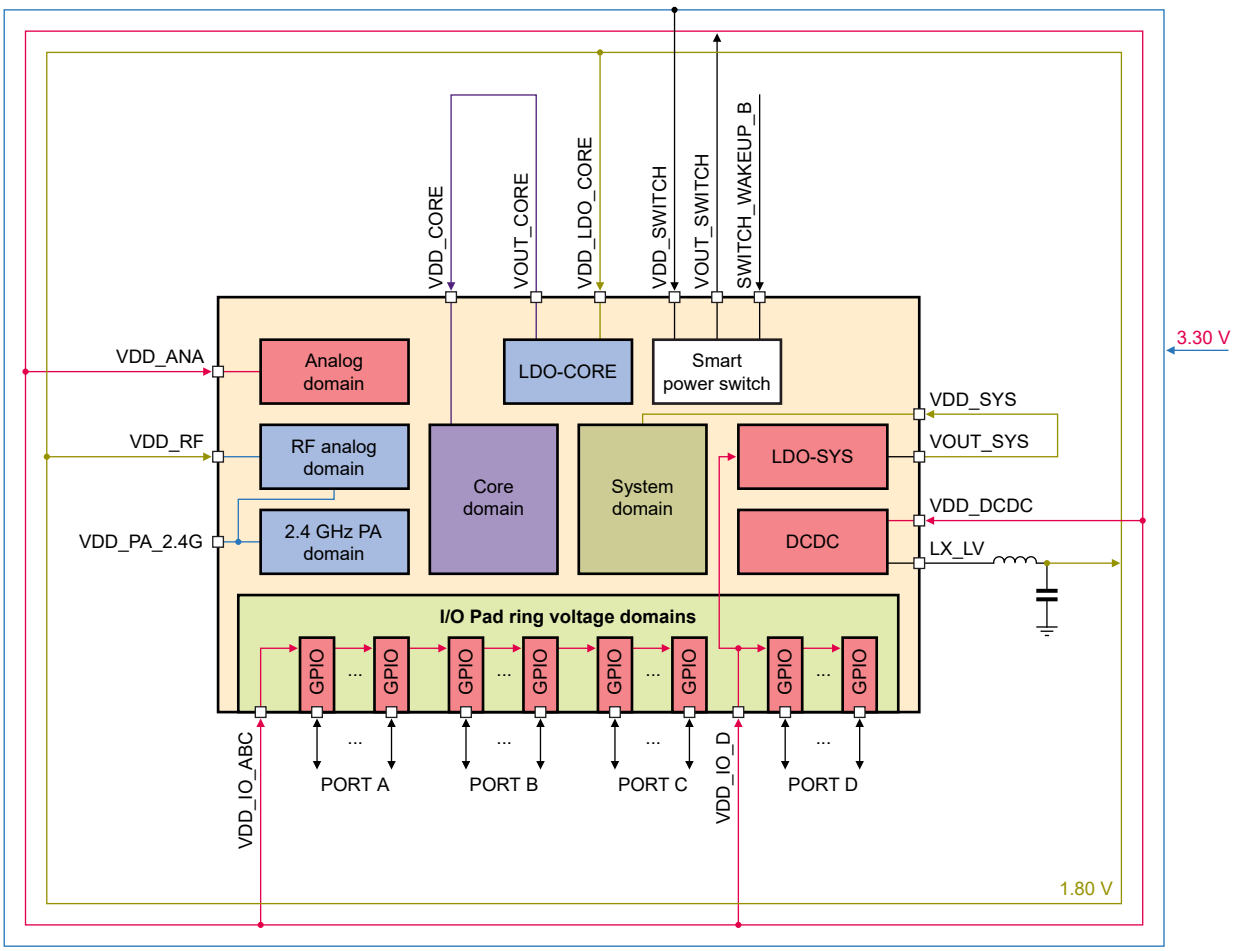

Figure 81. Power all supply

In Figure 82:

- External 3.3 V supply to Smart Power Switch and VDD_DCDC/VDD_IO_D
- Power switch output connected to VDD_ANA and VDD_IO_ABC
- DCDC output connected to LDO-CORE, VDD_RF

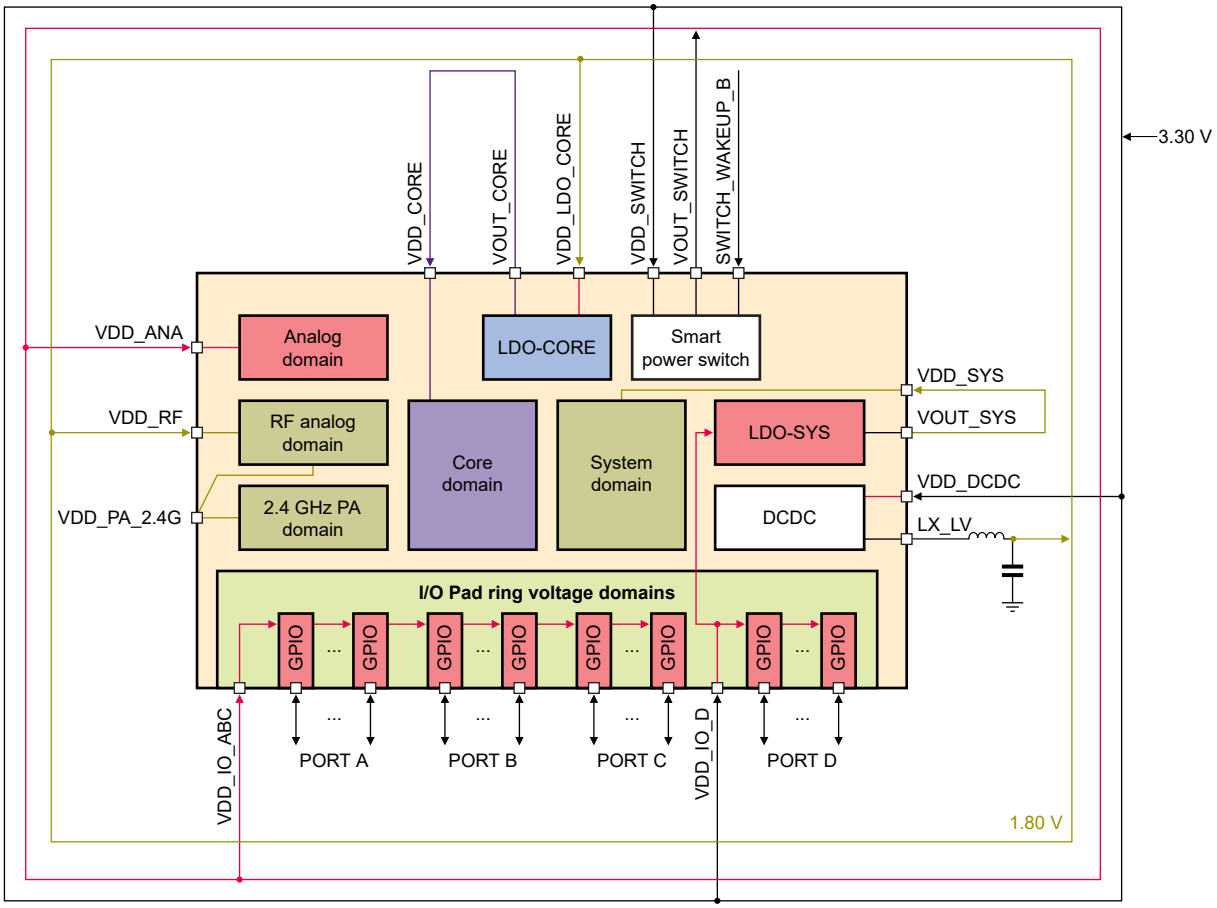

Figure 82. Power all supply except VDD_IO_D/VDD_DCDC

Figure 82 has a higher current drain relative to the scheme in Figure 81 because both VDD_IO_D and VDD_DCDC are on. However, the value of GPIO_D can be retained when the power switch is off.

29.2 Overview

CMC provides the sequencing of the CPU and associated logic through the different operating modes.

This chapter describes the available CPU operating modes, including reset, active mode, and low-power modes.

29.2.1 Block diagram

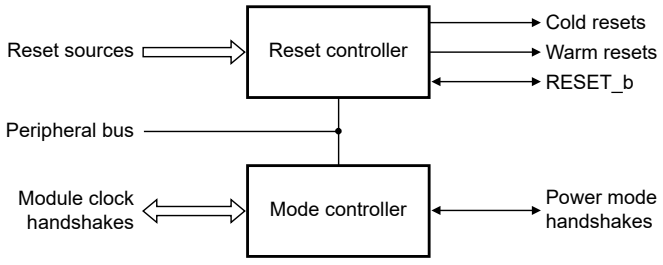

Figure 83. Block diagram

29.2.2 Features

- Configures the low-power mode options
- Provides reset controller including reset status register and warm reset configuration
- Provides boot mode register and status bits

29.3 Functional description

This section provides the functional description of the block.

29.3.1 Modes of operation

The Arm Cortex-M CPU enters a low-power mode with the execution of a WFI or WFE instruction or via the SLEEPONEXIT mechanism. CMC configures the low-power mode that is entered.

The following table describes the low-power modes available to each core.

Table 232. Operating modes

Mode	Entry	Exit	Description
Reset	POR Warm reset WUU via Power-Down	Active	Core and peripherals are reset. SRAM optionally retained on power-down wake-up.
Active	Reset NVIC WUU	WFI WFE SLEEPONEXIT	Core executing instructions, peripherals optionally active.
Sleep	WFI WFE SLEEPONEXIT	NVIC Reset	Core waiting for interrupt or event, peripherals optionally active. Core and peripherals retain state, SRAM optionally retained.
Deep Sleep	WFI WFE SLEEPONEXIT	WUU via Active Reset	Core and peripherals waiting for wake-up. Core and peripherals retain state, SRAM optionally retained.
Power-Down	WFI WFE SLEEPONEXIT	WUU via Reset Reset	Core and peripherals not retained, SRAM optionally retained.
Deep-Power Down	WFI WFE SLEEPONEXIT	WUU via Reset Reset	Core, peripherals, and SRAM not retained.

29.3.2 Active mode

This section describes power options in Active mode.

29.3.2.1 Flash memory

This section describes the Flash Memory Low-Power mode.

You can place the internal flash memory in Low-Power mode under the following conditions:

- Under software control (FLASHCR[FLASHDIS])
- When CPU is sleeping (FLASHCR[FLASHDOZE])
- When the chip enters a low-power mode

When FLASHCR[FLASHDIS] or FLASHCR[FLASHDOZE] becomes 1, you can configure the internal flash memory to automatically exit Low-Power mode during the access on any attempted read access to flash memory space (but not flash peripheral space). FLASHCR[FLASHWAKE] controls this.

When the internal flash memory enters a low-power mode, the wake-up time of the flash memory automatically delays the first access upon exit from Low-Power mode. If there is no access between the internal flash memory exiting Low-Power and subsequent re-entry of Low-Power mode, the wake-up time of the flash memory delays the re-entry.

29.3.2.2 System SRAM

The system SRAM is divided into 11 different power partitions. You can individually power gate these partitions either all the time or only in low-power modes. System SRAM contents in a power gated partition are not retained. You must not access system SRAM partitions when they are power gated.

- Write 1 to SRAMDIS[*i*] to always power gate system SRAM power partition "i".
- Write 1 to SRAMRET[*i*] to power gate system SRAM power partition "i" during a low-power mode only.

29.3.3 Low-power modes

This section describes the low-power modes.

29.3.3.1 Low-power entry

The following steps occur during the Low-Power mode entry sequence.

Table 233. Entry sequence

Step	CKMODE (min)	LPMODE (min)	Description
1	0h	0h	Core enters Low-Power mode by WFI/WFE instruction or via SLEEPONEXIT.
2	1h	0h	• Wake-up interrupt controller is enabled. • Core is clock gated.
3	3h	0h	• Request AHB initiators to enter Low-Power mode. • Wait for acknowledge. • AHB initiators are clock gated.
4	3h	0h	• Request AHB peripherals to enter Low-Power mode. • Wait for acknowledge. • AHB peripherals are clock gated.

Table continues on the next page...

Table 233. Entry sequence (continued)

Step	CKMODE (min)	LPMODE (min)	Description
5	7h	0h	• Request peripherals to enter Low-Power mode. • Wait for acknowledge. • Peripherals are clock gated.
6	Fh	0h	Request power management (regulators, bandgap) to enter Low-Power mode.
7	Fh	1h	• SRAMs enter Low-Power mode. • System clocks are gated.
8	Fh	3h	Power domain is placed in Low-Power retention state (Deep Sleep).
9	Fh	7h	Power domain is switched off (Power-Down).
10	Fh	Fh	Regulators are powered off (Deep Power-Down).

29.3.3.2 DMA wakeup

You can configure the DMA to generate a wake-up when a DMA request for configured channel asserts. This is supported when you request the DMA to enter Low-Power mode and retain the DMA state (not Power Down or Deep Power Down).

The DMA wakeup triggers an exit from Low-Power mode for everything except the core, which remains clock gated. Re-enter Low-Power mode after the DMA request negates, and the normal low-power mode entry sequence is followed.

Because a DMA wake-up results in everything except the core from exiting Low-Power mode, you must ensure that other modules not involved in the wakeup remain in a known state. To accomplish this, disable the modules before the initial entry in Low-Power mode or configure the Doze field in selected modules.

If the flash memory is not required during the DMA wakeup, NXP recommends that FLASHCR[FLASHDOZE] = 1.

NOTE

If the DMA request does not negate due to the DMA transfer, the chip remains in a higher power state until an interrupt or other wake-up sources can wakeup the core.

An interrupt that occurs during a DMA wakeup causes an immediate exit from Low-Power mode without affecting the DMA transfer.

29.3.3.3 Power domains

CMC configures Low-Power mode of 2 different power domains when the core enters a low-power mode with CKMODE = Fh. You can configure the different power domains to enter different low-power modes , but you must not configure the WAKE domain to a lower-power mode than any of the other domains.

NOTE

The WAKE domain LPMODE register setting must always be less than or equal to the LPMODE register setting for all other power domains.

CMC controls the following power domains:

- MAIN
- WAKE

The table below lists allowed combinations for MAIN and WAKE.

Table 234. Power Mode Combinations for MAIN and WAKE

CMC PMCTRLMAIN	CMC PMCTRLWAKE
0x0	0x0
0x1	0x1
0x3	0x3
0x3	0x1
0xF	0xF

Configure all power domains to the same Low-Power mode using Global Power Mode Control (GPMCTRL). Alternatively, configure each PMCTRL register to assign an individual low-power mode to each domain.

29.3.3.4 Debug in low-power modes

When the debugger asserts CDBGPWRUPREQ, it requests the debug logic to power up and enable the functionality depending on DBGCTL[SOD].

- When DBGCTL[SOD] = 0, the core clock remains enabled even when the core is sleeping (CKMODE = 0h). CDBGPWRUPACK remains asserted.
- When DBGCTL[SOD] = 1, ignore the debug request when the core sleeps. CDBPWRUPQACK negates when the core is sleeping.

NOTE

Do not attach a debugger when the JTAG/SWD logic is powered down.

29.3.4 Clocks

- The slow bus clock clocks CMC registers and logic.
- 1 MHz clock clocks the timeout counters.

29.3.5 Reset

This section describes the sources of reset and the different resets that you can generate.

29.3.5.1 Reset sources

This section describes the different reset sources.

Power-on reset (POR)

When you initially apply power to the MCU or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition.

The POR condition asserts a cold reset in all power domains. SRS[POR] and SRS[LVD] become 1 on a POR condition.

Low voltage detect (LVD)

The LVD circuit enables by default and keeps the MCU in reset until the supply voltage rises above the LVD rising threshold. When the LVD circuit is enabled, it triggers an LVD reset condition if the supply voltage is below the LVD falling threshold.

SRS[LVD] becomes 1 on an LVD reset condition. The LVD reset condition asserts a cold reset in all power domains. Only the LVD or HVD detection logic is unaffected by LVD or HVD resets.

High voltage detect (HVD)

The HVD circuit disables by default, but when enabled, it triggers an HVD reset condition if the supply voltage exceeds the HVD threshold.

SRS[HVD] becomes 1 on an HVD reset condition. The HVD reset condition asserts a cold reset in all power domains. Only the LVD or HVD detection logic is unaffected by LVD or HVD resets.

Wakeup (WAKEUP)

On a wakeup from Power Down or Deep-Power Down mode, the power management logic triggers a Wake-up reset in the power domains that had powered off.

The wake-up reset condition asserts a cold reset in all power domains that were powered down. The system power domain, including the RESET_b pin, is unaffected by a wake-up from Power Down or Deep-Power Down mode (unless another reset source triggers the wake-up). SRS[WAKEUP] becomes 1 on a wake-up reset condition.

External pin reset (RESET_b)

The RESET_b pin is a bidirectional open-drain pin with an internal pull-up resistor. The RESET_b pin function depends on the mode:

- During reset, the RESET_b drives low until the MCU completes initialization, at which point the RESET_b pin is released. If the RESET_b pin asserts externally, then the MCU remains in reset until the RESET_b input is pulled high.
- During active and low-power modes, the RESET_b pin can assert externally to force the MCU into the PIN reset condition.

The RESET_b pin implements a digital filter that you can configure to filter out glitches on the RESET_b pin that are less than 1–32 CMC clock cycles. The filter bypasses in low-power modes when you disable the CMC clock.

The PIN reset condition asserts a warm reset in all power domains. SRS[PIN] and SRS[WARM] become 1 on a PIN reset condition.

Debug access port reset (DAP)

Any debug access port that can initiate a reset request from a connected debugger triggers the DAP reset condition.

The DAP reset condition asserts a warm reset in all power domains. SRS[DAP] and SRS[WARM] become 1 on a DAP reset condition.

Reset timeout (RSTACK)

The reset state machine includes a timeout counter that is triggered by the reset state machine not progressing within 8192 cycles of the 1 MHz clock. This triggers the RSTACK reset condition.

The RSTACK reset condition asserts a warm reset in all power domains. SRS[RSTACK], SRS[FATAL], and SRS[WARM] become 1 on an RSTACK reset condition.

Low-power timeout (LPACK)

The low-power entry state machine includes a timeout counter that triggers if a module does not acknowledge entry into Low-Power mode after 8192 cycles of the 1 MHz clock. This triggers the LPACK reset condition.

The LPACK reset condition asserts a warm reset in all power domains. SRS[LPACK] and SRS[WARM] become 1 on an LPACK reset condition.

System clock generation (SCG)

The system clock generation includes loss of clock and loss of lock monitors that you can configure to generate a reset, this triggers the SCG reset condition.

The SCG reset condition asserts a warm reset in all power domains. SRS[SCG], SRS[FATAL], and SRS[WARM] become 1 on an SCG reset condition.

Watchdog 0 (WDOG0)

The watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WDOG0 reset condition.

The WDOG0 reset condition asserts a warm reset in all power domains. SRS[WDOG0] and SRS[WARM] become 1 on a WDOG0 reset condition.

Software (SW)

The software can request a system reset by configuring the system reset request in the Cortex-M33 core, this triggers the software reset condition.

The software reset condition asserts a warm reset in all power domains. SRS[SW] and SRS[WARM] become 1 on a software reset condition.

Lockup (LOCKUP)

The Cortex-M33 core enters Lockup state as a result of certain illegal operations, this triggers the LOCKUP reset condition.

The LOCKUP reset condition asserts an MCU reset in all power domains. SRS[LOCKUP] and SRS[WARM] become 1 on a LOCKUP reset condition.

Watchdog 1 (WDOG1)

The watchdog timer monitors the software by expecting periodic refreshing of the watchdog counter. When this does not occur, it triggers the WDOG1 reset condition.

The WDOG1 reset condition asserts a warm reset in all power domains. SRS[WDOG1] and SRS[WARM] become 1 on a WDOG1 reset condition.

Security violation (SECVIO)

When a security module detects a security violation, it triggers the SECVIO reset condition.

The SECVIO reset condition asserts a warm reset in all power domains. SRS[SECVIO], SRS[FATAL], and SRS[WARM] become 1 on a SECVIO reset condition.

29.3.5.2 Reset types

This section describes the different resets that you can generate.

Cold reset

Each power domain generates a cold reset to reset the debug logic and mode control logic. The cold reset for each power domain can assert as a result of the following events.

- Initial POR of the chip
- Voltage detect monitor (LVD, for example)
- Power domain wake-up from Power Down or Deep-Power Down (varies per domain)

A cold reset does not guarantee the contents of on-chip SRAM, except for a Power Down wake-up and then only for the SRAM that is configured to retain state.

Warm reset

- Cold Reset or any of the remaining warm reset sources generates a warm reset.
- A warm reset resets most of the logic in each power domain.
- Warm resets are divided into fatal reset sources and non-fatal reset sources.

You can configure the non-fatal reset sources to generate an interrupt instead of the warm reset. The warm reset averts if you can clear the non-fatal reset source (including status flag) within 8192 cycles of the 1 MHz clock. Non-fatal resets retain the contents of on-chip SRAM.

You cannot configure the fatal reset sources to generate an interrupt and do not guarantee the contents of on-chip SRAM.

29.3.5.3 Reset sequence

Power-on reset

Perform the following steps as part of the POR (or voltage detect monitor) sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. POR or LVD signals negate and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and their initialization sequences commence.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Read the ISP pin status and record it in the Mode (MR0) register.
8. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
9. Internal reset signals negate.
10. Core exits reset and fetches the initial program counter and stack pointer from ROM.

Deep-power down wake-up

Perform the following steps as part of the deep-power down wake-up sequence:

1. Internal reset signals asserted.
2. Wake-up signal negates and clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded.
7. Internal reset signals negate.
8. Core exits reset and fetches the initial program counter and stack pointer from ROM.

A wake-up from deep-power down via the RESET_b pin follows the warm reset sequence.

Power down wake-up

Perform the following steps as part of the power down wake-up sequence:

1. Internal reset signals asserted.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal trim registers are loaded.
5. Internal reset signals negate.
6. Core exits reset and fetches the initial program counter and stack pointer from ROM.

A wake-up from power down via the RESET_b pin follows the warm reset sequence.

Warm reset

Perform the following steps as part of the warm reset sequence:

1. RESET_b pin drives low and internal reset signals asserted.
2. Clocks are enabled in their default configuration.
3. Internal reset remains asserted for 8 CMC clock cycles.
4. Internal reset to flash memory and fuse controllers negates and commence their initialization sequences.
5. Initialization sequences for flash memory and fuse complete.
6. Internal trim registers are loaded and RESET_b pin is tri-stated.
7. Read the ISP pin status and record it in the Mode (MR0) register.
8. Reset state machine waits for RESET_b pin input to pull high or drive high externally.
9. Internal reset signals negate.
10. Core exits reset and fetches the initial program counter and stack pointer from ROM.

29.3.6 Interrupts

CMC generates a single interrupt, which System Reset Interrupt Enable (SRIE) configures.

29.4 External signals

Table 235. External signals

Signal	Description	Direction
RESET_B	Bidirectional open-drain reset pin with pullup that asserts low during warm reset except when waking up from a low-power mode.	Input or output
BOOT_CONFIGn	The input pin is sampled at the end of the RESET_B assertion and stored in Mode (MR0).	Input

29.5 Initialization

By default, the digital glitch filter is disabled on RESET_b pin. To enable the filter, configure:

- RPC[LPFEN], RPC[FILTEN], or both.
- RPC[FILTCFG].

29.6 Application information

To configure for Deep-Power Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 8h to Power Mode Protection (PMPROT)
3. Write Fh to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Power-Down Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 4h to Power Mode Protection (PMPROT)
3. Write 7h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 2h to Power Mode Protection (PMPROT)
3. Write 3h to Global Power Mode Control (GPMCTRL)
4. Execute WFI instruction

To configure for MAIN in power-down and WAKE in Deep Sleep Low-Power mode entry:

1. Write Fh to Clock Control (CKCTRL)
2. Write 3h to Power Mode Protection (PMPROT)
3. Write 3h to PMCTRLMAIN
4. Write 1h to PMCTRLWAKE
5. Execute WFI instruction

29.7 Memory map and register descriptions

This section describes the registers in the CMC module.

29.7.1 CMC register descriptions

NOTE

Different CMC registers reset on different reset types.

NOTE

You must read back the last register written to before executing the WFI instruction. This ensures that before the MCU enters the low power mode, all register writes associated with setting up the low power mode are complete, failure to do this may result in the low power mode not being entered correctly.

29.7.1.1 CMC memory map

CMC0 base address: 4000_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0302_0000h

110h	Core Control (CORECTL)	32	RW	0000_0000h
120h	Debug Control (DBGCTL)	32	RW	0000_0000h

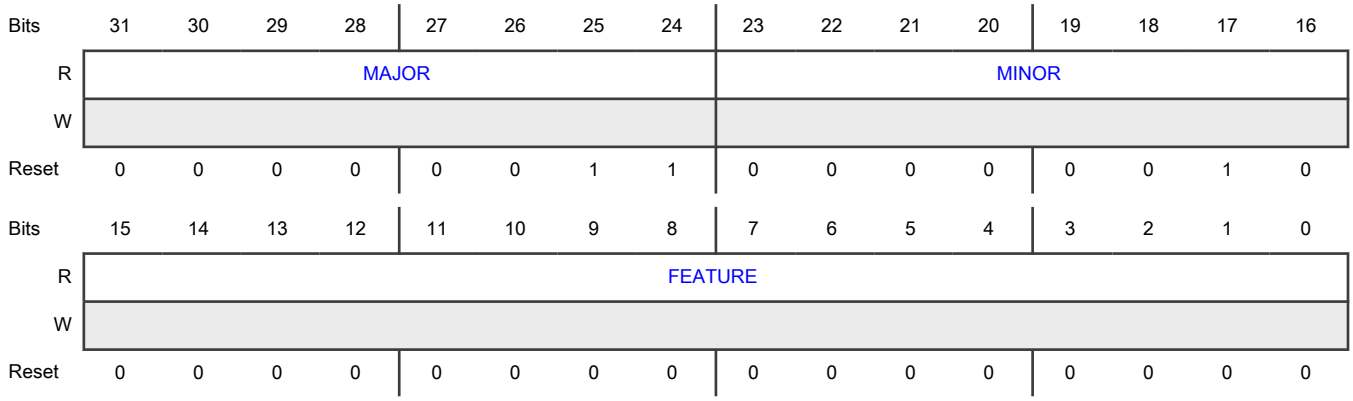
29.7.1.2 Version ID (VERID)

Offset

Register	Offset
VERID	0h

Function
Contains version numbers for module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15-0 FEATURE	Feature Specification Number Returns the feature set number.

29.7.1.3 Clock Control (CKCTRL)

Offset

Register	Offset
CKCTRL	10h

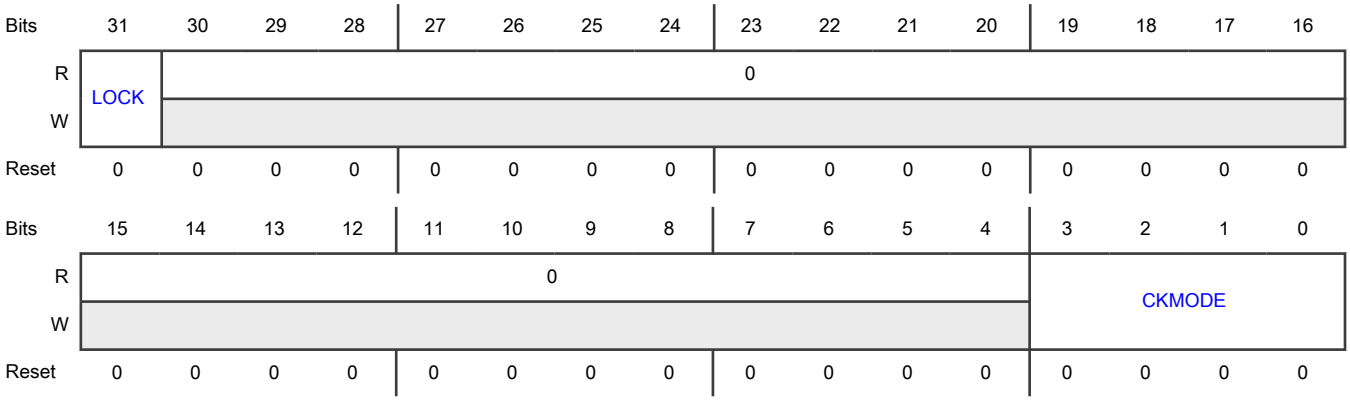
Function

Configures the amount of clock gating when the core asserts sleeping due to WFI, WFE, or SLEEPONEXIT.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31 LOCK	Lock Locks the register and blocks writes until the next reset. 0b - Allowed 1b - Blocked
30-4 —	Reserved
3-0 CKMODE	Clocking Mode Configures the amount of clock gating when the core enters a low-power mode because of WFI, WFE or SLEEPONEXIT. Configuring CKMODE > 0 requires the SLEEPDEEP field in the Arm core to become 1. Configuring PMCTRLx[LPMODE] > 0 requires writing Fh to CKMODE. 0000b - Core clock is on 0001b - Core clock is off 0011b - Core and platform clocks are off 0111b - Core, platform, and peripheral clocks are off, but no change in Low-Power mode 1111b - Core, platform, and peripheral clocks are off, and core enters Low-Power mode

29.7.1.4 Clock Status (CKSTAT)

Offset

Register	Offset
CKSTAT	14h

Function

Returns the clock gating status and wake-up source from the previous Low-Power mode entry, provided the core was clock gated. This requires configuring CKCTRL[CKMODE] > 0 and the wake-up event must occur after the core is clock gated. The register contents are only valid when CKSTAT[VALID] = 1.

NOTE

This register resets on WAKE warm reset.

Diagram

30-15 —	Reserved
14-8 WAKEUP	Wake-up Source Returns any wake-up sources from the previous Low-Power mode entry. [0] - Wake-up source is reset interrupt or wakeup from Deep Power-Down [1] - Wake-up source is debug request [2] - Wake-up source is interrupt [3] - Wake-up source is DMA wakeup [4] - Wake-up source is WUU request [5] - Wake-up source is bus master wakeup [6] - Wake-up source is bus master wakeup A wakeup from Power-Down or Deep Power-Down writes 1 to WAKEUP[0]. Depending on Low-Power mode, other wake-up bits may not become 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	Reserved
3-0 CKMODE	Low Power Status Returns the result of the previous Low-Power mode entry. 0000b - Core clock is on 0001b - Core clock is off 0011b - Core and platform clocks are off 0111b - Core, platform, and peripheral clocks are off, but no change in Low-Power mode 1111b - Core, platform, and peripheral clocks are off, and core enters Low-Power mode All other values are reserved.

29.7.1.5 Power Mode Protection (PMPROT)

Offset

Register	Offset
PMPROT	18h

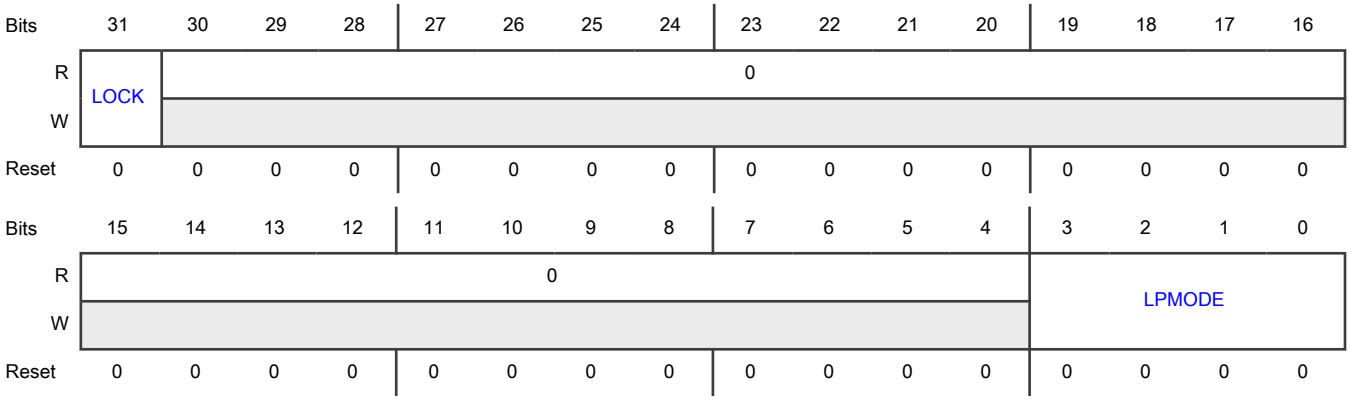
Function

Provides protection for entry in low-power modes, you must allow a low-power mode before configuring any Power Mode Control register (PMCTRLx) to that mode.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31 LOCK	Lock Register Locks the register and blocks writes until the next reset. 0b - Allowed 1b - Blocked

Fields

Field	Function
31-10 —	Reserved
9 LPFEN	Low-Power Filter Enable Enables the low-power reset pin filter in both Active and Low-Power modes when this field = 1. The RESET_b pin must assert for more than three 32.768 KHz clock cycles to always propagate through the filter. A glitch less than two 32.768 KHz clock cycles never propagates through the filter. 0b - Disables 1b - Enables
8 FILTEN	Filter Enable Enables the slow clock reset pin filter in Active modes. The RESET_b pin must assert for more than FILTCFG + 1 slow system clock cycles to always propagate through the filter. A glitch less than FILTCFG slow system clock cycles never propagates through the filter. If RPC[LPFEN] also becomes 1, then the filters operate in series. 0b - Disables 1b - Enables
7-5 —	Reserved
4-0 FILTCFG	Reset Filter Configuration Configures the reset pin filter's width from 1 to 32 slow system clock cycles.

29.7.1.10 Sticky System Reset Status (SSRS)

Offset

Register	Offset
SSRS	88h

Function

Stores all sources of system reset that has generated a system reset since the last WAKE cold reset and that you have not cleared. SSRS does not update following a core software reset.

NOTE

This register resets on WAKE cold reset.

29.7.1.11 System Reset Interrupt Enable (SRIE)

Offset

Register	Offset
SRIE	8Ch

Function

Delays the assertion of a system reset for 8194 cycles of the 1 MHz clock when an interrupt is generated. This allows you to perform a graceful shutdown or to abort the warm reset provided you can clear the pending reset source by resetting the source and then clearing the pending flag. This feature cannot delay a cold or fatal warm reset source. System Reset Status (SRS) updates after the warm reset occurs.

The reset interrupt is not supported in Power Down or Deep-Power Down mode.

NOTE

This register is reset on WAKE Cold Reset.

Fields

Field	Function
31-8 —	Reserved
7-0 COUNT	Count Number of reset sequences completed since the last WAKE Cold Reset. When the count reaches the maximum value, it will saturate and no longer increment.

29.7.1.14 Mode (MR0)

Offset

Register	Offset
MR0	A0h

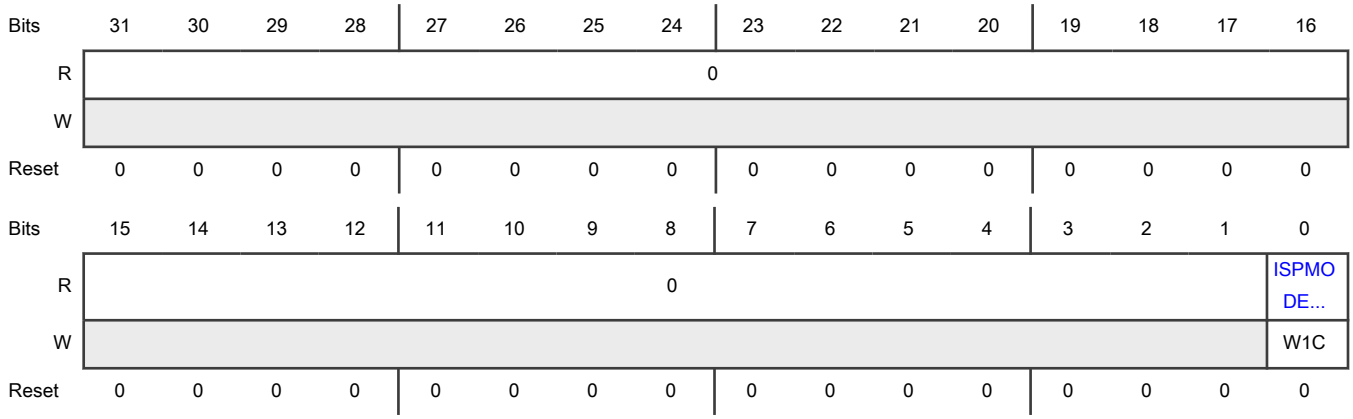
Function

Contains the state of the boot mode pins sampled at the end of the reset.

NOTE

This register resets on WAKE warm reset, and the reset value may vary depending on the pin state.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ISPMODE_n	Boot Configuration Returns the logic state of the BOOT_CONFIGn pin on the last negation of RESET_b pin.

29.7.1.15 Force Mode (FM0)

Offset

Register	Offset
FM0	B0h

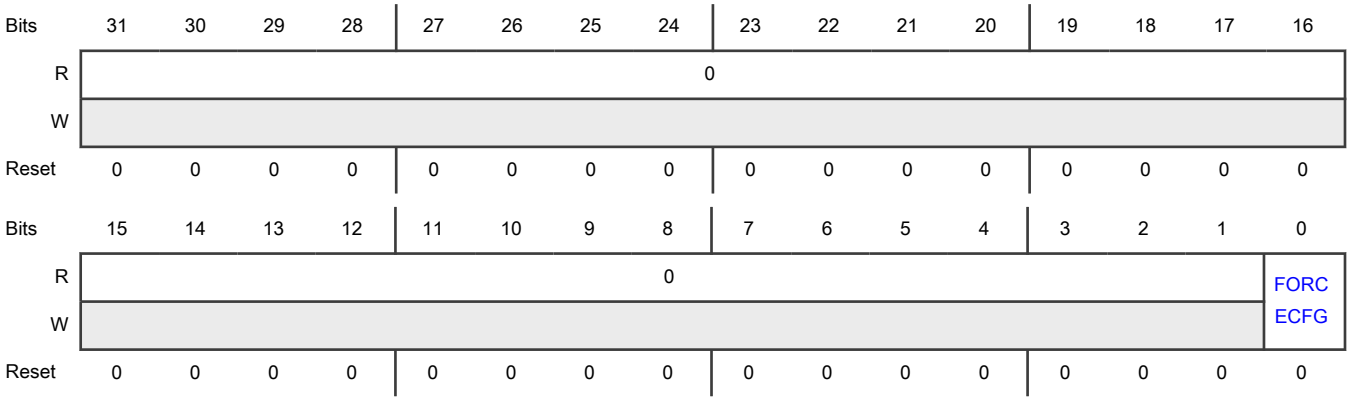
Function

Contains registers that override the state of the boot mode pins.

NOTE

This register resets on WAKE cold reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 FORCECFG	Boot Configuration Forces the corresponding field in Mode (MR0) to assert on next system reset. 0b - No effect 1b - Asserts

29.7.1.16 SRAM Disable (SRAMDIS0)

Offset

Register	Offset
SRAMDIS0	C0h

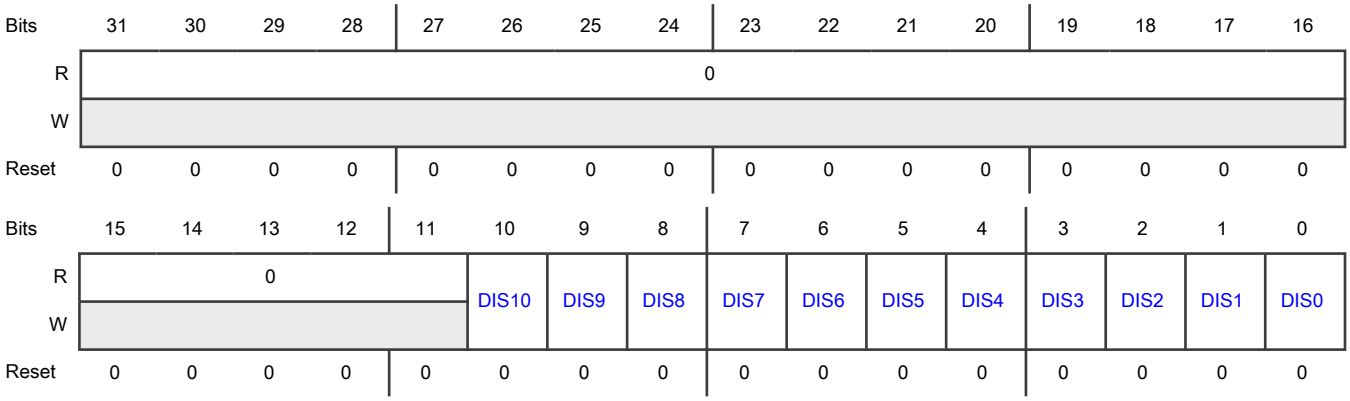
Function

Powers off the specific on-chip System SRAM arrays whenever the corresponding register field becomes 1. You must not access the SRAM array and also do not retain the SRAM array contents.

NOTE

This register resets on MAIN warm reset.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-0 DISn	Shut Down Enable **NOTE** See the chip-specific CMC section for register bit details.

29.7.1.17 SRAM Retention (SRAMRET0)

Offset

Register	Offset
SRAMRET0	D0h

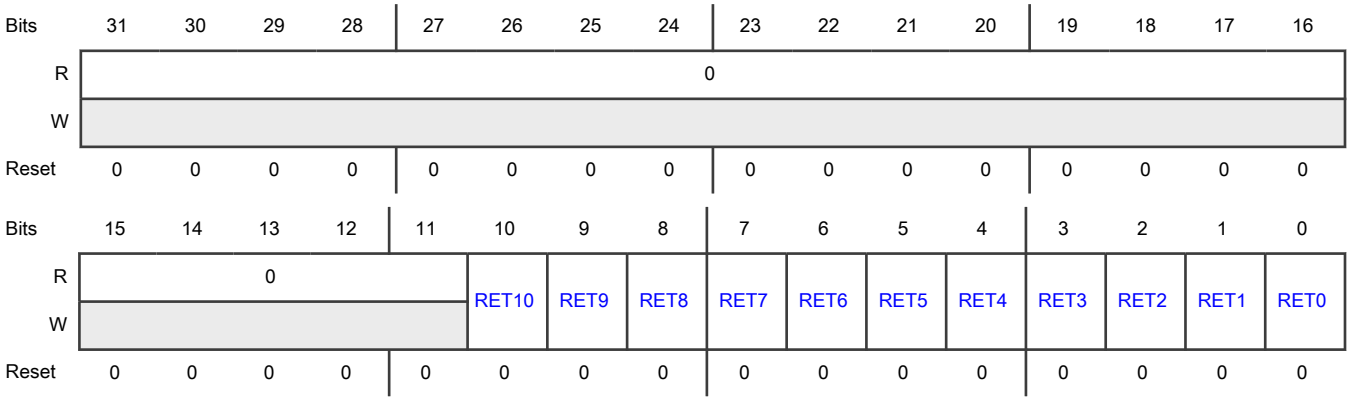
Function

Configures if the on-chip System SRAM arrays are retained or powered off in low-power modes.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-0 RETn	Deep Sleep Enable Controls whether the SRAM array is retained or powered off in Low-Power modes. **NOTE** You cannot retain SRAM arrays in Low-Power modes if their power domain is switched off. See the chip-specific CMC section for register bit details.

29.7.1.18 Flash Control (FLASHCR)

Offset

Register	Offset
FLASHCR	E0h

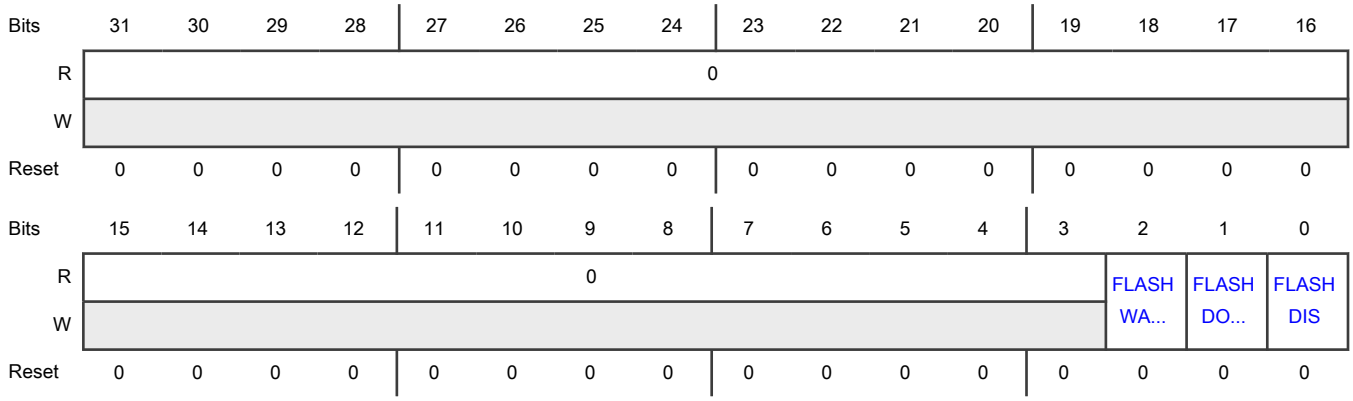
Function

Controls Low-Power mode of the on-chip flash memory.

NOTE

This register resets on WAKE warm reset.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 FLASHWAKE	Flash Wake Specifies that when this field becomes 1, an attempt to read the flash memory when it is in Low-Power state because of FLASHCR[FLASHDIS] or FLASHCR[FLASHDOZE], causes the flash memory to exit Low-Power state for the duration of the flash memory access. 0b - No effect 1b - Flash memory is not disabled during flash memory accesses
1 FLASHDOZE	Flash Doze Disables flash memory accesses and places flash memory in Low-Power state whenever the core clock is gated (CKMODE > 0) because of execution of WFI, WFE, or SLEEPONEXIT. Other bus masters that attempt to access the flash memory stalls until the core is no longer sleeping. 0b - No effect 1b - Flash memory is disabled when core is sleeping (CKMODE > 0)
0 FLASHDIS	Flash Disable Places flash memory in Low-Power state when this field becomes 1. Relocate the interrupts out of flash memory before disabling it. 0b - No effect 1b - Flash memory is disabled

29.7.1.19 Device Initialization Error Register (DIER)

Offset

Register	Offset
DIER	F0h

Function

This registers contains status flags to indicate if any errors occurred during the reset initialization sequence.

NOTE

This register resets on WAKE warm reset.

Diagram

31-0 STAT	Device initialization status flags **NOTE** See the chip-specific CMC section for register bit details.

29.7.1.20 BootROM Lock Register (BLR)

Offset

Register	Offset
BLR	FCh

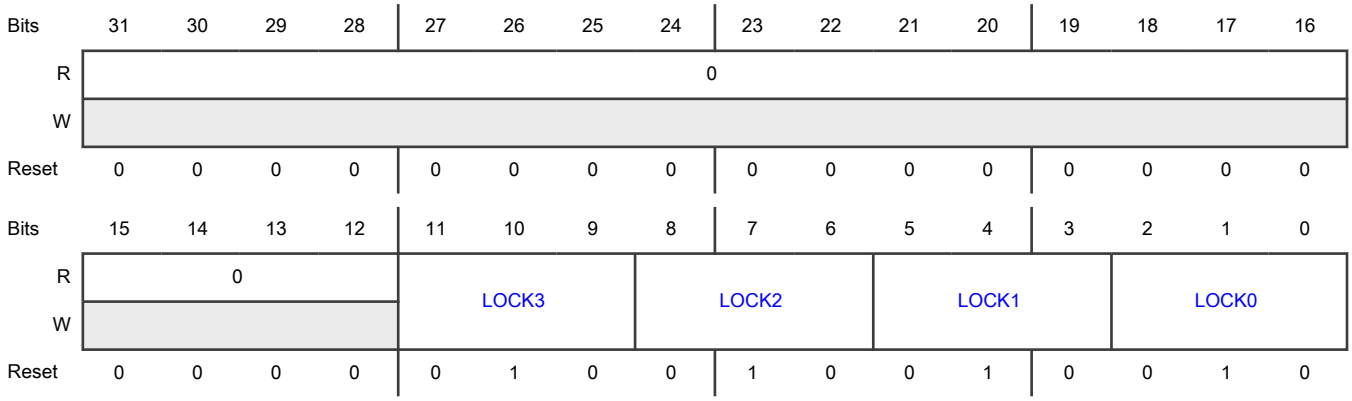
Function

The BootROM Lock Register can only be written using 32-bit writes and provided the BootROM Lock Register equals its reset value.

NOTE

This register is reset on MAIN Warm Reset.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-9 LOCK3	Lock Scratch 3 The corresponding BootROM Scratch Register can only be written when the Lock field equals 010. All other values are reversed and will lock the scratch register. 010b - BootROM Scratch Register can be written 101b - BootROM Scratch Register cannot be written
8-6 LOCK2	Lock Scratch 2 The corresponding BootROM Scratch Register can only be written when the Lock field equals 010. All other values are reversed and will lock the scratch register. 010b - BootROM Scratch Register can be written 101b - BootROM Scratch Register cannot be written
5-3 LOCK1	Lock Scratch 1 The corresponding BootROM Scratch Register can only be written when the Lock field equals 010. All other values are reversed and will lock the scratch register. 010b - BootROM Scratch Register can be written 101b - BootROM Scratch Register cannot be written
2-0 LOCK0	Lock Scratch 0 The corresponding BootROM Scratch Register can only be written when the Lock field equals 010. All other values are reversed and will lock the scratch register. 010b - BootROM Scratch Register can be written 101b - BootROM Scratch Register cannot be written

29.7.1.21 BootROM Scratch Register (BSR0 - BSR3)

Offset

Register	Offset
BSR0	100h
BSR1	104h
BSR2	108h
BSR3	10Ch

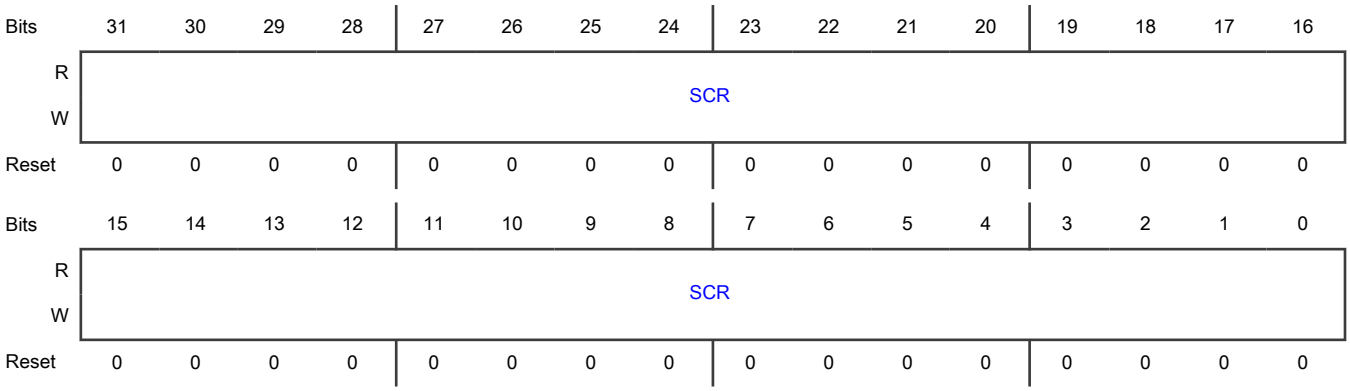
Function

This register can only be written using 32-bit writes and provided the corresponding field in BootROM Lock Register equals 010.

NOTE

This register resets on WAKE cold reset.

Diagram



Fields

Field	Function
31-0 SCR	Register used by the BootROM **NOTE** See the BootROM section of the security reference manual for details.

29.7.1.22 Core Control (CORECTL)

Offset

Register	Offset
CORECTL	110h

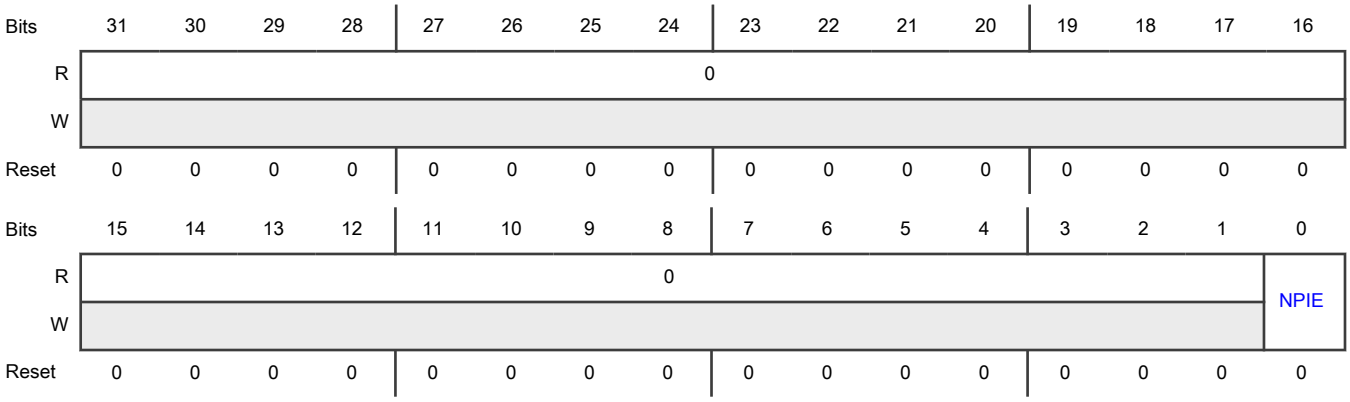
Function

Configures options for the core.

NOTE

This register resets on MAIN warm reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 NPIE	Non-maskable Pin Interrupt Enable Enables or disables the pin interrupt. You can write to this field only when NPIE = 0. 0b - Disables 1b - Enables

29.7.1.23 Debug Control (DBGCTL)

Offset

Register	Offset
DBGCTL	120h

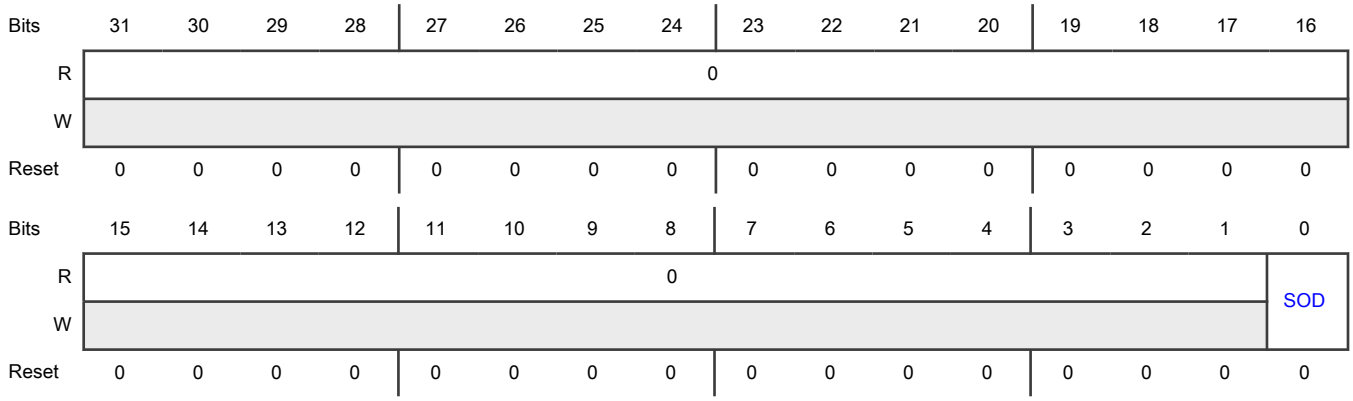
Function

Configures options for debug.

NOTE

This register resets on WAKE cold reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SOD	Sleep Or Debug Configures whether the debug remains enabled when core sleeps. 0b - Remains enabled 1b - Disabled

Chapter 30
System Power Control (SPC)

30.1 Chip-specific SPC information

Table 236. Reference links to related information

Topic	Related module	Reference
Full description	SPC	SPC
System memory map		System memory map
Power Management		Power Management
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing
Reset		Reset

NOTE

The "switch" in this chapter refers to the "smart power switch" in the Power Management.

30.1.1 Module instances

- This device has one instance of the SPC module, SPC0.
- If the LPCMP is being used in DPDOWN then the low power IREF must remain enabled.

30.1.2 Voltage regulators

This section describes the various on-chip regulators.

Table 237. On-chip regulators

Regulator name	Description
DCDC_LV	The DCDC_LV can be used to power VDD_SYS domain. It can power the IO ring, other on-chip modules, and external components as well. However, user should take care that the total load current doesn't exceed the maximum capacity.
LDO_CORE	The LDO_CORE can be used to power VDD_CORE domain.
LDO_SYS	The LDO_SYS can be used to power VDD_SYS domain. It can power the IO ring, other on-chip modules, and external components as well. However, user should take care that the total load current doesn't exceed the maximum capacity.

30.1.3 Voltage monitors

30.1.3.1 VDD_SYS voltage monitors

The following sections describe the voltage monitors inspecting the VDD_SYS supply.

30.1.3.1.1 Power-On-Reset (POR)

During power-on, the POR keeps the device under reset until the VDD_SYS supply voltage reaches the specified threshold. When VDD_SYS is above the VPOR limit, the device POR reset is released. However, the device stays in reset until the LVD on VDD_SYS is released.

30.1.3.1.2 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on VDD_SYS input voltage. The LVD monitors the VDD_SYS power supply voltage by comparing it to a programmable threshold. When VDD_SYS drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The VDD_SYS LVD circuit is ON by default. The user can disable the VDD_SYS LVD through software.

30.1.3.1.3 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on VDD_SYS input voltage. The HVD monitors the VDD_SYS power supply voltage by comparing it to a programmable threshold. When VDD_SYS rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The VDD_SYS HVD circuit is OFF by default. The user can enable the VDD_SYS HVD through software.

30.1.3.2 VDD_CORE voltage monitors

The following sections describe the voltage monitors for the VDD_CORE supply.

30.1.3.2.1 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on VDD_CORE input voltage. The LVD monitors the VDD_CORE power supply voltage by comparing it to a programmable threshold. When VDD_CORE drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The VDD_CORE LVD circuit is ON by default. The user can disable the VDD_CORE LVD through software.

30.1.3.2.2 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on VDD_CORE input voltage. The HVD monitors the VDD_CORE power supply voltage by comparing it to a programmable threshold. When VDD_CORE rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The VDD_CORE HVD circuit is OFF by default. The user can enable the VDD_CORE HVD through software.

30.1.3.3 VDD_IO_ABC voltage supply monitors

The following sections describe the voltage monitors for the power supply that powers PORTA, PORTB and PORTC.

30.1.3.3.1 Low Voltage Detect

This device integrates a Low Voltage Detector (LVD) circuit on the input voltage that powers PORTA. The LVD monitors that power supply voltage by comparing it to a programmable threshold. When input voltage powering PORTA drops below the threshold, the user has the option of generating an LVD reset or an LVW interrupt. The LVD circuit for this power supply is ON by default. The user can disable the LVD through software.

30.1.3.3.2 High Voltage Detect

This device integrates a High Voltage Detector (HVD) circuit on the input voltage that powers PORTA. The HVD monitors that power supply voltage by comparing it to a programmable threshold. When the input voltage powering PORTA rises above the threshold, the user has the option of generating an HVD reset or an HVW interrupt. The HVD circuit for this power supply is OFF by default. The user can enable the HVD through software.

30.1.4 SC[ISO_CLR] bits

Each bit in the SC[ISO_CLR] field controls the ISO for one of the chip LV power domains:

- Bit 16 - Core Main domain
- Bit 17 - Core Wake domain
- Bit 18 - Core Radio domain

Refer to Power domains for more details.

30.1.5 EVD_CFG[EVDISO], EVD_CFG[EVDLPISO], and EVD_CFG[EVDSTAT] fields

Each bit of the EVDISO, EVDLPISO, and EVSTAT fields corresponds to one of the IO or analog supplies.

- [0] - VDD_IO_ABC
- [1] - VDD_IO_D
- [2] - VDD_ANA

30.1.6 SRAMCTL[VSM] field

For this device, the VSM has only two options.

- [01b] - SRAM configured for 1.0 V operation and the values in SRAM_TMTR1 is loaded for the read/write timing margin
- [10b] - SRAM configured for 1.1 V operation and the values in SRAM_TMTR2 is loaded for the read/write timing margin

Follow the steps below to change the SRAM settings, refer to Active mode voltage updates for more details.

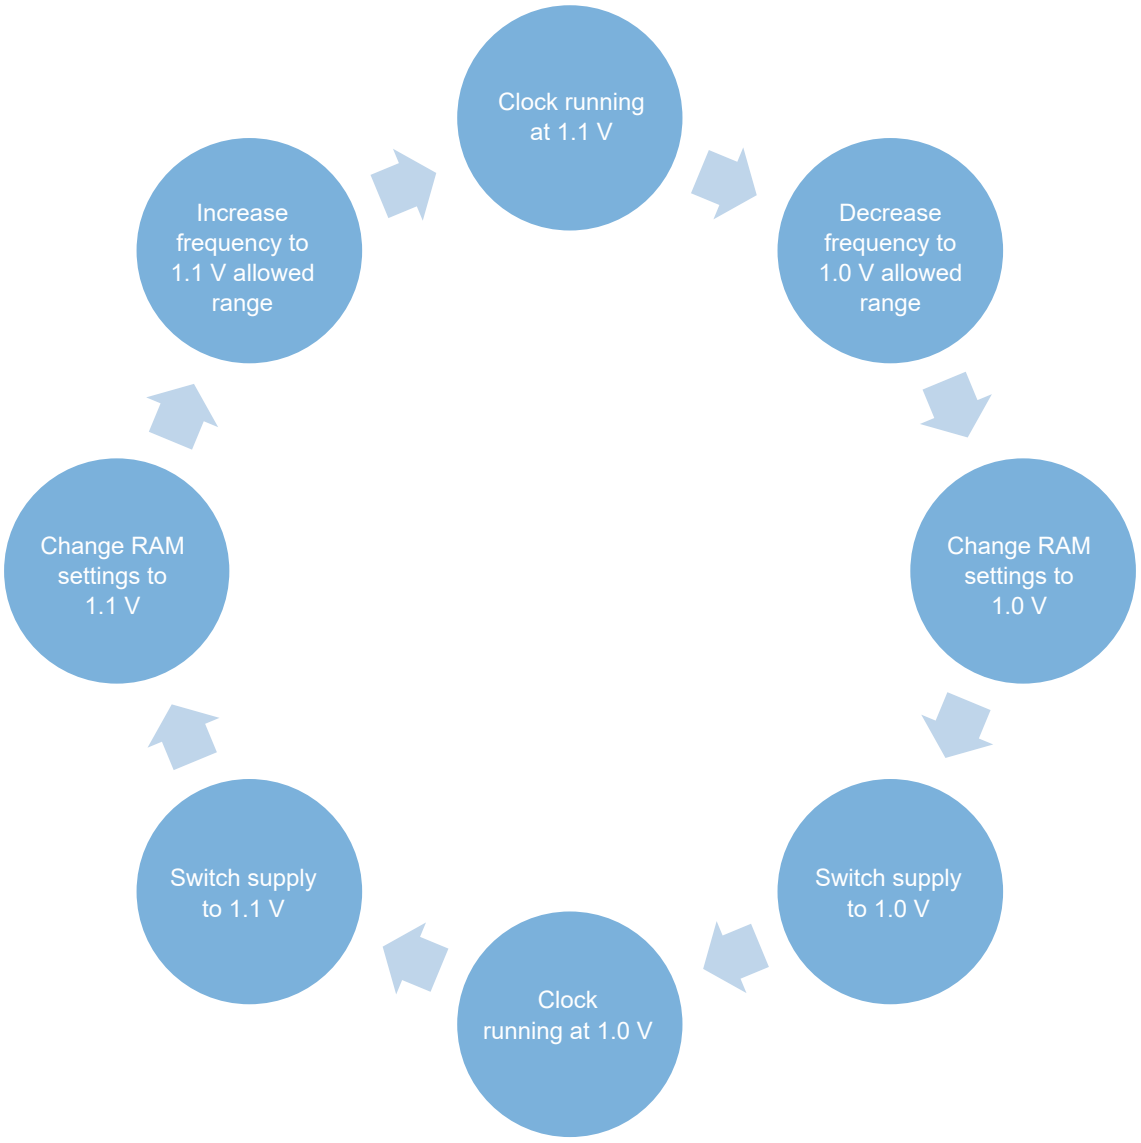


Figure 84. SRAM settings change steps

30.1.7 LP_CFG[IO_HVDE] field

If the LP_CFG[IO_HVDE] is set to 1, it monitors VDD_IO_ABC on PORTA, PORTB and PORTC.

30.1.8 DCDC pulsed mode clocking

DCDC can optionally enter in DCDC pulsed mode. In DCDC pulsed mode, the DCDC refresh period is based on a clock counter which is feed by the 32K_CLK clock in this device.

30.2 Overview

SPC contains and controls the following components:

- Regulator for SRAM domain providing the retention voltage to SRAM array in low power modes.
- Two low-drop-out (LDO) voltage regulators (LDO_CORE and LDO_SYS)

- One DCDC used for regulating system, core, and radio power
- Circuits that monitor and assure correct voltage levels:
  - Power-on reset (POR)
  - Low-voltage detect (LVD)
  - Analog glitch detector
  - High-voltage detect (HVD)

SPC turns these components on and off, and switches them to different power mode levels based on power-mode change requests from each chip power domain.

30.2.1 Block diagram

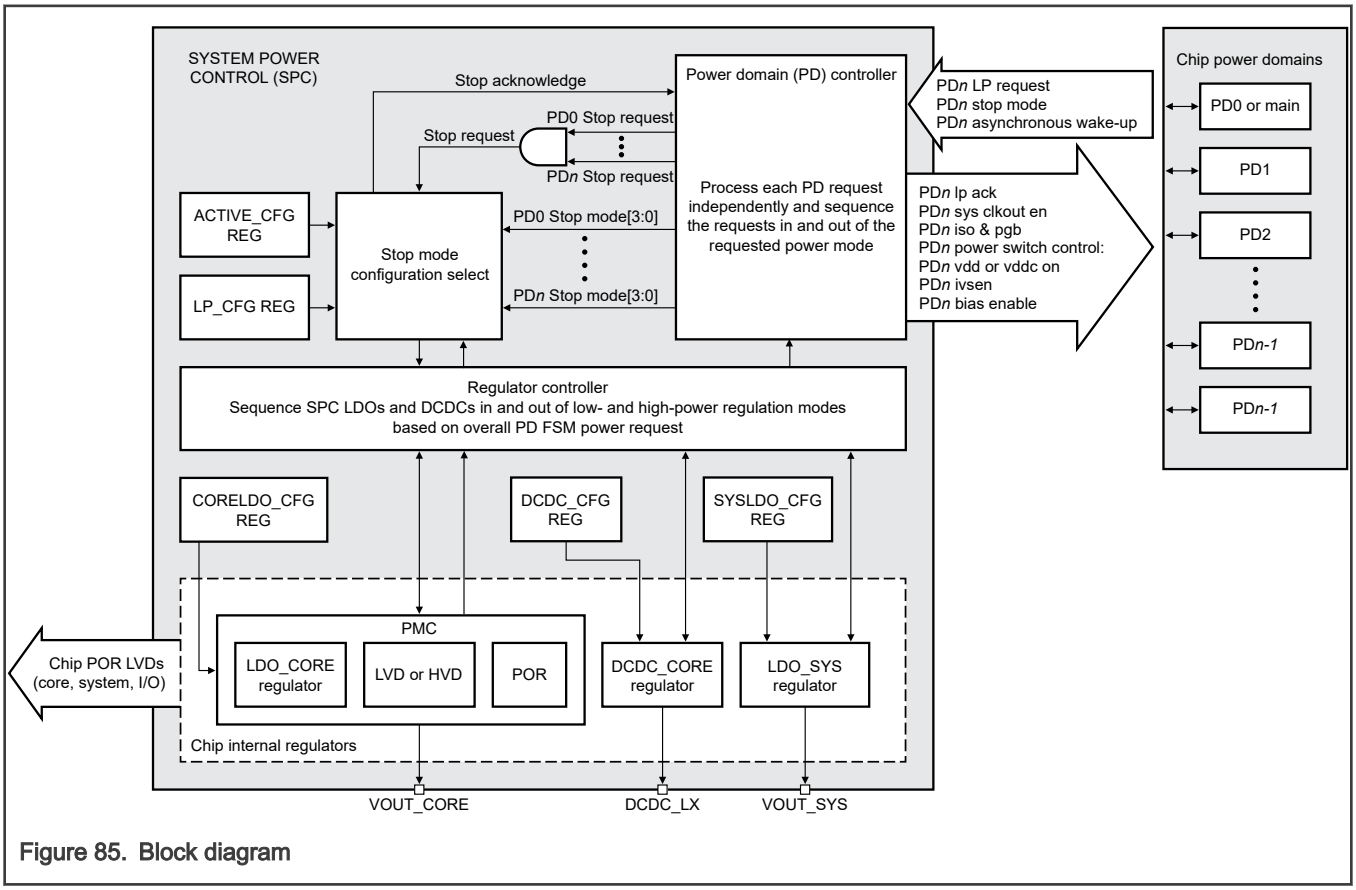

Figure 85. Block diagram

30.2.2 Features

- Selectable core internal voltage regulator (LDO_CORE or DCDC)
- Selectable system internal voltage regulator (1.8 V LDO_SYS)
- Radio voltage regulator (1.8 V LDO_SYS or 1.8 V DCDC)
- Active POR providing brown-out detect
- Low-voltage detect
- High-voltage detect
- Core power gate control
- Analog glitch detector

30.3 Functional description

30.3.1 Power mode transitions

Figure 86 shows the power mode state transitions available for each power-down domain. A POR or LVD reset initially returns the power-down domains to ACTIVE state.

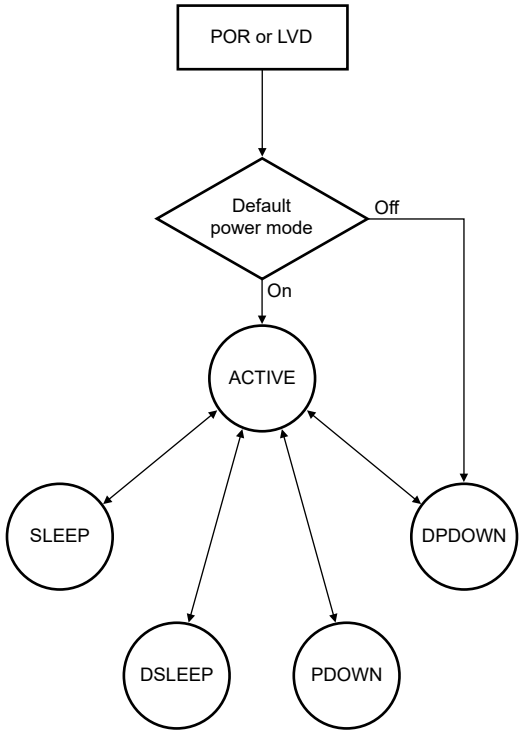

Figure 86. Power mode state diagram

SPC allows each power domain to enter or exit low-power modes independently of the other. You must ensure that any common system resources (for example, clock sources) are always available whenever required for a power-domain current power mode. For example, if a clock source in power domain 0 drives power domain 1, you must ensure that power domain 0 does not enter a low-power mode, because that would disable the clock source.

Figure 87 defines the low-power entry and exit flow for each of the SPC power-down domains.

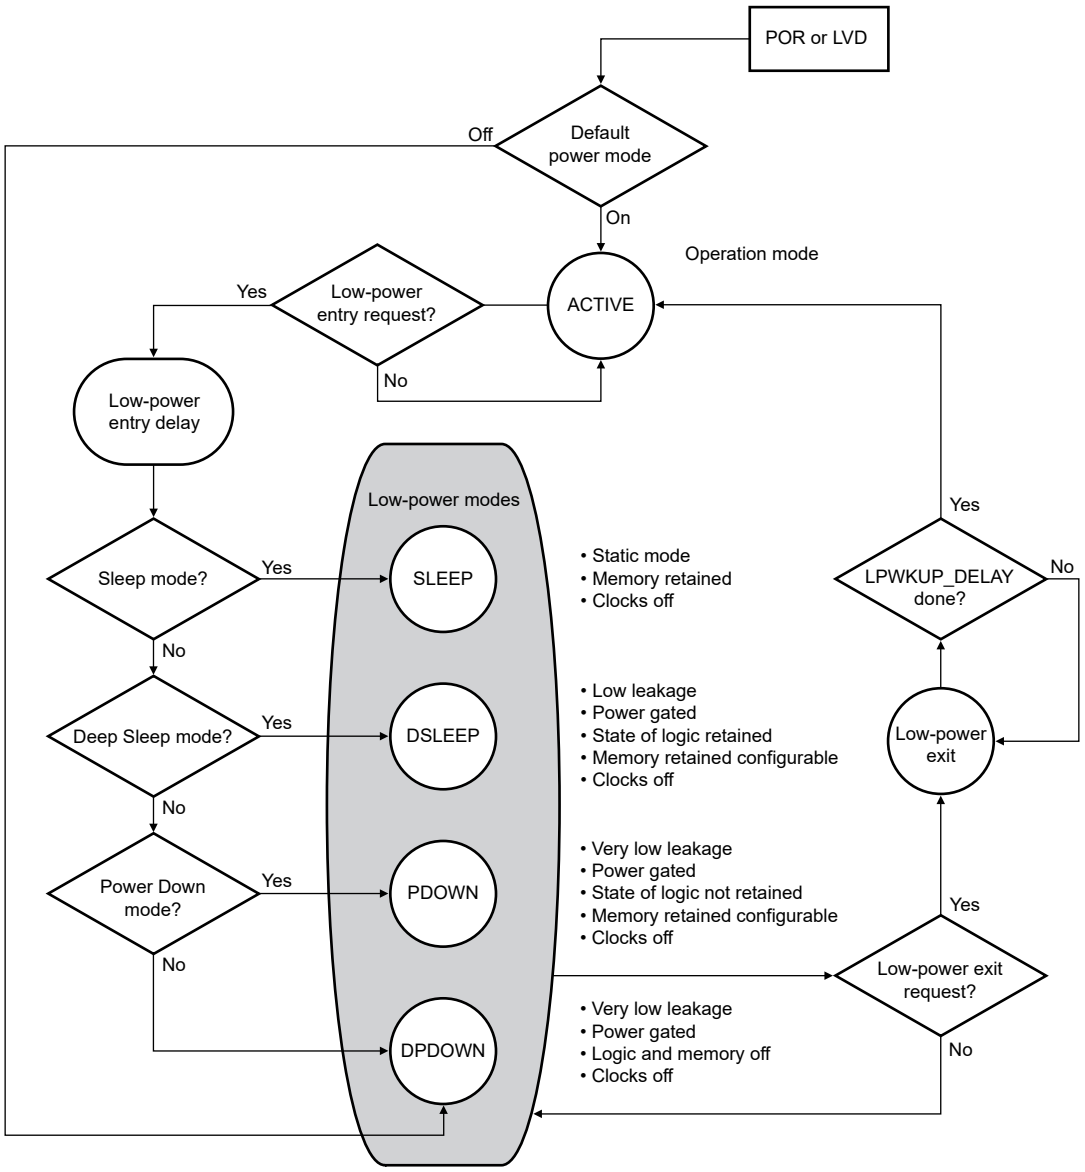

Figure 87. SPC regulator power mode state diagram

NOTE

This section mentions the power modes supported by the module. For the power modes supported on your device, see the chip-specific Power management chapter.

30.3.2 Active mode voltage updates

This section describes voltage and frequency changes in Active mode.

The active mode voltage can also be set by High Power Mode Configuration (HP_CFG). HP_CFG will be selected to set the active mode voltage level when in active mode and if HP_CNFG_CTRL[HP_REQ_EN] is enabled and if any of the following conditions are true:

- HP_CNFG_CTRL[OVERRIDE_EN] = 0 and the external HP request is asserted by the secondary core domain.
- HP_CNFG_CTRL[OVERRIDE_EN] = 1 and HP_CNFG_CTRL[OVERRIDE_SEL] = 1.

You can alter the operating voltage and frequency during Active mode to optimize power consumption depending on the application's performance requirements.

When increasing voltage and frequency in Active mode, you must perform the following steps:

1. Increase voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
2. Wait for voltage change to complete (SC[BUSY] = 0).
3. Configure flash memory to support higher voltage level and frequency (FMU_FCTRL[RWSC].
4. Configure SRAM to support higher voltage levels (SRAMCTL[VSM]).
5. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
6. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
7. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
8. Increase frequency to a new level (for example, SCG_RCCR).
9. You can continue execution.

When decreasing voltage and frequency in Active mode perform the following steps:

1. Decrease frequency to a new level (for example, SCG_RCCR).
2. Configure flash memory to support lower voltage level and frequency (FMU_FCTRL[RWSC].
3. Configure SRAM to support lower voltage levels (SRAMCTL[VSM]).
4. Request SRAM voltage update (write 1 to SRAMCTL[REQ]).
5. Wait for SRAM voltage change to complete (SRAMCTL[ACK] = 1).
6. Clear request for SRAM voltage change (write 0 to SRAMCTL[REQ]).
7. Decrease voltage to a new level (ACTIVE_CFG[CORELDO_VDD_LVL] and/or ACTIVE_CFG[DCDC_VDD_LVL]).
8. Wait for voltage change to complete (SC[BUSY] = 0).
9. You can continue execution.

30.3.3 Low-Power Request (LPREQ) pin

The LPREQ pin asserts after low-power entry and negates after low-power wakeup.

The pin is intended to control external switches (for example, if certain power supply rails are switched off in the low-power mode).

SPC controls the state of the LPREQ pin based on how you configure Low-Power Request Configuration (LPREQ_CFG). You control the LPREQ pin in Active mode. SPC controls the pin when the chip transitions from Active to a low-power mode, and after wake-up from these power modes.

NOTE

If the power supply rails are switched off externally, software must configure the internal isolation of these power domains using External Voltage Domain Configuration (EVD_CFG).

To use the LPREQ pin:

1. Specify the pin polarity (LPREQ_CFG[LPREQPOL]).
2. Enable the pin output (LPREQ_CFG[LPREQOE]).
3. Configure the pin mux for the desired pin using the PORT PCR registers.
4. If switch needs additional time after wake-up, use Low Power Wake-Up Delay (LPWKUP_DELAY) to extend the wake-up time.

30.3.4 DCDC

DCDC is a hysteretic converter. It is active during a burst period, when it switches the output to charge to a specific voltage. Then DCDC stops switching for a quiet period until the output voltage drops to a lower level, and it does another active burst.

30.3.4.1 DCDC drive strength

DCDC supports multiple drive strength options that you can choose:

- Normal
- Low
- Pulse refresh

The normal and low drive strengths differ in these DCDC characteristics:

- Maximum load current
- Quiescent current
- Transient response

With low drive strength, you can benefit from the lower quiescent current if:

- The load current is below the I_{LOAD} specification in the data sheet.
- Your application can tolerate the slower transient response.

Be careful when choosing low drive strength. If you exceed I_{LOAD} or require faster transient response, you must use normal drive strength. Furthermore, most other DCDC features are only available with normal drive strength.

Pulse-refresh drive strength offers even lower quiescent current in low-power modes, by deactivating DCDC when not active. This strength has an active pulsing period where DCDC charges the output voltage. Then DCDC deactivates for a configurable amount of time. No analog comparator is powered to monitor the DCDC output voltage. Instead, this drive strength is time-based using an SPC timer where DCDC_BURST_CFG[PULSE_REFRESH_CNT] specifies the timer period. Every period, SPC enables DCDC to charge the voltage again. When DCDC is off, no voltage regulation occurs. You must specify DCDC_BURST_CFG[PULSE_REFRESH_CNT] to manage the voltage drop on the DCDC capacitor and avoid a brownout condition.

30.3.4.2 DCDC burst

You can control and monitor the DCDC burst. Synchronizing with the quiet period between bursts can be valuable for noise-sensitive applications—for example, during a high-resolution ADC measurement or a radio transmission.

Before requesting a burst to start, clear the DCDC_BURST_CFG[BURST_ACK] flag. Then, your firmware can request a burst by writing 1 to DCDC_BURST_CFG[BURST_REQ]. SPC sets the DCDC_BURST_CFG[BURST_ACK] flag when the burst has completed and DCDC enters a quiet period.

SPC also provides signals to synchronize the burst activity with other peripherals in the chip. If DCDC_BURST_CFG[EXT_BURST_EN] = 1 before a burst starts, the output DCDC_BURST_TRIG_PULSE signal asserts when a burst completes, and can trigger other actions such as an ADC conversion. Another SPC output signal is DCDC_BURST_ACTIVE, which EXT_BURST_EN does not gate. DCDC_BURST_ACTIVE can also trigger other peripherals such as a timer. You can use this signal to estimate the power that DCDC delivers.

When bursting, you can control the DCDC switching center frequency with the frequency-stabilization feature. DCDC_CFG[FREQ_CNTRL_ON] enables this feature, and when the feature is enabled, DCDC_CFG[FREQ_CNTRL] controls it. The main parameters that control the period between active bursts and quiet period are:

- Load current
- External capacitor
- DCDC hysteresis

NOTE

Writing 1 to DCDC_CFG[FREQ_CNTRL_ON] stabilizes the frequency by limiting DCDC current. See the DCDC I_{LOAD} maximum limit in the data sheet for this mode.

30.3.4.3 DCDC voltage changes

To support power optimization of applications, DCDC can provide multiple output voltages.

Two separate registers, which specify Active mode output and Low-Power mode output, independently control the DCDC output voltage. Whenever an SoC mode change occurs, by using two independent registers, there is no need to reconfigure the output voltage. ACTIVE_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is Active or in Sleep mode. The DCDC drive strength is normal (ACTIVE_CFG[DCDC_VDD_DS] = 10b). LP_CFG[DCDC_VDD_LVL] controls the DCDC output voltage when the SoC mode is in a Low-Power mode (i.e., not Active or Sleep mode) or the DCDC drive strength is low (ACTIVE_CFG[DCDC_VDD_DS] = 01b) and the SoC is in an Active or Sleep mode.

When Active Power Mode Configuration (ACTIVE_CFG) controls the output, DCDC output options present:

- 1.25 V
- 1.35 V
- 1.5 V
- 1.8 V
- 2.5 V

When the device is in active mode, DCDC Configuration (DCDC_CFG) can support an additional DCDC output voltage option used for radio transmission up to 10 dBm when it supplies VDD_RF.

See Active mode voltage updates to change the DCDC output level in Active mode.

When Low-Power Mode Configuration (LP_CFG) controls the output, DCDC output options present:

- 1.25 V
- 1.35 V
- 1.5 V
- 1.8 V

When entering SoC power-down mode with IVS disabled, SPC supports only the 0.7 V option. You have to configure LPWKUP_DELAY to the correct value. In Deep Sleep mode, you must also align the output voltage with the clock frequencies of any clocks kept alive in the Low-Power mode. If you keep some clock sources active, ensure to leave the bandgap enabled.

To change the DCDC output level in Low-Power mode, follow this procedure:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.
2. Configure LP_CFG[DCDC_VDD_DS] = 0x1.
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level as in configure LP_CFG[DCDC_VDD_LVL].

30.3.4.4 DCDC voltage ramping up control

DCDC integrates a voltage ramp control feature that inserts a delay in the DCDC voltage update when DCDC is transitioning to a higher voltage. This helps to control the DCDC max transient current during the transition, decreasing the current peak due to DCDC capacitor recharge. This feature is only available when switching DCDC voltage to a higher voltage level in active modes, when the DCDC Drive Strength is set to Normal.

DCDC ramp control feature can be enabled and adjusted depending on the application requirements. DCDC_CFG[RAMP_CNTRL_EN] provides an enable control of the feature, and DCDC_CFG[RAMP_CNTRL] can adjust the ramp rate during the voltage transition.

30.3.5 Clocking

Table 238. Clocks

SPC component:	Clock source
Registers and logic	Slow bus clock
Delay counters	10 MHz internal clock

SPC uses the internal clock that PMC analog block generates to sequence the system regulator and chip power domains in and out of different power modes. This clock has a frequency of 10 MHz. SPC automatically enables the clock when it detects a power mode change, including entry into low-power modes and exit from low-power modes of any of the system power domains, or configuration changes to either Active Power Mode Configuration (ACTIVE_CFG) , or High Power Mode Configuration (HP_CFG), or Low-Power Mode Configuration (LP_CFG). This clock cannot run unless the PMC bandgap is up and enabled. Once SPC completes all transactions and is not busy, that is, SC[BUSY] = 0, this clock will turn off synchronously.

30.3.6 Reset

30.3.6.1 Reset sources

30.3.6.1.1 Power-on reset (POR)

When you initially apply power to the chip, or the supply voltage is below the POR falling threshold, the POR circuit triggers the POR condition. The POR condition asserts a cold reset in all power domains.

30.3.6.1.2 Low-voltage detect (LVD)

SPC supports the following LVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and keeps the chip in reset until each of these supply voltages rises above the LVD rising threshold. Enabling any of the LVD circuits triggers an LVD reset condition if the corresponding supply voltage is below the LVD falling threshold.

The LVD reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding LVD reset condition occurs.

30.3.6.1.3 High-voltage detect (HVD)

SPC supports the following HVD circuits:

- Core VDD
- System VDD
- I/O VDD

Each of these circuits is enabled by default and triggers an HVD reset condition if the corresponding supply voltage is above the HVD threshold.

Any of these reset condition asserts a cold reset in all power domains. The LVD- and HVD-detection logic is the only logic that HVD and LVD resets do not affect. The corresponding status fields in Voltage Detect Status (VD_STAT) become 1 after the corresponding HVD reset condition occurs.

30.3.6.1.4 Glitch detect

This chip guards against short pulses on the core VDD and VSS. This security feature can detect glitches due to a hacking attack and alerts the core to reset the chip or generate an interruptn operation.

After power-on reset, the core VDD glitch-detect system is enabled. When the system is in Active mode, use ACTIVE_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system. When the system is in Low-Power mode, use LP_CFG[GLITCH_DETECT_DISABLE] to enable or disable the glitch-detect system.

The glitch-detect system uses a 4-bit ripple counter to monitor the quantity of detected glitches. The VDD_CORE_GLITCH_DETECT_SC[GLITCH_DETECT_FLAG] status flags capture the state of each of these counters.

NOTE

The chip has analog voltage glitch detector (aGDET) that enhances protection against voltage manipulation. After the chip is out of reset, the NXP FMU logic configures aGDET to reset the chip when voltage manipulation is detected. The aGDET is validated on silicon across multiple process, voltage, and temperature corners by activating a large number of possible data paths. To avoid false detections due to unforeseen environment or application behavior, NXP recommends disabling aGDET in the early start-up code. You can also configure hardware interrupt for aGDET and handle action in the interrupt handler by disabling default reset actions. aGDET can be used by the application when security-critical operations, for example, cryptographic operation using private or symmetric keys (digital signature, encryption, decryption, and so on) or sensitive decision-making process. However, you must ensure that the system remains free from false detections in those circumstances. See the SDK example in this document for details on sensor usage.

30.3.6.2 Reset sequence

The following steps occur as part of the POR, LVD, or HVD sequence:

1. The RESET_b pin deasserts.
2. The internal reset signals assert.
3. The POR or LVD signals negate.
4. System clocks are enabled.

30.3.7 Interrupts

SPC generates a single interrupt. The trigger for this interrupt comes from:

- Any of the LVD, HVD, or glitch-detect circuits when they are not configured for reset and their corresponding HVDIE or LVDIE register.
- The Interrupt Enable (IE) register (for the glitch-detect case).

30.4 External signals

Signal	Description	Direction
LPREQ	Low-power request pin used to signal external power-management circuits for a change in supply voltage	Output
VOUT_CORE	Output of the LDO_CORE regulator	Output
VOUT_SYS	Output of the LDO_SYS regulator	Output
DCDC_LX	Output of the DCDC_CORE regulator	Output

30.5 Initialization

To initialize SPC with LDO_CORE off, write 0 to CNTRL[CORELDO_EN].

To initialize SPC with LDO_SYS off, write 0 to CNTRL[SYSLDO_EN].

To initialize SPC with DCDC_CORE off, write 0 to CNTRL[DCDC_EN].

Except for the above, SPC does not require any special initialization.

30.6 Application information

To change DCDC level in Low-Power mode:

1. Configure LP_CFG[DCDC_VDD_LVL] to desired level.
2. Configure LP_CFG[DCDC_VDD_DS] = 0x1
3. Configure ACTIVE_CFG[DCDC_VDD_LVL] to same level programmed in Configure LP_CFG[DCDC_VDD_LVL]

To disable Bandgap in Active mode:

1. Disable all LVD's and HVD's in ACTIVE_CFG[29:24]= 0x00
2. Disable Glitch Detect, ACTIVE_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in ACTIVE_CFG register
4. Configure ACTIVE_CFG[BGMODE] = 0x0

To disable Bandgap in Low-Power mode:

1. Disable all LVD's and HVD's in LP_CFG[29:24]= 0x00
2. Disable Glitch Detect, LP_CFG[GLITCH_DETECT_DISABLE] = 1
3. Configure LDO's and DCDC to Low Drive Strength in LP_CFG register
4. Configure LP_CFG[BGMODE] = 0x0

30.7 SPC register descriptions

Different chip reset types affect the reset of different SPC registers. Each register description provides details. See the Reset chapter for more information about the types of reset on this chip.

You may use only 32-bit writes for any writable SPC registers. 8-bit or 16-bit writes cause a transfer error.

30.7.1 SPC memory map

30.7.2 Version ID (VERID)

Offset

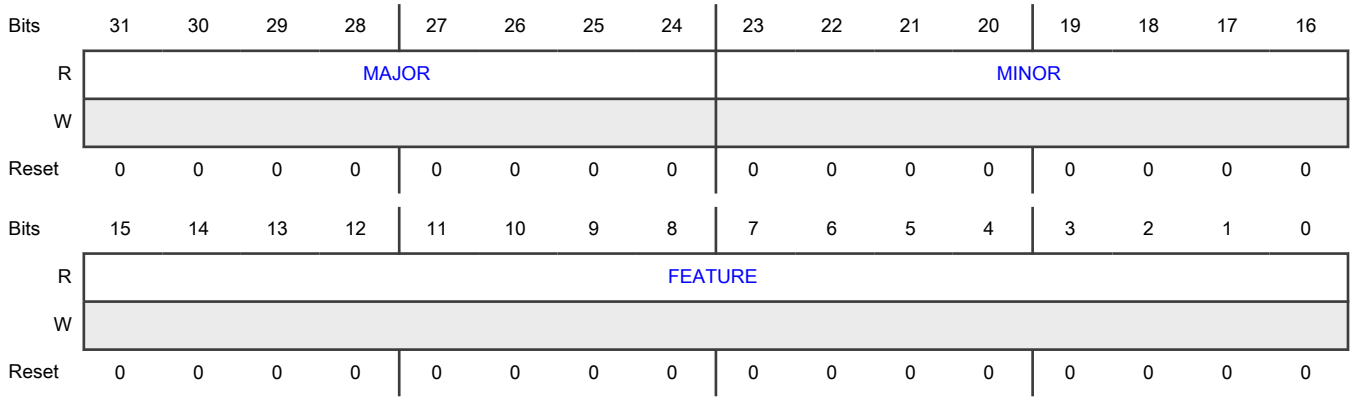
Register	Offset
VERID	0h

Function

Indicates:

- The version integrated for this instance on the chip.
- Inclusion or exclusion of several optional features.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Specification Number Indicates the feature set number. 0000_0000_0000_0000b - Standard features All other values are reserved.

30.7.3 Status Control (SC)

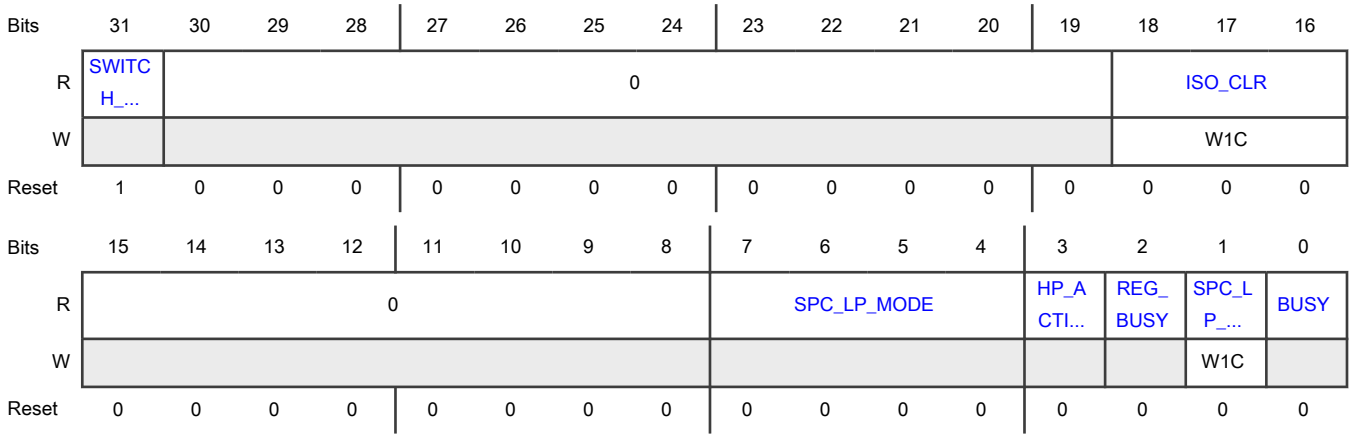
Offset

Register	Offset
SC	10h

Function

Indicates the current SPC status.

Diagram



Fields

Field	Function
31 SWITCH_STATE	Power Switch State Indicates the power switch state. 0b - Off 1b - On
30-19 —	Reserved
18-16 ISO_CLR	Isolation Clear Flags Indicates whether certain peripherals and I/O pads are in a latched state as a result of having been in DPDOWN mode. Each bit of this field is a flag associated with a module on this chip. See the chip-specific SPC information for the module-bit association. For each flag: • A value of 0 means that peripherals and I/O pads are in the normal run state. • A value of 1 means that peripherals and I/O pads can retain their state in their power domain. If a flag in this field is 1, writing 1 to that flag clears the flag and releases the I/O pads and peripherals to their normal run-mode state. After recovering from a power-down mode, you must restore the chip configuration before clearing a flag in this field. In particular, you must restore the pin configuration for enabled WUU wake-up to avoid any WUU flag from being falsely set when the associated ISO_CLR flag is cleared. This field resets after a system reset(not Deep Power Down wakeup reset).
15-8 —	Reserved
7-4	Power Domain Low-Power Mode Request Indicates the last low-power mode that the power domain requested.

Table continues on the next page...

Table continued from the previous page...

Field	Function
SPC_LP_MODE	0000b - Sleep mode with system clock running 0001b - SLEEP with system clock off 0010b - DSLEEP with system clock off 0100b - PDOWN with system clock off 1000b - DPDOWN with system clock off
3 HP_ACTIVE	HP_CFG Select Status Flag Indicates which active CFG register (HP_CFG or ACTIVE_CFG) is selected as the active configuration register. 0b - ACTIVE_CFG selected 1b - HP_CFG selected
2 REG_BUSY	SPC REG Busy Status Flag Indicates whether SPC is busy updating regulator settings. SPC sets this flag: • When SPC executes any type of regulator settings in Active mode or any of the chip low-power modes. • Due to LP_CFG[CORELDO_VDD_LVL] and LP_CFG[DCDC_VDD_LVL] changes while in Active mode. **NOTE** Wait until this flag is clear before changing power-mode configuration registers. 0b - Not busy 1b - Busy
1 SPC_LP_REQ	SPC Power Mode Configuration Status Flag Indicates when all power-down domains requested low-power mode and SPC entered a low-power state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - SPC is in Active mode; the ACTIVE_CFG register has control 1b - All power domains requested low-power mode; SPC entered a low-power state; power-mode configuration based on the LP_CFG register When writing 0b - No effect 1b - Clear the flag
0	SPC Busy Status Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
BUSY	Indicates whether SPC is busy. SPC sets this flag: • When SPC executes any type of power mode transition in Active mode or any of the chip low-power modes. • Due to LP_CFG[CORELDO_VDD_LVL] and LP_CFG[DCDC_VDD_LVL] changes while in Active mode. **NOTE** Wait until this flag is clear before changing power-mode configuration registers. 0b - Not busy 1b - Busy

30.7.4 SPC Regulator Control (CNTRL)

Offset

Register	Offset
CNTRL	14h

Function

Enables the SPC regulators.

You can write to the fields in this register only one time.

The register resets only after a POR, LVD, or HVD event.

30.7.8 SRAM Control (SRAMCTL)

Offset

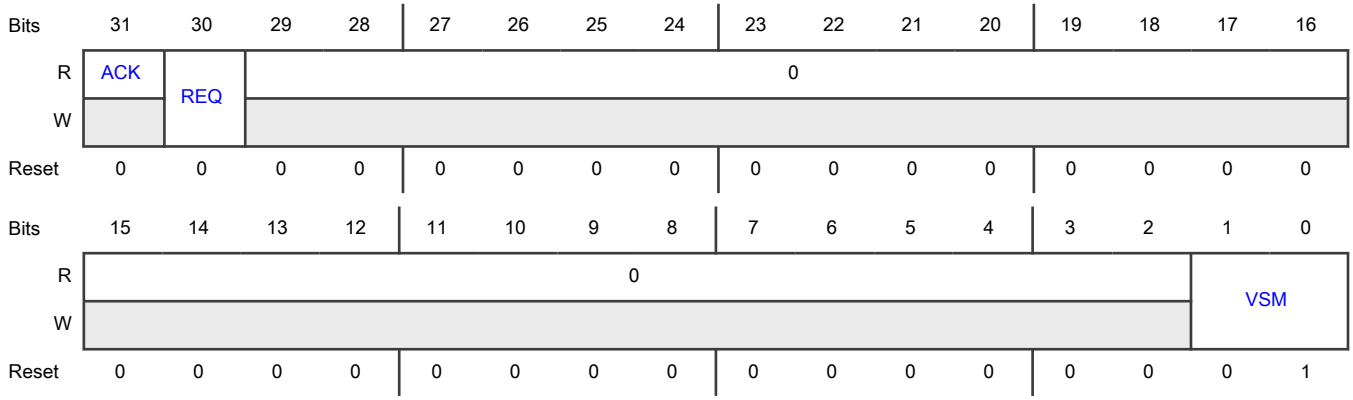
Register	Offset
SRAMCTL	40h

Function

Configures the SRAM timing for different voltage levels.

When transitioning between two voltage levels, you must keep the SRAM timing at the lowest voltage level until the voltage change is complete.

Diagram



Fields

Field	Function
31 ACK	SRAM Voltage Update Request Acknowledge Indicates whether SPC acknowledged the request for an SRAM trim-value change. 0b - Not acknowledged 1b - Acknowledged
30 REQ	SRAM Voltage Update Request Allows you to request an SRAM trim value change. After requesting the change, you must wait for the ACK field to become 1, then write 0 to REQ. 0b - Do not request 1b - Request
29-2 —	Reserved
1-0 VSM	Voltage Select Margin Specifies the operating voltage for the SRAM's read/write timing margin. 00b - Reserved 01b - 1.0 V 10b - 1.1 V 11b - SRAM configured for "1.2" V operation

30.7.9 High Power Config Control (HP_CNFG_CTRL)

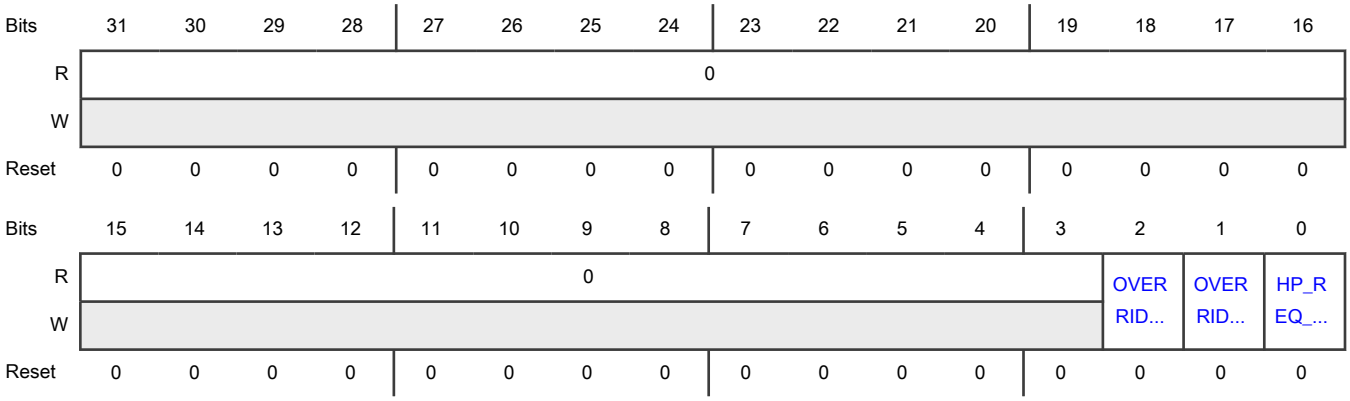
Offset

Register	Offset
HP_CNFG_CTRL	60h

Function

Control the HP_CNFG operation.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 OVERRIDE_SEL	Override Select Overrides the external HP request and forces the HP request to the OVERRIDE_SEL value. **NOTE** OVERRIDE_SEL is ignored if OVERRIDE_EN is set to 0. 0b - Force the HP request to 0 1b - Force the HP request to 1
1 OVERRIDE_EN	Override Enable Overrides the high power request to a value set by the OVERRIDE_SEL 0b - Override Disabled 1b - Override Enabled
0 HP_REQ_EN	High Power Request Enable Enables the high power request and forces SPC to switch the active power configuration from ACTIVE_CFG to HP_CFG when a high power request is detected. **NOTE** 0b - High Power request Disable 1b - High power reqeust Enable

30.7.10 General Purpose Wake-up (WAKEUP)

Offset

Register	Offset
WAKEUP	E0h

Function

Specifies the wake-up value that the boot ROM uses.

This register resets after POR, LVD ,or any system reset except wake-up from Power Down or Deep Power Down modes.

Diagram

Fields

Field	Function
31-0 WAKEUP	Wake-up Specifies the value that the boot ROM uses to quickly restore Cortex-M33 core context or to switch execution to a defined address in the flash memory or SRAM after wake-up.

30.7.11 Active Power Mode Configuration (ACTIVE_CFG)

Offset

Register	Offset
ACTIVE_CFG	100h

Function

Controls the SPC regulators settings in the Active power mode.

Changes to the drive strength or voltage level for any of the LDOs or DCDC sets the SC[BUSY] flag until SPC changes its state to the new value.

NOTE

The LVDE and HVDE fields reset only with a POR. All other fields reset only with a system reset.

18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. 0b - Disable 1b - Enable
17-16 —	Reserved
15 —	Reserved
14-13 —	Reserved
12 GLITCH_DETECT_DISABLE	Glitch Detect Disable Reset on POR only. State of GLITCH_DETECT_DISABLE will be ignored if Bandgap is disabled and Glitch Detect hardware will be forced to OFF state. 0b - Low Voltage Glitch Detect enabled 1b - Low Voltage Glitch Detect disabled
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. When switching the DCDC drive strength from low to normal, ensure that the DCDC high VDD LVL setting is set to the same level that was set prior to switching the DCDC to low drive strength. Otherwise, if the LVDs are enabled, an unexpected LVD can occur. 00b - Low undervoltage voltage (1.25 V) 01b - Mid voltage (1.35 V) 10b - Normal voltage (1.5 V) 11b - Overdrive voltage (1.8 V)
9-8	DCDC VDD Drive Strength

Table continues on the next page...

Table continued from the previous page...

Field	Function
DCDC_VDD_DS	Specifies the DCDC VDD regulator drive strength. If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. 01b - Low 10b - Normal All other values are reserved.
7 —	Reserved
6 SYSLDO_VDD_LVL	LDO_SYS VDD Regulator Voltage Level Specifies the LDO_SYS VDD regulator level. You must write 0 to SYS_HVDE before writing 1 to SYSLDO_VDD_LVL. The VDD_SYS voltage can only operate at the overdrive voltage for a limited amount of time for the life of the chip. See the chip data sheet for the maximum voltage and time specifications. This is intended only for programming eFuses. 0b - Normal voltage (1.8 V) 1b - Overdrive voltage (2.5 V)
5 —	Reserved
4 SYSLDO_VDD_DS	LDO_SYS VDD Drive Strength Specifies the LDO_SYS VDD regulator drive strength If you specify normal drive strength, you must write a value to ACTIVE_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. SPC forces a normal drive strength when SYSLDO_VDD_LVL = 1. 0b - Low 1b - Normal
3-2 CORELDO_VDD_LVL	LDO_CORE VDD Regulator Voltage Level Selects the LDO_CORE VDD regulator level. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when CORELDO_VDD_DS=1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When switching CORELDO_VDD_DS from low to normal drive strength, ensure the LDO_CORE high VDD LVL setting is set to the same level that was set prior to switching to the LDO_CORE drive strength (CORELDO_VDD_DS). Otherwise, if the LVDs are enabled, an unexpected LVD can occur. 00b - Reserved 01b - Regulate to mid voltage (1.05 V) 10b - Regulate to normal voltage (1.1 V) 11b - Reserved
1 —	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Selects the LDO_CORE VDD regulator drive strength **NOTE** When setting CORELDO_VDD_DS to Normal, BGMODE must be programmed to a value that enables the Bandgap. Writes to set drive strength to Low will be ignored if LVD/HVDs are kept enabled. 0b - Low 1b - Normal

30.7.12 Low-Power Mode Configuration (LP_CFG)

Offset

Register	Offset
LP_CFG	108h

Function

Controls the SPC regulator settings in low-power stop modes.

This register resets only after a POR or LVD event.

Diagram

Fields

Field	Function
31-30 —	Reserved
29 IO_HVDE	IO High Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information. This field resets only after a POR, LVD, or HVD event. When IO_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
28 SYS_HVDE	System High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
27 CORE_HVDE	Core High Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_HVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
26 IO_LVDE	IO Low Voltage Detect Enable This field monitors VDD IO on PORT. For port details, see the chip-specific SPC information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field resets only after a POR, LVD, or HVD event. When IO_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
25 SYS_LVDE	System Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When SYS_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
24 CORE_LVDE	Core Low Voltage Detect Enable This field resets only after a POR, LVD, or HVD event. When CORE_LVDE = 1, you must use LP_CFG[BGMODE] to enable the bandgap. If you enable the bandgap to support voltage detection, the low-power mode Idd increases. 0b - Disable 1b - Enable
23 LP_IREFEN	Low-Power IREF Enable You can disable the low-power IREF only when all power domains are in DPDOWN mode. In all other low-power modes, writing to this field has no effect and the low-power IREF is always enabled. See the chip-specific SPC information for the modules that require the low-power IREF to be enabled in DPDOWN mode when you use the module in DPDOWN mode. 0b - Disable for power saving in Deep Power Down mode 1b - Enable
22 —	Reserved
21-20 BGMODE	Bandgap Mode Specifies the bandgap mode configuration. BGMODE will be set to 01b to keep the Bandgap enabled if a write to disable Bandgap is detected while keeping any of the regulators in normal drive strength or if any of the LVD/HVDs are kept enabled or if VDD CORE glitch detect are kept enabled. 00b - Bandgap disabled 01b - Bandgap enabled, buffer disabled 10b - Bandgap enabled, buffer enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Reserved
19 —	Reserved
18 LPBUFF_EN	CMP Bandgap Buffer Enable Enables the buffer-stored reference voltage to CMP. The CMP bandgap buffer is automatically disabled and turned off in DPDOWN mode. 0b - Disable 1b - Enable
17 COREVDD_IVS_EN	CORE VDD Internal Voltage Scaling (IVS) Enable Enables the IVS regulator. When enabled, the IVS regulator scales the external input CORE VDD to a lower voltage level to reduce internal leakage during Deep Sleep and Power Down modes. COREVDD_IVS_EN is automatically 0 in SLEEP or DPDOWN modes. CORE VDD can only get IVS in DSLEEP and PDOWN modes. 0b - Disable 1b - Enable
16 —	Reserved
15 —	Reserved
14-13 —	Reserved
12 GLITCH_DETECT_DISABLE	Glitch Detect Disable This field resets only after a POR, LVD, or HVD event. If you have disabled the bandgap, SPC ignores the value of GLITCH_DETECT_DISABLE and deactivates the glitch-detect hardware. 0b - Enable 1b - Disable
11-10 DCDC_VDD_LVL	DCDC VDD Regulator Voltage Level Specifies the DCDC VDD regulator level. 00b - Low undervoltage (1.25 V)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Mid voltage (1.35 V) 10b - Normal voltage (1.5 V) 11b - Overdrive voltage (1.8 V)
9-8 DCDC_VDD_DS	DCDC VDD Drive Strength Specifies the drive strength of the DCDC VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. The DCDC regulator is always turned off and disabled in DPDOWN mode. Pulse Refresh mode is invalid in SLEEP mode. If you have enabled LVDs or HVDs, and attempt to specify low or pulse drive strength, SPC ignores the attempt and forces the normal drive strength. SPC ignores writes to reserved values. 00b - Pulse refresh 01b - Low 10b - Normal 11b - Reserved
7 —	Reserved
6-5 —	Reserved
4 SYSLDO_VDD_DS	LDO_SYS VDD Drive Strength Specifies the drive strength of the LDO_SYS VDD regulator. If you specify normal drive strength, you must write a value to LP_CFG[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal
3-2 CORELDO_VDD_LVL	LDO_CORE VDD Regulator Voltage Level Specifies the LDO_CORE VDD regulator level for low-power sleep modes. If the CORELDO_VDD_DS fields are set to the same value in both the ACTIVE_CFG and LP_CFG registers, the CORELDO_VDD_LVL's in the ACTIVE_CFG and LP_CFG register must be set to the same voltage level settings. You can change the core VDD levels for the LDO_CORE low power regulator only when ACTIVE_CFG[CORELDO_VDD_DS] = 1. So, before entering any of the low-power states (DSLEEP,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	PDOWN, DPDOWN) with LDO_CORE low power regulator selected (LP_CFG[CORELDO_VDD_DS] = 0), you must use CORELDO_VDD_LVL to select the correct regulation level during ACTIVE run mode. Updating CORELDO_VDD_LVL sets the SC[BUSY] flag. That flag remains set for at least the total time delay that Active Voltage Trim Delay (ACTIVE_VDELAY) specifies. Before changing CORELDO_VDD_LVL, you must wait until the SC[BUSY] flag clears before entering the selected low-power sleep mode. This ensures the correct core VDD voltage levels are set after the chip is in the chosen mode. When LP_CFG[DCDC_VDD_LVL] is not 00b, you must program LP_CFG[CORELDO_VDD_LVL] to have same value as LP_CFG[DCDC_VDD_LVL], even if LDO_CORE is off. When LP_CFG[DCDC_VDD_LVL] is 00b, you must disable VDD_CORE LVD in Low-Power mode, and LP_CFG[CORELDO_VDD_LVL] can be different with LP_CFG[DCDC_VDD_LVL]. 00b - Reserved 01b - Mid voltage (1.05 V) 10b - Normal voltage (1.1 V) 11b - Reserved
1 ——	Reserved
0 CORELDO_VDD_DS	LDO_CORE VDD Drive Strength Specifies the drive strength of the LDO_CORE VDD regulator. The LDO_CORE regulator is forced to disabled in DPDOWN Sleep mode. If you specify normal drive strength, you must write a value to LP[BGMODE] that enables the bandgap. If you have enabled LVDs or HVDs, and attempt to specify low drive strength, SPC ignores the attempt. 0b - Low 1b - Normal

30.7.13 High Power Mode Configuration (HP_CFG)

Offset

Register	Offset
HP_CFG	110h

Function

Controls the SPC regulators settings in the High Power active mode.

High Power configuration mode is selected as the active configuration register when HP_REQ_EN=1, a high power(HP) request is detected and HP_CNFG_CTRL[OVERRIDE_EN] is not set or when HP_CNFG_CTRL[OVERRIDE_EN] is set and HP_CNFG_CTRL[OVERRIDE_SEL] is set 1.

Changes to the drive strength or voltage level for any of the LDOs or DCDC set SC[BUSY] and SC[REG_BUSY] until SPC changes its state to the new value.

NOTE

The LVDE and HVDE fields reset only with a POR. All other fields reset only with a system reset.

Writes to set drive strength to Low will be ignored if LVD/HVDs are kept enabled. 0b - Low 1b - Normal

30.7.14 Low Power Wake-Up Delay (LPWKUP_DELAY)

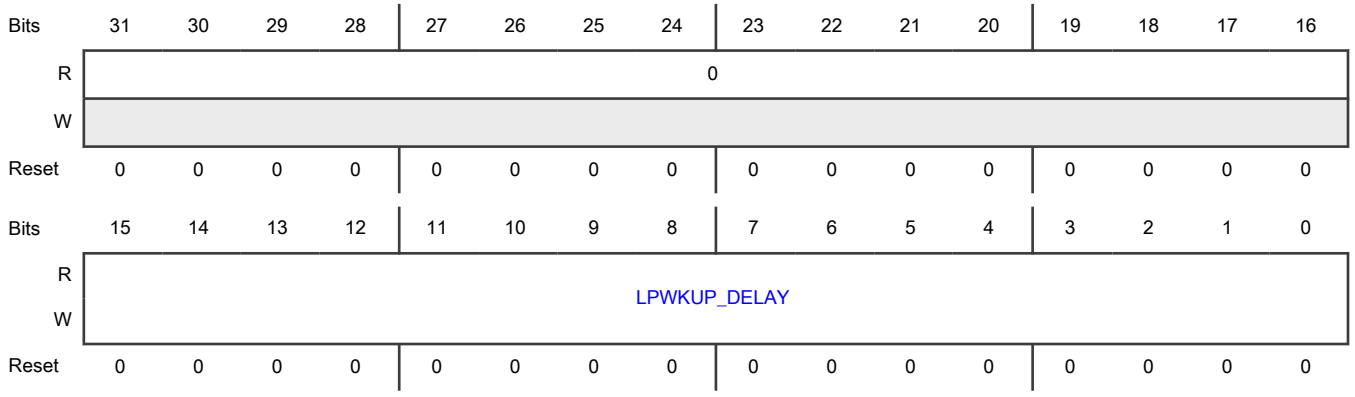
Offset

Register	Offset
LPWKUP_DELAY	120h

Function

Works with the LPREQ pin to extend the wake-up time if the switch needs additional time after wake-up.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 LPWKUP_DELAY	Low-Power Wake-Up Delay Specifies the number of SPC timer clock cycles that SPC waits after exiting low-power modes. This field resets only after a POR, LVD, or HVD event. When voltage levels are not the same between ACTIVE mode and Low Power mode, you must write a nonzero value to this field.

30.7.15 Active Voltage Trim Delay (ACTIVE_VDELAY)

Offset

Register	Offset
ACTIVE_VDELAY	124h

Function

Specifies the delay due to voltage level changes to the regulators in Active mode.

This register resets only after a POR event.

SPC loads the ACTIVE_VDELAY values are loaded from IFR or FUSE after any reset. NXP trims this reset value for the recommended wait time.

Diagram

15-0 ACTIVE_VDELAY	Active Voltage Delay Specifies the number of SPC timer clock cycles that SPC waits when changing the core-regulator voltage level in Active mode.

30.7.16 Voltage Detect Status (VD_STAT)

Offset

Register	Offset
VD_STAT	130h

Function

Displays the LVD or HVD captured for:

- Core VDD.
- System VDD.
- IO VDD.

This register resets only after a POR event.

30.7.17 Core Voltage Detect Configuration (VD_CORE_CFG)

Offset

Register	Offset
VD_CORE_CFG	134h

Function

Provides these functions:

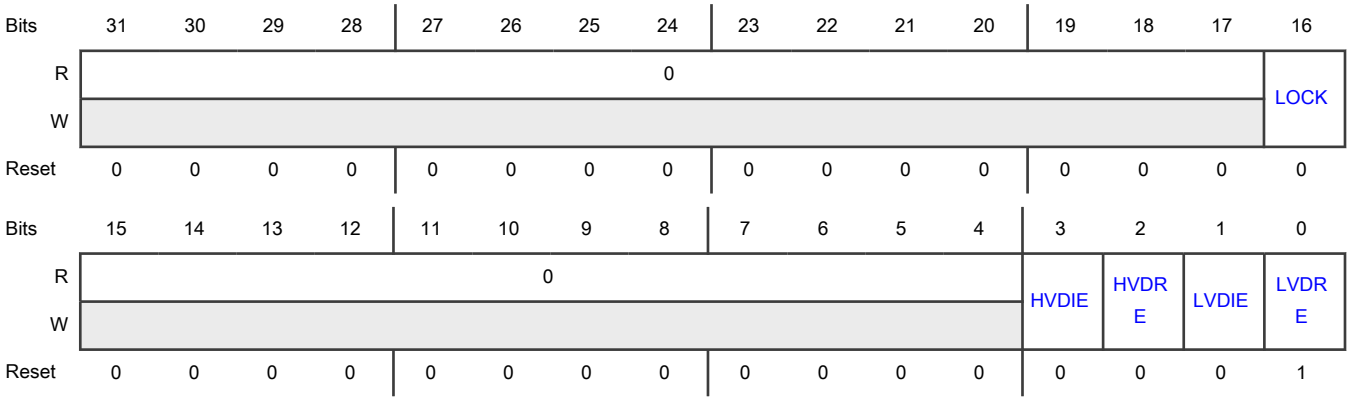
- Configures the low-voltage trip point.
- Enables the core LVD reset and interrupts.

This register resets only after a POR event.

NOTE

If you write 1 to both LVDRE and LVDIE, SPC generates an interrupt after exiting from LVDRE reset. If you don't want this to occur, configure the LVD or HVD so only one is enabled.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 LOCK	Core Voltage Detect Reset Enable Lock Allows writing to the LVDRE and HVDRE fields. 0b - Allow 1b - Deny
15-4 —	Reserved
3 HVDIE	Core VDD HVD Interrupt Enable Enables the Core VDD HVD (COREVDD_HVDF) event to generate a hardware interrupt. If you write 1 to HVDIE with HVD set, SPC automatically generates an HVD interrupt. 0b - Disable 1b - Enable
2 HVDRE	Core VDD HVD Reset Enable Enables the core VDD HVD (COREVDD_HVDF) event to generate a hardware reset. Before writing to this field, you must write 0 to LOCK. 0b - Disable 1b - Enable
1 LVDIE	Core LVD Interrupt Enable Enables the Core LVD (COREVDD_LVDF) event to generate a hardware interrupt. If you write 1 to LVDIE with LVDF set, SPC automatically generates an LVD interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 LVDRE	Core LVD Reset Enable Enables the core LVD (COREVDD_LVDF) event to generate a hardware reset. Before writing to this field, you must write 0 to LOCK. 0b - Disable 1b - Enable

30.7.18 System Voltage Detect Configuration (VD_SYS_CFG)

Offset

Register	Offset
VD_SYS_CFG	138h

Function

Provides these functions:

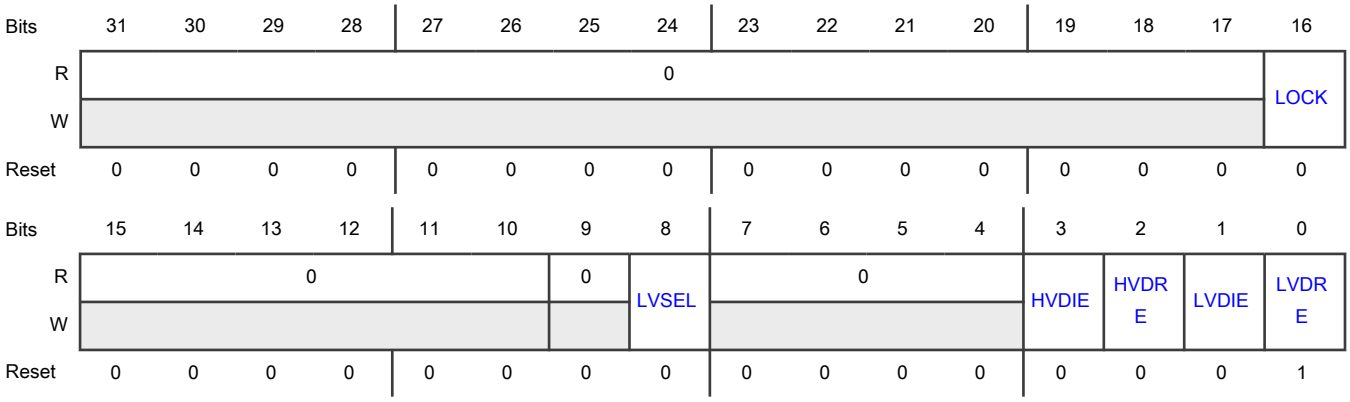
- Configures the low-voltage trip point.
- Enables the system LVD reset and interrupts.

This register resets only after a POR event.

NOTE

If you write 1 to both LVDRE and LVDIE, SPC generates an interrupt after exiting from LVDRE reset. If you don't want this to occur, configure the LVD or HVD so only one is enabled.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 LOCK	System Voltage Detect Reset Enable Lock Allows writing to the LVDRE, HVDRE, and LVSEL fields. 0b - Allow 1b - Deny
15-10 —	Reserved
9 —	Reserved
8 LVSEL	System Low-Voltage Level Select Specifies the LVD trip-point level for the system monitor. See the chip data sheet for the normal- and safe-level values. Before writing to this field, you must write 0 to LOCK. If you want to change LVSEL, you must do this after disabling the LVD reset and interrupt. Otherwise, SPC could generate an LVD due to the LVSEL change. 0b - Normal 1b - Safe
7-4 —	Reserved
3 HVDIE	System HVD Interrupt Enable Enables the system HVD (SYSVDD_HVDF) event to generate a hardware interrupt. If you write 1 to HVDIE with HVDF set, SPC automatically generates an HVD interrupt. 0b - Disable 1b - Enable
2 HVDRE	System HVD Reset Enable Enables the system HVD (SYSVDD_HVDF) event to generate a hardware reset. Before writing to this field, you must write 0 to LOCK. 0b - Disable 1b - Enable
1	System LVD Interrupt Enable Enables the system LVD (SYSVDD_LVDF) event to generate a hardware interrupt.

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVDIE	If you write 1 to LVDIE with LVDF set, SPC automatically generates an LVD interrupt. 0b - Disable 1b - Enable

30.7.19 IO Voltage Detect Configuration (VD_IO_CFG)

Offset

Register	Offset
VD_IO_CFG	13Ch

Function

Enables the IO VDD LVD and HVD reset and interrupts.

This register resets only after a POR event.

NOTE

If you write 1 to both LVDRE and LVDIE, SPC generates an interrupt after exiting from LVDRE reset. If you don't want this to occur, configure the LVD or HVD so only one is enabled.

30.7.20 External Voltage Domain Configuration (EVD_CFG)

Offset

Register	Offset
EVD_CFG	140h

Function

Isolates signals from external voltage domains under certain conditions.

Chip pins supply the external voltage domains. These domains are controlled at the board level. This register allows you to control internal isolations for signals from these domains if either of the following conditions is true:

- They are not powered on the board.
- They are powered off externally in low-power modes (using the SPC_LPREQ pin).

Any logic in the isolated voltage domain also resets, because the voltage domain is assumed to be powered off. This reset does not impact any VDD_CORE internal power domains or registers—only I/O pads, analog components, or both.

This register resets only after a POR event.

Each bit of the EVDISO, EVDLPISO, and EVDSTAT fields corresponds to one of the I/O or analog supplies according to Table 239.

Table 239. Mapping of bits to supplies

Bit position in field	Description
0	VDD_IO_ABE
1	VDD_IO_C
2	VDD_IO_D

NOTE

Bit 0 VDD_IO_ABE should not be set in EVD_CFG[EVDISO] and it should only be set in EVD_CFG[EVDLPISO] when moving to Deep Power Down mode.

15-14 —	Reserved
13-8 FREQ_CNTRL	DCDC Burst Frequency Control Specifies the frequency of the current burst.
7-4 —	Reserved
3-1 —	Reserved
0 FREQ_CNTRL_ON	DCDC Burst Frequency Control Enable Enables DCDC frequency stabilization. 0b - Disable 1b - Enable

30.7.25 DCDC Burst Configuration (DCDC_BURST_CFG)

Offset

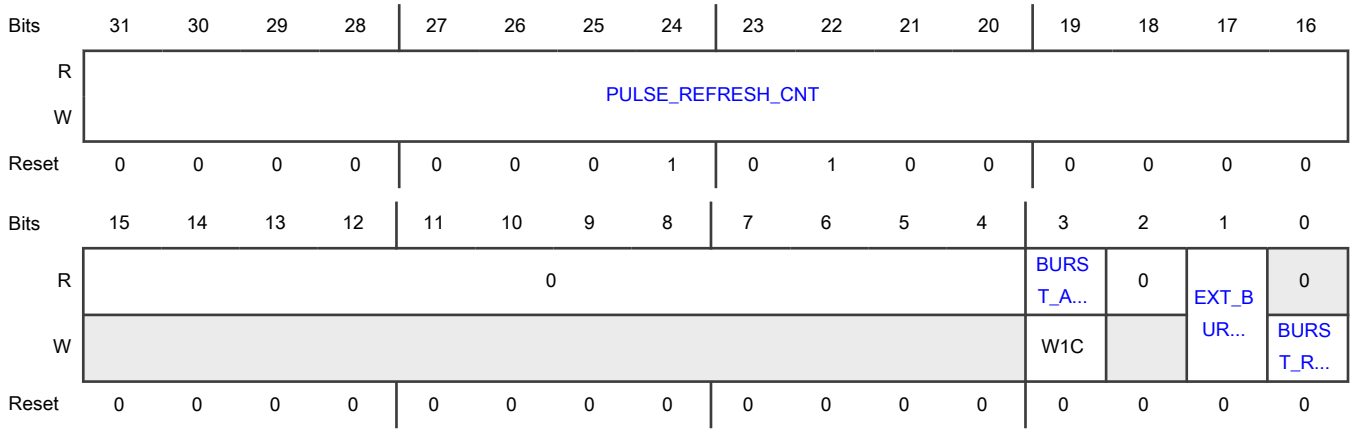
Register	Offset
DCDC_BURST_CFG	504h

Function

Controls the DCDC burst operation.

This register resets only after a POR, LVD, or HVD event.

Diagram



Fields

Field	Function
31-16 PULSE_REFRESH_CNT	Refresh Count Value Controls the DCDC refresh frequency when DCDC is in Pulse Refresh mode. When DCDC is enabled and running in Pulse Refresh mode, PULSE_REFRESH_CNT controls how often the DCDC is pulsed on and off based on a low-power reference clock. You must specify a count value that is long enough to allow a DCDC burst to occur. The pulse duration (time between on and off) is: (reference clock period) × (PULSE_REFRESH_CNT + 2) **NOTE** See the chip-specific information for more on DCDC pulsed mode clocking.
15-4 —	Reserved
3 BURST_ACK	Burst Acknowledge Flag Indicates that the DCDC burst completed, and therefore DCDC entered Quiet mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not complete 1b - Completed When writing 0b - No effect 1b - Clear the flag
2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 EXT_BURST_EN	External Burst Request Enable Enables external burst requests. When this field is 1, SPC asserts the output burst trigger DCDC_BURST_TRIG_PULSE after the DCDC burst request has been acknowledged. **NOTE** Enable external bursts before writing 1 to BURST_REQ and after BURST_ACK is 0. 0b - Disable 1b - Enable
0 BURST_REQ	Software Burst Request Generates a software burst request to DCDC. **NOTE** Do not generate a new burst request until the previous burst request has completed and you acknowledged this by clearing the BURST_ACK flag. 0b - Do not generate 1b - Generate

Chapter 31
Smart Power Switch (VBAT)

31.1 Chip-specific VBAT information

Table 240. Reference links to related information

Topic	Related module	Reference

Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

31.1.1 Signal naming

The table below lists the VBAT signal in this device.

Table 241. Device signal name - VBAT signal name

Device signal name	VBAT signal name
SWITCH_WAKEUP_B	WAKEUP_b

31.1.2 VBAT supply

VBAT is supplied from the chip power supply VDD_SWITCH.

31.1.3 VBAT backup SRAM LDO for memory retention

VBAT module in the device can optionally retain the contents of the 8KB SRAM STCM8 array that supports ECC.

31.2 Overview

VBAT works with the power management system to implement power-saving mechanisms. It provides bandgap timers and a voltage regulator to supply retention SRAM in low-power modes.

VBAT implements the 16 kHz internal clock source via FRO16K.

31.2.1 Block diagram

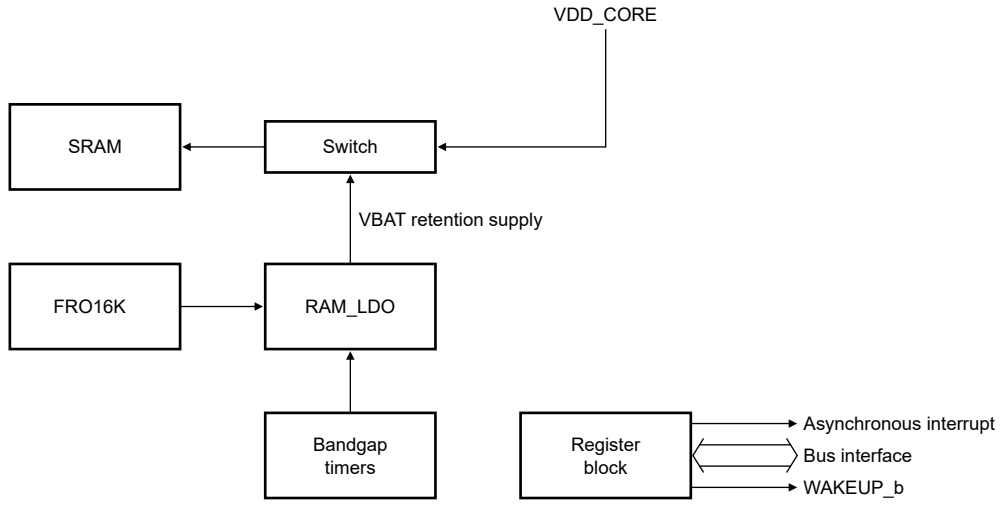

Figure 88. Block diagram

31.2.2 Features

- Supports internal 16 kHz free-running oscillator (FRO16K)
- Supports backup retention SRAM regulator

31.3 Functional description

The following sections describe the functional details of VBAT.

31.3.1 Operations

This section describes the operations of VBAT.

31.3.1.1 FRO 16.384 kHz clock

FRO16K is enabled by default on POR. You can disable it or lock it to prevent any change to the enable field. FRO 16k should be enabled prior to enabling the backup SRAM LDO regulator or VBAT bandgap timers.

31.3.1.2 SRAM LDO

SRAM LDO is a retention regulator that retains VBAT retention SRAM in low-power modes, including when VBAT is the only available supply. When STATUSA[LDO_RDY] becomes 1, the chip can enter into a low-power mode where the VBAT supply retains SRAM. Enable the bandgap and LDO before entering a low-power mode where the VBAT supply powers the retention SRAM. Enable Refresh mode for the lowest power consumption.

It takes approximately 8ms for the LDO_RDY flag to set after software enables the bandgap and LDO. When using the SRAM LDO it is recommended to leave it enabled in active modes to avoid this delay before entering a low power mode.

Although SRAM is automatically retained in all low-power modes, you can manually switch SRAM to the VBAT retention supply anytime. Do not access the SRAM when it receives power from the VBAT retention supply. You must manually reverse these steps before accessing the SRAM again.

To manually switch VBAT to power the SRAM:

1. Isolate the SRAM array (write 1 to LDORAMC[ISO]).
2. Switch the supply from VDD_CORE to the VBAT retention LDO (write 1 to LDORAMC[SWI]).

When SRAM LDO is disabled, LDORAMC[RETn] controls whether the retention of VBAT SRAM happens using VDD_CORE in low-power modes.

In general, using the SRAM LDO to retain the VBAT retention SRAM is a lower power option than using VDD_CORE directly.

NOTE

Enable FRO16K before enabling SRAM LDO or the bandgap.

31.3.1.3 Bandgap timer

Two software-configurable bandgap timers are available when the SRAM LDO bandgap is enabled. These timers share logic with the bandgap timer refresh logic to minimize power, so they use the FRO16K clock source and are only available when the bandgap is enabled. When you change the configured timeout, NXP recommends that you:

1. Disable the timer.
2. Clear the flag.
3. Write the new timeout value.
4. Enable the timeout again.

31.3.2 Low-power modes

VBAT remains functional in all low-power modes.

31.3.3 Debug mode

Debug modes do not affect VBAT.

31.3.4 Clocks

VBAT implements the following clock domains:

- Bus interface clock - access the registers
- FRO16K internal clock

31.3.5 Reset

Only the POR resets VBAT.

31.3.6 Interrupts

VBAT generates one interrupt combining the following sources:

- VBAT POR
- Wake-up pin assertion
- Bandgap timer 0
- Bandgap timer 1
- LDO ready

31.4 External signals

Table 242. External signals

Signal	Description	Direction
WAKEUP_b	Active low wake-up pin, falling edge sets the WAKEUP_FLAG. When WAKEUP_b pin is configured for open drain operation, an external wakeup source can drive this pin low, and the falling edge will assert the WAKEUP_FLAG	Input/Output

31.5 Initialization

To enable and lock the FRO16K:

1. Write 1h to FROCTLA[FRO_EN].
2. Write 1h to FROLCKA[LOCK].
3. Alter FROCLKE[CLKE] to clock gate different FRO16K outputs to different peripherals to reduce power consumption.

To enable and lock the LDO and bandgap:

1. Enable the FRO16K.
2. Write 7h to LDO_RAM Control A (LDOCTLA).
3. Wait for STATUSA[LDO_RDY] to become 1.
4. Write 1h to LDOLCKA[LOCK].

31.6 Application information

Configure the VBAT LDO to retain the state of any required SRAM to guard against an unexpected loss of power to the system:

1. Enable the LDO and bandgap.
2. Configure LDORAMC[RETn] to retain the appropriate arrays.

For a software-controlled power down, follow these steps to ensure robust retention of memory before switching off external power:

1. Write 1b to LDORAMC[ISO].
2. Write 1b to LDORAMC[SWI].

You must reverse the above steps to access the SRAM arrays, which the VBAT LDO retains. That is, follow these steps after external power is again switched on:

1. Write 0b to LDORAMC[SWI].
2. Write 0b to LDORAMC[ISO].

31.7 Memory map and register definition

This section includes VBAT memory map and detailed descriptions of all registers.

NOTE

The VBAT registers are reset on VBAT Cold Reset only (VBAT POR).

31.7.1 VBAT register descriptions

0 LOCK	Lock Blocks any write to the FRO16K registers when you write 1 to this field. VBAT POR writes 0 to this field. 0b - Do not block 1b - Block

31.7.1.9 FRO16K Clock Enable (FROCLKE)

Offset

Register	Offset
FROCLKE	220h

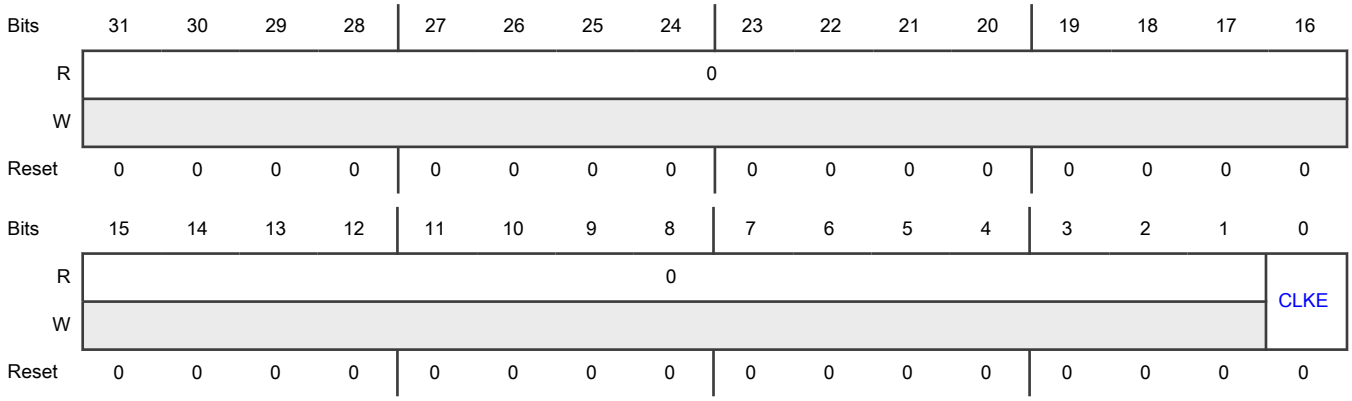
Function

Contains clock gating register field to gate the FRO16K clock to other modules.

NOTE

FROCLKE cannot be locked (not affected by FRO16K Lock A (FROLCKA)).

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CLKE	Clock Enable Enables the corresponding FRO16 kHz output clock to other modules when you write 1 to the corresponding bit in this field. See the chip-specific VBAT information section for more information.

31.7.1.10 LDO_RAM Control A (LDOCTLA)

Offset

Register	Offset
LDOCTLA	300h

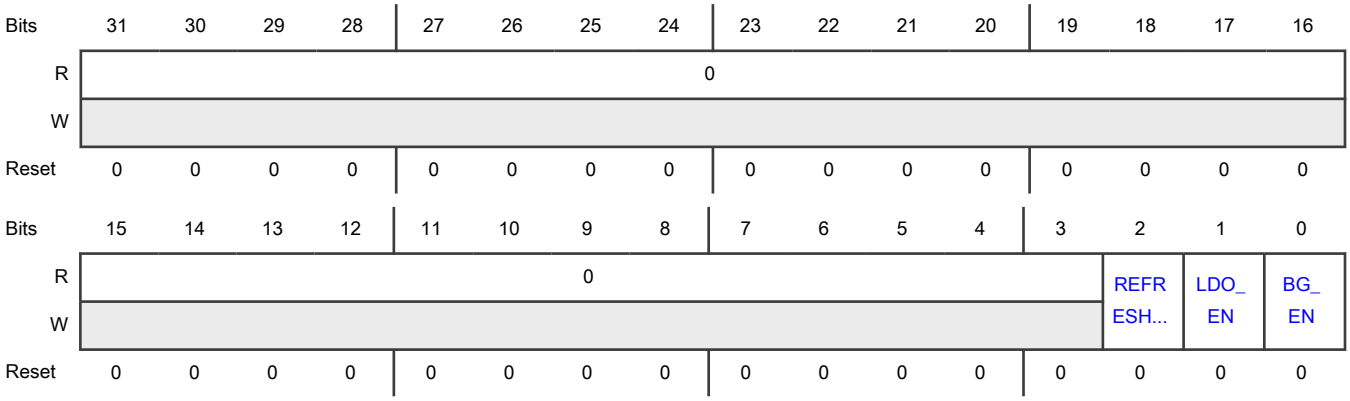
Function

Contains the LDO_RAM control field. When configuring the LDO_RAM, both control A and control B registers need to be programmed to the appropriate values. Writes to this register are blocked when LDOLCKA[LOCK] is 1.

NOTE

The FRO16K must be enabled before enabling the SRAM LDO or the bandgap

Diagram



Fields

Field	Function
31-3 —	Reserved
2 REFRESH_EN	Refresh Enable Enables the Bandgap Low-Power Refresh mode. The refresh mode must also be enabled for lowest power consumption. 0b - Refresh mode is disabled 1b - Refresh mode is enabled for low power operation
1 LDO_EN	LDO Enable Enables the backup SRAM regulator. LDOCTLA[BG_EN] must enable the bandgap when the backup SRAM regulator is enabled. After you enable the bandgap and backup SRAM regulator, you must wait until STATUSA[LDO_RDY] becomes 1 before the SRAM can enter a low-power state where the regulator supplies the array contents. 0b - Disable 1b - Enable
0 BG_EN	Bandgap Enable Enables the LDO_RAM bandgap. 0b - Disable 1b - Enable

31.7.1.11 LDO_RAM Lock A (LDOLCKA)

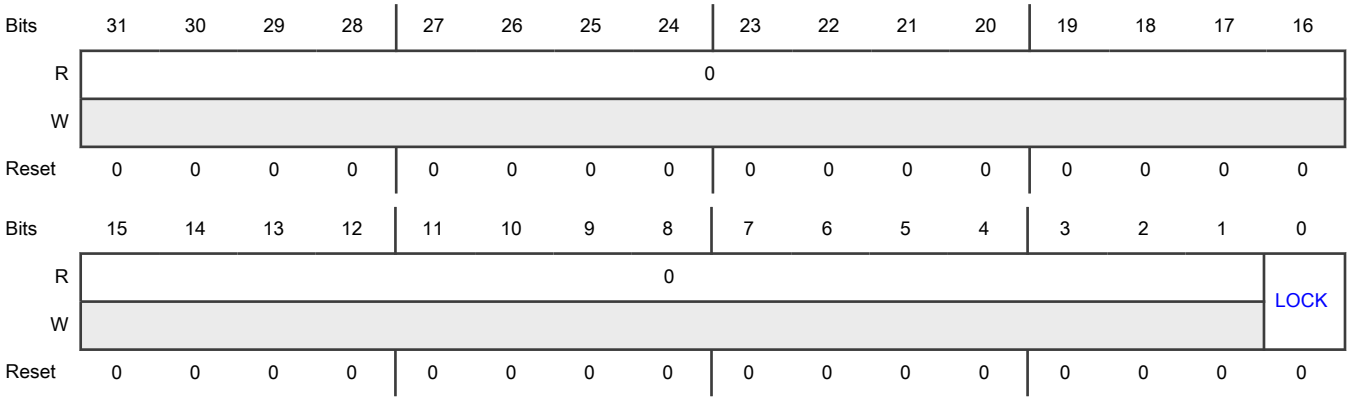
Offset

Register	Offset
LDOLCKA	318h

Function

Contains the lock field. Writes to this register are blocked when the LDO_RAM lock register is 1.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 LOCK	Lock Blocks any write to the LDO_RAM registers. VBAT POR writes 0 to this field. 0b - Do not block 1b - Block

31.7.1.12 RAM Control (LDORAMC)

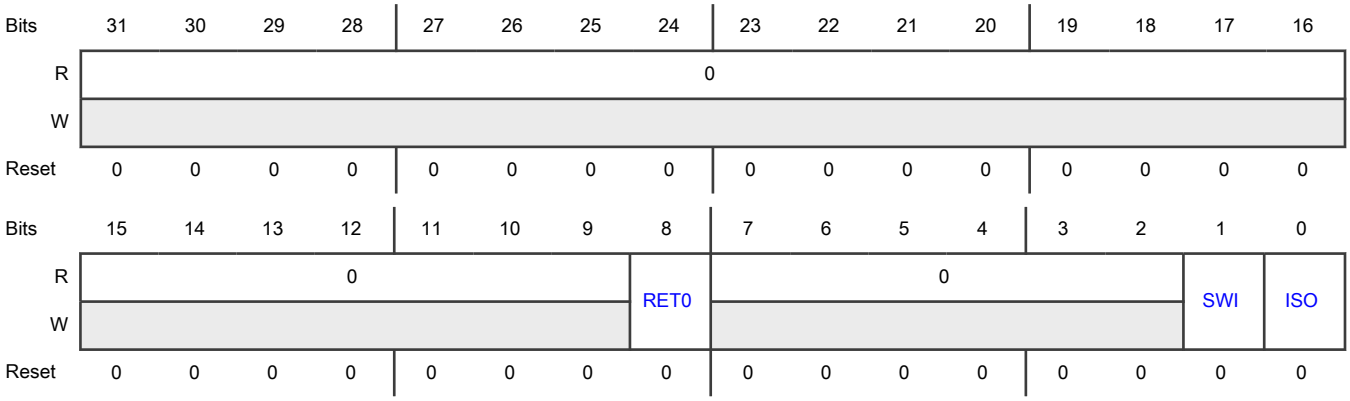
Offset

Register	Offset
LDORAMC	320h

Function

Contains software overrides for the SRAM isolation and backup switch. Always isolate the SRAM array before asserting or negating the switch control.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 RETn	Retention Configures retention of each SRAM array in low power modes. See the VBAT chip-specific section for more details on these SRAM arrays. When LDO_RAM is enabled, at least one SRAM array must be retained. When LDO_RAM is disabled, this field specifies whether VDD_CORE continues to provide power to the SRAM array. 0b - Corresponding SRAM array is retained in low-power modes 1b - Corresponding SRAM array is not retained in low-power modes
7-2 —	Reserved
1 SWI	Switch SRAM Specifies how the SRAM array is powered. Change this field when LDORAMC[ISO] = 1. 0b - Supply follows the chip power modes 1b - LDO_RAM powers the array
0 ISO	Isolate SRAM Specifies how the SRAM array is isolated. 0b - State follows the chip power modes 1b - Isolates SRAM and places it in Low-Power Retention mode

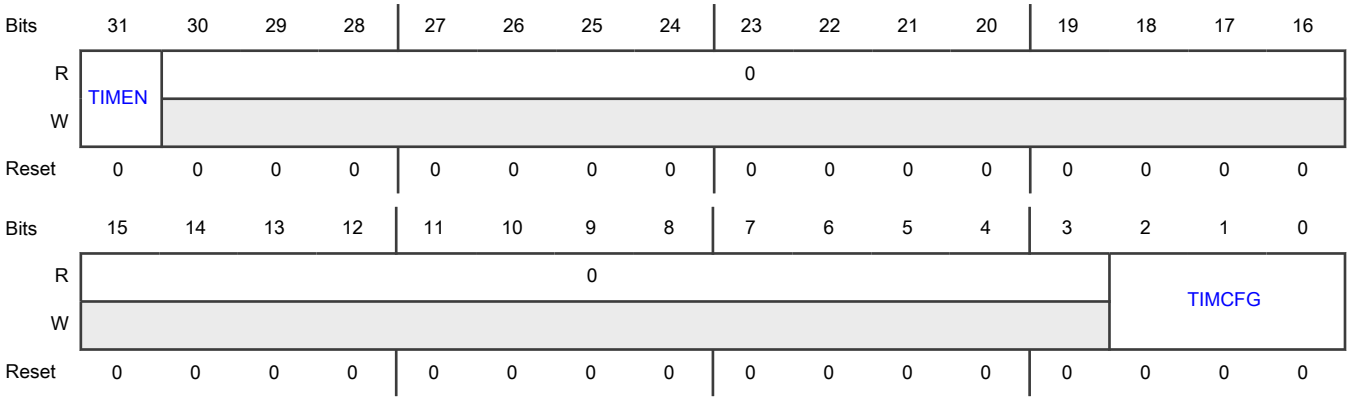
31.7.1.13 Bandgap Timer 0 (LDOTIMER0)

Offset

Register	Offset
LDOTIMER0	330h

Function
Controls one software-configurable timer when the bandgap is enabled and are clocked by FRO16K.

Diagram



Fields

Field	Function
31 TIMEN	Bandgap Timeout Period Enable 0b - Disable 1b - Enable
30-3 —	Reserved
2-0 TIMCFG	Timeout Configuration Configures the bandgap timeout 0 period. Changed when the timer is disabled. 000b - 1 s 001b - 500 ms 010b - 250 ms 011b - 125 ms 100b - 62.5 ms 101b - 31.25 ms 110b - 15.625 ms 111b - 7.8125 ms

31.7.1.14 Bandgap Timer 1 (LDOTIMER1)

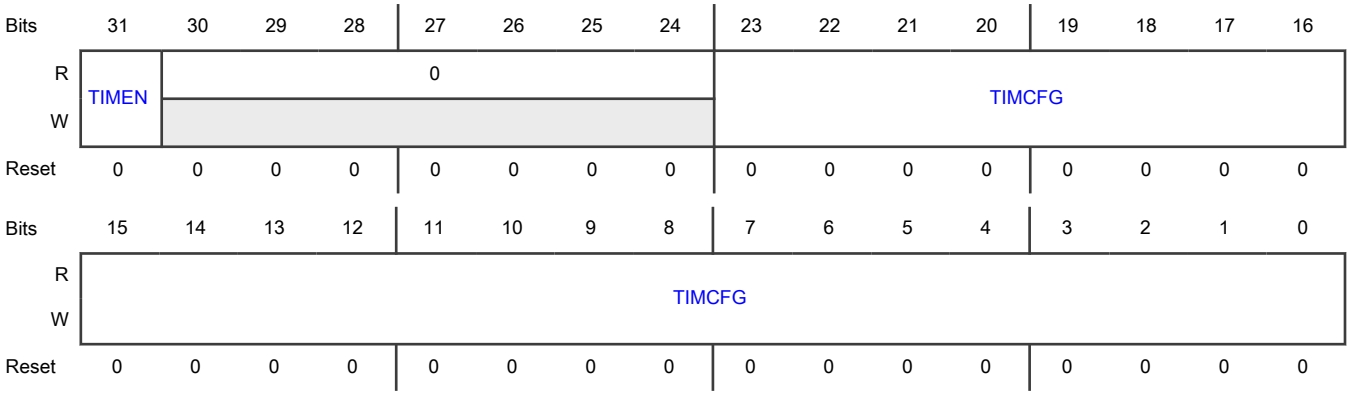
Offset

Register	Offset
LDOTIMER1	338h

Function

Controls the other software-configurable timer when the bandgap is enabled and are clocked by the FRO16K.

Diagram



Fields

Field	Function
31 TIMEN	Bandgap Timeout Period Enable 0b - Disable 1b - Enable
30-24 —	Reserved
23-0 TIMCFG	Timeout Configuration Configures the bandgap timeout 1 period. Configures timeout in number of seconds, ranging from 1 to 16,777,216 s. You can change this field when the timer is disabled.

Chapter 32
External Watchdog Monitor (EWM)

32.1 Chip-specific EWM information

Table 243. Reference links to related information

Topic	Related module	Reference
Full description	EWM	EWM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

32.1.1 Module instances

This device has one instance of the EWM module, EWM0.

32.2 Overview

For safety purposes, a redundant watchdog system, EWM, is designed to monitor external circuits and the MCU software flow. EWM provides a backup mechanism to the internal watchdog.

The internal watchdog resets the MCU's CPU and peripherals and is used to monitor the flow and execution of the embedded software within the MCU. It consists of a counter that, if allowed to overflow, forces an internal, asynchronous reset to all on-chip peripherals. The counter also optionally asserts the RESET_B pin to reset external devices and circuits. The watchdog counter must not overflow if the software code works well and services the watchdog to restart the actual counter.

The EWM does not reset the MCU's CPU and peripherals, making it different from internal watchdog. The EWM module provides an independent ewm_out_b signal that, when asserted, resets or places an external circuit into a safe mode. The ewm_out_b signal asserts upon EWM counter timeout. An optional external input, ewm_in, allows additional control when asserting the ewm_out_b signal.

32.2.1 Block diagram

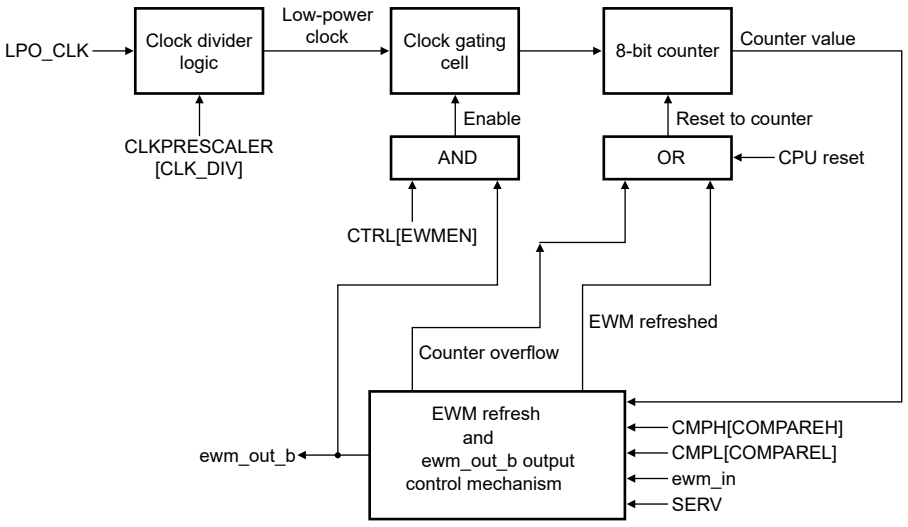


Figure 89. Block diagram

32.2.2 Features

- Independent LPO_CLK source
- Programmable timeout period, specified in terms of the number of EWM LPO_CLK cycles
- Windowed refresh option that provides:
  - A robust check to confirm that the program flow is faster than expected.
  - A programmable window.
  - Refresh outside the window, leading to assertion of the ewm_out_b signal.
- Robust refresh mechanism:
  - Write values of B4h and 2Ch to Service (SERV) within 15 peripheral bus clock cycles.
- One output port, ewm_out_b, which when asserted is used to reset or place the external circuit into Safe mode
- One input port, ewm_in, which allows an external circuit to control the assertion of the ewm_out_b signal

32.3 Functional description

The following sections discuss these aspects of EWM:

- Functional details
- Operating modes

NOTE

If the BUS_CLK is lost, EWM does not generate the ewm_out_b signal and no refresh operation is possible.

32.3.1 Modes of operation

32.3.1.1 Stop mode

When EWM is in Stop mode, the CPU cannot refresh EWM. After entering Stop mode, the EWM counter freezes.

Following are the possible ways to exit Stop mode:

- Through a reset: EWM remains disabled in this case.
- Through an interrupt: EWM is re-enabled and the counter continues to be clocked from the same value as prior to Stop mode entry.

NOTE

Consider the following if EWM enters Stop mode during the CPU refresh mechanism:

- While exiting Stop mode through an interrupt, the refresh mechanism starts from the previous state. That is, if you write the refresh command correctly and EWM enters Stop mode immediately, you must write the next command in 15 peripheral bus clocks after exiting Stop mode.
- You must mask all interrupts before executing the EWM refresh instructions.

32.3.1.2 Debug mode

EWM remains unimpacted when entering Debug mode:

- If EWM is enabled before entering Debug mode, it remains enabled.
- If EWM is disabled before entering Debug mode, it remains disabled.

32.3.2 Using the EWM counter

EWM uses an 8-bit ripple counter that is fed by a clock source independent of the peripheral bus clock source. As the preferred timeout is between 1 ms and 100 ms, the actual clock source must be in the kHz range.

The counter is reset to 0 in these conditions:

- After CPU reset
- After the EWM refresh action completes
- At counter overflow

The CPU cannot access the counter value.

32.3.3 Using compare registers

You can write to Compare Low (CMPL) and Compare High (CMPH) only once after a CPU reset and you cannot modify them until another CPU reset occurs. These registers are used to create a refresh window for the EWM module.

You cannot program Compare Low (CMPL) and Compare High (CMPH) with the same value. In case of any attempt, the ewm_out_b signal asserts as soon as the counter reaches the value of Compare Low (CMPL) + 1.

NOTE

- You must update Compare Low (CMPL) and Compare High (CMPH) before enabling EWM. Therefore, you must provide a reasonable time after POR for the external monitoring circuit to stabilize. You must also ensure that the ewm_in pin is deasserted.
- Updating Compare Low (CMPL) requires one clock cycle to propagate a new value. It is recommended to write Service (SERV) after one clock period of the slowest clock frequency. See the chip-specific information section for more information.

32.3.4 Using the refresh mechanism

Other than the initial configuration of EWM, the CPU can access EWM only through Service (SERV). The CPU must access this register by correctly writing unique data within the windowed time frame, as determined by Compare Low (CMPL) and Compare High (CMPH) for the correct EWM refresh operation. The following table describes conditions that exist and the refresh mechanisms that apply to those conditions.

Table 244. Refresh mechanisms

Condition	Mechanism
The EWM refresh action completes when the value of Compare Low (CMPL) ≤ the counter value ≤ the value of Compare High (CMPH).	The software behaves as expected and the EWM counter resets to 0. The ewm_out_b output signal remains in Deasserted state if, during the EWM refresh action, the ewm_in input is in Deasserted state.
The EWM refresh action completes when the counter value < the value of Compare Low (CMPL).	The software refreshes EWM before the windowed time frame, the counter resets to 0, and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.
The counter value becomes greater than the value of Compare High (CMPH) prior to completion of the EWM refresh action.	The software does not refresh EWM. The EWM counter resets to 0 and the ewm_out_b output signal asserts no matter what the value of the ewm_in input signal is.

See Service (SERV) for more on the refresh mechanism.

32.3.5 Interrupt

When the ewm_out_b signal asserts, an interrupt request can be generated to indicate the assertion of the EWM reset out signal. The interrupt is enabled when CTRL[INTEN] = 1. Writing 0 to this field clears the interrupt request but does not affect the ewm_out_b signal, which can be deasserted only by writing to Control (CTRL) after a system reset.

32.3.6 Clocking

The following table shows EWM clocks.

Table 245. EWM Clocks

Clock	Description
IPG_CLK	This is the system clock and should be turned on for EWM to be able to work properly. During low power modes in which the core is powered down, this clock is disabled,
IPG_CLK_S	This is the IPS clock and is synchronous with IPG_CLK. It is disabled except during IPS write accesses. it is enabled with EWM's IPS_MODULE_EN
LPO_CLOCK	This is a low power clock used for running EWM counter. This clock is gated when EWM is disabled or when ewm_out_b is asserted.

32.3.7 Using the counter clock prescaler

You can program CLKPRESCALER[CLK_DIV] to divide the EWM counter clock source. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must not exceed half the frequency of the bus clock.

32.4 External signals

EWM includes external signals, as shown in the following table.

NOTE

All active-low signals are represented with the suffix "_b" throughout the chapter.

Table 246. Signal descriptions

Signal	Description	I/O
ewm_in	EWM's input for the safety status of external safety circuits. You can program the polarity of ewm_in by using CTRL[ASSIN]. The default polarity is active-low.	I
ewm_out_b	EWM's reset out signal	O

32.4.1 Using the ewm_out_b signal

The ewm_out_b is a digital output signal having active-low behaviour; it is considered as "active" or asserted when its value is logic 0 or ground, and conversely, "inactive" or deasserted when its value is logic 1. It is used to gate an external circuit (application-specific) that controls critical safety functions.

The ewm_out_b signal remains deasserted when the CPU regularly refreshes EWM within the programmable refresh window, indicating that the application code is executing as expected.

The ewm_out_b signal asserts in any of the following conditions:

- An EWM refresh action occurs when the counter value is less than the value of Compare Low (CMPL).
- The EWM counter value becomes greater than the value of Compare High (CMPH) and no EWM refresh occurs.
- The functionality of the ewm_in pin is enabled and the ewm_in pin asserts when refreshing EWM.

32.4.2 Using the ewm_out_b pin state in low-power modes

During Wait, Stop, and Power-Down modes, the ewm_out_b pin enters a high-impedance state. You have the option to control the logic state of the pin by using an external pull device or by configuring the internal pull device. When the CPU enters Run mode from Wait or Stop mode recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode after exiting Power-Down mode, the pin returns to its reset state.

32.4.3 Using the ewm_in signal

The ewm_in signal is a digital input signal for the safety status of external safety circuits. This signal allows an external circuit to control the assertion of the ewm_out_b signal. For example, in the application, an external circuit monitors a critical safety function, and if there is a fault with the safety function, the external circuit can actively initiate the ewm_out_b signal, which controls the gating circuit.

The ewm_in signal is ignored if EWM is disabled, or if CTRL[INEN] = 0 after any reset.

After you enable EWM (by writing 1 to CTRL[EWMEN]) and the ewm_in functionality (by writing 1 to CTRL[INEN]), the ewm_in signal must be in Deasserted state before the CPU starts refreshing EWM. This ensures that the ewm_out_b signal stays in Deasserted state; otherwise, the ewm_out_b output signal asserts.

32.5 Memory map and register definitions

This section contains the module memory map and registers.

NOTE

EWM supports only 8-bit register accesses; 16-bit and 32-bit accesses are not supported.

32.5.1 EWM register descriptions

32.5.1.1 EWM memory map

EWM0 base address: 4001_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CTRL)	8	RW	00h
1h	Service (SERV)	8	RW	00h
2h	Compare Low (CMPL)	8	RW	00h
3h	Compare High (CMPH)	8	RW	FFh
5h	Clock Prescaler (CLKPRESCALER)	8	RW	00h

32.5.1.2 Control (CTRL)

Offset

Register	Offset
CTRL	0h

Function

Controls the functionality of EWM.

NOTE

You can write to CTRL[INEN], CTRL[ASSIN], and CTRL[EWMEN] only once after a CPU reset. Modifying these fields more than once generates a bus transfer error.

Diagram

Bits	7	6	5	4	3	2	1	0
R	0				INTEN	INEN	ASSIN	EWMEN
W								
Reset	0	0	0	0	0	0	0	0

Fields

Field	Function
7-4 —	Reserved
3 INTEN	Interrupt Enable Enables interrupt request generation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field = 1 and the ewm_out_b signal is asserted, an interrupt request is generated. To deassert interrupt requests, write 0 to this field. 0b - Deasserts interrupt requests 1b - Generates interrupt requests
2 INEN	Input Enable Enables the ewm_in port. When this field = 1, it enables the ewm_in port. 0b - Disables 1b - Enables
1 ASSIN	Assertion State Select Specifies the asserted state of the ewm_in signal. By default, the asserted state of the ewm_in signal is logic 0 (active-low), which is when this field = 0. When this field = 1, the ewm_in asserted state is logic 1 (active-high). You can use this field to change the expected polarity of the ewm_in signal. 0b - Logic 0 1b - Logic 1
0 EWMEN	EWM Enable Enables the EWM module. If this field = 1, it enables the EWM module, and if the field = 0, it disables the EWM module. You cannot re-enable this field until the next reset because of its write-once nature. 0b - Disables 1b - Enables

32.5.1.3 Service (SERV)

Offset

Register	Offset
SERV	1h

Function

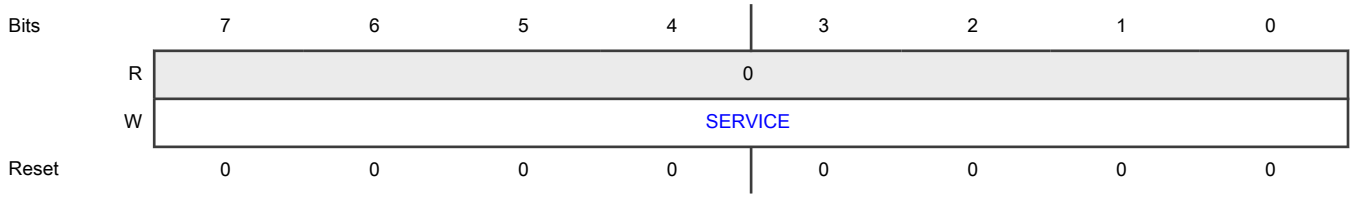
Provides an interface from the CPU to the EWM module.

Attempted reads of this register return 0.

NOTE

If CPU requests service, when EWM counter is in Stop mode, or in reset state, it will be served only when the EWM counter starts.

Diagram



Fields

Field	Function
7-0 SERVICE	Service Provides an interface from the CPU to the EWM module. The EWM refresh mechanism requires the CPU to write these values to this field: a first data byte of B4h, followed by a second data byte of 2Ch. The EWM refresh action is invalid if either of the following conditions is true: • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte, known as EWM_refresh_time. The number of peripheral bus clock cycles required for EWM_refresh_time is 15.

32.5.1.4 Compare Low (CMPL)

Offset

Register	Offset
CMPL	2h

Function

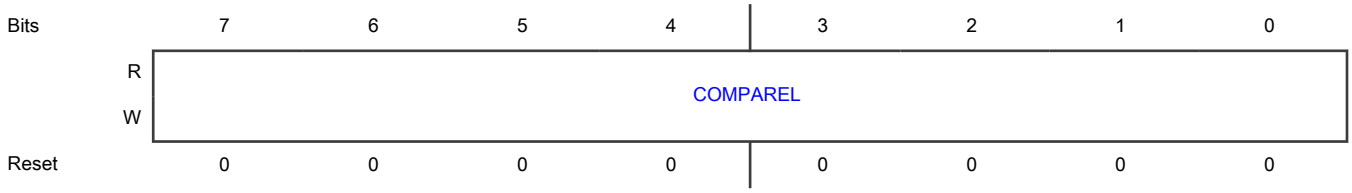
Determines the lower value of the windowed time frame for the correct EWM refresh operation.

This register is reset to 0 after a CPU reset. This provides no minimum time for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

Diagram



Fields

Field	Function
7-0 COMPAREL	Compare Low Configures the minimum counter value when refreshes are allowed. If a refresh is attempted while the counter value is lower than COMPAREL, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset even if the (default) minimum refresh time is required.

32.5.1.5 Compare High (CMPH)

Offset

Register	Offset
CMPH	3h

Function

Determines the higher value of the windowed time frame for the correct EWM refresh operation.

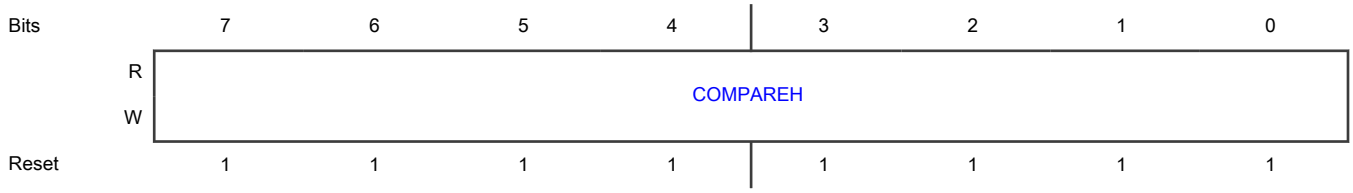
This register is reset to FFh after a CPU reset. This provides a maximum time of up to 256 clocks for the CPU to refresh the EWM counter.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error.

The valid values for this register are up to FEh because the EWM counter never expires when the value of COMPAREH = FFh. The expiration happens only if the EWM counter is greater than the value of COMPAREH.

Diagram



Fields

Field	Function
7-0 COMPAREH	Compare High Configures the maximum counter value till when refreshes are allowed. If a refresh is not attempted while the counter value is greater than COMPAREH, then the ewm_out_b signal is asserted. To prevent runaway code from changing the value of this field, you must write to this field after a CPU reset.

32.5.1.6 Clock Prescaler (CLKPRESCALER)

Offset

Register	Offset
CLKPRESCALER	5h

Function

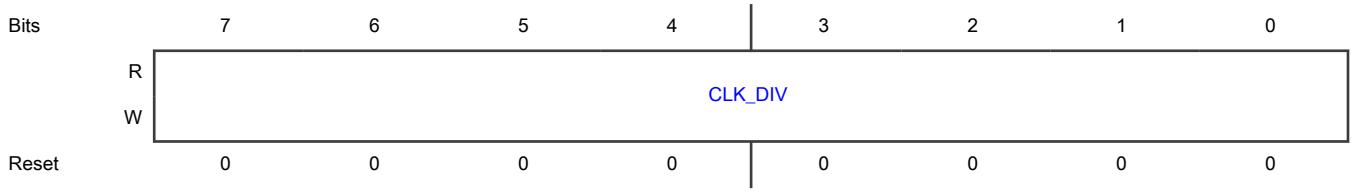
Prescales the EWM counter clock source by a clock divider.

This register is reset to 00h after a CPU reset.

NOTE

You can write to this register only once after a CPU reset. Writing to the register more than once generates a bus transfer error. You must write the required prescaler value before enabling EWM.

Diagram



Fields

Field	Function
7-0	Clock Divider Prescales the selected low-power clock source for running the EWM counter:

Table continues on the next page...

Field	Function
CLK_DIV	Prescaled clock frequency = low-power clock source frequency ÷ (1 + the value of CLK_DIV) See chip-specific information for low-power clock source frequency used in your device.

33.2 Overview

TRGMUX allows you to configure the trigger inputs for various peripherals.

33.2.1 Block diagram

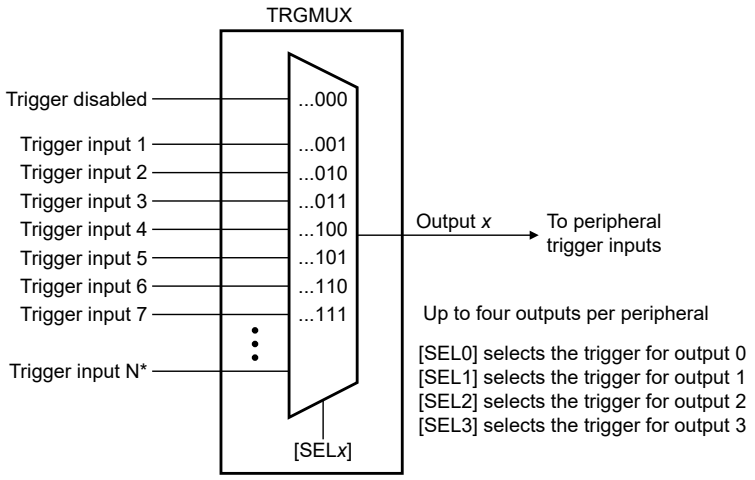

Figure 90. Block diagram

NOTE

Up to 255 trigger inputs may be available for SEL0, SEL1, and SEL2. For SEL3, up to 127 trigger inputs may be available. When the number of trigger inputs is 255, SEL3 is not available and becomes reserved. See the chip-specific TRGMUX information for details about trigger input and output configuration on this chip.

33.2.2 Features

- Configurable trigger sources for peripherals
- Dedicated TRGMUX register for each peripheral

33.3 Functional description

33.3.1 Clocking

This module has no clocking considerations.

33.3.2 Interrupts

This module has no interrupts.

33.4 External signals

This module has no external signals.

33.5 Initialization

This module does not require initialization.

33.6 TRGMUX register descriptions

33.6.1 TRGMUX memory map

You can only write to TRGMUX registers in Supervisor mode.

Table 248. Select bit fields

Field	Description
SEL*x*	Specifies the MUX select for the peripheral trigger inputs. Use this field to select the trigger sources for peripheral modules. 0h - Trigger function is disabled 1h - Trigger function is always high 2h - TRGMUX0 TRGMUX0_IN0 input is selected 3h - TRGMUX0 TRGMUX0_IN1 input is selected 4h - TRGMUX0 TRGMUX0_IN2 input is selected 5h - TRGMUX0 TRGMUX0_IN3 input is selected 6h - WUU0 Trigger Event input is selected 7h - RTC0 Alarm Event input is selected 8h - RTC0 Seconds Match input is selected 9h - LPTMR0 Counter Match input is selected Ah - LPTMR1 Counter Match input is selected Bh - LPIT0 Channel 0 input is selected Ch - LPIT0 Channel 1 input is selected Dh - LPIT0 Channel 2 input is selected Eh - LPIT0 Channel 3 input is selected Fh - TPM0 Channel 0 input is selected 10h - TPM0 Channel 1 input is selected 11h - TPM0 Channel 2 input is selected 12h - TPM0 Channel 3 input is selected 13h - TPM0 Channel 4 input is selected 14h - TPM0 Channel 5 input is selected 15h - TPM0 Overflow input is selected 16h - TPM1 Channel 0 input is selected 17h - TPM1 Channel 1 input is selected 18h - TPM1 Channel 2 input is selected 19h - TPM1 Channel 3 input is selected 1Ah - TPM1 Channel 4 input is selected 1Bh - TPM1 Channel 5 input is selected 1Ch - TPM1 Overflow input is selected 1Dh - LPI2C0 Master End of Packet input is selected 1Eh - LPI2C0 Slave End of Packet input is selected 1Fh - LPI2C1 Master End of Packet input is selected 20h - LPI2C1 Slave End of Packet input is selected

34.1.1 Module instances

This device contains one instance of the WUU module, WUU0.

34.1.2 WUU0 sources

The device uses the following inputs as wakeup sources to the WUU0 module. The WUU0_Px inputs are connections to external physical pins. The WUU0_MxIF inputs are connections to the internal peripheral interrupt flags from different modules that can operate in low-power modes. The WUU0_MxDR inputs are connections to the internal peripheral Asynchronous DMA or module Triggers from different modules that can operate in low-power modes.

NOTE

In addition to the WUU0 wakeup sources, the device also wakes from low power modes when NMI_b or RESET_b pins are enabled and the respective pin is asserted.

34.1.3 LPO clock

The LPO mentioned in this chapter is the 32 kHz clock from CCM32K, see 32 kHz Clock Control Module (CCM32K) for details.

34.2 Overview

WUU facilitates in selecting external pins and on-chip modules as interrupt wake-up sources from Deep Sleep/Power Down power modes. You can also configure the external pins to act as interrupt wake-up sources in all power modes. WUU helps pins and modules generate a temporary wake-up from Deep Sleep mode for servicing DMA or trigger events. Digital filtering is also available for the external wake-up pins.

See the chip-specific WUU information section for input sources to WUU.

34.2.1 Block diagram

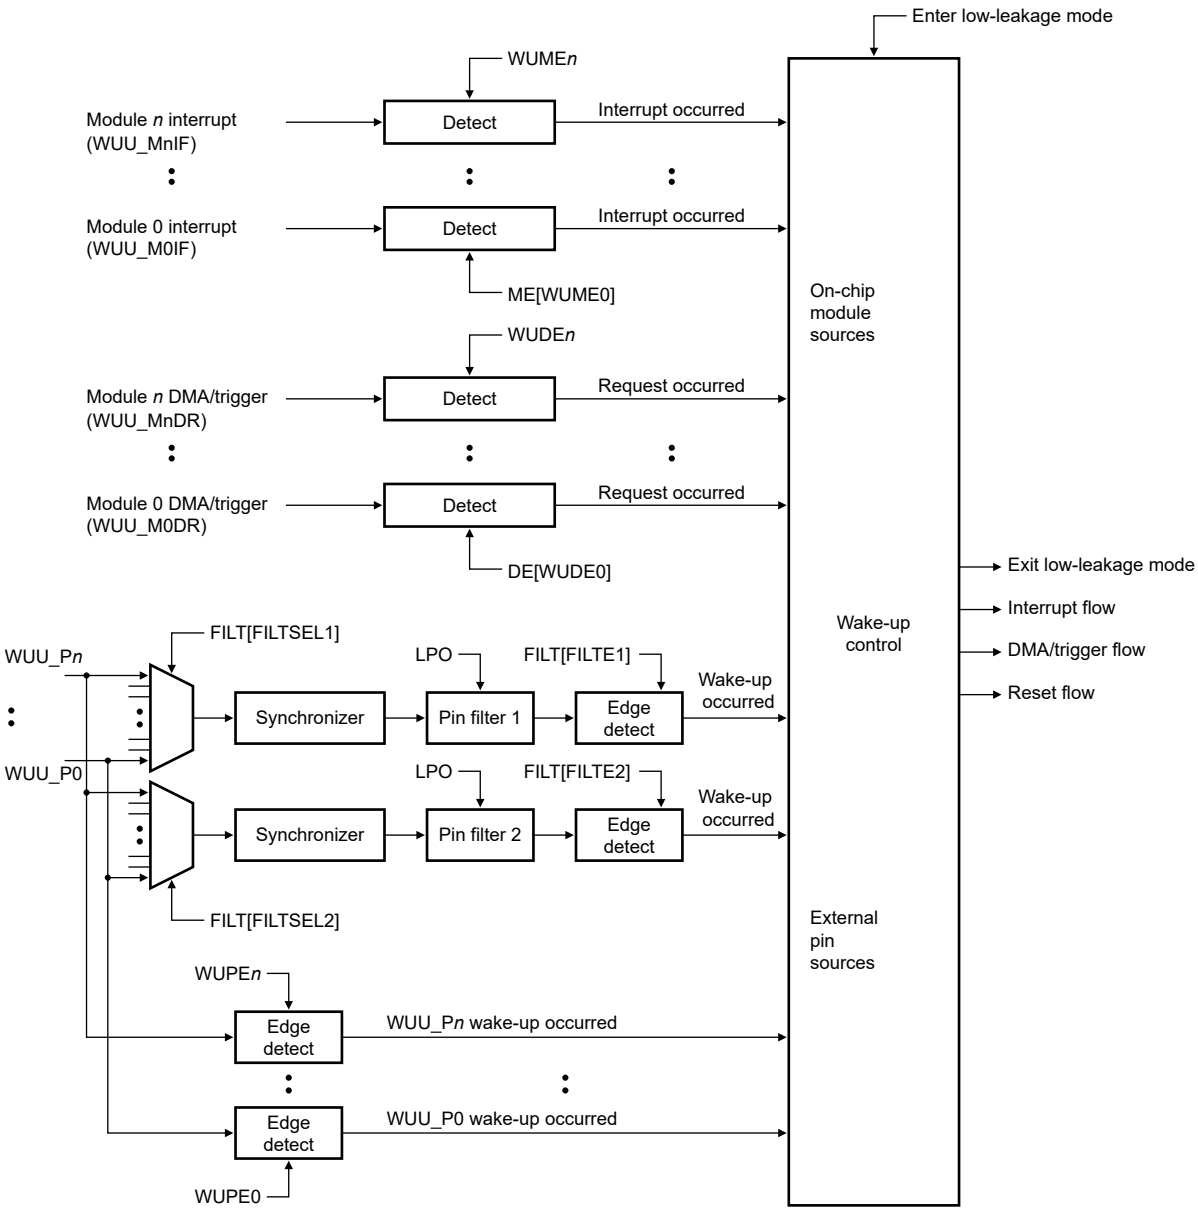

Figure 91. WUU block diagram

34.2.2 Features

- Supports external input pins and on-chip modules with individual enable bits to wake the chip from low-leakage modes.
- Contains input sources that may be external pins or from on-chip modules capable of running in Deep Sleep or Power Down power modes. See the chip-specific WUU information for the wake-up input sources for this chip.
- Supports configuring on-chip modules as DMA or trigger sources for temporary wake-up from Deep Sleep mode.
- Supports configuring external pins as DMA request or trigger sources for temporary wake-up from Deep Sleep mode.
- Provides external input pins programmable for falling-edge, rising-edge, or any edge detection.
- Provides optional digital filters to qualify an external pin detect. Disabling the LPO clock bypasses and disables filters.

- Filters all external input pins; but only 2 filters are available at a given time.
- Enables external input pin and filter detection in all power modes (not limited to Deep Sleep/Power Down power modes).

34.3 Functional description

34.3.1 Operation

WUU allows on-chip modules and external input pins as a source of wake-up from low-leakage modes.

WUU contains pin enables for each external pin and on-chip module. For each external pin, you can disable or select the edge type for the wake-up with the following options:

- Falling edge
- Rising edge
- Either edge

Exit due to a pin event triggers a WUU interrupt after wake-up is complete. When enabling an external pin as a wake-up source, configure the pin as an input pin. You can also configure a pin to generate an interrupt from a Deep Sleep/Power Down mode or a DMA/trigger event for temporary wake-up from Deep Sleep mode. Detection logic for a pin can optionally remain enabled during all power modes using Pin Mode Configuration (PMC).

On the basis of the LPO clock, WUU implements optional 3-cycle glitch filters. Detected external pin must remain asserted until the enabled glitch filter times out. Additional latency of up to two cycles is due to synchronization, which results in a total of up to five cycles of delay before the detect circuit alerts the system to the wake-up event when the filter function is enabled. Two wake-up detect filters are available for selected external pins. Glitch filtering is not provided for the on-chip modules. You can configure a filter to generate an interrupt from Deep Sleep/Power Down mode or a DMA/trigger event for temporary wake-up from Deep Sleep mode. Detection logic for a filter can optionally remain enabled during all power modes using Pin Filter Mode Configuration (FMC).

For on-chip module interrupts, ME[WUME*n*] enables the associated module interrupt as a wake-up source. Exit due to a module interrupt will not trigger a WUU interrupt.

For on-chip module DMA/trigger events, DE[WUDE*n*] enables the associated module DMA/trigger event as a wake-up source. Exit due to a module DMA/trigger event does not trigger a WUU interrupt.

34.3.2 Modes of operation

WUU becomes functional on entry into a low-leakage power mode. After recovery from Deep Sleep mode, WUU is immediately disabled. After recovery from Power Down mode, WUU continues to detect wake-up events until you have reinitialized the system and deasserted isolation. Detection of external pin/filter events can also optionally remain enabled in all power modes using Pin Mode Configuration (PMC)/Pin Filter Mode Configuration (FMC).

34.3.2.1 Deep Sleep mode

Wake-up events due to either an external pin input (WUU_Px) or an on-chip module interrupt (WUU_MxIF) result in a CPU interrupt flow to begin user code execution. The source of the wake-up determines the subsequent path of code execution:

- Pin events trigger the WUU interrupt service routine.
- Module interrupts trigger that same module's interrupt service routine.

NOTE

The interrupt controller must not mask the WUU interrupt to avoid a scenario where the system does not fully recover from Deep Sleep mode after an external pin event.

Wake-up events due to an on-chip module request (WUU_MxDR) DMA/trigger event result in a temporary exit from Deep Sleep mode to allow the request to be serviced when the CPU clock remains gated. The system reenters Deep Sleep mode after servicing the request.

Wake-up events due to an external pin (WUU_Px) DMA/trigger event result in a temporary exit from Deep Sleep mode to allow the request to be serviced when the CPU clock remains gated. The system reenters Deep Sleep mode after servicing the request.

34.3.2.2 Non–low-leakage modes

WUU is inactive in all non–low-leakage modes, with the exception of external pin/filter detection which can explicitly be kept enabled during all power modes using Pin Mode Configuration (PMC)/Pin Filter Mode Configuration (FMC). WUU chips are accessible in non–low-leakage modes and are available for configuring and reading status when bus transactions are possible.

34.3.3 Clocking

During chip low-power operation, in order to provide the wake-up function for the chip, ensure that clocking is available for WUU by the LPO clock. See the chip-specific WUU information for the chip clock connection details.

34.3.4 Reset

WUU resets after VSYS warm reset. This is the global chip reset, but it does not include the reset that asserts due to wake-up from low-power mode.

34.3.5 Interrupts

You can enable on-chip module interrupts as wake-up sources in Module Interrupt Enable (ME).

34.3.6 DMA

You can enable on-chip DMA requests as wake-up sources in Module DMA/Trigger Enable (DE).

With external pin inputs, you can generate a DMA request using either rising edge, falling edge, or both edge detection in Pin DMA/Trigger Configuration 1 (PDC1) and Pin DMA/Trigger Configuration 2 (PDC2).

34.4 External signals

Table 251. External signals

Signal	Description	I/O
WUU_Pn	External pin wake-up inputs; can be enabled to detect a rising edge, a falling edge, or any change.	I
WUU_MnIF	On-chip module interrupt flags	I
WUU_MnDR	On-chip module DMA/trigger events	I

34.5 Initialization

For an enabled module wake-up input, clear the module's flag before entering Deep Sleep or Power Down mode to avoid an immediate exit from the mode.

Clear the flags associated with external input pins, filtered and unfiltered, prior to entry to Deep Sleep or Power Down mode.

When an external wake-up pin filter is first enabled in Pin Filter (FILT), filter operation begins immediately. After enabling an external pin filter or changing its source pin, wait for at least five LPO clock cycles to allow the filter to initialize before entering Deep Sleep or Power Down mode or before enabling filter detection for all power modes in Pin Filter Mode Configuration (FMC).

NOTE

After recovering from a Power Down mode, you must restore the chip configuration before relaxing any power domain isolation controls. In particular, to avoid any WUU flag from being falsely set, restore the pin configuration for the enabled WUU wake-up pins before removing any voltage isolation between power domains.

34.6 Application information

To enable an external pin as a wake-up source in low-power modes, follow these steps:

1. If the flag is not 0, write 1 to PF[WUF*n*].
2. Configure the PDC*m*[WUPDC*n*] as either an interrupt or DMA request.
3. Configure the PE*m*[WUPE*n*] for rising edge, falling edge, or both edge detection.

When you have configured an external pin to be an active wake-up source in all power modes (PMC[WUPMC*n*] = 1), you must not change the corresponding wake-up pin enable (PE*m*[WUPE*n*]) and wake-up pin configuration (PDC*m*[WUPDC*n*]) settings for that pin. To modify the PE*m*[WUPE*n*] or PDC*m*[WUPDC*n*] settings, follow these steps:

1. Write 0 to PMC[WUPMC*n*] for that pin.
2. Update the corresponding PE*m*[WUPE*n*] or PDC*m*[WUPDC*n*] settings as needed.
3. Write 1 to PMC[WUPMC*n*] for that pin.

34.7 Memory map and register definition

This section includes the WUU module memory map and detailed descriptions of all registers.

34.7.1 WUU register descriptions

NOTE

You can write to WUU registers only in Supervisor mode. A bus error results from write accesses in User mode.

VSYS warm reset resets all WUU registers.

34.7.1.1 WUU memory map

WUU0 base address: 4001_9000h

34.7.1.5 Pin Enable 2 (PE2)

Offset

Register	Offset
PE2	Ch

Function

Contains the field to enable and select the edge detect type for the available external wake-up input pins in the range from WUU_P16 to WUU_P31.

NOTE

- Do not modify the value of PE2[WUPE*n*] when its corresponding PMC[WUPMC*n*] = 1.
- VSYS warm reset resets this register.

34.7.1.8 Pin Flag (PF)

Offset

Register	Offset
PF	20h

Function

Contains the wake-up flags indicating which wake-up source caused the chip to exit Deep Sleep (if the corresponding PMC[WUPMC*n*] = 1) or Power Down mode. For Deep Sleep mode, this is the source causing the CPU interrupt flow. For Power Down mode, this is the source causing the chip reset flow.

To clear a flag, write a 1 to the corresponding PF[WUF*n*]. If set, the wake-up flag (WUF*n*) remains set even if the associated pin wake-up is disabled in its PE*m*[WUPE*n*] field.

NOTE

VSYS warm reset resets this register.

34.7.1.9 Pin Filter (FILT)

Offset

Register	Offset
FILT	30h

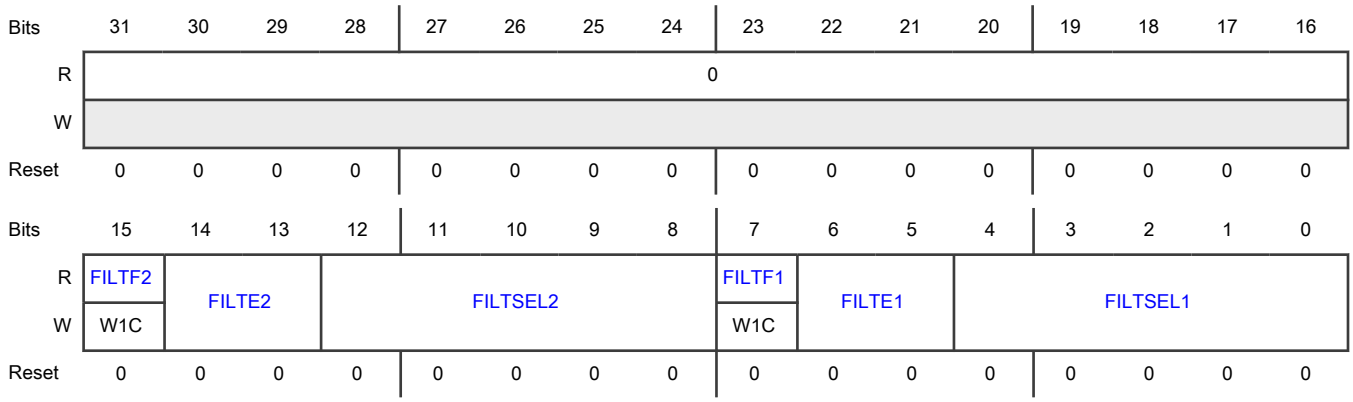
Function

Contains control and status fields to enable and configure the digital filter features for an external wake-up pin.

NOTE

VSYS warm reset resets this register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 FILTF2	Filter 2 Flag Indicates that the filtered external pin was a source of exiting a low-leakage power mode. 0b - No 1b - Yes
14-13 FILTE2	Filter 2 Enable Enables the filter for wake-up. This field configures the edge detection as follows: • For field value = 01b, when configured as an interrupt/DMA request: Detect on rising edge. When configured as a trigger event: Detect on high level • For field value = 10b, when configured as an interrupt/DMA request: Detect on falling edge. When configured as a trigger event: Detect on low level • For field value = 11b, when configured as an interrupt/DMA request: Detect on any edge 00b - Disable 01b - Enable (Detect on rising edge or high level) 10b - Enable (Detect on falling edge or low level) 11b - Enable (Detect on any edge)
12-8 FILTSEL2	Filter 2 Pin Select Selects and filters the external pin WUU_Pn, where *n* equals the value programmed into FILTSEL2.
7 FILTF1	Filter 1 Flag Indicates that the filtered external pin was a source of exiting a low-leakage power mode. 0b - No 1b - Yes
6-5 FILTE1	Filter 1 Enable Enables the filter for wake-up. This field configures the edge detection as follows: • For field value = 01b, when configured as an interrupt/DMA request: Detect on rising edge. When configured as a trigger event: Detect on high level • For field value = 10b, when configured as an interrupt/DMA request: Detect on falling edge. When configured as a trigger event: Detect on low level • For field value = 11b, when configured as an interrupt/DMA request: Detect on any edge 00b - Disable 01b - Enable (Detect on rising edge or high level) 10b - Enable (Detect on falling edge or low level)

34.7.1.10 Pin DMA/Trigger Configuration 1 (PDC1)

Offset

Register	Offset
PDC1	38h

Function

Configures the available external wake-up input pins in the range from WUU_P0 to WUU_P15 to generate an interrupt, DMA, or a trigger event when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in Pin Enable 1 (PE1) is detected and remains asserted until the corresponding flag is cleared in Pin Flag (PF).
- When configured as a DMA request, the request is asserted when the edge programmed in Pin Enable 1 (PE1) is detected and remains asserted until either the corresponding flag is cleared in Pin Flag (PF) or until the requested DMA transfer is complete.
- When configured as a trigger event, the trigger is asserted when the level programmed in Pin Enable 1 (PE1) is detected and remains asserted when the input pin is asserted. The corresponding flag in Pin Flag (PF) will not be set.

NOTE

- Do not modify the value of PDC*m*[WUPDC*n*] field when its corresponding PMC[WUPMC*n*] = 1.
- VSYS warm reset resets this register.

34.7.1.11 Pin DMA/Trigger Configuration 2 (PDC2)

Offset

Register	Offset
PDC2	3Ch

Function

Configures the available external wake-up input pins in the range from WUU_P16 to WUU_P31 to generate an interrupt, DMA, or a trigger event when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in Pin Enable 2 (PE2) is detected and remains asserted until the corresponding flag is cleared in Pin Flag (PF).
- When configured as a DMA request, the request is asserted when the edge programmed in Pin Enable 2 (PE2) is detected and remains asserted until either the corresponding flag is cleared in Pin Flag (PF) or until the requested DMA transfer is complete.
- When configured as a trigger event, the trigger is asserted when the level programmed in Pin Enable 2 (PE2) is detected and remains asserted when the input pin is asserted. The corresponding flag in Pin Flag (PF) will not be set.

NOTE

- Do not modify the value of PDC*m*[WUPDC*n*] field when its corresponding PMC[WUPMC*n*] = 1.
- VSYS warm reset resets this register.

34.7.1.12 Pin Filter DMA/Trigger Configuration (FDC)

Offset

Register	Offset
FDC	48h

Function

Configures the external pin filters to generate an interrupt, DMA, or a trigger event when detected.

- When configured as an interrupt, the interrupt is asserted when the edge programmed in FILT*m*[FILTE*n*] is detected and remains asserted until the corresponding FILTF*n* flag is cleared.
- When configured as a DMA request, the request is asserted when the edge programmed in FILT*m*[FILTE*n*] is detected and remains asserted until either the corresponding FILTF*n* flag is cleared or until the requested DMA transfer is complete.
- When configured as a trigger event, the trigger is asserted when the level programmed in Pin Filter (FILT) is detected and remains asserted when the input pin is asserted. The corresponding FILTF*n* flag will not be set.

NOTE

VSYS warm reset resets this register.

You can modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn). 1b - Active during all power modes. Do not modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn).
1 WUPMC1	Wake-up Pin Mode Configuration for WUU_Pn Configures an external wake-up pin to provide active detection during all power modes. 0b - Active only during a low-leakage mode. You can modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn). 1b - Active during all power modes. Do not modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn).
0 WUPMC0	Wake-up Pin Mode Configuration for WUU_Pn Configures an external wake-up pin to provide active detection during all power modes. 0b - Active only during a low-leakage mode. You can modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn). 1b - Active during all power modes. Do not modify the corresponding fields within Pin Enable (PEn) or Pin DMA/Trigger Configuration (PDCn).

34.7.1.14 Pin Filter Mode Configuration (FMC)

Offset

Register	Offset
FMC	58h

Function

Configures the detection logic for external pin filters to remain enabled during all power modes, not just during Deep Sleep/Power Down mode.

NOTE

VSYS warm reset resets this register.

Chapter 35
Watchdog Timer (WDOG)

35.1 Chip-specific WDOG information

Table 252. Reference links to related information

Topic	Related module	Reference
Full description	WDOG	WDOG
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

35.1.1 Module instances

This device has two instances of the WDOG module, WDOG0 and WDOG1.

NOTE

On reset, the WDOG0 is enabled and the WDOG1 is disable by default.

35.1.2 CS[CLK] fields

The CS[CLK] configures the clock source that feeds the watchdog counter as below.

- 00b - SLOW_CLK
- 01b - 32K_CLK
- 11b - OSC-RF

35.1.3 CS[PRES] fields

NOTE

If the watchdog (WDOG) is using the 32 kHz clock source, don't enable the prescale bit before entering PD/DPD low power modes.

35.1.4 WDOG0 and ROM Bootloader

During a normal boot of ROM bootloader, The WDDOG0 is disabled during execution and re-enabled before the bootloader transfers control to the boot image. A normal boot occurs after each warm reset or when system wakes up from low power mode, if the low power wakeup path fails.

At each normal boot:

- The CS[TST] bit in the WDOG0 register is cleared and CS[UPDATE] bit is set.
- The typical value of WDOG0 CS register after a normal boot is 0000_32A0h.

Carefully configure the WDOG0 CS register, if normal boot is the boot path after waking up from a special Power Down mode. If the system enters a Power Down mode with the MAIN domain is Powered Down and the WAKE domain is in Deep Sleep. Take the following precautions before entering Power Down mode:

- Do not clear the CS[UPDATE] bit of WDOG0 (i.e., must not be set to 0b).
- Do not set the CS[CLK] field to 01b or select any clock source slower than 6 MHz.

If these conditions are not followed, it may result in boot failure upon wakeup.

If the system wakes up successfully from Power Down mode using the low power wakeup path, the ROM bootloader does not change the WDOG0 configuration.

35.2 Overview

WDOG is an independent timer that is available for system use. It provides a safety feature to ensure that the software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If WDOG is not serviced (refreshed) within a certain period, it resets the chip.

35.2.1 Block diagram

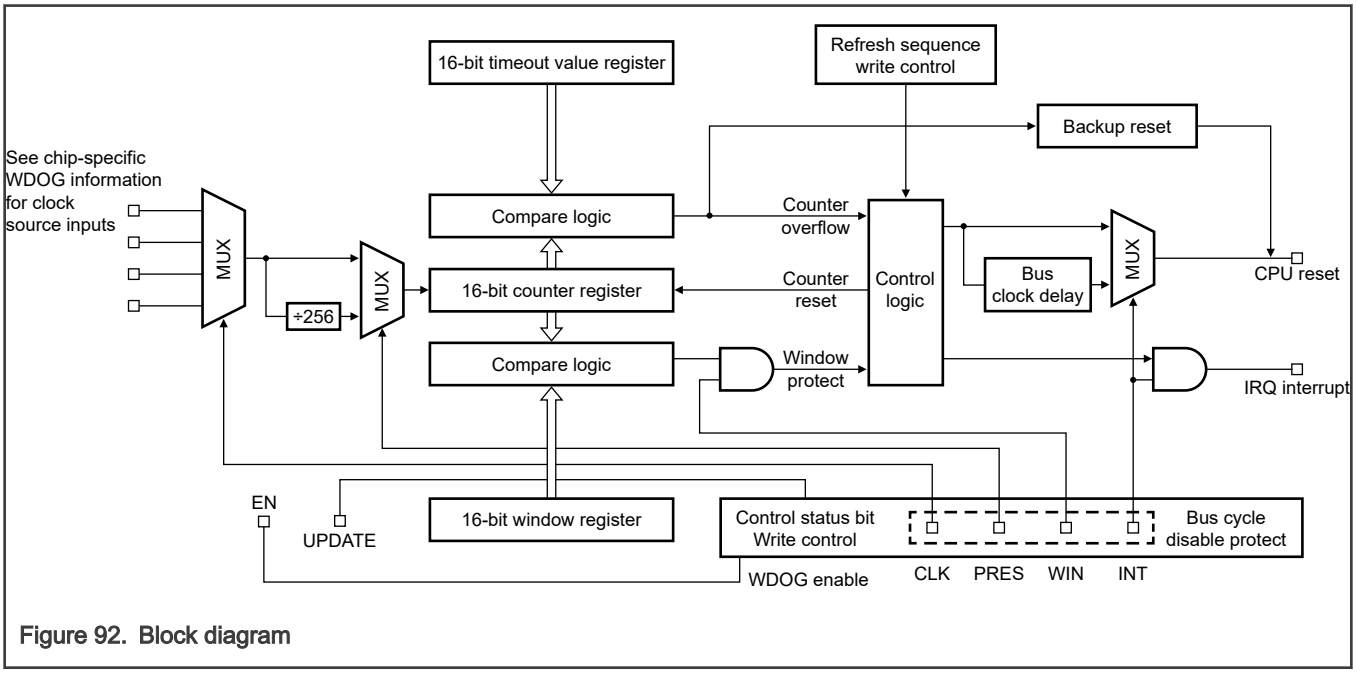

Figure 92. Block diagram

35.2.2 Features

- Configurable clock source inputs independent of the bus clock
- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional, fixed 256 clock prescaler when longer timeout periods are needed
- Robust write sequences for counter refresh: provision to refresh the sequence of writing to WDOG Counter (CNT)
- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Robust check to ensure that program flow is faster than expected
  - Early refresh attempts that trigger a reset
- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with an interrupt vector for an interrupt service routine (ISR)
  - Forced reset that occurs 128 bus clocks after the interrupt vector fetch
- Write-once-after-reset configuration fields to ensure that WDOG configuration is not altered mistakenly
- Robust write sequence for unlocking write-once configuration fields

— Unlock sequence of writing to WDOG Counter (CNT), for allowing updates to write-once configuration fields

— You must make updates within 1024 bus clocks after unlocking and before WDOG closing unlock window

35.3 Functional description

WDOG provides a fail-safe mechanism to ensure that you can reset the system to a known state of operation in case of system failure, such as the CPU clock stopping or there being a runaway condition in the software code. The WDOG counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not refreshed, it generates a reset triggering event.

35.3.1 Refresh mechanism

WDOG resets the chip if the WDOG counter is not refreshed. A robust refresh mechanism makes it very unlikely for a runaway code to refresh WDOG.

To refresh the WDOG counter, you must execute a refresh write sequence before the timeout period expires. In addition, in case of Window mode, you must not start the refresh sequence until you set the time value in Watchdog Window (WIN). See the following figure for more information.

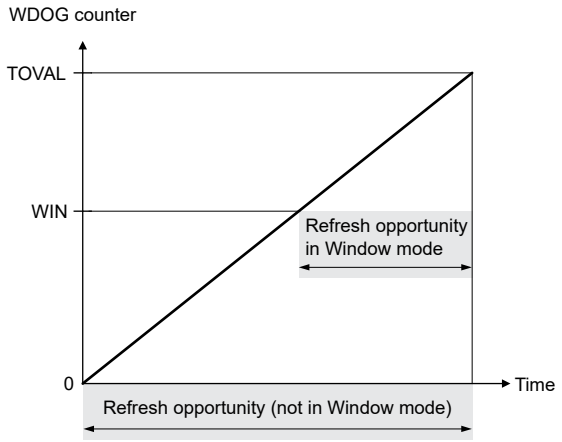

Figure 93. Refresh opportunity for the WDOG counter

35.3.1.1 Using Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, you can program WDOG to force a reset when refresh attempts are early.

When Window mode is enabled, you must refresh WDOG after the counter has reached a minimum expected time value; otherwise, WDOG resets the chip. The minimum expected time value is specified in Watchdog Window (WIN). Setting CS[WIN] enables Window mode.

35.3.1.2 Refreshing WDOG

The refresh write sequence is based on the following methods:

- Either two 16-bit writes (A602h, B480h) or four 8-bit writes (A6h, 02h, B4h, 80h) to WDOG Counter (CNT) if CS[CMD32EN] = 0 [1]
- One 32-bit write (B480_A602h) to WDOG Counter (CNT) if CS[CMD32EN] = 1

[1] The example sequence of four 8-bit writes is as below:

— write A6h to WDOG_CNT[CNTHIGH], write 02h to WDOG_CNT[CNTLOW];

— write B4h to WDOG_CNT[CNTHIGH], write 80h to WDOG_CNT[CNTLOW].

You must apply these methods before WDOG times out; otherwise, it resets the chip.

Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

See Application information for example code.

35.3.2 Configuring WDOG

35.3.2.1 Configuring WDOG once

All WDOG control bitfields, timeout value, and window value are write-once after reset. This means that after a write has occurred, they cannot be changed unless a reset occurs. You can ensure this by configuring the window and timeout values first, followed by the other control bitfields, when CS[UPDATE] = 0.

This provides a robust mechanism to configure WDOG and ensure that a runaway condition cannot mistakenly disable or modify the WDOG configuration, after the module is configured.

The new configuration takes effect only after you write to all registers except WDOG Counter (CNT) after reset. Otherwise, WDOG uses the reset values by default. If the Window mode is disabled (CS[WIN] is 0), you do not need to write to Watchdog Window (WIN) to bring the new configuration into effect.

35.3.2.2 Reconfiguring WDOG

In some cases (for example, when supporting a bootloader function), you may want to reconfigure or disable WDOG, without forcing a reset first:

- By writing 1 to CS[UPDATE] on the initial configuration of WDOG after a reset, you can reconfigure WDOG at any time by executing an unlock sequence.
- Conversely, if CS[UPDATE] remains 0, the only way to reconfigure WDOG is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

35.3.2.3 Unlocking WDOG

The unlock sequence is based on the following two methods:

- Either two 16-bit writes (C520h, D928h) or four 8-bit writes (C5h, 20h, D9h, 28h) to WDOG Counter (CNT), after WDOG is configured, if CS[CMD32EN] is 0 [2]
- One 32-bit write (D928_C520h) to WDOG Counter (CNT), after WDOG is configured, if CS[CMD32EN] is 1

An improper unlock sequence causes WDOG to reset. On completing the unlock sequence, you must reconfigure WDOG within 1024 bus clocks; otherwise, WDOG closes the unlock window.

NOTE

Because it requires 1024 bus clocks to reconfigure WDOG, you must insert some delays before executing STOP or WAIT instructions after reconfiguring WDOG. This ensures that WDOG's new configuration takes effect before the chip enters Low-Power mode. Otherwise, the chip may not wake up from Low-Power mode.

35.3.3 Functionality in Debug and Low-Power modes

By default, WDOG is not functional in Debug, Wait, or Stop modes. However, it can remain functional in these modes as follows:

- For Debug mode, write 1 to CS[DBG] (WDOG is functional in Debug mode even when Debug mode holds the CPU).

[2] The example sequence of four 8-bit writes is as below:

— write C5h to WDOG_CNT[CNTHIGH], write 20h to WDOG_CNT[CNTLOW];

— write D9h to WDOG_CNT[CNTHIGH], write 28h to WDOG_CNT[CNTLOW].

- For Wait mode, write 1 to CS[WAIT].
- For Stop mode, write 1 to CS[STOP] and CS[WAIT], and ensure that the clock source is active in Stop mode.

NOTE

WDOG can generate an interrupt in Stop mode.

Do not write 1 to CS[INT] in Stop mode. Otherwise, WDOG reset after a delay of 128 bus clocks (lose bus clock) will not occur, but backup reset will take effect.

For Debug and Stop modes, in addition to the aforementioned configuration, you must use a clock source other than the bus clock as the reference clock for the counter; otherwise, WDOG cannot function.

35.3.4 Fast testing of WDOG

Before executing the application code in safety-critical applications, you must test that WDOG works as expected and resets the chip. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 k clocks).

To help minimize the startup delay for application code after reset, WDOG implements a feature that tests its functioning more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for a timeout against the corresponding byte of WDOG Timeout Value (TOVAL). For a complete coverage when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.

Using this test feature reduces the test time to 512 clocks (not including overhead, such as, user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

In case POR bitfield in the system reset register is set, indicating a power-on reset occurs, you must perform the WDOG fast test.

35.3.4.1 Testing each byte of the counter

For procedure of test, follow these steps:

1. Program the preferred WDOG timeout value in WDOG Timeout Value (TOVAL) during the WDOG configuration period.
2. Select a byte of the counter to test by using the configuration CS[TST] = 10b for the low byte, and CS[TST] = 11b for the high byte.
3. Wait for WDOG to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because RAM is not affected by a WDOG reset, the timeout period of the WDOG counter can be compared with the software counter to verify whether the timeout period occurred as expected.

   The WDOG counter then times out and forces a reset.
4. Confirm that the WDOG flag in the system reset register is set, indicating that WDOG caused the reset (the POR flag remains clear).
5. Confirm that CS[TST] showing a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, and then select the next byte in step 2.

NOTE

Only a POR writes 0 to TST, which is not affected by other resets.

35.3.4.2 Entering User mode

After successfully testing the low and high bytes of the WDOG counter, you can configure TST to 01b to indicate that WDOG is ready for use in application User mode. Therefore, if a reset occurs again, you can recognize the reset trigger as a real WDOG reset caused by runaway or faulty application code.

As an ongoing test when using the default clock source, you can periodically read WDOG Counter (CNT) to ensure that the counter is being incremented.

35.3.5 Clocking

You can program CLK to select clock source options in the WDOG counter. See the chip-specific WDOG information for available clock inputs and the default option for this chip.

The option allows you to select a clock source that is independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the WDOG counter continues to run if the bus clock is somehow halted (see Backup reset).

For WDOG to function properly, you must enable the default WDOG clock source after its functional reset is deasserted.

An optional fixed prescaler for all clock sources allows longer timeout periods. When CS[PRES] is set to 1, the clock source is prescaled by 256 before clocking the WDOG counter.

The following table summarizes examples of the different available WDOG timeout periods. In the table, RCP means "reference clock period".

Table 253. WDOG timeout availability

Reference clock	Prescaler	WDOG timeout availability
REF_CLK	Pass through	1 × RCP to 65535 × RCP
	Enable	256 × RCP to 16776960 × RCP

NOTE

When you switch clock sources during reconfiguration, WDOG holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration period (1024 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

35.3.6 Backup reset

The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the WDOG counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

The backup reset becomes valid when an interrupt is enabled and the WDOG clock is not from a bus clock. If an interrupt is enabled, once the bus clock is cut off before exiting the interrupt routine, the normal watchdog reset is blocked. In this case, the second overflow causes a backup reset directly.

NOTE

You must use a clock source other than the bus clock as a reference clock for the counter; otherwise, the backup reset function becomes unavailable.

35.3.7 Interrupts

WDOG can generate an interrupt request to delay resets.

When interrupts are enabled (CS[INT] = 1), and after a reset-triggering event (such as a counter timeout or invalid refresh attempt), WDOG:

1. Generates an interrupt request.
2. Waits 128 bus clocks (from the interrupt vector fetch, not the reset-triggering event).
3. Forces a reset.

This process allows the ISR to perform tasks such as analyzing the stack to debug code.

When interrupts are disabled (CS[INT] = 0), WDOG does not wait before forcing a reset.

35.4 External signals

This module has no external signals.

35.5 Initialization

See Configuring WDOG once.

35.6 Application information

To disable or reconfigure WDOG, it should be completed before WDOG timeout. Disabling or reconfiguring WDOG should occur at the very beginning of the software code, for example, at the beginning of the startup or main function.

NOTE

- After you configure WDOG, it needs at least 2.5 periods of WDOG clock to take effect. This means a gap must have at least 2.5 clocks between two configurations.
- When the chip starts from boot ROM and then jumps to flash memory, you must disable WDOG at the beginning of the bootloader and enable it after the bootloader exits. To reconfigure WDOG using the flash memory program, it also needs the interval of at least 2.5 WDOG clocks after the bootloader exits.

To disable or reconfigure WDOG without forcing a reset, you must write 1 to CS[UPDATE] during the initial WDOG configuration. You can use the unlock sequence at any time, within the timeout limit, to reconfigure WDOG.

35.6.1 Disabling WDOG

To disable WDOG, you must first perform the unlock sequence. Then, write 0 to clear CS[EN]. The following code snippet shows an example of a 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK | WDOG_CS_UPDATE(1); //disable watchdog
EnableInterrupts; //enable global interrupt
```

35.6.2 Disabling WDOG after reset

All WDOG registers are unlocked by reset. Therefore, an unlock sequence is unnecessary but it needs to be written to all WDOG registers to make the new configuration take effect. The following code snippet shows an example of disabling WDOG after reset.

```
DisableInterrupts; // disable global interrupt
WDOG_CS &= ~WDOG_CS_EN_MASK; // disable watchdog
WDOG_TOVAL= 0xFFFF;
while(WDOG_CS[ULK]);  // waiting for lock
while(~WDOG_CS[RCS]); // waiting for new configuration to take effect
EnableInterrupts; // enable global interrupt
```

35.6.3 Configuring WDOG

WDOG can be configured once by clearing CS[UPDATE] = 0. After that, yWDOG cannot be reconfigured until a reset. To reconfigure without forcing a reset, write 1 to set CS[UPDATE] when configuring WDOG. The following example code shows how to configure WDOG without Window mode, clock source as LPO, interrupt enabled, and timeout value to 256 clocks. The following code snippet shows an example of a 32-bit write.

35.6.3.1 Configuring once

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
```

```
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

35.6.3.2 Configuring for Reconfigurable mode

```
DisableInterrupts; //disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
while(WDOG_CS[ULK]==0);  //wait until registers are unlocked
WDOG_TOVAL = 256; //set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) |
          WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); //wait until new configuration takes effect
EnableInterrupts; //enable global interrupt
```

35.6.4 Refreshing WDOG

To refresh WDOG and reset the WDOG counter to zero, a refresh sequence is required. The following code snippet shows an example of a 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt
```

35.7 Memory map and register definition

35.7.1 WDOG register descriptions

35.7.1.1 WDOG memory map

WDOG0 base address: 4001_A000h

WDOG1 base address: 4001_B000h

Offset	Register	Width (In bits)	Access	Reset value
0h	WDOG Control and Status (CS)	32	RW	See section
4h	WDOG Counter (CNT)	32	RW	0000_0000h
8h	WDOG Timeout Value (TOVAL)	32	RW	0000_FFFFh
Ch	Watchdog Window (WIN)	32	RW	0000_0000h

35.7.1.2 WDOG Control and Status (CS)

Offset

Register	Offset
CS	0h

Function

Describes watchdog control and status.

NOTE

TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

Diagram

Fields

Field	Function
31-16 —	Reserved
15 WIN	WDOG Window This write-once bitfield enables Window mode. 0b - Disable 1b - Enable
14 FLG	WDOG Interrupt Flag Acts as an interrupt indicator when CS[INT] = 1. 0b - No interrupt occurred 1b - An interrupt occurred
13 CMD32EN	Command 32 Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This write-once bitfield enables or disables WDOG support for 32-bit (otherwise 16-bit or 8-bit) refresh or unlock command write words. If this field = 0, it disables support for 32-bit refresh or unlock command write words. Only a 16-bit or 8-bit write is supported. If this field = 1, it enables support for 32-bit refresh or unlock command write words. A 16-bit or 8-bit write is not supported. You must unlock WDOG after writing to this field for reconfiguration. 0b - Disable 1b - Enable
12 PRES	WDOG Prescaler This write-once bitfield enables a fixed 256 prescaling of the WDOG counter reference clock. See Block diagram that shows the clock divider option. 0b - Disable 1b - Enable
11 ULK	Unlock Status Indicates whether WDOG is unlocked. 0b - Locked 1b - Unlocked
10 RCS	Reconfiguration Success Indicates whether the reconfiguration is successful. This field becomes 1 when new configuration takes effect, and becomes 0 with a successful unlock command. 0b - Unsuccessful 1b - Successful
9-8 CLK	WDOG Clock Selects the clock source that feeds the WDOG counter. You can write to this field only once. **NOTE** See chip-specific WDOG information for details of bitfield settings.
7 EN	WDOG Enable Enables the WDOG counter to start counting. You can write to this field only once. 0b - Disable 1b - Enable
6	WDOG Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
INT	Configures WDOG to immediately generate an interrupt request upon a reset-triggering event (timeout or illegal write to WDOG), before forcing a reset. After the interrupt vector fetch (that takes place after the reset-triggering event), the reset occurs after a delay of 128 bus clocks. If this field = 0, it disables WDOG interrupts (WDOG resets are not delayed). If this field = 1, it enables WDOG interrupts (WDOG interrupts are delayed by 128 bus clocks from the interrupt vector fetch). You can write to this field only once. 0b - Disable 1b - Enable
5 UPDATE	Updates Allowed Allows you to reconfigure WDOG without a reset. If this field = 0, you cannot update WDOG after the initial configuration, without forcing a reset. If this field = 1, you can modify the WDOG configuration registers within 1024 bus clocks after performing the unlock write sequence. You can write to this field only once. 0b - Updates not allowed 1b - Updates allowed
4-3 TST	WDOG Test Enables Fast Test mode, which allows you to exercise all bits of the counter to demonstrate that WDOG is functioning properly. See Fast testing of WDOG for more information. If this field = 0, it disables WDOG Test mode. If this field = 1, it enables WDOG User mode and disables WDOG Test mode. After testing WDOG, you must use this setting to indicate that WDOG is functioning normally in User mode. If this field = 10, it enables WDOG Test mode; only the low byte is used. CNTLOW is compared with TOVALLOW. If this field = 11, it enables WDOG Test mode; only the high byte is used. CNTHIGH is compared with TOVALHIGH. This write-once field is cleared (0:0) on POR only. Any other reset does not affect the value of this field. 00b - Disable WDOG Test mode 01b - Enable WDOG User mode 10b-11b - Enable WDOG Test mode
2 DBG	Debug Enable Enables WDOG to operate when the chip is in Debug mode. You can write to this field only once. 0b - Disable 1b - Enable
1 WAIT	Wait Enable Enables WDOG to operate when the chip is in Wait mode. You can write to this field only once.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 STOP	Stop Enable Enables WDOG to operate when the chip is in Stop mode. You can write to this field only once. 0b - Disable 1b - Enable

35.7.1.3 WDOG Counter (CNT)

Offset

Register	Offset
CNT	4h

Function

Provides access to the value of the free-running WDOG counter. You can read the counter register at any time but cannot write directly to it. However, the following write sequences to this register have special functions:

1. The refresh sequence resets WDOG counter to 0000h. See Refreshing WDOG for more information.
2. The unlock sequence allows WDOG to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See Configuring for Reconfigurable mode for more information.

NOTE

All other writes to this register are illegal and force a reset.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

Fields

Field	Function
31-16 —	Reserved
15-8 CNTHIGH	Counter High Byte Contains the WDOG high byte.
7-0 CNTLOW	Counter Low Byte Contains the WDOG low byte.

35.7.1.4 WDOG Timeout Value (TOVAL)

Offset

Register	Offset
TOVAL	8h

Function

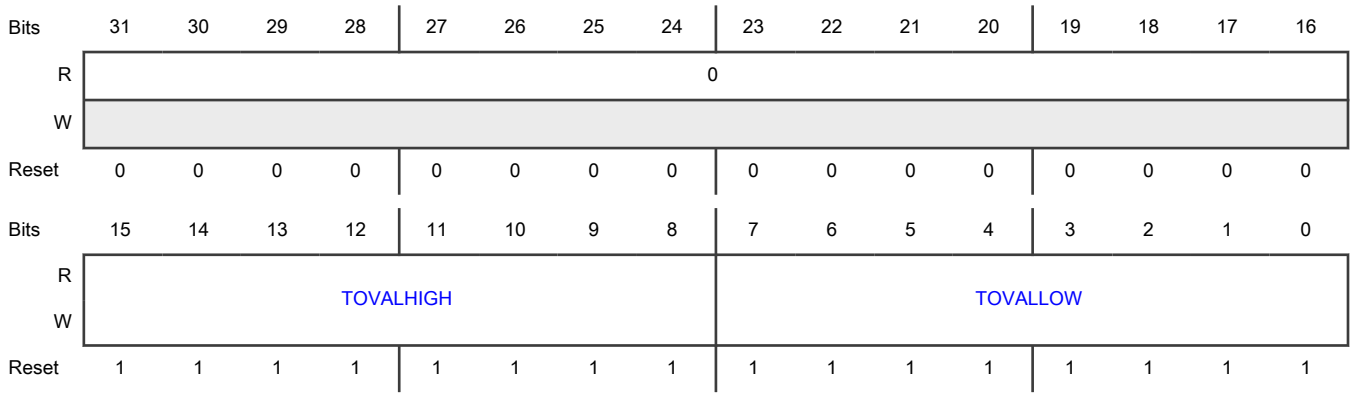
Contains the 16-bit value used to set the timeout period of WDOG.

The WDOG counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, WDOG forces a reset triggering event.

NOTE

Do not write 0 to this register (if CS[TST] = 11b, then TOVALHIGH cannot be written as 0; if CS[TST] = 10b, then TOVALLOW cannot be 0); otherwise, WDOG always generates a reset.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 TOVALHIGH	Timeout Value High Contains the high byte of the timeout value.
7-0 TOVALLOW	Timeout Value Low Contains the low byte of the timeout value.

35.7.1.5 Watchdog Window (WIN)

Offset

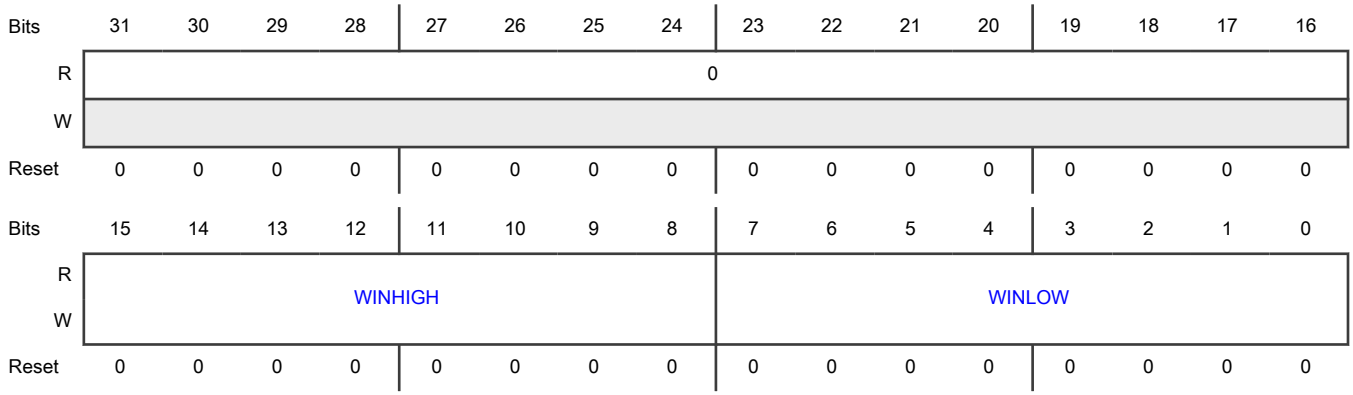
Register	Offset
WIN	Ch

Function

Determines the earliest time that a refresh sequence is considered valid, if CS[WIN] = 1. See Refresh mechanism for more information.

The WIN register value must be less than the TOVAL register value.

Diagram



Fields

Field	Function
31-16 —	Reserved

36.1.1 Module instances

This device has one instance of the CRC module, CRC0.

36.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

36.2.1 Block diagram

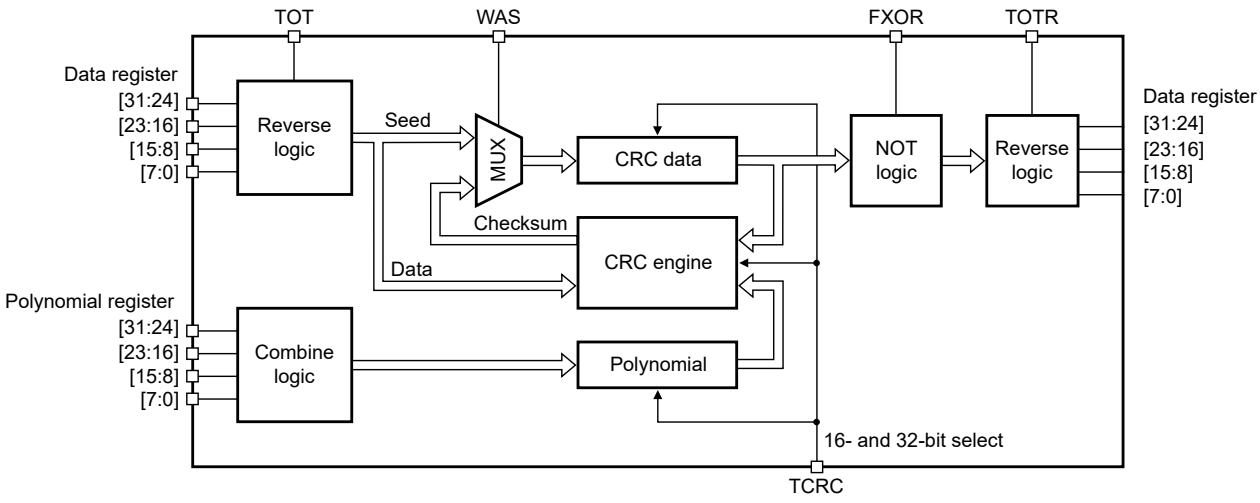

Figure 94. Block diagram

36.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers
- Programmable initial seed value and polynomial

- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

36.3 Functional description

36.3.1 Modes of operation

The following section describes mode of operation that affects the functionality of CRC: Run mode.

36.3.1.1 Run mode

Run mode is the basic mode of operation.

36.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

36.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

36.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA .
8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

36.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

36.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.
2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

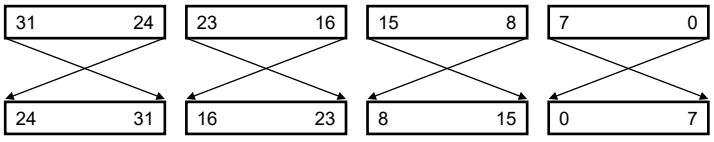

Figure 95. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

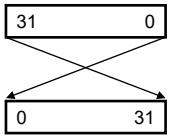

Figure 96. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

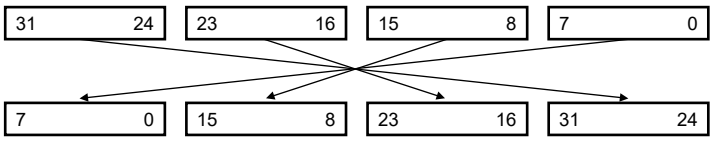

Figure 97. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

36.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

36.3.5 Clocking

Table 255. CRC clocks

Type of clock	Description
Bus clock	Used to control the access to the CRC registers and function the CRC module
Function clock	Used to function the CRC module

NOTE

See the chip-specific clocking chapter, to know the specific CRC clocks supported on your device.

36.3.6 Interrupts

This module has no interrupts.

36.4 External signals

There is no CRC signal that connects off chip.

36.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

36.6 Use cases

The following tables use the little-endian format.

36.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

Table 256. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]
CRC-16_CCITT_FALSE	1021h	FFFFh	0	0	0000h	0h	0h	0h

36.7 Memory map and register descriptions

NOTE

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

36.7.1 CRC register descriptions

36.7.1.1 CRC memory map

CRC0 base address: 4002_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Data (DATA)	32	RW	FFFF_FFFFh
4h	Polynomial (GPOLY)	32	RW	0000_1021h
8h	Control (CTRL)	32	RW	0000_0000h

36.7.1.2 Data (DATA)

Offset

Register	Offset
DATA	0h

Function

Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous, with the MSB of data value written first.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

Diagram

Fields

Field	Function
31-24 HU	Upper Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	Lower Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	Upper Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1,the values written to this field are part of the seed value.
7-0 LL	Lower Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1, the values written to this field are part of the seed value.

36.7.1.3 Polynomial (GPOLY)

Offset

Register	Offset
GPOLY	4h

Function

Configures polynomial value for CRC calculation.

- Sets the upper 16 bits of polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- Sets the lower 16 bits of polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 HIGH	High Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

36.7.1.4 Control (CTRL)

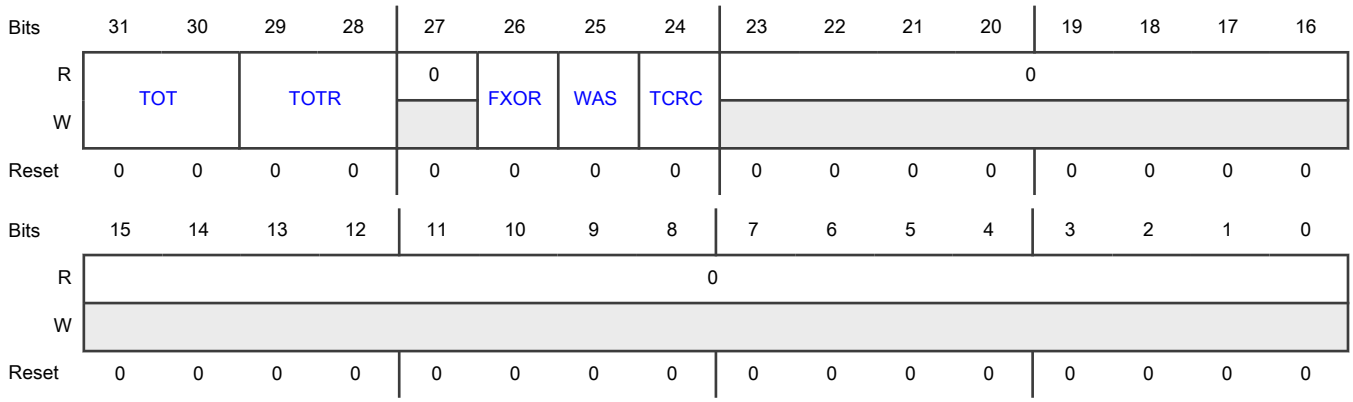
Offset

Register	Offset
CTRL	8h

Function

Sets control for CRC. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into DATA.

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Write Sets transpose type for the values written to DATA. See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
29-28 TOTR	Transpose Type for Read Sets transpose type for the values read from DATA . See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - Disables XOR on reading data. 1b - Inverts or complements the read value of the CRC Data.
25 WAS	Write as Seed Specifies whether writes to DATA are data values or seed values. When this field = 1, the value that you write to is considered as seed value. When this field = 0, the value that you write to is considered as data for CRC calculation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of CRC. 0b - 16 bits 1b - 32 bits
23-0 —	Reserved

- CFG[REFSEL]=01, VREFO voltage reference driven from the VREF block
- CFG[REFSEL]=10, VREFH reference pin has dedicated connection

37.1.4 ADC trigger inputs

ADC Trigger sources get routed through the Trigger Multiplexer (TRGMUX). See the TRGMUX chapter for available trigger sources.

37.2 Overview

The 16-bit analog-to-digital converter (ADC) is a dual successive approximation ADC designed for operation within an integrated microcontroller system-on-a-chip.

NOTE

For chip-specific modes of operation, see the power management information for the device.

37.2.1 Block diagram

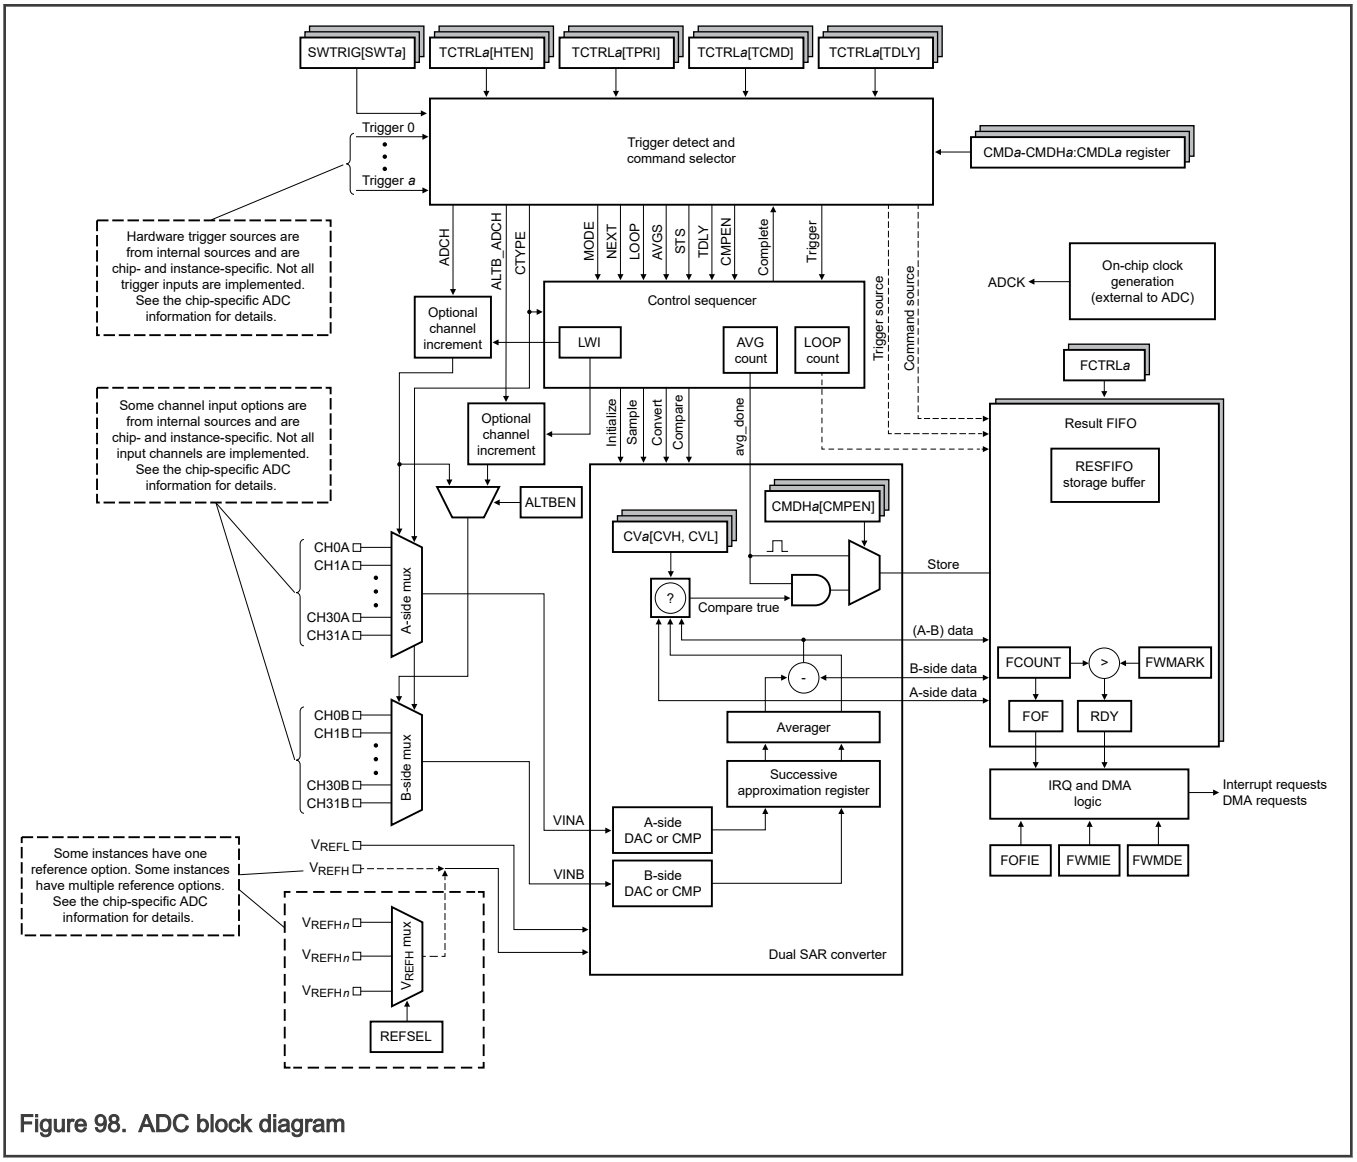

Figure 98. ADC block diagram

37.2.2 Features

ADC has these features:

- Linear successive approximation algorithm
  - Differential operation with 16-bit or 13-bit resolution
  - Single-ended operation with 16-bit or 12-bit resolution
  - Support for two simultaneous single-ended conversions
- Configurable analog input sample time
- Configurable speed options to accommodate operation in low-power modes of SoC
- Trigger detection with up to 4 trigger sources with priority level configuration. Software or hardware trigger option for each.
- 15 command buffers, to allow independent options selection and channel sequence scanning
- Automatic comparisons for less-than, greater-than, within range, or out-of-range with "store on true" and "repeat until true" options
- 2 independent result FIFOs, each containing 16 entries. Each FIFO has configurable watermark and overflow detection.
- Interrupt, DMA, or polled operation
- Linearity and gain adjustment calibration logic

37.3 Functional description

ADC performs analog-to-digital conversions on any of the software-selectable analog input channels via a successive approximation algorithm.

The ADC module can average the result of multiple conversions on a channel before storing the calculated result. The hardware average function is enabled by setting CMDHn[AVGS] to a non-zero value. The function operates in any conversion mode or configuration.

ADC can compare the result of a conversion with the contents of two value registers for less-than, greater-than, inside-range, or outside-range detection. The compare function operates in any conversion mode or configuration.

When the conversion and averaging loops finish, the resulting data is placed in one of 2 available FIFO data buffers . The data includes tag information associated with the result. When the number of stored data words exceeds the setting, a configurable watermark level supports interrupts or DMA requests. Interrupts can also be enabled to indicate when FIFO overflow errors occur.

The module initializes to its lowest power state during reset.

The ADC analog circuits can be pre-enabled to begin conversions sooner at the expense of higher idle currents. Conversions are initiated by selectable trigger events from software or hardware sources.

The trigger-detection logic includes a configurable enable and priority scheme for available trigger sources.

ADC includes multiple command buffers to provide flexibility for channel scanning and independent channel selections for different trigger sources. These command buffers can be configured for:

- Differential or single-ended conversion
- Sample time
- Averaging on a per-channel basis

ADC includes offset and linearity calibration logic. A request for calibration should be made upon reset or power up. Each successive approximation register (SAR) conversion uses calibration data calculated during the calibration routine.

The sequencing of an ADC command is summarized in the flow diagram below.

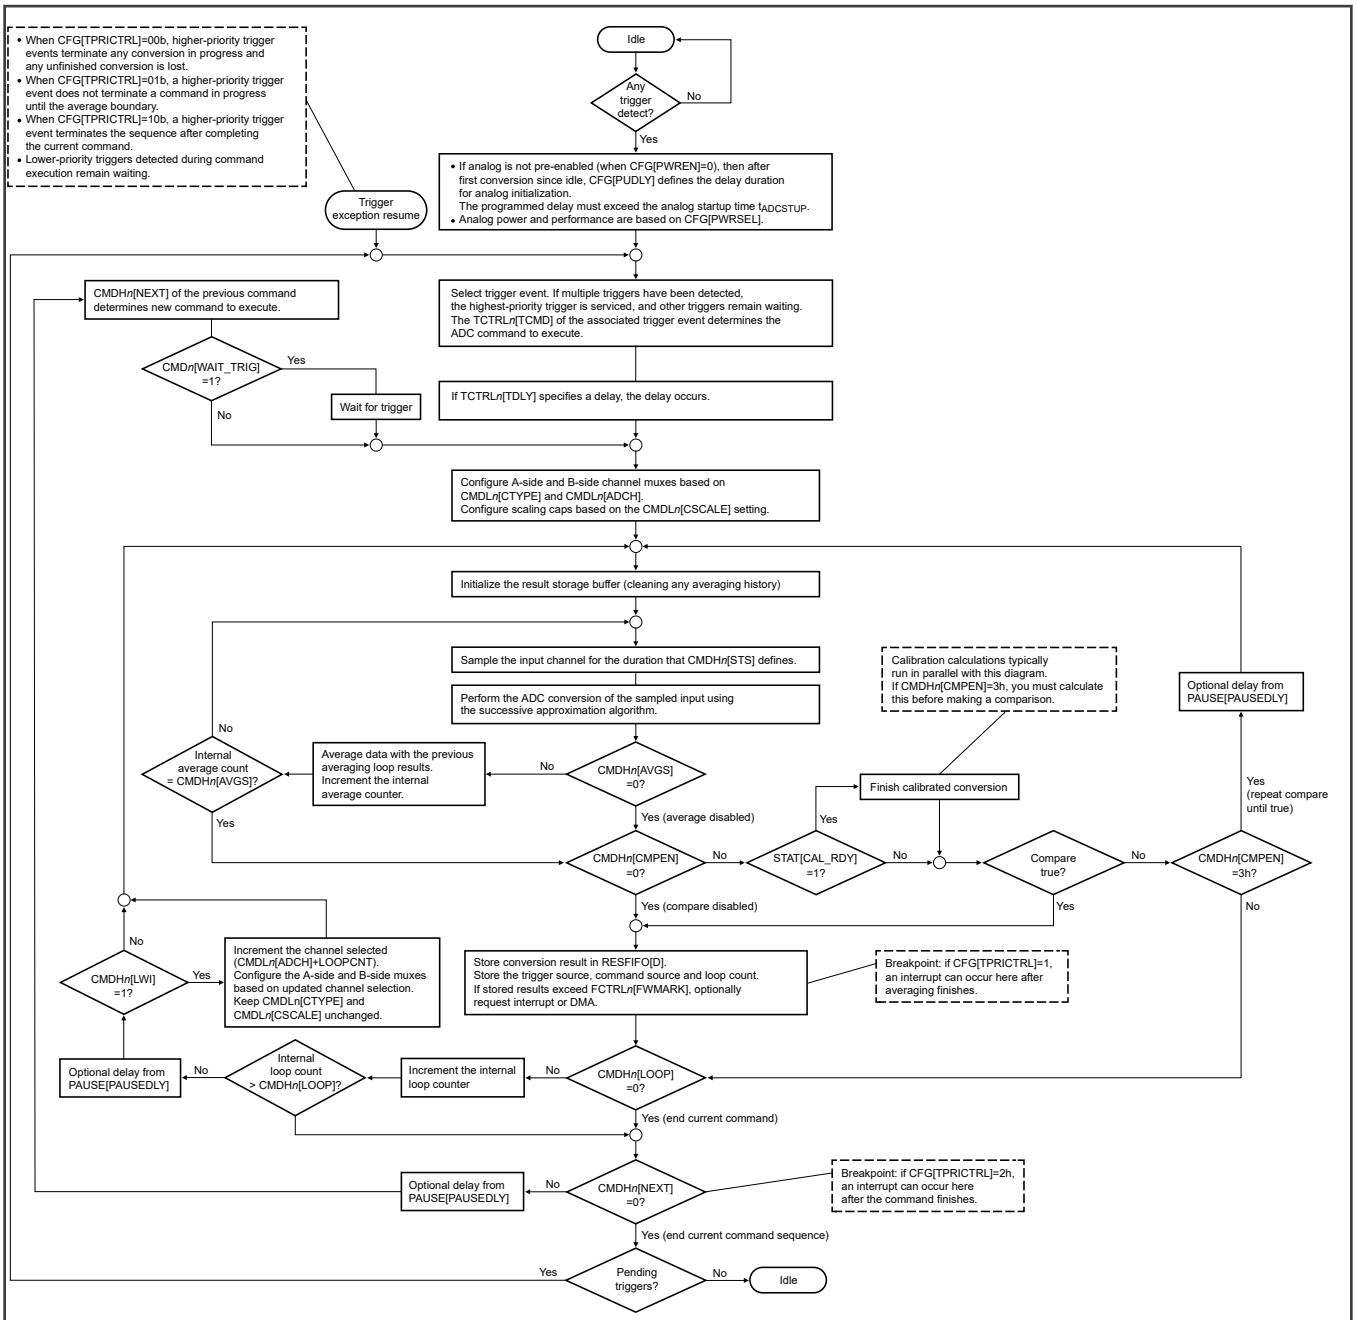

Figure 99. ADC command execution flow diagram

37.3.1 Power control mode

By default, the ADC analog circuits are disabled while ADC is in its idle state. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled. These circuits require a period of initialization before the first conversion cycle.

The value of CFG[PUDLY] should be set to incur a delay longer than $t_{ADCSTUP}$. The accuracy of initial conversions after activation is degraded if the value of CFG[PUDLY] is too low.

You can achieve faster conversion startup times by setting CFG[PWREN] to pre-enable the analog circuits of ADC. This faster conversion consumes extra power, even while ADC is in an idle state. When CFG[PWREN] is 1, the Power Enable timer is

activated. The timer enforces the minimum time required (configured by CFG[PUDLY]) before detected triggers can initiate ADC conversions.

ADC also has options for controlling power and performance summarized in the table below. See the device data sheet for specification of the available power modes.

Table 261. Power option settings

CFG[PWRSEL]	Description
00b (Default)	Slowest speed and lowest power
01b	Faster speed and higher power
10b	Even faster speed and even higher power
11b	Fastest speed and highest power

37.3.2 ADC behavior in low-power mode

ADC supports system-level low-power modes. In low-power modes where ADC can remain functional, CTRL[DOZEN] controls ADC behavior.

When CTRL[DOZEN] = 0, if ADC was configured and enabled before entering low-power mode, ADC can continue operating while the system transitions to the low-power state. Any conversion in progress is not disrupted. External hardware trigger detection and active conversions are operational.

When CTRL[DOZEN] = 1, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request.

When entering a low-power mode where ADC cannot remain functional, the module:

- Ignores CTRL[DOZEN].
- Waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request.

After entering the low-power state, the ADC is kept inactive until the system exits the low-power state. The setting of CFG[PWREN] is ignored and the ADC analog circuits are forced to their lowest-power state. Upon waking from the low-power state, the analog circuits are automatically re-enabled and the power-up delay timer begins, if:

- The analog circuits were pre-enabled before entering Stop mode (CFG[PWREN] = 1), and
- The control registers retained their states in low-power mode.

Any triggered conversion is stalled until the power-up delay associated with CFG[PUDLY] has finished.

37.3.3 Voltage reference

The voltage reference high (V_{REFH}) used by ADC is supplied from either an on-chip voltage reference source or from an off-chip source via external pins. V_{REFL} is always from an external pin and must be at the same voltage as the Analog Power Domain Ground.

This block supports a programmable selection of the Voltage Reference High used for ADC conversions (via CFG[REFSEL]).

See the chip configuration information on the voltage reference options specific to this packaged device.

37.3.4 Trigger detect and command execution

See Figure 99 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 4 trigger sources. Each trigger can be software-generated by writing 1b to the corresponding SWTRIG[SWTn] field. Alternatively, asynchronous input sources at the periphery of the module can generate hardware triggers. The number and sources of hardware triggers implemented is device-specific. See the chip-specific ADC information for descriptions of available hardware trigger sources for this device.

Each hardware trigger source is enabled by setting the associated enable field (TCTRLn[HTEN]). Each trigger source is assigned a priority via the associated priority control field (TCTRLn[TPRI]). Each of the trigger sources is associated with a command buffer via the associated command select field (TCTRLn[TCMD]).

When a hardware trigger input is enabled, hardware trigger events are detected on the rising edge of the associated hardware trigger source.

Each trigger source has an associated priority field TCTRLn[TPRI] which allows arbitration between trigger sources. Arbitration selects two things: which trigger sequence to execute next, and how to handle a trigger exception. Trigger exceptions are defined as allowing a higher-priority trigger sequence to interrupt operation of a lower-priority sequence. When a trigger exception occurs, programmable arbitration allows the configurable stop and resume points for low-priority sequences. The fields affecting arbitration are CFG[HPT_EXDI], CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL].

1. When CFG[HPT_EXDI] = 1b, trigger exceptions are disabled and any higher priority triggers are left pending until the current sequence completes. New triggers are accepted based on priority.
2. When CFG[HPT_EXDI] = 0b (default), exceptions are enabled and the higher-priority sequence begins executing at a user-specified breakpoint.

Breakpoint locations are determined by CFG[TPRICTRL], which affects latency for accepting trigger exceptions.

1. When CFG[TPRICTRL] = 0h, a higher-priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started.
2. When CFG[TPRICTRL] = 1h, the current conversion is allowed to complete (including averaging) before the higher-priority exception starts. In this mode, if the command is running through a series of averages, this series completes. However, there is no requirement to finish the entire command before being interrupted. For example, if the command consists of four loop iterations, there is no requirement to complete all four iterations before the interrupt occurs.
3. When CFG[TPRICTRL] = 2h, a higher-priority trigger begins once the current command is completed. If a command consists of five loop iterations each containing eight averages, then all 40 conversions must be completed before accepting the trigger exception.

CFG[TCMDRES] and CFG[TRES] determine what ADC does after accepting a trigger exception. The module can be programmed to resume commands after returning from a trigger exception.

1. When CFG[TRES] = 0h, commands are not automatically resumed after being stopped by an exception. However, an interrupt is set to indicate that this case has occurred. The flag TSTAT[TEXC_NUM] can be used to resolve which trigger was stopped by the exception.
2. When CFG[TRES] = 1h, ADC automatically resumes commands after they were stopped by an exception.

Using CFG[TRES] with CFG[TCMDRES], the module can be programmed to resume commands at one of two possible locations.

1. When CFG[TCMDRES] = 0h, the trigger which was stopped by an exception is resumed from the beginning of its associated command sequence. Triggers that are waiting to be resumed take the same priority programmed to TCTRLn[TPRI].
2. When CFG[TCMDRES] = 1h, the trigger is resumed from the command that it was executing before being interrupted by an exception.

If a trigger occurs with priority lower than the priority of the currently executing command, trigger detection is left pending until the current command sequence finishes. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or command sequence) completes.

When a conversion is completed (including hardware averaging when CMDHn[AVGS] is non-zero), the result is placed in a RESFIFO buffer. When an ADC command selects looping (when CMDHn[LOOP] is non-zero) a command stores multiple conversion results to the FIFO during execution of that command.

At the end of command execution, CMDHn[NEXT] selects the next command to be executed. Multiple commands can be executed sequentially by configuring the CMDHn[NEXT] field of each command. Setting the next command to 0h causes conversions to terminate at the completion of the current command. Unending circular command execution is allowed by setting the CMDHn[NEXT] field of the last command in a sequence to the first command in the sequence.

By default, command sequences execute automatically in the order in which CMDHn[NEXT] fields are programmed. However, by using CMDHn[WAIT_TRIG], command execution can be stalled and launched based on trigger inputs. For example, if TRIGGER2 is programmed to start the command sequence CMD1, CMD2, CMD3, then this sequence is run once unconditionally to completion upon receiving TRIGGER2. If CMDH2[WAIT_TRIG] = 1h, however, the sequence pauses after CMD1 until TRIGGER2 is received again. In this way, sequences can be stalled until a trigger assertion is received.

Disabling ADC by writing 0b to CTRL[ADCEN] terminates any active ADC command processing. Writing 0b to CTRL[ADCEN] causes the current command (or command sequence) to terminate, clears any pending triggers, and sends the ADC module to an idle state.

37.3.5 Pause option

When an application does not require the maximum conversion rate, the effective conversion rate can be reduced:

- By implementing periodic trigger events to initiate ADC conversions, or
- By selecting a reduced-frequency clock as the ADCK source.

Both options are chip-specific and are dependent on ADC triggering and clocking options external to the ADC module. The latency associated with ADC analog power-up delays limits the maximum conversion rate when using periodic triggering.

Conversion rates can also be reduced by inserting a pause of a programmable duration:

- Between loop iterations
- Between commands in a sequence
- Between conversions, when a command is executing in the Compare Until True configuration

When PAUSE[PAUSEEN] = 1, PAUSE[PAUSEDLY] controls the duration of pausing during command execution sequencing. The pause delay is a count of (PAUSE[PAUSEDLY] * 4) ADCK cycles.

NOTE

Do not change the PAUSE register while CTRL[ADCEN] = 1. Writes to the PAUSE register while CTRL[ADCEN] is 1 can lead to metastable operation.

See Figure 99 for the places during command execution sequencing where the pause can be inserted.

37.3.6 Temperature sensor

ADC has a dedicated input channel for an on-chip temperature sensor. See the chip-specific channel definition to determine which channel is connected to the on-chip temperature sensor.

To calculate the temperature, you must first execute a conversion of the temperature sensor channel with configuration requirements. The sequence to convert the temperature sensor channel is:

1. Configure a command buffer register to convert the temperature sensor channel (CMDLn[ADCH]).
2. Program the command buffer with the following parameters:
   - Resolution set to 16b mode: CMDLn[MODE] = 1h
   - Differential: CMDLn[CTYPE] = 2h
   - Max averaging: CMDHn[AVGS] = Ah
   - Max sample time: CMDHn[STS] = 7h
   - LOOP set to 1: CMDHn[LOOP] = 1h
   - Loop with increment disabled: CMDHn[LWI] = 0h
   - Compare function disabled: CMDHn[CMPEN] = 0h
3. Configure a trigger control register TCTRLn with the following parameters:
   - TCTRLn[TCMD] = command buffer used in steps 2 and 3.

- TCTRLn[FIFO_SEL_A] directs conversion results to FIFO0 orFIFO1

4. Trigger a conversion of the temperature sensor channel. You trigger the conversion by writing 1 to the associated bit in Software Trigger Register (SWTRIG) (that is, the trigger configured in the previous step).

After completing the conversion of the temperature sensor channel, two results are stored in the FIFO selected by TCTRLn[FIFO_SEL_A]. Each result corresponds to a component of the overall temperature value. Read these values from the FIFO and use the following equation to calculate the ambient temperature.

$$\text{Temp} = A\left[\frac{\alpha(\text{Vbe8}-\text{Vbe1})}{\text{Vbe8} + (\alpha(\text{Vbe8}-\text{Vbe1}))}\right] - B$$

Equation 1. Temperature sensor function

In the preceding equation:

- Vbe1 is the first value stored to the FIFO as a result of the temperature sensor channel conversion.
- Vbe8 is the second value stored to the FIFO as a result of the temperature sensor channel conversion.
- A is the slope factor.
- B is the offset factor.
- α is the bandgap coefficient.

A, B, and α are specified constant values from the ADC electrical information in the chip data sheet.

37.3.7 Result FIFO operation

ADC includes 2 16-entry FIFOs in which the result of ADC conversions are stored. In addition, a valid indicator bit, the trigger source, the source command, and the loop count are also stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in each RESFIFO.

A programmable watermark threshold supports configurable notification of data availability. When FCTRLn[FCOUNT] is greater than FCTRLn[FWMARK], the associated RDY flag is asserted. When IE[FWMIEn] = 1, a watermark interrupt request is issued. When DE[FWMDEn] = 1, a DMA request is issued. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. When FCTRLn[FCOUNT] falls equal to or below FCTRLn[FWMARK], the RDY flag is cleared.

Each FIFO can be emptied by successive reads of RESFIFOn. When RESFIFOn[VALID] is 1, the associated FIFO entry is valid. Reading RESFIFOn when the FIFO is empty (when RESFIFOn[VALID] = 0 and FCTRLn[FCOUNT] = 0h) provides an undefined data word. All FIFOs are reset by writing 1b to CTRL[RSTFIFOn].

If ADC attempts to store a data word to the FIFO when the FIFO is full, the FIFO overflow flag (FCTRLn[FOF]) is set. When IE[FOFIEn] = 1, an overflow interrupt request is issued. The FOF flag is cleared by writing 1 to STAT[FOFn]. When overflow events occur, no new data is stored and the data associated with the storage event that triggered the overflow is lost.

Conversion results can be steered to any FIFO in the design. TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine into which FIFO the final result is written. Depending on which trigger is executing, the results can be steered to different locations. Depending on the type of conversion selected, the FIFO destination register fields are interpreted differently. During either differential or single-ended mode (CMDLn[CTYPE] != 3h) only one result is produced. The destination during these modes is determined from TCTRLn[FIFO_SEL_A]. In dual-single-ended mode, both TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] determine the Channel A and Channel B destinations respectively.

37.3.8 Sampling Modes

The ADC module supports three different sampling modes: dual single-ended, single-ended, and differential. The sampling mode is determined by the currently executing command using CMDLn[CTYPE].

When executing a command in dual single-ended mode, two independent conversion results are calculated and stored in selectable FIFO destinations. Command processing, however, is not individually controlled for each independent channel being sampled. When operating in dual single-ended mode both channels are sampled and processed simultaneously.

The selection of Channel B is controlled by CMDLn[ALTBEN].

- When CMDLn[ALTBEN] = 1, the channel for the B-side is selected independently (via the value of CMDLn[ALTB_ADCH]).
- When CMDLn[ALTBEN] = 0, the Channel B selection is controlled by CMDLn[ADCH] and Channel A and Channel B are paired (CH0A/CH0B, CH1A/CH1B, and so on).

If comparisons are enabled in dual single-ended mode, only the A-side channels (CH0A, CH1A, and so on) are used for the comparison. The A-side comparison determines whether both the A-side and B-side results are written to the FIFOs.

- If the A-side comparison passes, both the A-side and B-side results are stored.
- If the A-side comparison fails, A-side and B-side results are not written to the FIFOs.

Single-ended mode is configurable to allow either A-side or B-side channels to be sampled. In single-ended mode, the results from each conversion can be written to a selectable FIFO using TCTRLn[FIFO_SEL_A].

In differential mode, the final SAR calculation is equivalent to V(CHA) - V(CHB). If the result is negative, then the value is stored in sign-extended two's complement format. TCTRLn[FIFO_SEL_A] also determines where differential conversion results are stored.

In dual single-ended mode, however, two independent results are produced. Individual control is provided by using TCTRLn[FIFO_SEL_A] and TCTRLn[FIFO_SEL_B] to select a FIFO destination for both results during this mode. Both single-ended results may be written to the same destination by programming TCTRLn[FIFO_SEL_A] = TCTRLn[FIFO_SEL_B]. In this case, the CH_A result is always stored before the CH_B result.

37.3.9 Compare Function

After the input is sampled and converted and any averaging iterations are performed, CMDHn[CMPEN] determines:

- Whether to use the automatic compare function, storing the conversion result when true.
- Whether to repeat the channel acquisition until the automatic compare function returns a true result.

The command-sequencing options related to the compare function are summarized in the table below.

NOTE

Latency is added to the end of a compare-until-true conversion to resolve the next command or loop in a sequence. This latency is necessary to calibrate the SAR data before resolving the result of a comparison. Delay for this feature is only added when resolving the result of a conversion. Intermediate samples during averaging do not include extra latency; only loop and command boundaries experience this delay. The latency is always less than or equal to five ADC clock cycles.

Table 262. Compare modes

CMDHn[CMPEN]	Compare function	Description
00b	Compare disabled	Do not perform compare operation. Always store the conversion result to the FIFO.
01b	Reserved	
10b	Store on true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Regardless of the comparison result, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required.
11b	Repeat compare until true	Perform compare operation. Store conversion result to FIFO after averaging only when the result of the comparison is true. Once a comparison is true, the LOOP setting is considered. The LOOP counter is incremented before deciding whether the current command has completed or additional LOOP iterations are required. When a comparison is false, the conversion is repeated without considering the LOOP setting, and the LOOP counter is not incremented.

The compare operation checks the result based on the values of CVn[CVH] and CVn[CVL], as shown in the following table.

Table 263. Compare operations

CVn[CVL] vs. CVn[CVH]	Operation	Description
set CVn[CVL] < CVn[CVH]	Outside range (General form)	True if the result is less than CVn[CVL] **or** greater than CVn[CVH].
set CVn[CVH] to maximum value set CVn[CVL] to compare point	Less than	True if the result is less than CVn[CVL].
set CVn[CVL] to minimum value set CVn[CVH] to compare point	Greater than	True if the result is greater than CVn[CVH].
set CVn[CVL] > CVn[CVH]	Inside range	True if the result is less than CVn[CVL] **and** greater than CVn[CVH].

NOTE

When ADC continues operating in a low-power mode, the compare function can monitor the voltage and wake the device only when the compare condition is met.

37.3.10 Cycles per conversion

The number of ADCK cycles needed to complete a conversion, varies based on the selected resolution (CMDLa[MODE]), the sample time configured, and several other configuration options discussed below.

To calculate the cycle count, first, determine the Base Cycles Count from Table 264. Next, add the Sample Time Adder based on CMDHa[STS] setting as summarized in Table 265. If averaging is enabled (CMDHa[AVGS] does not equal to 0), then the total cycle (Base Cycles Count + Sample Time Adder) should be multiplied by the number of averages configured as summarized in Table 266.

$$CycleCount\ /\ Conversion = [(BaseCycleCount + SampleTimeAdder) * AverageMultiplier]$$

Equation 2. Cycle Count/Conversion

Note that there is latency associated with trigger detection and starting an initial conversion. There is additional latency associated with offset and gain error adjustment of a raw conversion result and storage of a final result to the FIFO. Due to the pipe-lining of conversions when looping or command chaining is configured, the next conversion is immediately started while a raw conversion result is being adjusted and stored and thus the conversion rate is maximized.

The base cycles per conversion are variable depending on CMDLa[MODE] setting as summarized in the following table:

Table 264. Base cycles per conversion

Base ADCK cycles/conversion[1]	
16-bit CMDLa[MODE] = 1	12-bit CMDLa[MODE] = 0
24	19

1. This cycle count includes min sample time of 3.5 ADCK cycles.

In addition to the base cycles per conversion, the configured sample time needs to be considered. The sample time adder is variable depending on CMDHa[STS] setting and is summarized in the following table:

Table 265. Sample time cycle adder

CMDHa[STS] (default 000)	Add ADCK cycles/conversion
000	0
001	2
010	4
011	8
100	16
101	32
110	64
111	128

Table 266. Averaging multiplier

CMDHa[AVGS] (default 0000)	Averaging multiplier
0000	1
0001	2
0010	4
0011	8
0100	16
0101	32
0110	64
0111	128
1000	256
1010	512
1011	1024

When LOOPing is used:

CMDHa[LOOP] allows iteration of a command (that is a channel can be converted multiple times). This feature adds 3 additional cycles between conversions.

NOTE

When commands are chained using CMDHa[NEXT] to execute back-to-back conversions the ADC does not have the 3 stall cycles between commands.

For a command that executes multiple conversions of the same channel using LOOPing the total cycle count is:

$$CycleCount\ /\ Command = [(BaseCycleCount + SampleTimeAdder) * AverageMultiplier * (CMDHa[LOOP] + 1)] + (3 * CMDHa[LOOP])$$

Equation 3. Cycle Count/Command

37.3.11 Clocking

ADC uses the ADCK clock input provided by an on-chip clock select block. It is used by the SAR conversion-control sequencing logic and the FIFO storage buffer. The ADCK frequency must be within the specified frequency range for ADCK, and varies based on CFG[PWRSEL]. See the device data sheet for supported frequency ranges.

ADC continues operating in low-power mode as long as CTRL[DOZEN] = 0 and the on-chip clock select block supplies an ADCK clock source.

NOTE

When in low-power mode with CTRL[DOZEN] = 0, the bus clock can be shut off, and asynchronous interrupts and DMA requests can be configured. ADC continues processing commands and writing data to the internal FIFO.

ADC has four sources for asynchronous interrupts during low-power mode: watermark, FIFO overflow, TCOMP, and TEXC. To enable them, configure IE[FWMIEx], IE[FOFIEx], IE[TCOMP_IE], and IE[TEXC_IE] before entering low-power mode.

When CTRL[DOZEN] = 1 in low-power mode, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power mode entry. Any pending triggers are dropped when a low-power mode request is made in this mode. ADC is forced into its lowest-power setting after acknowledging the low-power mode request.

37.3.12 Resets

Table 267. ADC Resets

Reset source	Description
Chip reset	Resets the ADC logic and registers to their default states.
Software reset	Resets, by using CTRL[RST], logic and registers (except Control Register (CTRL), Gain Calculation Result (GCR0 - GCR1), Calibration General A-Side Registers (CAL_GAR0 - CAL_GAR32), and Calibration General B-Side Registers (CAL_GBR0 - CAL_GBR32) to their default states.
FIFO reset	Resets CTRL[RSTFIFO0] and CTRL[RSTFIFO1] by implementing write-only control. After a FIFO is reset, that FIFO becomes empty.

37.3.13 Interrupts and DMA requests

ADC includes several sources for interrupts and DMA requests. The table below summarizes these sources.

A programmable watermark threshold supports configurable notification of data availability and can generate either an interrupt exception or a DMA request. When FCTRLn[COUNT] is greater than FCTRLn[FWMARK], the associated STAT[RDYn] flag is asserted. The IE[FWMIEn] and DE[FWMDEn] control fields control the masking for this exception. When STAT[RDYn] becomes 1 and IE[FWMIEn] = 1, a watermark interrupt request is issued. When STAT[RDYn] becomes 1 and DE[FWMDEn] = 1, a DMA request is issued.

The other exception sources can only generate interrupts and do not have a DMA request option. Each source has a mask control field in the IE register and no corresponding field in the DE register.

Table 268. ADC Interrupts and DMA Requests

Status Register (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDYn	Result FIFO n Ready Flag	Conversion result data is written to Result FIFO and has a watermark configurable trigger level to generate an exception request as controlled by FCTRLn[FWMARK].	Y	Y	Y

Table continues on the next page...

Table 268. ADC Interrupts and DMA Requests (continued)

Status Register (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
FOFn	Result FIFO n Overflow Flag	Attempting to store data to the FIFO when the FIFO is full is an error condition.	Y	N	Y
TCOMP_INT	Trigger Completion Flag	A trigger sequence has been completed. All associated commands have been run.	Y	N	Y
TEXC_INT	High Priority Trigger Flag	A high priority trigger exception has occurred.	Y	N	Y

37.4 External signals

The ADC module supports analog channel inputs with differential and single-ended conversion options for all channels.

See chip-specific section for supply and ground connections.

Table 269. ADC signal descriptions

Signal	Description	I/O
CHnA - CH0A[1]	A-side Analog Channel Inputs	I
CHnB - CH0B[1]	B-side Analog Channel Inputs	I

1. where n is the maximum channel number supported in the chip. See the chip-specific information for the number of channels supported on your device.

37.4.1 Analog channel inputs (CHnA and CHnB)

CMDLn[ADCH] and CMDLn[CTYPE] control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each CMDLn[ADCH] channel selection has an associated A side and an associated B side input. Each CMDLn[ADCH] pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels from on-chip sources, such as temperature sensors and reference voltage sources, may only be connected to individual instances of ADC. Some input channel options in the field-setting descriptions may not be available for your device. See chip-specific information for the channels supported on this device.

37.5 Initialization

37.5.1 Calibration functions

The ADC module has multiple calibration functions that must be executed as part of ADC setup to achieve the specified accuracy. Calibration must be run after any reset and before a conversion is initiated. Before offset calibration or calibration, the user must configure the clock source and frequency of ADC for the clock source availability and needs of the application. ADC must be enabled (CTRL[ADCEN] = 1h) before a calibration function runs. If calibration is requested while ADC is actively converting, that sequence completes before starting calibration.

Averaging multiple conversions can achieve improved accuracy during the calibration routines. CTRL[CAL_AVGS] is used during a calibration routine to control how many samples are averaged together. If the application uses ADC in a wide variety of

configurations, the configuration for which the highest accuracy is required should be selected. Alternatively, multiple calibrations can be done for the different configurations.

37.5.1.1 Offset calibration

The Offset Trim Register (OFSTRIM) is used to trim for ADC comparator offset voltage. The ADC supports an offset calibration function in which the OFSTRIM register is automatically updated. To perform offset calibration:

1. Configure for the desired averaging via CTRL[CAL_AVGS].
2. Initiate Offset Calibration by setting CTRL[CALOFS].
3. Poll the STAT[CAL_RDY] flag. When STAT[CAL_RDY] is asserted, the offset calibration function has completed, and the OFSTRIM register has updated.

37.5.1.2 ADC Calibration

ADC includes hardware calibration logic in which the A-side and B-side converters are calibrated for gain error and linearity error correction of the raw conversion result. GCR0[GCALR] and the CAL_GAR registers control calibration for the A-side converter. GCR1[GCALR] and the CAL_GBR registers control calibration for the B-side converter. ADC supports a calibration function in which the CAL_GAR and CAL_GBR registers are automatically updated. The calibration function also updates GCC0[GAIN_CAL] (associated with A-side calibration) and GCC1[GAIN_CAL] (associated with B-side calibration). For A-side calibration, a software calculation is required to derive GCR0[GCALR] from GCC0[GAIN_CAL]. For B-side calibration, a corresponding calculation is required to derive GCR1[GCALR] from GCC1[GAIN_CAL].

To complete calibration setup:

1. Execute Offset calibration steps. The Offset Trim Register (OFSTRIM) is used during calibration to trim for comparator offset voltage.
2. Configure the averaging via CTRL[CAL_AVGS].
3. Initiate the calibration routine by writing 1 to CTRL[CAL_REQ]. CTRL[CAL_REQ] remains 1 until the CAL routine has been accepted by the ADC. After acceptance, CTRL[CAL_REQ] automatically becomes 0.
4. The A-side calibration data is updated first. Poll the GCC0[RDY] flag. When it is asserted, the hardware controlled A-side calibration operation is complete, and CAL_GAR and GCC0[GAIN_CAL] registers are updated. The updated value in GCC0[GAIN_CAL] is required for further software processing described in the following steps.
5. Read GCC0[GAIN_CAL] and store for use in the gain_adjustment calculation.
6. Calculate the A-side gain_adjustment: (131072)/(131072-GCC0[GAIN_CAL]). GCC0[GAIN_CAL] is a 16-bit unsigned value. This calculation results in a floating point value between 1 and 2.
7. The integer value of the gain_adjustment calculation is always 1 and can be discarded. The fractional component must be stored to GCR0[GCALR]. Write the fractional component value to GCR0[GCALR].
8. Execute the same calculation for the B-side converter. Poll the GCC1[RDY] flag. When it is asserted, the hardware controlled B-side calibration operation is complete, and CAL_GBR and GCC1[GAIN_CAL] registers are updated. The updated value in GCC1[GAIN_CAL] is needed for further software processing.
9. Read the GCC1[GAIN_CAL] register and store for use in the gain_adjustment calculation.
10. Calculate the B-side gain_adjustment = (131072)/(131072-GCC1[GAIN_CAL]). Formatting for the value is the same as the A-side.
11. Like the A-side, round the fractional component of the B-side gain_adjustment to 16-bits and store it in GCR1[GCALR].
12. Once GCR0[GCALR] and GCR1[GCALR] contain the results from the gain_adjustment calculations, set the GCR0[RDY] and GCR1[RDY] flags to indicate they are valid. It is acceptable for the GCRn[GCALR] and corresponding GCRn[RDY] field to be updated on the same write cycle.

After completing the steps above, the calibration sequence is complete and the STAT[CAL_RDY] flag is set. The STAT[CAL_RDY] flag remains set until the user resets the system or requests a new calibration sequence.

When STAT[CAL_RDY] is set, ADC is configured to run in calibrated mode. Each conversion uses a combination of linearity and gain calibration results to correct SAR data. Calibration conversion latency is required to process each sample. However, due to the pipelined nature of data and control sequences, each conversion can still be initiated without experiencing this calibration delay.

37.5.1.3 Calibration General A-Side and B-Side Widths

The general calibration value registers CAL_GARn and CAL_GBRn have non-uniform widths. The following table defines the bit widths of each register.

Table 270. Calibration General Widths

Element CAL_GxR[N]	Width (Bits)
N = 00h, 20h	11
N = 01h	12
N = 02h–03h	13
N = 0x04–07h	14
N = 0x08–0Fh	15
N = 0x10–1Fh	16

These registers are typically updated automatically during the self-calibration sequence. To reduce the latency associated with ADC setup, the CAL_GxR values from a calibration sequence can be stored in non-volatile memory after an initial calibration. These values can then be written to the CAL_GxR registers via software prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

NOTE

These values can only be written in a single access, byte accesses are not supported.

37.6 ADC register descriptions

This section describes the ADC registers.

37.6.1 ADC memory map

ADC0 base address: 4004_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID Register (VERID)	32	R	0200_2C0Bh
4h	Parameter Register (PARAM)	32	R	0F0F_1004h

37.6.2 Version ID Register (VERID)

Offset

Register	Offset
VERID	0h

Function

Indicates the version integrated for this instance on the device and the inclusion of optional features.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15 —	Reserved
14-12 NUM_FIFO	Number of FIFOs Indicates the number of result FIFOs implemented in the design. 000b - N/A 001b - One 010b - Two 011b - Three 100b - Four
11 NUM_SEC	Number of Single-Ended Outputs Supported Indicates the number of single-ended channels which can be processed simultaneously. 0b - One 1b - Two
10 CALOFSI	Calibration Function Implemented Indicates whether ADC contains hardware calibration functions. When supported, CTRL[CAL_REQ] can be used to request the calibration routine. 0b - Not implemented

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Implemented
9 IADCKI	Internal ADC Clock Implemented Indicates whether this implementation of the ADC block includes an internal clock source. 0b - Not implemented 1b - Implemented
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented Indicates whether a control bit is implemented to select the input voltage range on Voltage Reference Option 1. 0b - Range control not required. 1b - Range control required.
7 —	Reserved
6-4 CSW	Channel Scale Width Indicates whether channel scaling is supported. When supported, each command buffer has a control field (CMDLn[CSCALE]) for setting input scaling. 000b - Not supported. 001b - Supported with one-bit CSCALE control field. 110b - Supported with six-bit CSCALE control field.
3 MVI	Multiple Vref Implemented Indicates whether multiple voltage reference high (VREFH) inputs are supported. When multiple voltage references are supported, CFG[REFSEL] selects voltage reference high options. 0b - Single VREFH input supported. 1b - Multiple VREFH inputs supported.
2 —	Reserved
1 DIFFEN	Differential Supported Indicates whether differential operation is supported. When supported, each command buffer has control fields (CMDLn[CTYPE]) for configuring for differential operation and expanding the number of supported channels from 32 to 64. 0b - Not supported 1b - Supported. CMDLn[CTYPE] controls fields implemented.
0	Resolution

Table continues on the next page...

Table continued from the previous page...

Field	Function
RES	Indicates the maximum accuracy supported. 0b - Up to 13-bit differential or 12-bit single-ended resolution supported. 1b - Up to 16-bit differential or 16-bit single-ended resolution supported. CMDLn[MODE] available for selecting the resolution of conversions for the associated command.

37.6.3 Parameter Register (PARAM)

Offset

Register	Offset
PARAM	4h

Function

The Parameter register indicates the size of several variable integration options for this instance on the device.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W							RSTFIFO1	RSTFIFO0								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
19-16 CAL_AVGS	Auto-Calibration Averages Selects how many ADC conversions are averaged to calculate each calibration value. Selecting a higher number of averages will lead to more accurate conversions after completing calibration. The CAL_AVGS bit field applies to both CALOFS and CAL_REQ calibration types. This value should be fixed when requesting and running calibration with CTRL[CAL_REQ] or CTRL[CALOFS]. 0000b - Single conversion. 0001b - 2 conversions averaged. 0010b - 4 conversions averaged. 0011b - 8 conversions averaged. 0100b - 16 conversions averaged. 0101b - 32 conversions averaged. 0110b - 64 conversions averaged. 0111b - 128 conversions averaged. 1000b - 256 conversions averaged. 1001b - 512 conversions averaged. 1010b - 1024 conversions averaged.
15-10 —	Reserved
9 RSTFIFO1	Reset FIFO 1 0b - No effect. 1b - FIFO 1 is reset.
8 RSTFIFO0	Reset FIFO 0 0b - No effect. 1b - FIFO 0 is reset.
7-5 —	Reserved
4 CALOFS	Offset Calibration Request Indicates whether a request for a hardware calibration calculation has been made. Writing 1 to this field initiates a hardware offset calibration calculation. Any conversions in progress are completed before launching the offset calibration function. After being accepted, ADC calculates the OFSTRIM[OFSTRIM] value and updates the OFSTRIM register automatically. This field becomes 0 upon completion of the offset calibration calculation. STAT[CAL_RDY] indicates when the offset calibration routine has completed. 0b - Calibration function disabled 1b - Request for offset calibration function

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 CAL_REQ	Auto-Calibration Request Indicates whether a request for the hardware calibration routine has been made. Automatically becomes 0 when the system accepts the hardware calibration request. STAT[CAL_RDY] indicates when this calibration routine has been completed. 0b - No request made. 1b - Request has been made.
2 DOZEN	Doze Enable Controls system transition to low-power modes while ADC is converting. When 0, immediate entries to low-power modes are allowed and ADC conversion functions remain enabled. Any conversion in progress is not disrupted. The selected clock source provided from the on-chip clock source must be able to continue operating. When 1, the ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging the low-power entry request. After entering the low-power state, ADC is kept inactive until the system exits the low-power state. When the system enters a low-power mode in which ADC operation is not supported, the DOZEN bit is ignored and ADC waits for the current transfer to complete any pending operation. 0b - ADC is enabled in low-power mode. 1b - ADC is disabled in low-power mode.
1 RST	Software Reset Resets all internal logic and registers, except for Control Register (CTRL), Gain Calculation Result (GCR0 - GCR1), Calibration General A-Side Registers (CAL_GAR0 - CAL_GAR32) , and Calibration General B-Side Registers (CAL_GBR0 - CAL_GBR32). This field remains 1 until you write 0 to it. 0b - ADC logic is not reset. 1b - ADC logic is reset.
0 ADCEN	ADC Enable 0b - Disabled 1b - Enabled

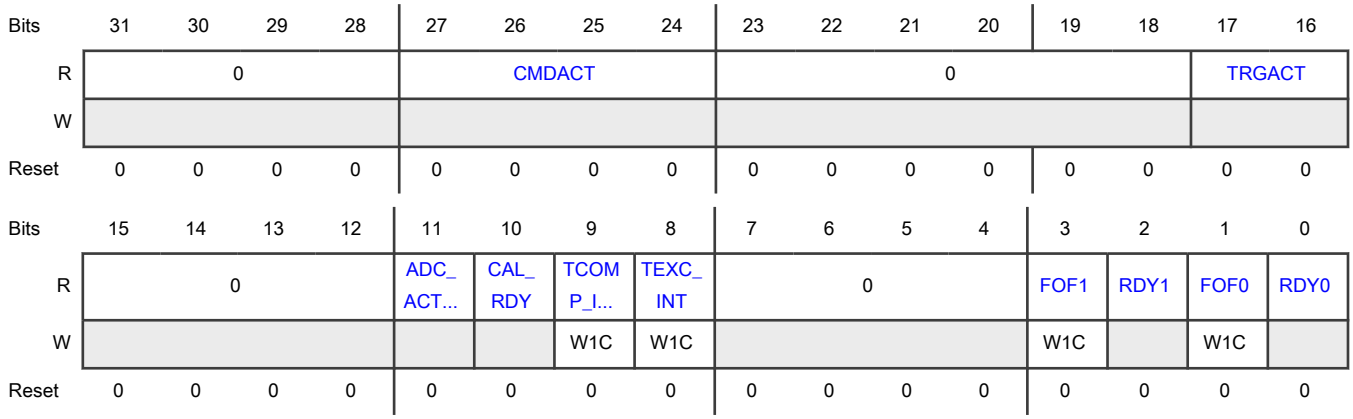
37.6.5 Status Register (STAT)

Offset

Register	Offset
STAT	14h

Function
Provides the status of the ADC module.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 CMDACT	Command Active Indicates the command actively being processed. Commands are only shown here when they are actively being processed by the SAR routine. Use with STAT[ADC_ACTIVE] to determine which conversion is running. 0000b - No command currently in progress. 0001b - Command 1 currently being executed. 0010b - Command 2 currently being executed. 0011b-1111b - Associated command number currently being executed.
23-18 —	Reserved
17-16 TRGACT	Trigger Active Indicates the trigger actively being processed. This field can be used to determine which trigger is running through a trigger delay or being converted by the SAR routine. The command associated with this field is running through a conversion when STAT[CMDACT] is not zero. 00b - Command (sequence) associated with Trigger 0 currently being executed. 01b - Command (sequence) associated with Trigger 1 currently being executed. 10b - Command (sequence) associated with Trigger 2 currently being executed. 11b - Command (sequence) associated with Trigger 3 currently being executed.
15-12 —	Reserved
11	ADC Active

Table continues on the next page...

Table continued from the previous page...

Field	Function
ADC_ACTIVE	Indicates whether the module is processing a conversion, or has pending triggers to service. 0b - ADC is idle. There are no pending triggers to service and no active commands are being processed. 1b - ADC is processing a conversion, running through the power-up delay, or servicing a trigger.
10 CAL_RDY	Calibration Ready Indicates whether the ADC request for calibration (CTRL[CAL_REQ] or CTRL[CALOFS]) has been completed and the results are ready. This flag is automatically cleared when a new hardware calibration or OFSTRIM request is made. 0b - Calibration is incomplete or has not been run. 1b - ADC is calibrated.
9 TCOMP_INT	Interrupt Flag For Trigger Completion Indicates when a trigger sequence has been completed (all associated commands have been run). IE[TCOMP_IE] must be 1 for the specific trigger source to flag an interrupt upon completion. 0b - Either IE[TCOMP_IE] = 0, or no trigger sequences have run to completion. 1b - Trigger sequence has been completed and all data is stored in the associated FIFO.
8 TEXC_INT	Interrupt Flag For High-Priority Trigger Exception Indicates when a high-priority trigger exception has occurred and CFG[TRES] = 0. This flag only asserts if trigger exception interrupts are enabled (IE[TEXC_IE] = 1h). This flag can be used with TSTAT[TEXC_NUM] to resolve which trigger source was interrupted. 0b - No trigger exceptions have occurred. 1b - A trigger exception has occurred and is pending acknowledgment.
7-4 —	Reserved
3 FOF1	Result FIFO1 Overflow Flag Indicates that more data has been written to the Result FIFO 1 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE1]. However, an interrupt request is issued only if IE[FOFIE1] is 1. 0b - No result FIFO1 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO1 overflow has occurred since the last time that the flag was cleared.
2 RDY1	Result FIFO1 Ready Flag Indicates when the number of valid data words in the result FIFO 1 is greater than the level set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE1]. However, an interrupt request or DMA request occurs only when the associated control bit (IE[FWMIE1] and DE[FWMDE1]) is set. This flag is cleared when FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not above watermark 1b - Above watermark
1 FOF0	Result FIFO 0 Overflow Flag Indicates that more data has been written to the Result FIFO 0 than it can hold. The newer data is not stored and the FIFO holds the original contents. This flag asserts regardless of the value of IE[FOFIE0]. However, an interrupt request is issued only if IE[FOFIE0] is 1. 0b - No result FIFO 0 overflow has occurred since the last time that the flag was cleared. 1b - At least one result FIFO 0 overflow has occurred since the last time that the flag was cleared.
0 RDY0	Result FIFO 0 Ready Flag Indicates when the number of valid data words in the result FIFO 0 is greater than the watermark set in FCTRL0[FWMARK]. This flag asserts regardless of the value of IE[FWMIE0]. However, an interrupt request or DMA request occurs only when the associated control field (IE[FWMIE0] and DE[FWMDE0]) is 1. This flag is cleared when the FCTRL0[FCOUNT] (which decrements on each read of the RESFIFO register) is less than or equal to the level set in FCTRL0[FWMARK]. 0b - Not above watermark 1b - Above watermark

37.6.6 Interrupt Enable Register (IE)

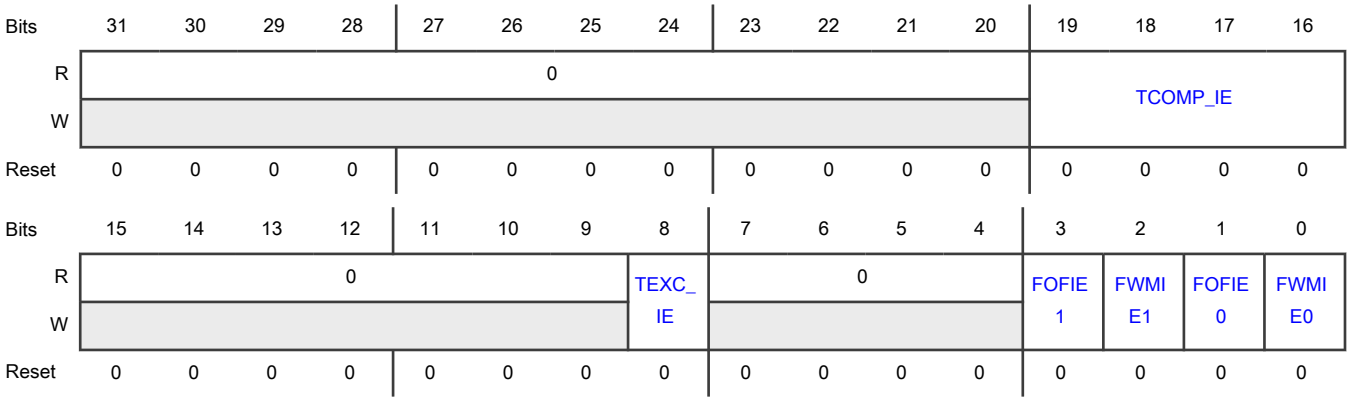
Offset

Register	Offset
IE	18h

Function

Includes system interrupt masking control bits.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 TCOMP_IE	Trigger Completion Interrupt Enable Enables generation of interrupt requests to indicate when complete trigger command sequences are executed. Each bit in TCOMP_IE corresponds to a trigger source. (TCOMP_IE[0] corresponds to trigger 0, and so on.) All results are stored in the FIFO when a sequence is considered complete. 0000b - All disabled 0001b - Trigger completion interrupts are enabled for trigger source 0 only. 0010b - Trigger completion interrupts are enabled for trigger source 1 only. 0011b-1110b - Associated trigger completion interrupts are enabled. 1111b - All enabled
15-9 —	Reserved
8 TEXC_IE	Trigger Exception Interrupt Enable Enables ADC to assert an interrupt request when a high-priority trigger exception occurs. TSTAT[TEXC_NUM] contains the value of the corresponding trigger affected by the exception. 0b - Disabled 1b - Enabled
7-4 —	Reserved
3 FOFIE1	Result FIFO1 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF1 flag is asserted. 0b - Disabled 1b - Enabled
2 FWMIE1	FIFO1 Watermark Interrupt Enable Enables generation of watermark interrupt requests when STAT[RDY1] flag is asserted. 0b - Disabled 1b - Enabled
1 FOFIE0	Result FIFO 0 Overflow Interrupt Enable Enables generation of overflow interrupt requests when FOF flag is asserted. 0b - Disabled 1b - Enabled

Table continues on the next page...

Table continued from the previous page...

Field	Function

Field	Function
—	
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When setting this field, user code should delay for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling ADC for operation. The module is still operational even when this field is 0, but command execution start is delayed for a period defined by CFG[PUDLY]. See the device data sheet for ADC idle and active power consumption parameters. 0b - ADC analog circuits are only enabled while conversions are active. Analog startup delays affect performance. 1b - ADC analog circuits are pre-enabled and ready to execute conversions without startup delays, at the cost of higher DC current consumption. A single power-up delay (CFG[PUDLY]) is executed immediately once PWREN is set. No detected triggers begin ADC operation until the power-up delay time has passed. After this initial delay expires, the analog circuits remain pre-enabled, and no additional delays are executed.
27-24 —	Reserved
23-16 PUDLY	Power-up Delay Defines the power-up delay executed after an initial trigger wakes ADC from its idle state. Must be programmed to a non-zero value to enable the ADC. Depending on the value of CFG[PWREN], the delay is executed in one of two modes: • When CFG[PWREN] = 0, the ADC analog circuits are only powered on while the module is active. The power-up delay allows time for the analog circuits to stabilize after being powered on. The startup delay count of (PUDLY * 4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversions after activation is degraded if CFG[PUDLY] is set to too small a value. After active conversions, if no subsequent conversions are pending, the ADC analog circuits are automatically reverted to their low-power idle state. When ADC is awakened with a later trigger, the power-up delay runs again. • When CFG[PWREN] = 1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by CFG[PUDLY] is executed immediately. After the delay has been executed, the analog circuits remain enabled regardless of ADC activity. This configuration begins conversions immediately after trigger event detection, at the cost of increased DC power consumption in the analog circuits. **NOTE** ADC does not begin an initial conversion until the power-up delay has executed, regardless of the value of CFG[PWREN].
15 —	Reserved
14-11 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 HPT_EXDI	High-Priority Trigger Exception Disable Disables high-priority trigger exceptions. See Trigger detect and command execution for a detailed description on trigger exception handling. When 1, exceptions are disabled and CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL] are ignored. 0b - Enabled 1b - Disabled
9 TCMDRES	Trigger Command Resume Determines where a trigger sequence resumes when interrupted by a high-priority trigger exception. To use this field, CFG[TRES] must be 1. 0b - Trigger sequence automatically restarted. 1b - Trigger sequence resumed from the command that was executed prior to the exception.
8 TRES	Trigger Resume Enable Determines whether trigger sequences interrupted by a high-priority exception are automatically resumed or restarted. If 1, the sequence can be resumed along command boundaries or restarted from the beginning of a sequence, as determined by CFG[TCMDRES]. If 0, interrupted triggers can be resumed via software by monitoring STAT[TEXC_INT] (or via ISR handling for trigger exception interrupt when IE[TEXC_IE] = 1). Software determines which trigger was interrupted by reading TSTAT[TEXC_NUM] and restarts the trigger by writing 1 to the corresponding field in the SWTRIG register. 0b - Not automatically resumed or restarted 1b - Automatically resumed or restarted
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE** See the chip-specific ADC information for voltage reference options specific to this packaged device. 00b - Option 1 01b - Option 2 10b - Option 3 11b - Reserved
5-4 PWRSEL	Power Configuration Select Configures the module for power and performance. In the highest-power setting, the highest conversion rates are possible. Refer to the device data sheet for power and performance capabilities for each setting.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Lowest power 01b - Higher power than 00b 10b - Higher power than 01b 11b - Highest power
3-2 —	Reserved
1-0 TPRICTRL	ADC Trigger Priority Control Controls how higher-priority trigger exceptions are handled when they are received during command processing. See Trigger detect and command execution for a detailed explanation of trigger event handling. 00b - Current conversion is aborted and the new command specified by the trigger is started. 01b - Current command is stopped after completing the current conversion. If averaging is enabled, the averaging loop is completed. CMDHn[LOOP] is ignored and the higher-priority trigger is serviced. 10b - Current command is completed (averaging, looping, compare) before servicing the higher-priority trigger. 11b - Reserved

37.6.9 Pause Register (PAUSE)

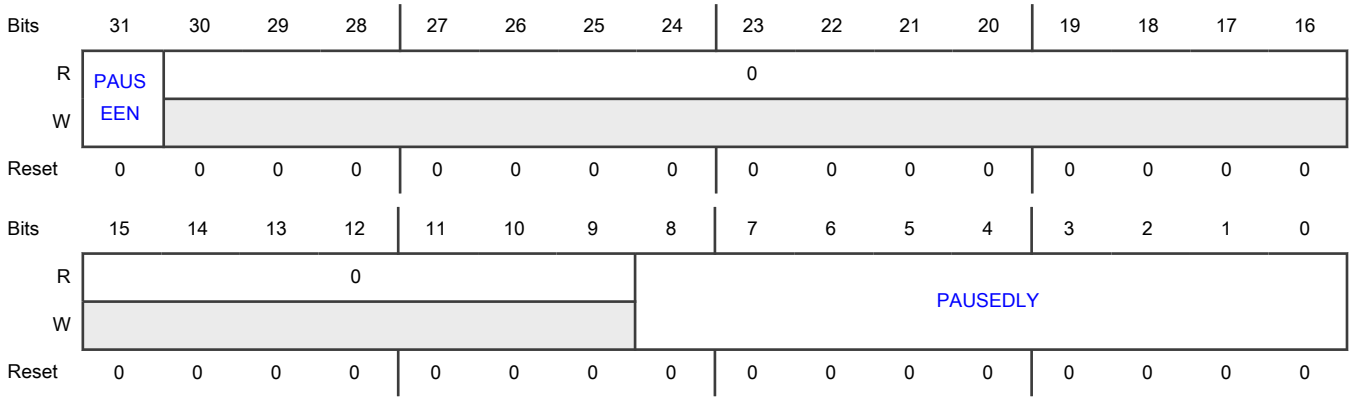
Offset

Register	Offset
PAUSE	24h

Function

Controls the optional inserted delay between conversions. When CTRL[ADCEN] = 1, this register should not be modified.

Diagram



Fields

Field	Function
31 PAUSEEN	Pause Enable Enables the ADC pausing function. When enabled, a programmable delay is inserted during command execution sequencing: • Between LOOP iterations. • Between commands in a sequence. • Between conversions, when a command is executing in compare-until-true configuration. **NOTE** CMDHn[WAIT_TRIG] and PAUSE are mutually exclusive. CMDHn[WAIT_TRIG] takes priority over PAUSE between commands when both are enabled. 0b - Disabled 1b - Enabled
30-9 —	Reserved
8-0 PAUSEDLY	Pause Delay Controls the duration of pauses during command execution sequencing when PAUSE[PAUSEEN] = 1. The pause delay is a count of (PAUSEDLY * 4) ADCK cycles.

37.6.10 Software Trigger Register (SWTRIG)

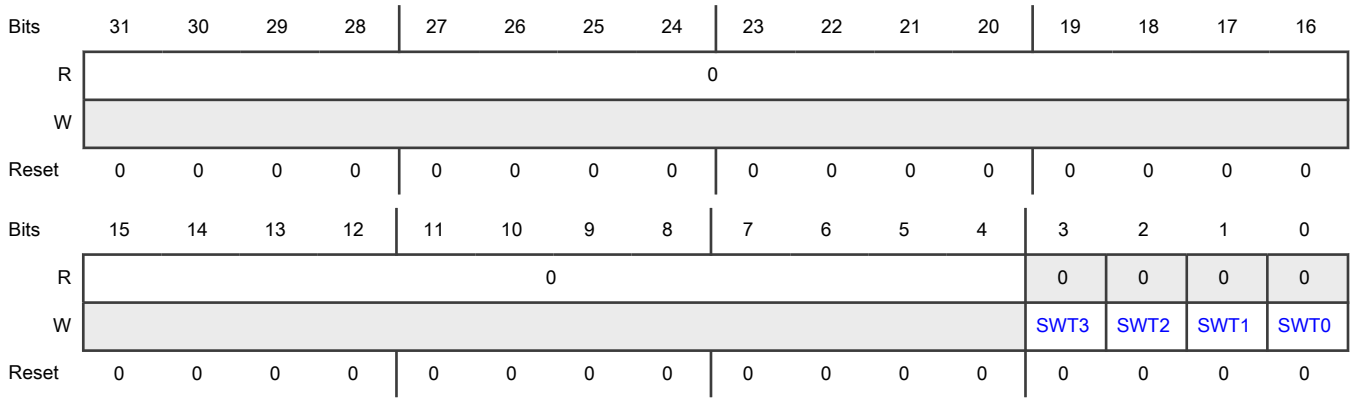
Offset

Register	Offset
SWTRIG	34h

Function

Initiates software-triggered conversions when written to. Writes to this register are ignored while CTRL[ADCEN] = 0. There is an approximately three ADC-clock-cycle synchronization delay between asserting CTRL[ADCEN] and when SWTRIG can be accepted.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 SWT3	Software Trigger 3 Write 1 to SWT3 generates a trigger 3 event. Writing 1 to SWT3 is ignored while the trigger 3 event is being serviced or is pending. 0b - No trigger 3 event generated. 1b - Trigger 3 event generated.
2 SWT2	Software Trigger 2 Write 1 to SWT2 generates a trigger 2 event. Writing 1 to SWT2 is ignored while the trigger 2 event is being serviced or is pending. 0b - No trigger 2 event generated. 1b - Trigger 2 event generated.
1 SWT1	Software Trigger 1 Write 1 to SWT1 generates a trigger 1 event. Writing 1 to SWT1 is ignored while the trigger 1 event is being serviced or is pending. 0b - No trigger 1 event generated. 1b - Trigger 1 event generated.
0 SWT0	Software Trigger 0 Generates a trigger 0 event. Writing 1 to this field is ignored while the trigger 0 event is being serviced or is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No trigger 0 event generated. 1b - Trigger 0 event generated.

37.6.11 Trigger Status Register (TSTAT)

Offset

Register	Offset
TSTAT	38h

Function

Contains status flags to indicate when trigger sequences have been completed or interrupted by a high-priority trigger exception. Each field in this register is set by hardware and cleared by software.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												TCOMP_FLAG			
W													W1C

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												TEXC_NUM			
W													W1C			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16 TCOMP_FLAG	Trigger Completion Flag Indicates which triggers have been completed. Each bit in this field corresponds to a trigger. When a trigger sequence has completed, the corresponding bit in TCOMP_FLAG is set. For example, if trigger 3 has been completed, then bit 19 is set in the TSTAT register. This register is active only if the corresponding bit in IE[TCOMP_IE] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE A synchronization delay may be added to the end of the final conversion in a sequence, prior to this flag being set. This delay can range from two to four ADC CLK cycles. 0000b - No triggers have been completed. Trigger completion interrupts are disabled. 0001b - Trigger 0 has been completed and trigger 0 has enabled completion interrupts. 0010b - Trigger 1 has been completed and trigger 1 has enabled completion interrupts. 0011b-1110b - Associated trigger sequence has completed and has enabled completion interrupts. 1111b - Every trigger sequence has been completed and every trigger has enabled completion interrupts.
15-4 —	Reserved
3-0 TEXC_NUM	Trigger Exception Number Indicates which triggers have been interrupted by exceptions. Each bit in this field corresponds to a trigger. When the corresponding trigger sequence is interrupted by a high-priority trigger exception, the corresponding bit is set. For example, if trigger 3 has been interrupted, then bit 3 is set in this register. This register is active regardless of the value in IE[TEXC_IE]. 0000b - No triggers have been interrupted by a high-priority exception. Or CFG[TRES] = 1. 0001b - Trigger 0 has been interrupted by a high-priority exception. 0010b - Trigger 1 has been interrupted by a high-priority exception. 0011b-1110b - Associated trigger sequence has interrupted by a high-priority exception. 1111b - Every trigger sequence has been interrupted by a high-priority exception.

37.6.12 Offset Trim Register (OFSTRIM)

Offset

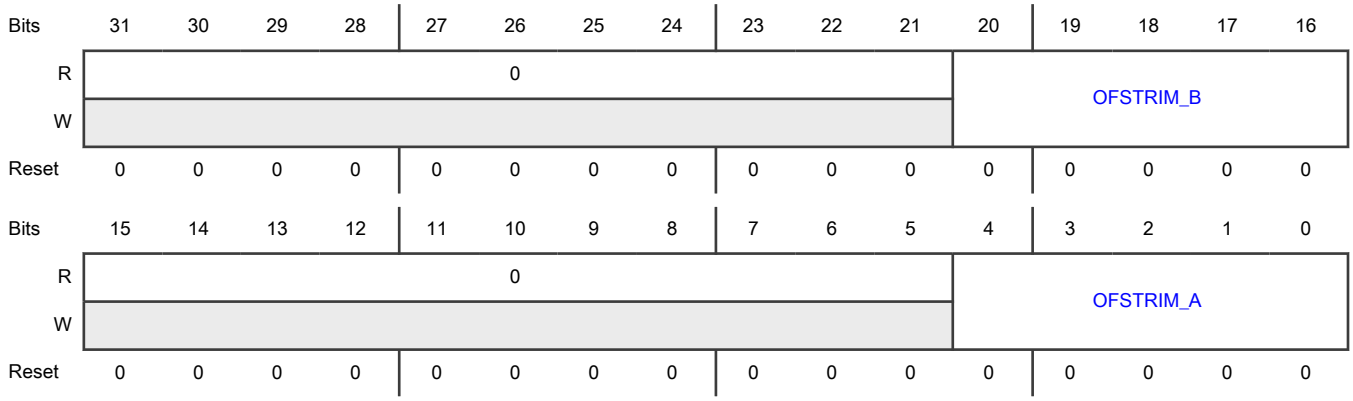
Register	Offset
OFSTRIM	40h

Function

Used to trim for offset. ADC supports a calibration step in which the ADC determines the value needed in the OFSTRIM register.

To determine the value to put in the OFSTRIM register, write 1 to CTRL[CALOFS]. This setting automatically begins a sequence to calculate this value. Once the sequence has completed, the OFSTRIM register is updated with a signed value between -16 and 15. This value is used to minimize offset during normal operation.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 OFSTRIM_B	Trim for Offset OFSTRIM is a 5-bit signed value between -16 and 15. This value applies to the ADC B-side conversion results.
15-5 —	Reserved
4-0 OFSTRIM_A	Trim for Offset OFSTRIM_A is a 5-bit signed value between -16 and 15. This value applies to the ADC A-side conversion results.

37.6.13 Trigger Control Register (TCTRL0 - TCTRL3)

Offset

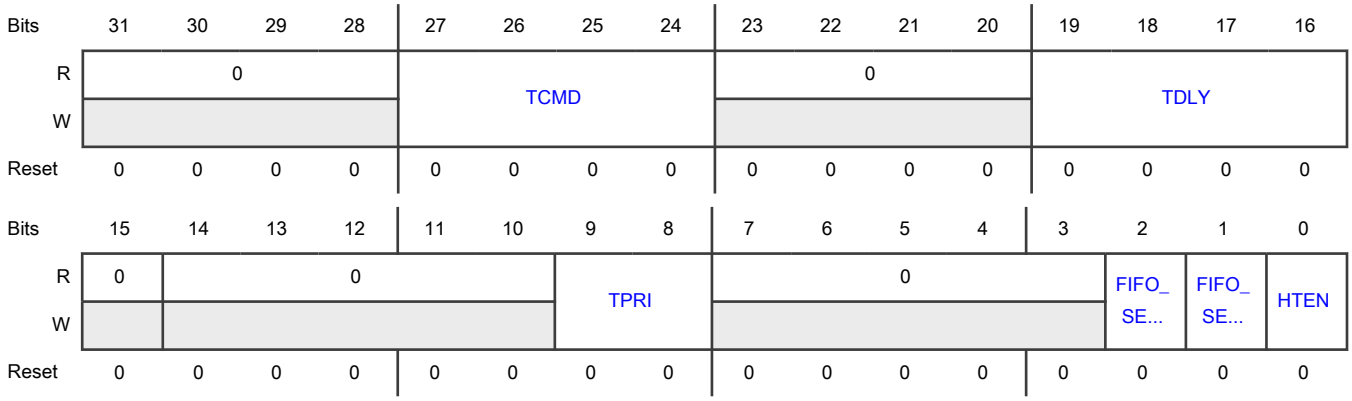
Register	Offset
TCTRL0	A0h
TCTRL1	A4h
TCTRL2	A8h
TCTRL3	ACh

Function

Implements control fields associated with each trigger source. When ADC is executing commands, only one TCTRLn register controls ADC conversions.

Do not update the controlling TCTRLn register while ADC is active. Writing to a TCTRLn register while that trigger control register controls the ADC operation may cause unpredictable behavior.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 TCMD	Trigger Command Select Selects the command from the command buffer to execute upon detection of the associated trigger event. When a higher-priority trigger is received while ADC is converting, the command in this register associated with the new trigger is executed. This execution is done under the control of CFG[TPRICTRL]. See Trigger detect and command execution for details about the relationship between CFG[TPRICTRL] and TCMD. 0000b - Not a valid selection from the command buffer. Trigger event is ignored. 0001b - CMD1 0010b-1110b - Corresponding CMD is executed 1111b - CMD15
23-20 —	Reserved
19-16 TDLY	Trigger Delay Select Selects the trigger delay duration for the start of servicing a trigger event. Each trigger source has an associated programmable delay prior to beginning an initial conversion. When this field is 0, no delay is incurred. When this field is set to a non-zero value, the duration of the delay is 2^{TDLY} ADCK cycles.
15 —	Reserved
14-10 —	Reserved
9-8	Trigger Priority Setting

Table continues on the next page...

Table continued from the previous page...

Field	Function
TPRI	Specifies the priority of the associated trigger source. When determining ADC trigger aborts based on higher priority trigger interrupt, ADC hardware only considers if the new trigger TCTRLn[TPRI] is programmed with a lower value than the running trigger. If both triggers are programmed with the same priority no abort occurs. ADC determines the next active trigger number/order when detecting two or more triggers with the same TCTRLn[TPRI] value. In such case, the system processes the trigger with the lower order first. 00b - Highest priority, Level 1 01b-10b - Set to corresponding priority level. 11b - Lowest priority, Level 4
7-3 —	Reserved
2 FIFO_SEL_B	SAR Result Destination for Channel B Indicates the FIFO to which SAR results are written for Channel B. This field is only used in dual single-ended mode (CMDLn[CTYPE] = 11b). In this mode, the SAR result from Channel B is written to the FIFO number specified by this field. See Sampling Modes for more information. 0b - FIFO 0 1b - FIFO 1
1 FIFO_SEL_A	SAR Result Destination for Channel A Indicates the FIFO to which SAR results are written for Channel A. This field provides the destination for all single-ended and differential conversions and for all A-side conversions in dual single-ended mode. Conversion results are stored in the FIFO number specified, under the following conditions: • Single-ended mode: CMDLn[CTYPE] = 00b or CMDLn[CTYPE] = 01b. • Differential mode: CMDLn[CTYPE] = 10b. • Dual single-ended mode: CMDLn[CTYPE] = 11b. 0b - FIFO 0 1b - FIFO 1
0 HTEN	Trigger Enable Enables hardware trigger source to initiate conversion on the rising edge of the input trigger source. **NOTE** Enabling the hardware trigger does not disable software triggers. 0b - Disabled 1b - Enabled

37.6.14 FIFO Control Register (FCTRL0 - FCTRL1)

Offset

Register	Offset
FCTRL0	E0h
FCTRL1	E4h

Function

Contains control and status fields for each FIFO in the design. A programmable watermark can be set for each FIFO, which can be used to trigger an interrupt. In addition, the number of entries stored in each FIFO can be monitored by reading FCTRLn[FCOUNT].

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0												FWMARK			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												FCOUNT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16 FWMARK	Watermark Level Selection Selects the storage threshold for the ADC Result FIFO. When the number of data words stored in the FIFO is greater than this value, the STAT[RDY0] flag is asserted. When IE[FWMIEn] = 1, an interrupt request is generated. When DE[FWMDEn] = 1, a DMA request is generated.
15-5 —	Reserved
4-0 FCOUNT	Result FIFO Counter Indicates the number of data words stored in the result FIFO. This value may be used with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. This field is incremented with each storage of new data into the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to CTRL[RSTFIFOn], which initializes FCTRLn[FCOUNT] to 0h.

37.6.15 Gain Calibration Control (GCC0 - GCC1)

Offset

Register	Offset
GCC0	F0h
GCC1	F4h

Function

Holds intermediate values used as part of the calibration steps. GCC0 is associated with the A-side converter and GCC1 is associated with the B-side converter. GCCn[GAIN_CAL] is calculated with hardware and automatically updated during the calibration steps. Once the hardware calibration sequence has updated, GCCn[RDY] is asserted automatically.

Requesting a calibration routine automatically clears the GCCn[RDY] flag until the new GCCn[GAIN_CAL] value is calculated. To complete calibration, further software processing is needed, where GCCn[GAIN_CAL] is used to calculate the gain adjustment. The result is stored to GCRn[GCALR]. See Calibration functions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							RDY	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GAIN_CAL															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calibration Value Valid Indicates whether the data stored in GCCn[GAIN_CAL] is valid and should be used to derive GCRn[GCALR]. If the data in GCCn[GAIN_CAL] is invalid, you can run the hardware calibration routine to correct this issue. 0b - Invalid 1b - Valid
23-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
15-0 GAIN_CAL	Gain Calibration Value Indicates the calculated value of the gain calibration. As part of the hardware calibration steps, this field is automatically updated with a 16-bit unsigned number. It is used in the gain adjustment calculations to derive the value written to GCRn[GCALR]. See Calibration functions.

37.6.16 Gain Calculation Result (GCR0 - GCR1)

Offset

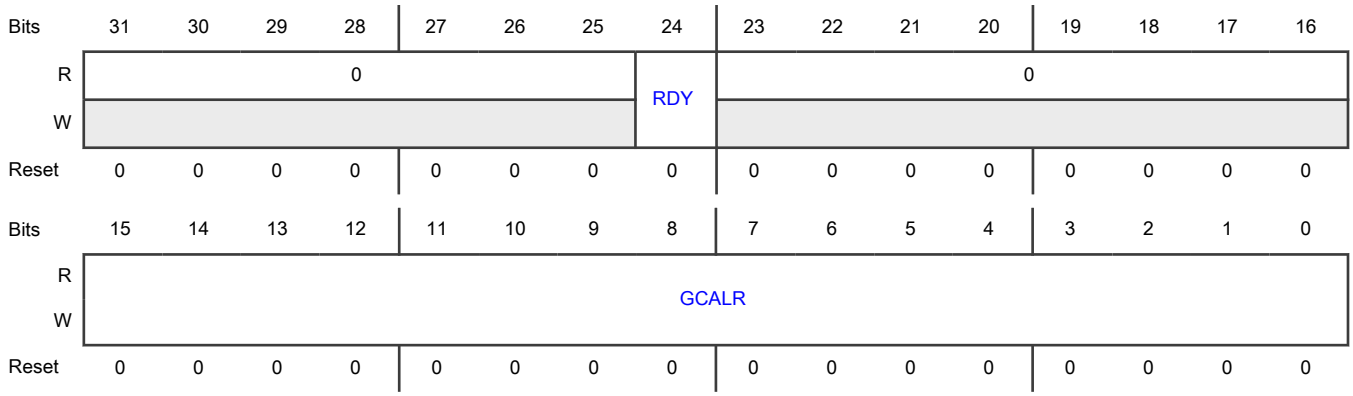
Register	Offset
GCR0	F8h
GCR1	FCh

Function

Used during ADC conversions for automated gain error adjustment. GCR0 is associated with the A-side converter and GCR1 is associated with the B-side converter. Determining the values to store to GCR0[GCALR] and GCR1[GCALR] is the result of software calculations described in setup steps in Calibration functions. Upon writing the GCRn[GCALR] value, the user should also write 1 to GCRn[RDY] to indicate that the gain adjustment result is valid.

A calibration sequence begins by writing 1 to CTRL[CAL_REQ], and the calibration sequence is not complete until GCRn[GCALR] is calculated and GCRn[RDY] is 1. The gain adjustment calculation produces a floating-point value between 1 and 2. GCRn[GCALR] holds the 16-bit fractional component of the gain adjustment calculation. To convert the GCRn[GCALR] value to the gain adjustment value in decimal format, use this formula: 1 + 0.5 * GCRn[15] + 0.25 * GCRn[14] + 0.125 * GCRn[13] + (and so on)

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calculation Ready Indicates whether the data stored in GCRn[GCALR] is valid and is used for gain adjustment. GCRn[GCALR] must be written from memory or calculated each time the calibration routine is run. The user must write 1 to this GCRn[RDY] after writing valid data to GCRn[GCALR]. This field becomes 0 automatically when requesting a new calibration sequence. 0b - Invalid 1b - Valid
23-16 —	Reserved
15-0 GCALR	Gain Calculation Result Holds the 16-bit fractional component generated from the gain adjustment calculation during the auto-calibration routine.

37.6.17 Command Low Buffer Register (CMDL1 - CMDL15)

Offset

For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and varying conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

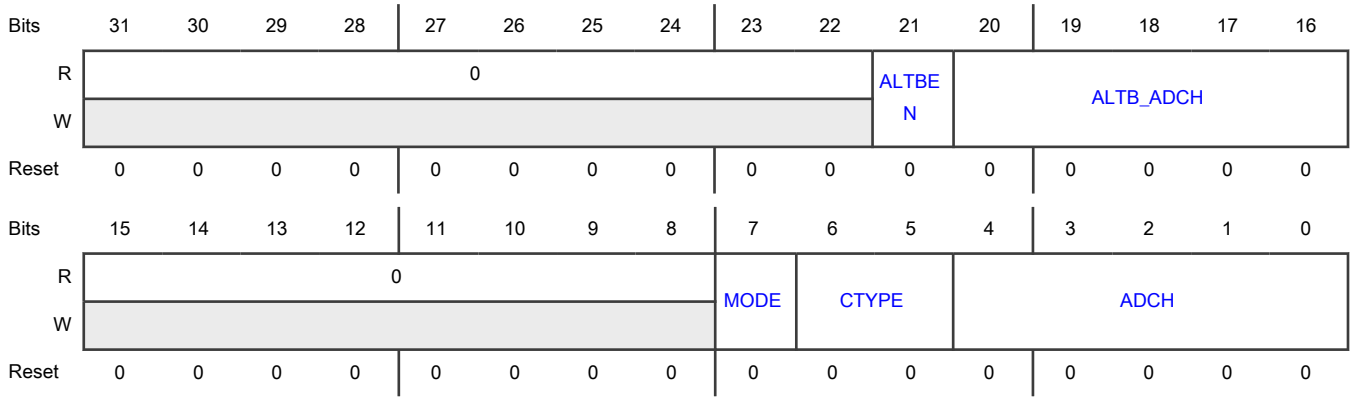
and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

The CMDLn[ADCH] and CMDLn[CTYPE] fields control selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each ADCH channel selection has an associated A-side and B-side input. Each ADCH pair can be converted in differential mode, but only limited pairs should be converted as differential channels (for example, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions for your device, see the Chip Configuration details.

NOTE

Some input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of ADC. Some input channel options in the field descriptions may not be available for your device. See the chip-specific information for the channels supported on this device.

Diagram



Fields

Field	Function
31-22 —	Reserved
21 ALTBEN	Alternate Channel B Select Enable Enables the ALTB_ADCH to select the input for Channel B independent of ADCH register settings when CTYPE is configured to 01b or 11b. **NOTE** Setting CTYPE to differential (10b) still works but is not recommended. 0b - ALTBEN_ADCH disabled. Channel-A and Channel-B inputs are selected based on ADCH settings. 1b - ALTBEN_ADCH enabled. Channel-A inputs are selected by ADCH setting and Channel-B inputs are selected by ALTB_ADCH setting.
20-16 ALTB_ADCH	Alternate Channel B Input Channel Select When ALTBEN is set, ALTB_ADCH selects the Channel B input when CTYPE is configured to 01b or 11b.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Some input channels are from internal resources such as temperature sensors and band gap voltage sources and may only be connected to individual instances of ADC. Some input channel options in field descriptions might not be available for your device. See the chip-specific information for the ADC channel assignments for your device. 0_0000b - Select CH0B 0_0001b - Select CH1B 0_0010b - Select CH2B 0_0011b - Select CH3B 0_0100b-1_1101b - Select corresponding channel CHnB 1_1110b - Select CH30B 1_1111b - Select CH31B
15-8 —	Reserved
7 MODE	Select Resolution of Conversions Selects the ADC resolution. 0b - Standard resolution. Single-ended 12-bit conversion; differential 13-bit conversion with 2's complement output. 1b - High resolution. Single-ended 16-bit conversion; differential 16-bit conversion with 2's complement output.
6-5 CTYPE	Conversion Type Chooses how a pair of A and B channels are converted. 00b - Single-Ended mode. Only A-side channel is converted. 01b - Single-Ended mode. Only B-side channel is converted. 10b - Differential mode. A-B. 11b - Dual-Single-Ended mode. Both A-side and B-side channels are converted independently.
4-0 ADCH	Input Channel Select Selects the input from one of the channel inputs or one of the input pairs, with CMDLn[CTYPE]. Each ADCH channel selection has an associated A-side and B-side input. **NOTE** Not all pairs should be converted as differential channels. See the chip-specific information for the pin pairings available for differential conversions for your device.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Some input channels are from internal resources such as temperature sensors and band gap voltage sources and may only be connected to individual instances of ADC. Some input channel options in field descriptions might not be available for your device. See the chip-specific information for the ADC channel assignments for your device. 0_0000b - CH0A or CH0B or CH0A/CH0B pair. 0_0001b - CH1A or CH1B or CH1A/CH1B pair. 0_0010b - CH2A or CH2B or CH2A/CH2B pair. 0_0011b - CH3A or CH3B or CH3A/CH3B pair. 0_0100b-1_1101b - Select corresponding channel CHnA or CHnB or CHnA/CHnB pair. 1_1110b - CH30A or CH30B or CH30A/CH30B pair. 1_1111b - CH31A or CH31B or CH31A/CH31B pair.

37.6.18 Command High Buffer Register (CMDH1 - CMDH15)

Offset

For a = 1 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

Function

Controls channel selection and conversion options. There are 15 command buffers (CMDn), each constructed from two 32-bit registers (CMDHn:CMDLn) that can be configured for different channel selection and conversion options. Any command buffer is selected and used as the controlling command by association with a trigger event via configuration of TCTRLn[TCMD]. When ADC is executing commands, only one of the CMD buffers controls ADC conversions. Do not update the controlling CMD buffer while ADC is active. A write to a CMD buffer while that CMD buffer controls the ADC operation may cause unpredictable behavior.

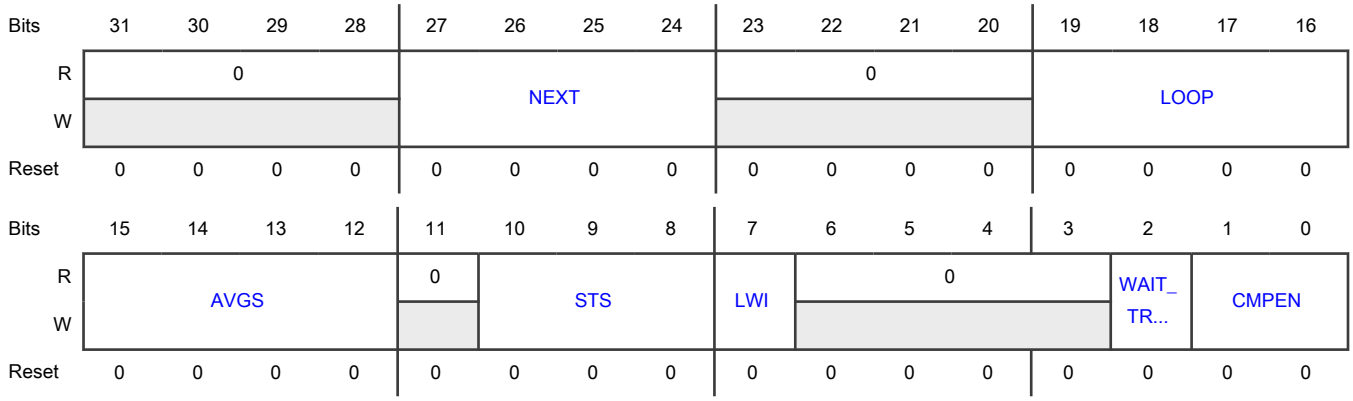
NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these buffers are likely to be defined as two 15-element arrays that are indexed from 0. For example, the type declaration would be:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

and software would access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 NEXT	Next Command Select Selects the next command to be executed after this command completes. Multiple commands can be configured in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order. The order of execution is strictly controlled by this field. For example, a sequence of commands could be CMD2 to CMD1 to CMD3. Unending circular command execution can be configured by setting the NEXT field in the last command in a sequence to the first command in the sequence. It is also allowed for a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0h causes conversions to terminate at the completion of the command. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or sequence of commands) completes. 0000b - No next command defined. Terminate conversions at completion of current command. If lower priority trigger pending, begin command associated with lower priority trigger. 0001b - CMD1 0010b-1110b - Select corresponding CMD command buffer register as next command 1111b - CMD15
23-20 —	Reserved
19-16 LOOP	Loop Count Select Selects the number of times that this command executes (and stores conversion result to RESFIFO) before finishing and transitioning to the next command or idle state. CMDHn[LWI] controls whether a single channel is converted on each iteration or an automatic channel increment results in channel scanning functionality. 0000b - Looping not enabled. Command executes one time. 0001b - Loop one time. Command executes two times.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0010b - Loop two times. Command executes three times. 0011b-1110b - Loop corresponding number of times. Command executes LOOP + 1 times. 1111b - Loop 15 times. Command executes 16 times.
15-12 AVGS	Hardware Average Select Selects how many ADC conversions are averaged to create the ADC result (2^{AVGS}). An internal storage buffer captures temporary results while the averaging iterations are executed. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description for usage of AVGS, LOOP, and NEXT fields in command execution sequencing. 0000b - Single conversion 0001b - 2 0010b - 4 0011b - 8 0100b - 16 0101b - 32 0110b - 64 0111b - 128 1000b - 256 1001b - 512 1010b - 1024
11 —	Reserved
10-8 STS	Sample Time Select Selects the total sampling time. When this field contains a non-zero value, the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower-impedance inputs. Extending sample time allows higher-impedance inputs to be sampled accurately. Longer sample times can lower overall power consumption when command looping and sequencing are configured and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles. 001b - 5.5 ADCK cycles. ($3.5 + 2^1$ ADCK cycles) 010b - 7.5 ADCK cycles. ($3.5 + 2^2$ ADCK cycles) 011b - 11.5 ADCK cycles. ($3.5 + {}^3$ ADCK cycles) 100b - 19.5 ADCK cycles. ($3.5 + 2^4$ ADCK cycles) 101b - 35.5 ADCK cycles. ($3.5 + 2^5$ ADCK cycles) 110b - 67.5 ADCK cycles. ($3.5 + 2^6$ ADCK cycles) 111b - 131.5 ADCK cycles. ($3.5 + 2^7$ ADCK cycles)

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 LWI	Loop with Increment Enables automatic channel incrementing. When 0, the LOOP field selects the number of times the selected channel is converted consecutively. When 1, automatic channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 8h, LWI = 0b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Convert on channel 13A 9 times. Example 2: LOOP = 8h, LWI = 1b, CMDLn[CTYPE] = 0h, CMDLn[ADCH] = Dh. Run channels 13A-21A each one time. Maximum channel scanning using a single command buffer is defined by the maximum value of the LOOP field (16). 0b - Disabled 1b - Enabled
6-3 —	Reserved
2 WAIT_TRIG	Wait for Trigger Assertion Before Execution Selects whether commands execute automatically or a trigger must be received before execution. When 0, wait states are added before the command until the active trigger is asserted again. When WAIT_TRIG = 0, each command is automatically executed when called. 0b - Command executes automatically. 1b - Active trigger must be asserted again before executing this command.
1-0 CMPEN	Compare Function Enable Enables the automatic compare function. Selects whether to store only when the comparison operation is true, following ADC channel input sampling, conversion, and averaging. When the compare function is enabled, the conversion result is compared to the compare value registers (CVn[CVH] and CVn[CVL]). See Compare Function for details about the options for command sequencing related to the compare function. 00b - Disabled 01b - Reserved 10b - Enabled. Store on true. 11b - Enabled. Repeat channel acquisition (sample, convert, and compare) until true.

37.6.19 Compare Value Register (CV1 - CV15)

Offset

For a = 1 to 15:

Register	Offset
CVa	1FCh + (a × 4h)

Function

Contains values used to compare the conversion result when the compare function is enabled. This register is formatted like the D field in Data Result FIFO Register (RESFIFO0 - RESFIFO1), which has in different definitions for bit position and value format in different modes. There is a direct association of each compare value register to a specific command buffer register. For example, CV1 is only used during execution of CMD1 command.

When ADC is executing commands, do not update the CVn register associated with the active command (CMDn). Writes to associated CVn register during this time may result in unpredictable behavior.

NOTE

The 15 compare value registers are numbered [CV1] through [CV15]. In NXP-supplied header files, these registers are likely to be defined as a 15-element array indexed from 0. For example, the type declaration would be:

```
unsigned int CV[15];
```

and software would access ADC0 CV1 as `ADC0->CV[0]` and ADC0 CV15 as `ADC0->CV[14]`.

See Compare Function for a description of CVL usage.

37.6.20 Data Result FIFO Register (RESFIFO0 - RESFIFO1)

Offset

Register	Offset
RESFIFO0	300h
RESFIFO1	304h

Function

Stores the data result of ADC conversions in a 16-entry FIFO. Several tag fields of source command and trigger information are stored with the data. FCTRLn[FCOUNT] indicates how many valid data words are stored in the RESFIFO. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRLn[FCOUNT]. The FIFO can be emptied by successive reads of RESFIFO. The FIFO is reset by writing 0b1 to CTRL[RSTFIFOn].

The following table describes the format of data in the result FIFO in different modes of operation. The sign bit is the MSB in signed 2's complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] become 0. When configured for 13-bit differential mode, D[15] is the sign bit, and D[2:0] becomes 0.

Table 271. Data result register format description

Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed 2's complement
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned, 16-bit magnitude
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed 2's complement, left justified, zero extended
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, zero in D[15] and D[2:0]

NOTE

S: Sign bit;

D: Data, 2's complement data when indicated

Field	Function
17-16 TSRC	Trigger Source Indicates the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using CMDHn[NEXT], this field indicates the trigger source that started the command sequence. 00b - Trigger source 0 01b - Trigger source 1 10b - Trigger source 2 11b - Trigger source 3
15-0 D	Data Result Contains the result of an ADC conversion. The formatting for the data in D is summarized in Table 271.

37.6.21 Calibration General A-Side Registers (CAL_GAR0)

Offset

Register	Offset
CAL_GAR0	400h

Function

Corrects for linearity errors of the A-side converter. All 33 A-side general calibration value registers (CAL_GAR0-CAL_GAR32) contain calibration information that is automatically updated during the self-calibration sequence. See Calibration functions for more information on completing ADC calibration steps.

The calibration values in the CAL_GAR registers affect the conversion result by conditionally being subtracted from the conversion before the result is transferred into the FIFOs. Calibration must be run each time ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GAR values can be stored in non-volatile memory after an initial calibration. These values can be recovered prior to the first ADC conversion. If these registers are set to values not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GAR registers are only read-and-write accessible when ADC is disabled with CTRL[ADCEN] = 0. Access time when writing to these registers is larger than three ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GAR register. The width of each register in this array is non-uniform. The exact width of each register is summarized in Calibration General A-Side and B-Side Widths.

Chapter 38
Low Power Comparator (LPCMP)

38.1 Chip-specific LPCMP information

Table 272. Reference links to related information

Topic	Related module	Reference
Full description	LPCMP	LPCMP
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

38.1.1 Module instances

This device has two instances of the LPCMP module, LPCMP0 and LPCMP1.

38.1.2 Input connections

Table 273. Input connections

Index	CMP0	CMP1	Description
0	CMP0_IN0	CMP1_IN0	Pinned out in VDD_IO
1	CMP0_IN1	CMP1_IN1	VDD_IO domain
2	CMP0_IN2	CMP1_IN2	VDD_IO domain
3	CMP0_IN3	CMP1_IN3	VDD_IO domain
4	PMC BG	PMC BG	VDD_SYS domain
5	VREFO	VREFO	VDD_ANA domain
7	CMP0 8-bit DAC	CMP1 8-bit DAC	Internal DAC

38.1.3 VREFH_EXT

The DCR[VRSEL] is used to configure the VREFH_EXT:

- VRSEL=0, VREFH0 is selected, which is VDD_IO_ABC
- VRSEL=1, VREFH1 is selected, which is VREF_OUT (must be in VREFH / VDD_ANA domain)

38.2 Overview

The LPCMP module provides a circuit to compare two analog input voltages. It includes the following:

- A low power comparator (CMP)
- A DAC
- An analog mux (ANMUX)

See Block diagram for more information.

LPCMP can operate across the full range of the supply voltage, known as rail-to-rail operation.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. DAC divides the supply reference V_{in} into 256 voltage levels. An 8-bit digital signal input selects the output voltage level, which varies from V_{in} to $V_{in}/256$.

You can select V_{in} from the following voltage sources:

- VREFH0
- VREFH1

See the Chip-specific LPCMP information for more information on source of VREFH0 and VREFH1.

NOTE

The LPCMP's internal DAC output is available as an on-chip internal signal only and is not available for an external chip pin.

ANMUX allows you to select an analog input signal from among eight channel options. One channel option is the DAC output. Other chip resources are connected to the other channels. See the Chip-specific LPCMP information section for more information. ANMUX can operate across the full range of the supply voltage.

38.2.1 Block diagram

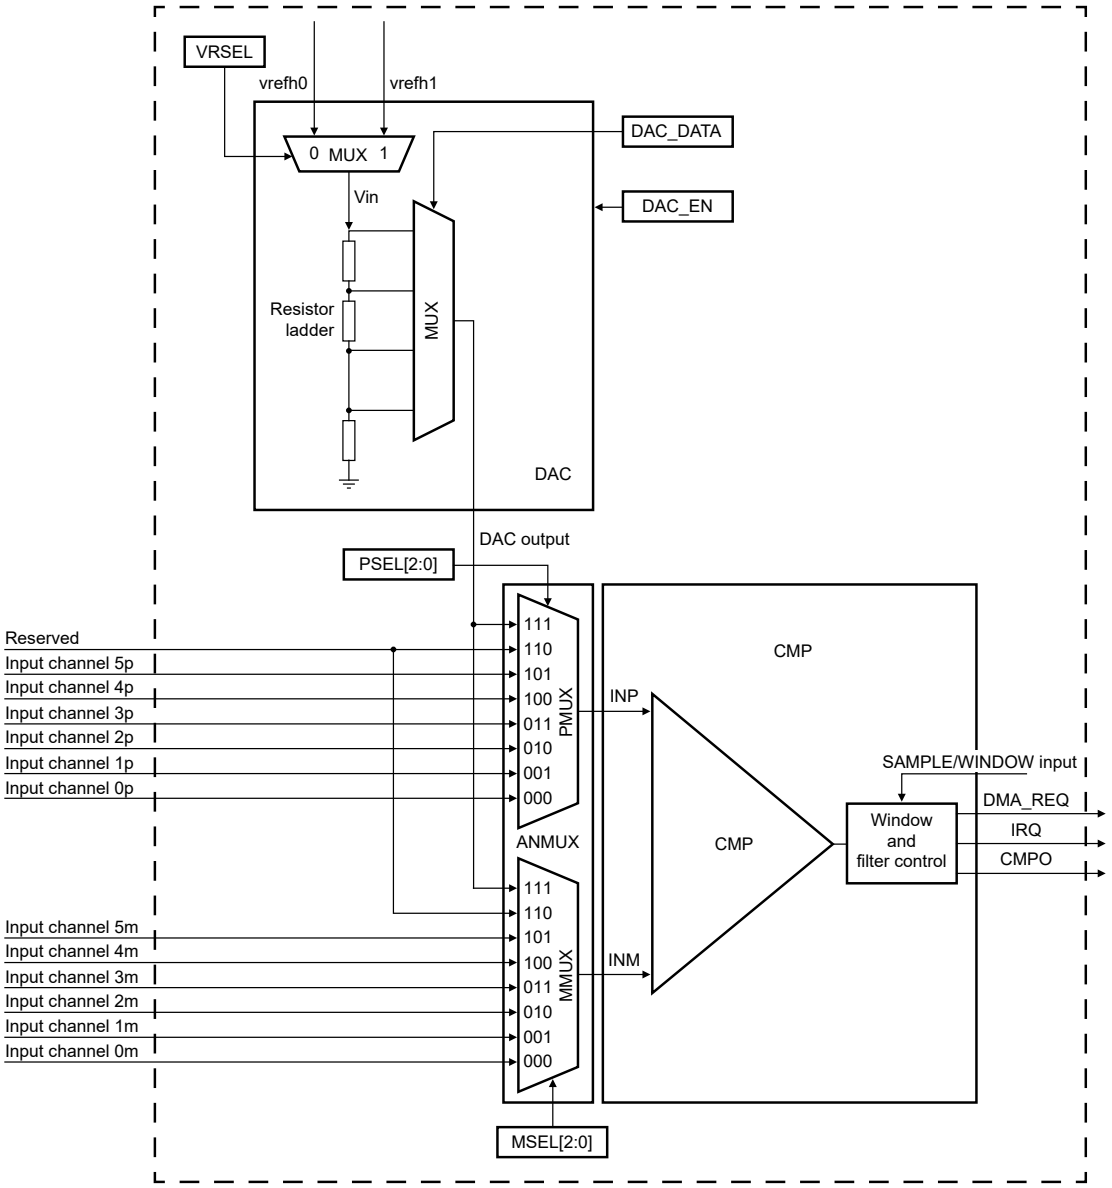

Figure 100. Block diagram

38.2.2 Features

The features of the LPCMP module include：

- Includes two 8-to-1 channel MUXes to select input signal from eight channels
- Supports multiple operation modes to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered
- Provides the following advance features for window and sample:

- Window and sample signals can be inverted.
- CMPO rising, falling or both edges closes the window.
- CMPO level can be defined when window is closed.

- Provides selectable performance levels:
  - Nano-Power mode
  - Low-Power (speed) mode
  - High-Power (speed) mode
- Supports programmable hysteresis control
- Provides a selectable inversion on comparator output
- Uses an external hysteresis at the same time the output filter is used for internal functions
- Provides interrupt and DMA support
- Includes an 8-bit resolution DAC
- Provides a selectable supply reference source for DAC
- Provides a configurable Low-Power (speed) mode or High-Power (speed) mode for DAC

38.3 Functional description

38.3.1 Functional block diagram

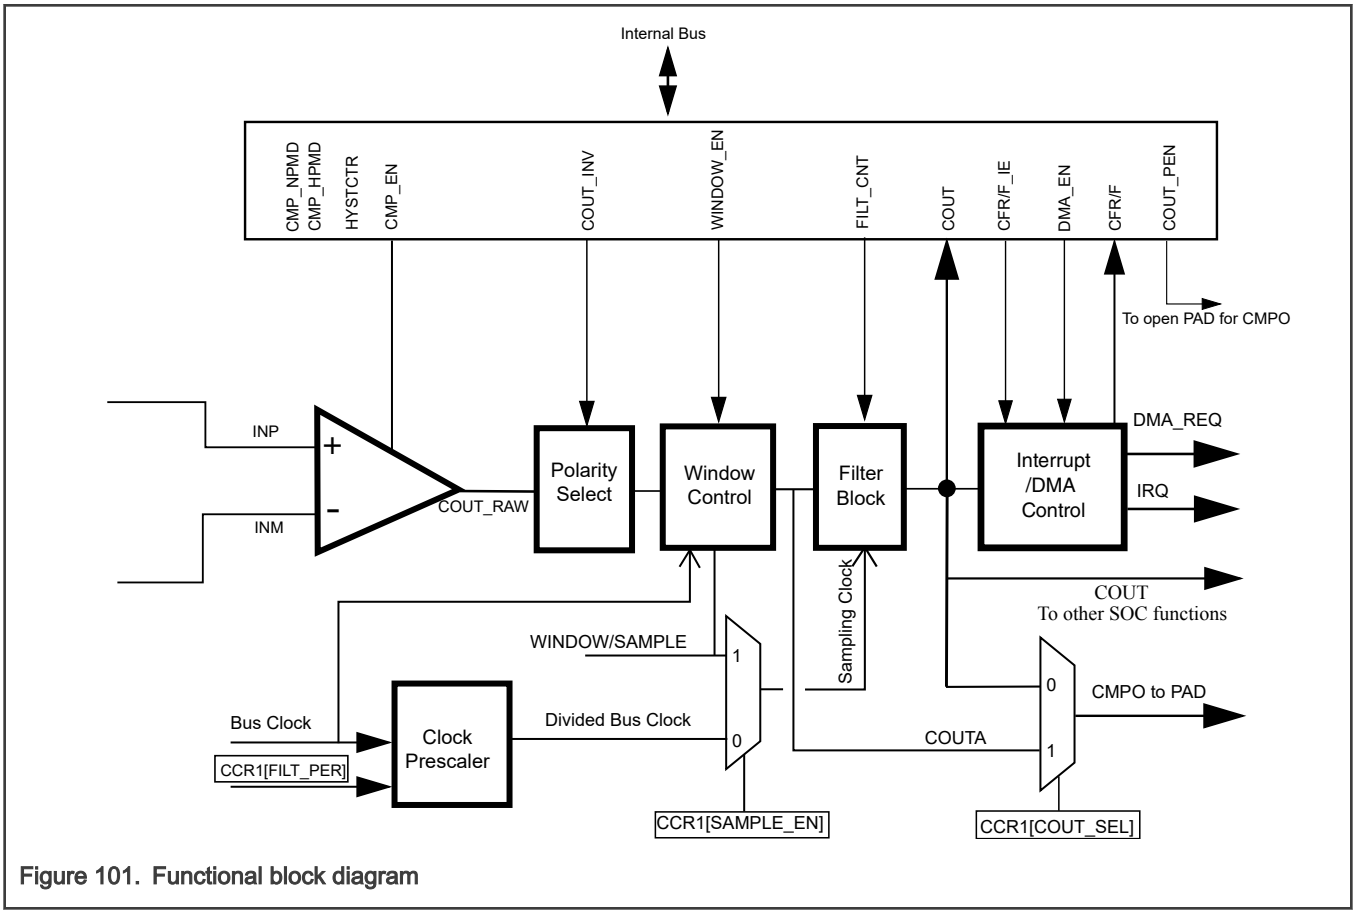

Figure 101. Functional block diagram

As shown in the block diagram, the functions are:

- Compared two analog input voltages applied to INP and INM, COUT_RAW is high when the INP input voltage is greater than the INM input voltage, and COUT_RAW is low when the INP input voltage is less than the INM input voltage.
- The COUT_RAW signal can be inverted by enabling CCR1[COUT_INV].
- The optionally inverted comparator output COUT_RAW is sampled on every bus clock when you enable the CCR1[WINDOW_EN] to generate COUTA. In this case, the comparator output is ignored during time periods when the input voltages are not valid. This is useful when you implement zero-crossing-detection for certain PWM applications.
- The window control block is bypassed when CCR1[WINDOW_EN] is disabled.
- The filter block acts as a simple sampler when CCR1[FILT_CNT] is set to 01h.
- The filter block acts as a filter based on multiple samples when CCR1[FILT_CNT] is set to be greater than 01h.
  - If CCR1[SAMPLE_EN] is set to 1, use the external SAMPLE input as the sampling clock.
  - If CCR1[SAMPLE_EN] is set to 0, use the divided bus clock as the sampling clock.
- Bypasses the filter block when it is not in use.

```
Bypass_Filter_Block = (FILT_CNT == 0x00) |  (~SAMPLE_EN & (FILT_PER == 0x00))
```

- Both COUTA and COUT can be configured as module output CMPO by configuring CCR1[COUT_SEL], and are used for different purposes within the system.
- The optionally filtered COUT can be read directly in CSR[COUT].
- The SAMPLE/WINDOW signal can be inverted by setting CCR1[WINDOW_INV].
- The SAMPLE/WINDOW signal can be closed by CMPO's falling edge and/or rising edge by setting CCR1[WINDOW_CLS] in Window mode.
- In Window mode, when window is closed, define the COUTA value as CCR1[COUTA_OW] by setting CCR1[COUTA_OWEN]. If CCR1[COUTA_OWEN] is not set, COUTA holds the last sampled value.

NOTE

See the chip configuration section for the source of SAMPLE/WINDOW input.

38.3.2 Low-pass filter mode

The low-pass filter mode operates on an unfiltered, optionally inverted comparator output COUTA, and generates the filtered and synchronized output COUT. You can configure both COUTA and COUT as module outputs and use for different purposes within the system.

Synchronization and edge detection determine the bit values of status register. They also apply to COUT for all sampling and windowed modes. You can perform filtering using an internal timebase defined by CCR1[FILT_PER], or use an external sample input to determine sample time.

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, generate a high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

38.3.2.1 Enabling low-pass filter mode

You can enable low-pass filter mode by setting the following:

- CCR1[FILT_CNT] > 01h
- CCR1[FILT_PER] to a nonzero value or writing 1 to CCR1[SAMPLE_EN].

If you use the divided bus clock to drive the low-pass filter, it samples COUTA every CCR1[FILT_PER] bus clock cycle.

If CCR1[SAMPLE_EN] is set to 1, the low-pass filter samples COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CCR1[FILT_CNT] samples agree that the output value has changed.

38.3.2.2 Latency issues

Program the value of CCR1[FILT_PER] or sample period such that the sampling period is longer than the period of the expected noise, ensuring that a given noise spike corrupts only one sample. You must choose the value of CCR1[FILT_CNT] to reduce the probability of noisy samples causing an incorrect transition to recognize. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CCR1[FILT_CNT].

You must trade off the values of CCR1[FILT_PER] or sample period and CCR1[FILT_CNT] against the need for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CCR1[FILT_CNT].

Table 275 summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency restarts each time the noise masks an actual output transition.

38.3.3 Low power mode operation

Below table introduces the mode of operation of lower power.

Table 274. Low power mode operation

Mode of operation	Description
Sleep	LPCMP can operate only in Continuous mode.

38.3.4 Functional modes

You can combine the comparator window and filter features as shown in the following table.

Table 275. Functional modes

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
1	0	X	X	X	X	See the Disabled mode (#1).	N/A
2A	1	0	X	0x00	X	See the Continuous mode (#2A and #2B).	T_{PD}
2B	1	0	0	X	0x00		
3A	1	0	1	0x01	X	See the Sampled, non-filtered mode (#3A and #3B).	$T_{PD} + T_{SAMPLE} + 3T_{per}$
3B	1	0	0	0x01	> 0x00		$T_{PD} + (FILT_PER * T_{per}) + 3T_{per}$
4A	1	0	1	> 0x01	X	See the Sampled, filtered mode (#4A and #4B).	$T_{PD} + (FILT_CNT * T_{SAMPLE}) + 3T_{per}$
4B	1	0	0	> 0x01	> 0x00		$T_{PD} + (FILT_CNT * FILT_PER \times T_{per}) + 3T_{per}$
5A	1	1	0	0x00	X	See the Windowed mode (#5A and #5B).	$T_{PD} + 2T_{per}$
5B	1	1	0	X	0x00		

Table continues on the next page...

Table 275. Functional modes (continued)

Mode #	CMP_EN	WINDOW_EN	SAMPLE_EN	FILT_CNT	FILT_PER	Operation	Maximum latency[1]
6	1	1	0	0x01	> 0x00	See the Windowed/ Resampled mode (#6).	T_{PD} + (FILT_PER * T_{per}) + $3T_{per}$
7	1	1	0	> 0x01	> 0x00	See the Windowed/ Filtered mode (#7).	T_{PD} + (FILT_CNT * FILT_PER x T_{per}) + $3T_{per}$
All other combinations of CMP_EN, WINDOW_EN, SAMPLE_EN, FILT_CNT, and FILT_PER are illegal.							

1. T_{PD} represents the intrinsic delay of the analog component plus the polarity select logic. T_{SAMPLE} is the clock period of the external sample clock. T_{per} is the period of the bus clock.

38.3.4.1 Disabled mode (#1)

In this mode:

- The analog comparator is non-functional and consumes no power.
- CSR[COUT] and CMPO are the same as CCR1[COUT_INV].

38.3.4.2 Continuous mode (#2A and #2B)

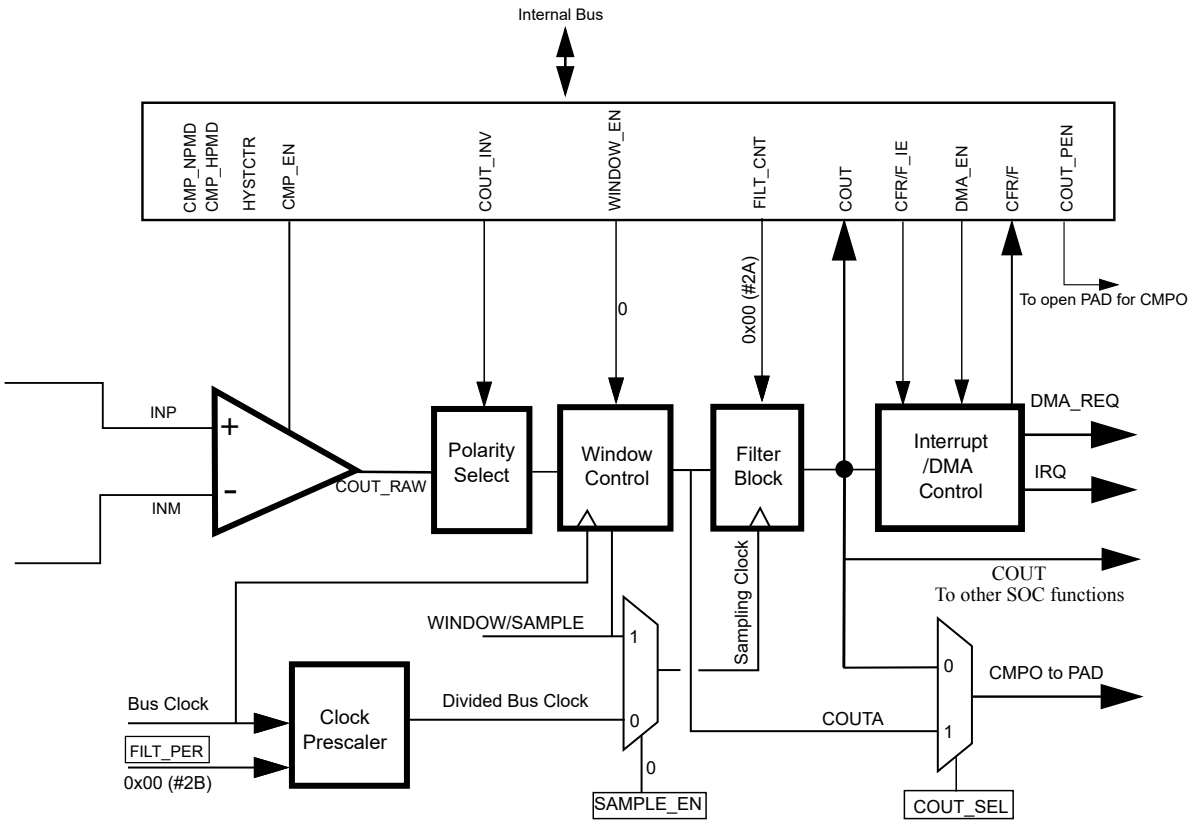

Figure 102. Comparator operation in continuous mode

COUT_RAW is optionally inverted in this mode but is not subject to external sampling or filtering. Both window control and filter blocks bypass completely, and CSR[COUT] updates continuously. The path from comparator input pins to output pins operates in a combinational (unclocked) mode. COUT and COUTA are identical in this mode.

For cases where a comparator drives a fault input, you must configure it to operate in Continuous mode so that an external fault can immediately pass to the target fault circuitry through the comparator.

38.3.4.3 Sampled, non-filtered mode (#3A and #3B)

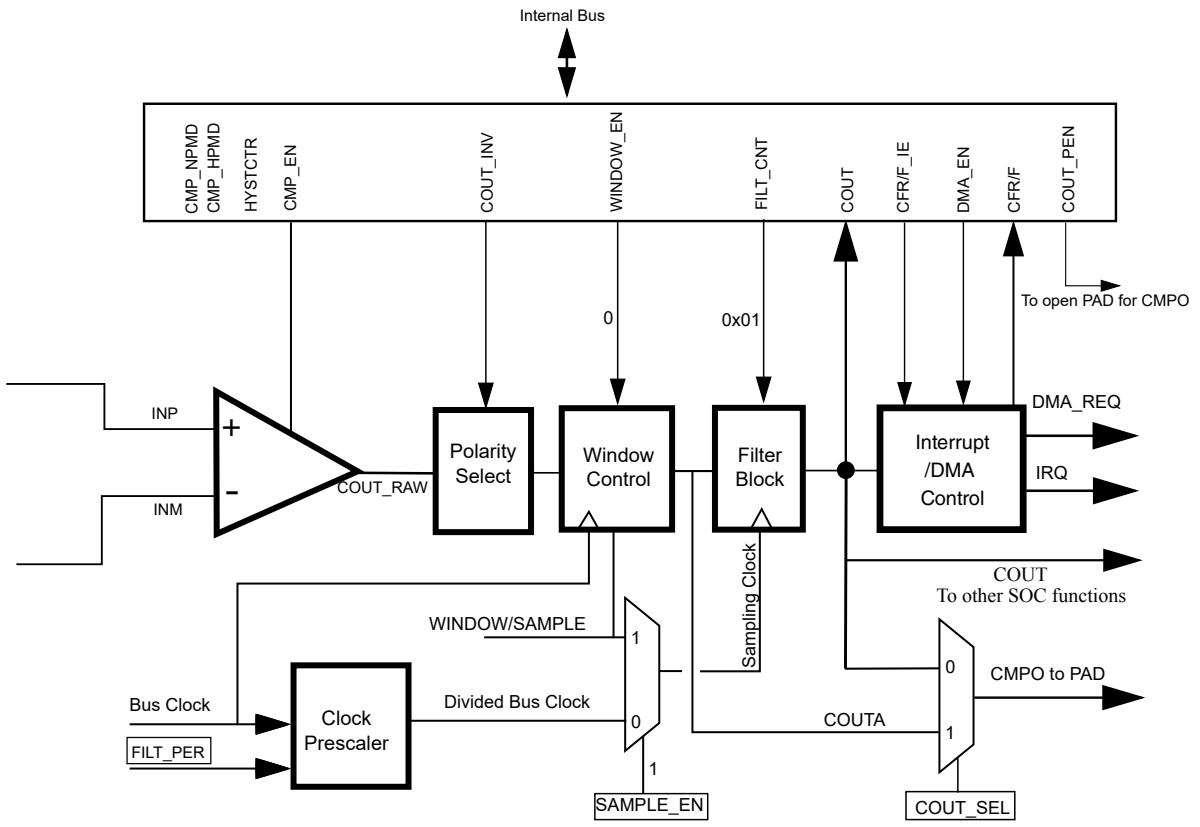

Figure 103. Sampled, non-filtered (#3A): sampling point externally derived

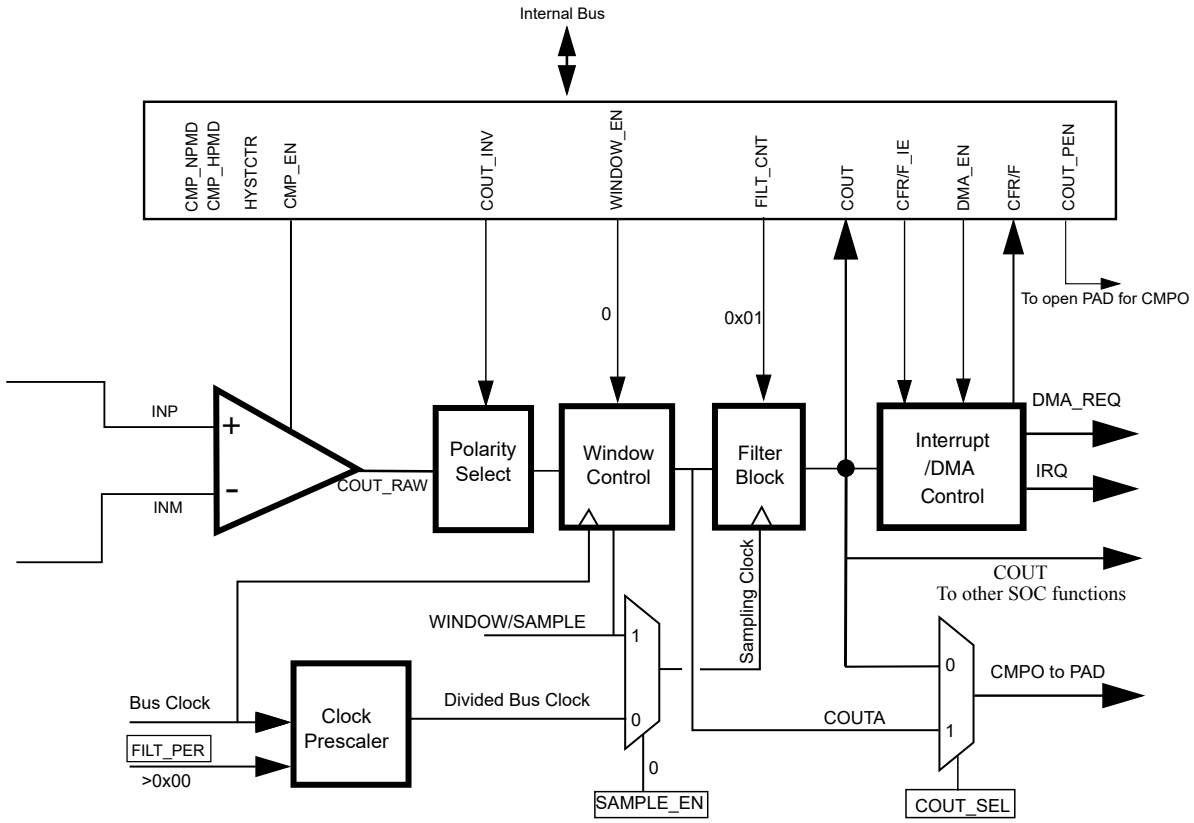

Figure 104. Sampled, Non-Filtered (#3B): sampling interval internally derived

In this mode, the path from analog inputs to COUTA is combinational (unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The difference in two operation modes (#3A and #3B) of sampled, non-filtered mode is that how you drive the clock to the filter block. In #3A, the clock to filter block drives externally, and in #3B, the clock to filter block drives internally.

The filter block has no other function than sample or hold of the comparator output in this mode.

The following figure shows the comparator operation in this mode, assuming that the polarity select sets to a non-inverting state.

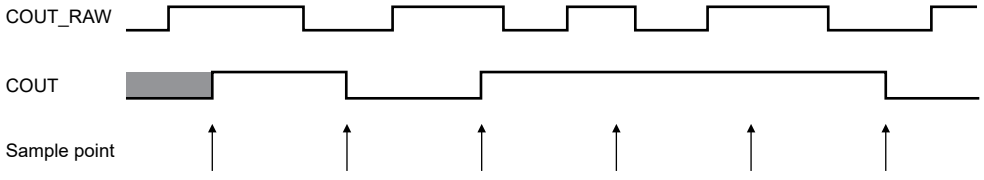

Figure 105. Sampled, Non-Filtered mode timing diagram

38.3.4.4 Sampled, filtered mode (#4A and #4B)

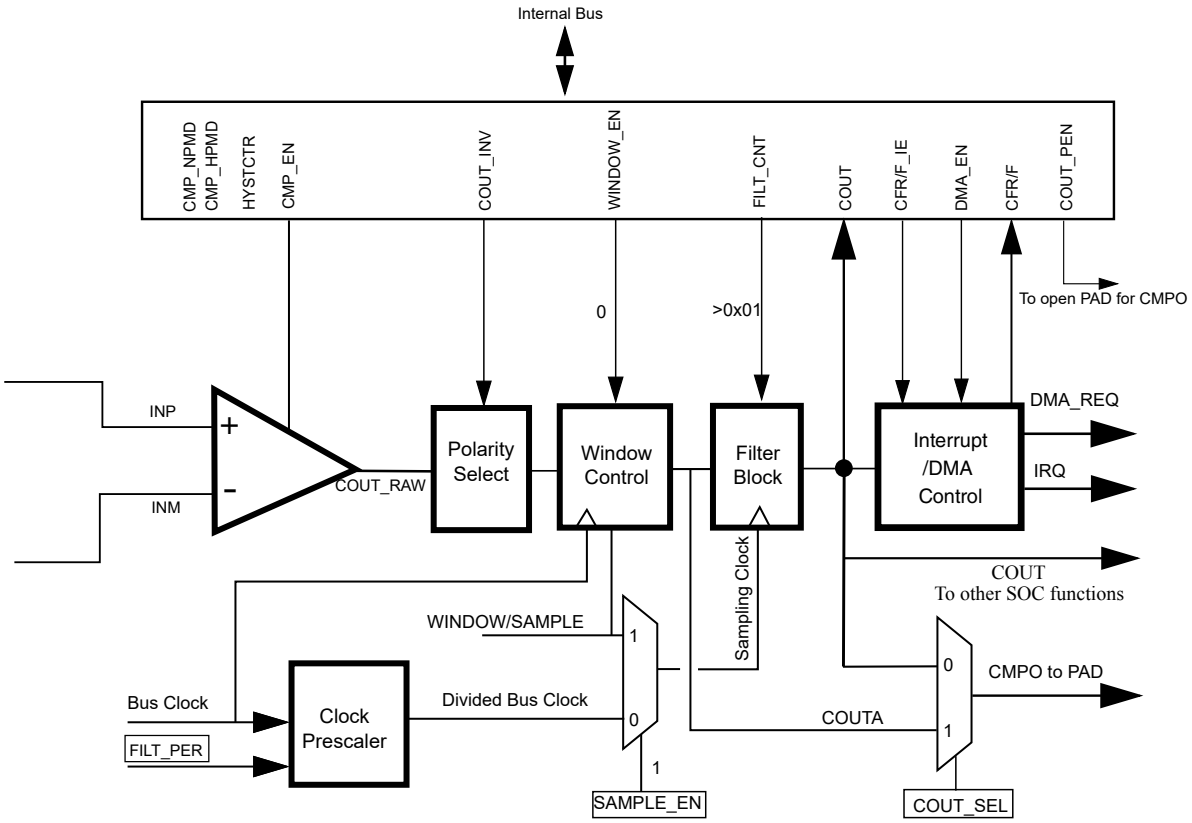

Figure 106. Sampled, filtered (#4A): sampling point externally derived

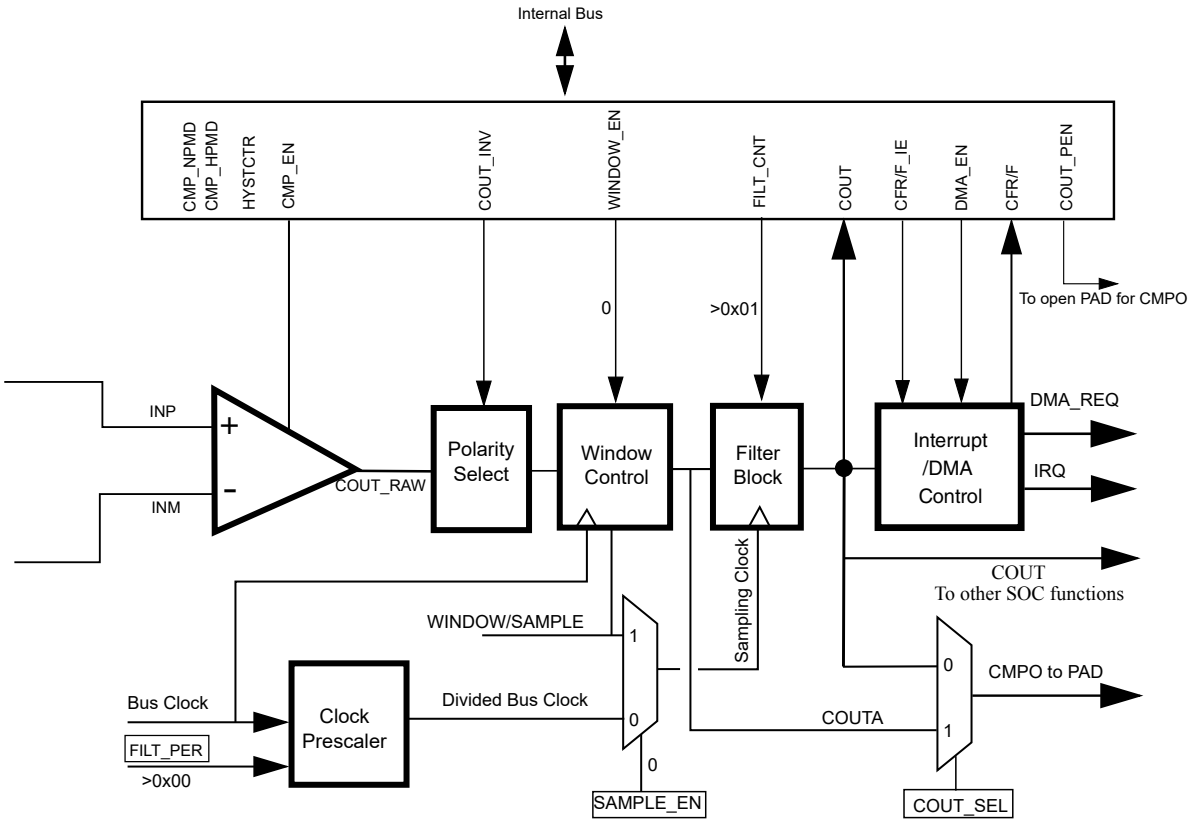

Figure 107. Sampled, filtered (#4B): sampling point internally derived

In this mode, the path from the analog inputs to COUTA is combinational(unclocked). Windowing control bypasses completely. You can sample COUTA whenever you detect a rising edge on the sampling clock.

The only difference in operation between sampled, non-filtered (#3A) mode and sampled, filtered (#4A) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

The only difference in operation between sampled, non-filtered (#3B) mode and sampled, filtered (#4B) mode is that CCR1[FILT_CNT] is larger than 1, which activates filter operation.

38.3.4.5 Windowed mode (#5A and #5B)

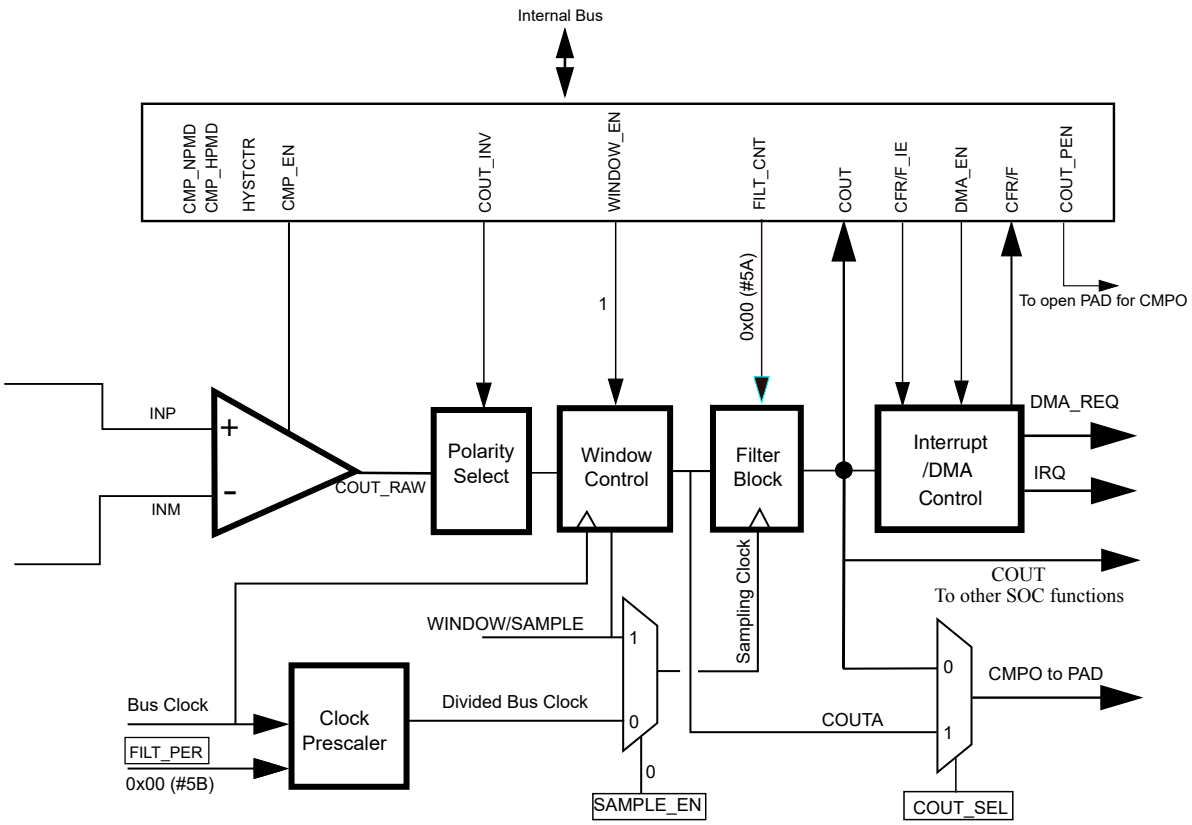

Figure 108. Windowed mode

The bus clock clocks COUTA whenever you enable the window in this mode. The last latched value holds after you disable the window and the filter block is bypassed.

The following figure shows the comparator operation in this mode, ignoring the latency of the analog comparator, polarity select, and window control block. The polarity select sets to a non-inverting state.

COUTA may lag the analog inputs by up to two functional clock cycles plus the combinational path delay through the comparator and polarity select logic in the actual operation.

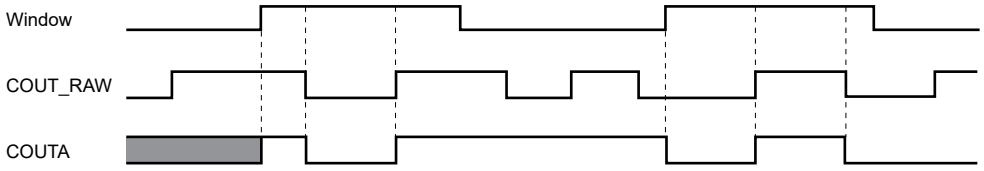

Figure 109. Windowed mode timing diagram

The following figure shows that if CCR1[COUTA_OWEN] becomes 1, you can define COUTA level as CCR1[COUTA_OW], after you closes the window.

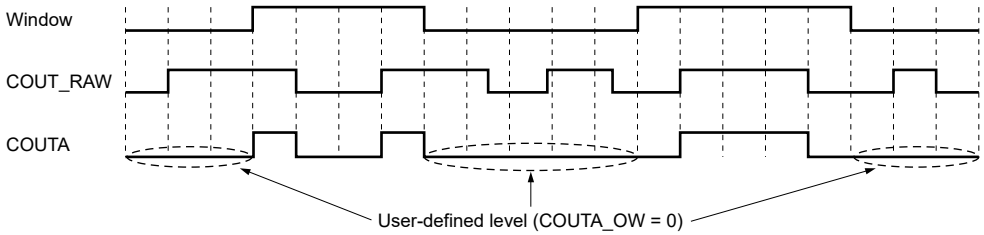

Figure 110. Windowed mode timing diagram with user defined value 0 outside window

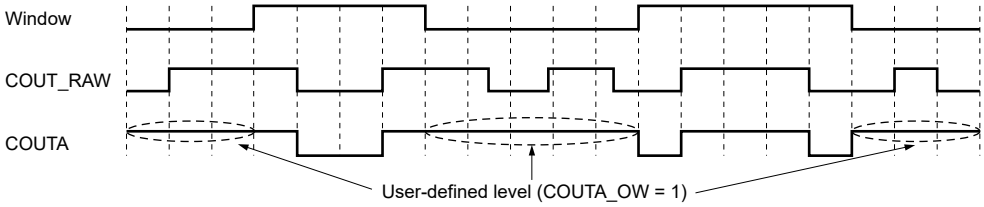

Figure 111. Windowed mode timing diagram with user defined value 1 outside window

NOTE

When the window is open, COUT_A will switch from COUTA_OW to COUT_RAW. When the window is closed, COUT_A will switch from COUT_RAW to COUTA_OW. This may generate unnecessary transition flags, for instance, CFR or CFF. User needs to choose COUTA_OW carefully according to the actual application, and select the appropriate flag CFR or CFF to generate interrupt.

If CCR1[WINDOW_CLS] becomes 1, you can define the CMPO event (rising edge, falling edge or both edges that CCR1[EVT_SEL] selects) to close the window. The external window signal has to go to zero and back to one to enable the internal window again. The following figure shows an example that CMPO rising edge closes the internal window.

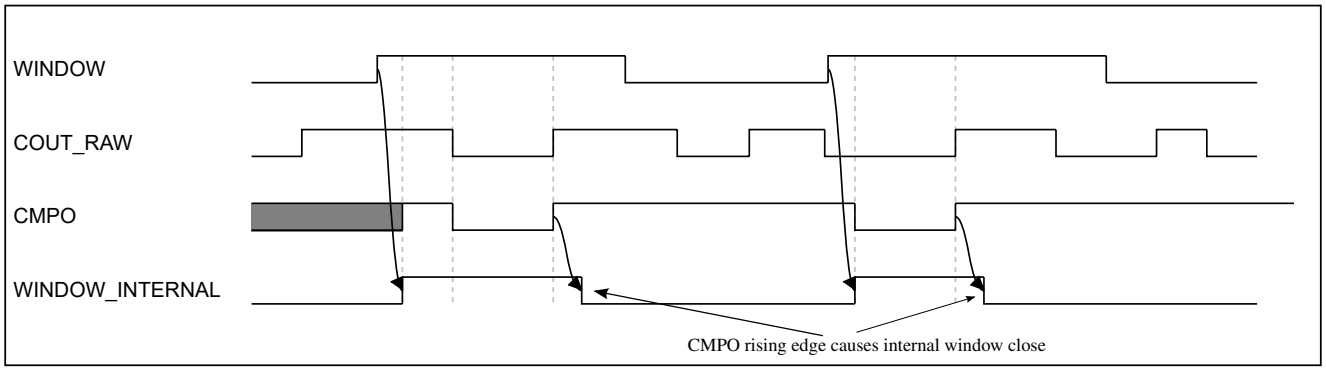

Figure 112. Windowed mode timing diagram with CMPO rising edge close window

The following figure shows that if CCR1[WINDOW_INV] becomes 1, you can invert the window signal before you use it.

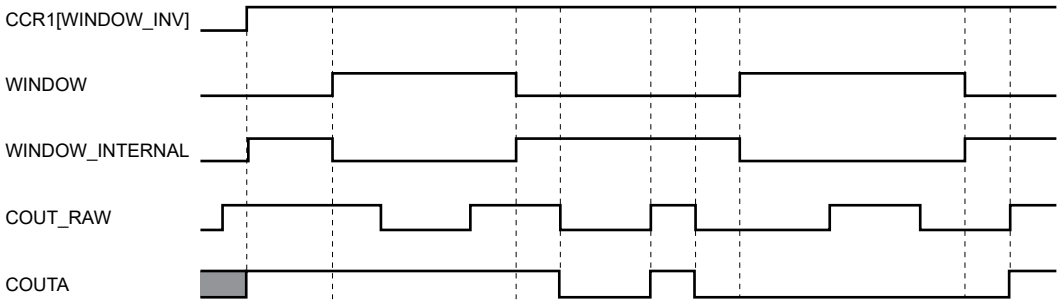

Figure 113. Windowed mode timing diagram with window signal inverted

38.3.4.6 Windowed/Resampled mode (#6)

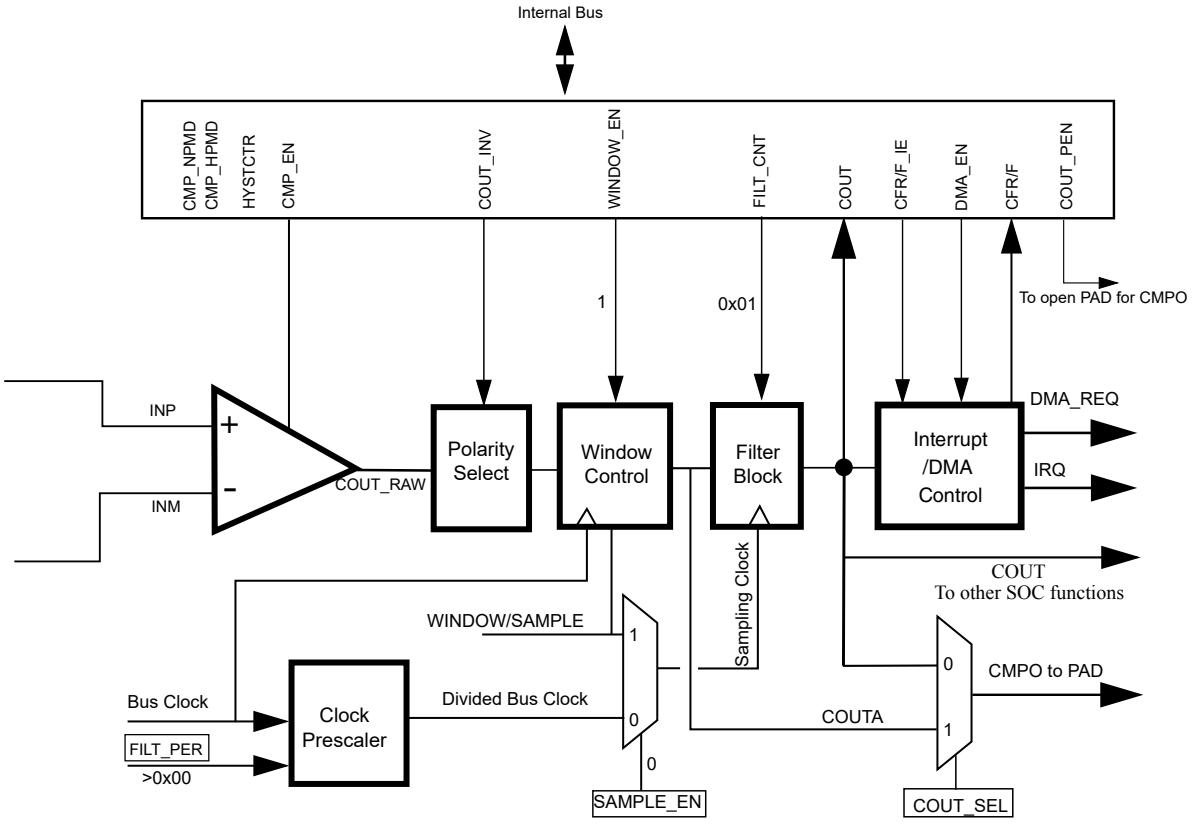

Figure 114. Windowed/Resampled mode

This mode of operation results in an unfiltered string of comparator samples where CCR1[FILT_PER] and the bus clock rate determines the interval between the samples. The following section shows that the configuration for this mode is virtually identical to that for the Windowed/Filtered mode. The only difference is that the value of CCR1[FILT_CNT] must be 1 in this mode.

The following figure uses the same input stimulus shown in Figure 109, and adds resampling of COUTA to generate COUT. The arrows in the figure indicate the time points at which the samples are taken. You can ignore prop delays and latency for clarity.

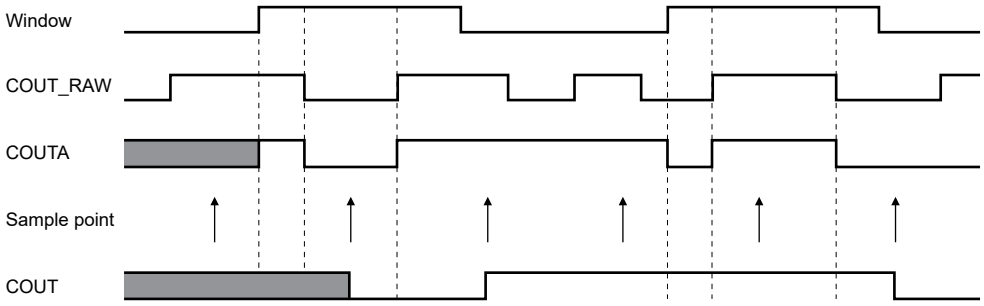

Figure 115. Windowed/Resampled mode operation

This example demonstrates the operation of the comparator in Windowed/Resampled mode, and does not reflect any specific application. Based on the sampling rate and window placement, COUT may not see zero-crossing events that the analog comparator detects. You must carefully consider the sampling period and/or window placement for a given application.

38.3.4.7 Windowed/Filtered mode (#7)

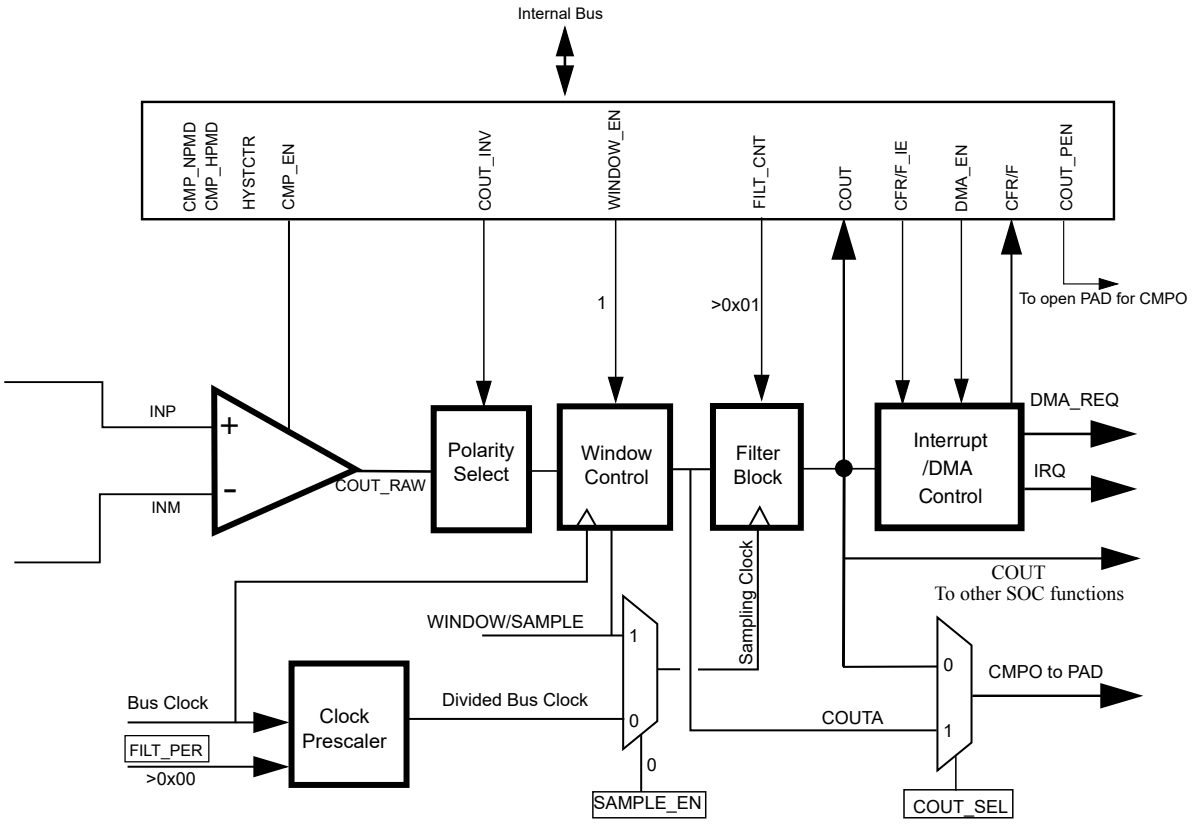

Figure 116. Windowed/Filtered mode

The only difference in operation between Windowed/Resampled mode (#6) and Windowed/Filtered mode (#7) is that CCR1[FILT_CNT] is >1, which activates filter operation.

This mode is the most complex mode of operation for the comparator block, as it utilizes both windowing and filtering features. It also has the highest latency of any of the modes. This is approximately: up to 2 peripheral clock synchronization in the window function + ((CCR1[FILT_CNT] x CCR1[FILT_PER]) + 1) x peripheral clock for the filter function.

38.3.5 DMA

After DMA is enabled by writing 1 to CCR1[DMA_EN] and interrupt is enabled by writing 1 to IER[CFR_IE], IER[CFF_IE], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt. After the DMA completes the transfer, it sends a transfer completing indicator signal that deasserts the DMA transfer request and clears the flags (both CSR[CFR] and CSR[CFF]) to allow a subsequent change on comparator output to occur and forces another DMA request.

The comparator can remain functional in Sleep modes if CCR0[CMP_STOP_EN] becomes 1.

A DMA transfer request wakes up the system from Sleep mode. After completing the data transfer, the system go back again to Sleep mode. See the DMA chapters in this document for more information on the asynchronous DMA function.

38.3.6 Clocking

LPCMP requires the following clocks to operate:

Table 276. LPCMP clocks

Type of clock	Description
Bus	Controls the access to LPCMP registers and window/ filter function.

38.3.7 Resets

The global chip reset signal resets LPCMP.

38.3.8 Interrupts

After the corresponding IER becomes 1, CSR[CFR], CSR[CFF], and can generate an interrupt, assuming that CCR1[DMA_EN] is not 1. You can clear either the flag or IER to deassert the interrupt.

38.4 External signal descriptions

Below table introduces external signals.

Table 277. External signal descriptions

Signal	Description	I/O
CMPO	Filtered or unfiltered comparator output	O
Input_Analog_Channels	Analog input channels (see the chip-specific information for more on the connections).	I
VREFH_EXT	External reference voltage for the CMP-DAC (see the chip-specific information for more on the connections).	I

38.5 Initialization

You can enable LPCMP by writing 1 to CCR0[CMP_EN], and then configuring the control registers (CCR1, CCR2, DCR, and so on).

To disable LPCMP, write 0 to CCR0[CMP_EN]. Switching operation modes or changing control register fields on-the-fly (when CCR0[CMP_EN] is set to 1) may cause noise on the COUT or COUTA signals. To avoid unwanted signal noise, you must ensure to disable the module before switching modes or changing control fields.

The time required to stabilize COUT is the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function, and filter (see the Comparator and 8-bit DAC electrical specifications section of LPCMP datasheet for more information on propagation delay and power-up delay). Table 275 specifies the delay that the windowing and filter function causes.

During operation, you must always consider the propagation delay of the selected data paths. It can take many bus clock cycles for COUT and CSR[CFR]/CSR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

38.6 Application information

38.6.1 Hysteresis

The following diagram illustrates implementation of an external hysteresis resistor bridge between the asynchronous comparator output and the INP input of the Comparator. Since positive feedback is required, CCR1[COUT_INV] must be set to 0 when the hysteresis resistor bridge is added to the INP input of the comparator. CCR1[COUT_INV] must be set to 1 when the hysteresis resistor bridge is added to the INM input of the comparator.

The option of adding an external resistor bridge for the purpose of adding hysteresis to the comparator and the amount of hysteresis depends on the user's individual requirements. Hysteresis can be important in some system designs. In the absence of hysteresis, the continuous comparison of nearly identical analog inputs may add noise and waste power by generating high-frequency oscillations at CMPO.

If external hysteresis is added to the comparator, the bridge must be designed to consider other issues than simply how much hysteresis is needed. The resistor values must be sufficiently high so that they do not cause the drive strength of the digital output driver in the CMPO IO cell to be exceeded. Also, if any digital function other than CMPO must operate on the CMPO pad in the presence of such a bridge, the resistor values must be sufficiently high so that the IO cell can function appropriately in its digital role.

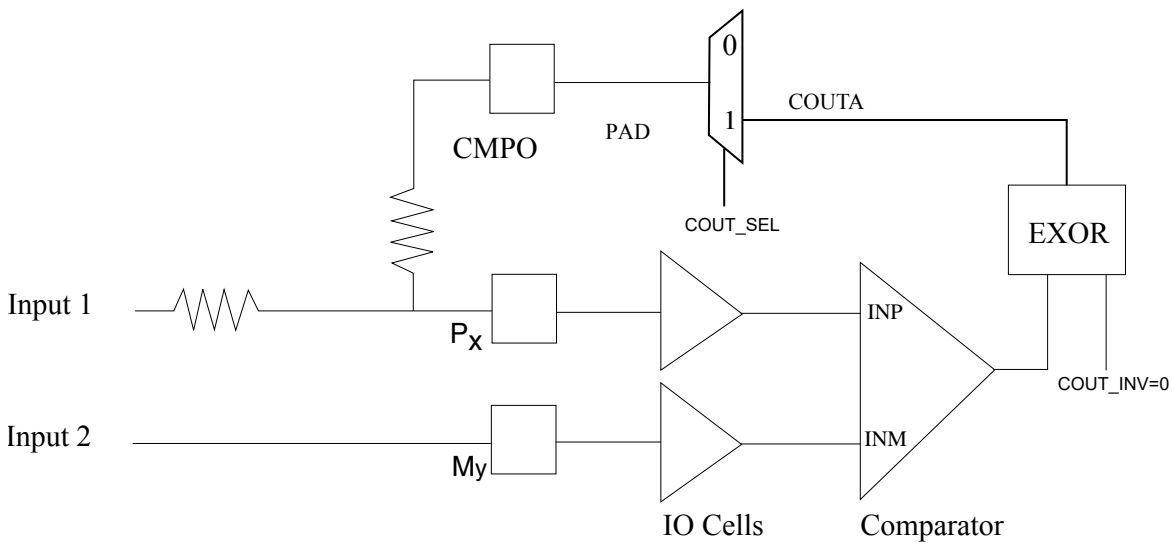

Figure 117. External hysteresis circuit

38.7 LPCMP register descriptions

The memory map comprises of 32-bit aligned registers, which you can access via 8-, 16- or 32-bit reads and 32-bit write. Attempted accesses using unsupported write data sizes, writes to read-only resources, or to reserved spaces terminate with an error. Read access to reserved address generates a transfer error and the read data bus shows all 0s.

1 DAC_HPMD	DAC High Power Mode Enables the DAC high power mode. 0b - Disable 1b - Enable
0 DAC_EN	DAC Enable Enables the DAC. When disabled, power-down the DAC to conserve power. 0b - Disable 1b - Enable

38.7.8 Interrupt Enable (IER)

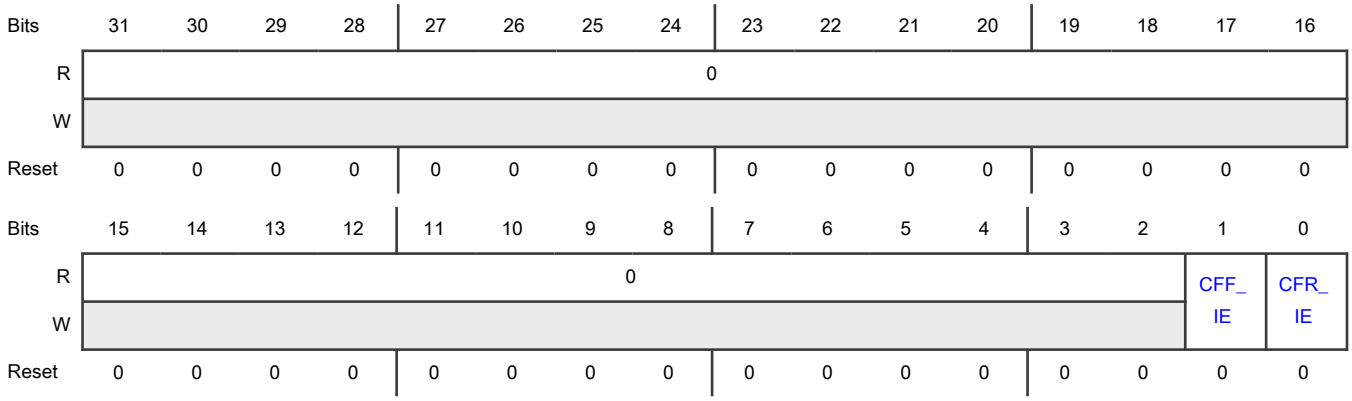
Offset

Register	Offset
IER	1Ch

Function

Provides enable fields for the comparator and round-robin flag interrupts.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 CFF_IE	Comparator Flag Falling Interrupt Enable Enables or disables the comparator flag falling interrupt. 0b - Disables the comparator flag falling interrupt. 1b - Enables the comparator flag falling interrupt when CFF is set.
0 CFR_IE	Comparator Flag Rising Interrupt Enable Enables or disables the comparator flag rising interrupt. 0b - Disables the comparator flag rising interrupt. 1b - Enables the comparator flag rising interrupt when CFR is set.

38.7.9 Comparator Status (CSR)

Offset

Register	Offset
CSR	20h

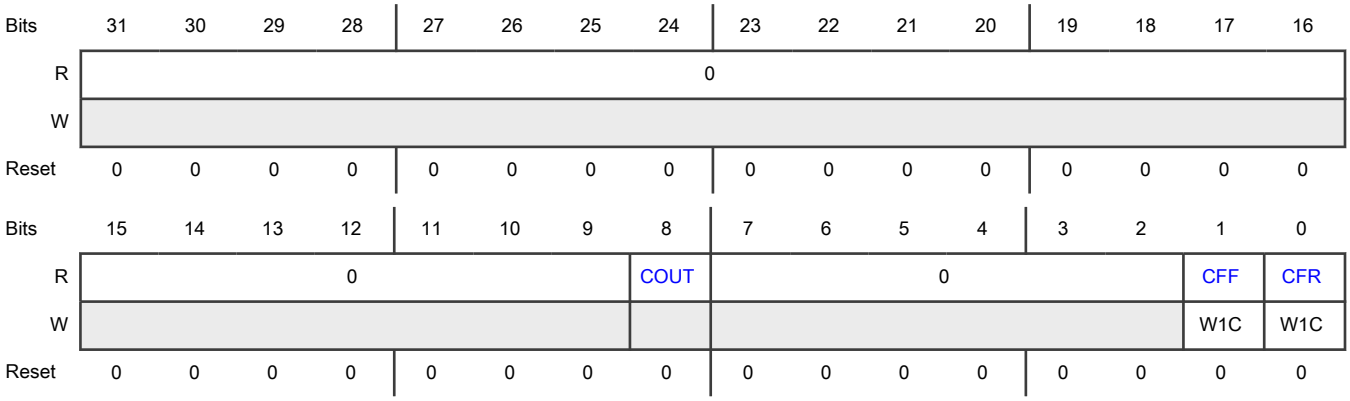
Function

Indicates comparator status, including COUT, CFF, CFR.

NOTE

LPCMP may output a glitch and affect the value of CSR[CFF] and CSR[CFR] at the moment of enabling CMP. In order to ensure correctness, it is recommended to write one to clear (W1C) CSR[CFF] and CSR[CFR] before further configuring CMP.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 COUT	Analog Comparator Output Returns the current value of the analog comparator output when read. This field resets to 0 and reads as CCR1[COUT_INV] after the analog comparator module disables when CCR0[CMP_EN] = 0. Writing to this field is ignored.
7-2 —	Reserved
1 CFF	Analog Comparator Flag Falling Detects when a falling edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected
0 CFR	Analog Comparator Flag Rising Detects when a rising edge on COUT occurs. Write 1 to clear this field when CCR1[DMA_EN] is disabled. If CCR1[DMA_EN] is enabled, the flag automatically clears after DMA is done. This field clears when CCR0[CMP_EN] is not 1. 0b - Not detected 1b - Detected

Chapter 39
Voltage Reference (VREF)

39.1 Chip-specific VREF information

Table 278. Reference links to related information

Topic	Related module	Reference
Full description	VREF	VREF
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

NOTE

The VREF_OUT signal introduced in this chapter is the VREFO signal in the Signal Muxing and Pinout.

39.1.1 Module instances

This device has one instance of the VREF module, VREF0.

39.2 Overview

VREF provides a buffered reference voltage that you can set to levels ranging from 1.0 V to 2.1 V for use as an external reference. When VREF is enabled, the reference voltage, VREF_OUT, is connected to a dedicated output pin. In addition, the buffered reference is available internally for use with on-chip peripherals.

You can trim the VREF voltage output in fine or coarse voltage steps:

- For fine-tuning, use UTRIM[VREFTRIM] to trim the output with (0.05% x VREF_OUT) resolution, where VREF_OUT is the value of the voltage reference output (measured in volts) after using UTRIM[TRIM2V1] to trim the output. For example, after using UTRIM[TRIM2V1] to trim the output VREF_OUT = 1 V, the fine step resolution is : (0.05% x 1) = 0.5 mV.
- For coarse-tuning, use UTRIM[TRIM2V1] to trim the output with 100 mV resolution. For details about possible configurations of the voltage reference, see Table 279

39.2.1 Features

- Programmable User Trim (UTRIM) with 0.05% x VREF_OUT steps in fine-tuning and 100 mV in coarse-tuning. When reset, User Trim (UTRIM) is automatically loaded with a factory-trimmed value.
- Programmable Buffer mode selection:
  - Off
  - Standby mode (Bandgap enabled and output buffer disabled)
  - High-Power Buffer mode (output buffer enabled in High-Power mode)
  - Low-Power Buffer mode (output buffer enabled in Low-Power mode)
- Low-power bandgap and high-accurate bandgap selection
- Support for a dedicated output pin, VREF_OUT

39.2.2 Block diagram

Figure 118 shows the VREF block diagram.

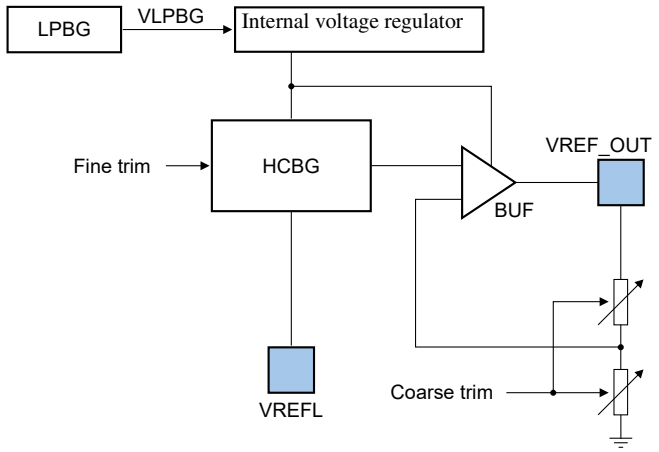


Figure 118. VREF block diagram

39.3 Functional description

VREF is a bandgap buffer system that uses unity gain amplifiers. Both internal and external peripherals use the VREF_OUT signal in Low- and High-Power Buffer modes.

NOTE

When using VREF, a 220 nF capacitor must always be connected between VREF_OUT and Analog Domain Power Supply Ground.

If CSR[HCBGEN] = 1, the voltage reference is enabled, you must set different modes by using CSR[BUF21EN] and CSR[HI_PWR_LV].

The following table shows possible configurations of the voltage reference.

Table 279. VREF_OUT values and related settings

UTRIM[TRIM2V1]	VREF_OUT (V)
0000	1.0
0001	1.1
0010	1.2
0011	1.3
0100	1.4
0101	1.5
0110	1.6
0111	1.7
1000	1.8
1001	1.9
1010	2.0
1011	2.1
11XX	1.0

39.3.1 Voltage reference disabled

When CSR[LPBGEN] = 0, CSR[HCBGEN] = 0, and CSR[BUF21EN] = 0, the voltage reference is disabled and the VREF bandgap and output buffers are disabled. VREF is in Off mode.

39.3.2 Voltage reference enabled

Enabling voltage reference results into the following main high-level configuration options:

- Write 1 to CSR[LPBGEN] and CSR[LPBG_BUF_EN]. This configuration enables the low power bandgap (LPBG) bias current and voltage output.
- Write 1 to CSR[LPBGEN], CSR[REGEN], CSR[BUF21EN], and CSR[HCBGEN], this configuration enables the VREF supply voltage on VREF_OUT.

39.3.2.1 CSR[BUF21EN] = 0, CSR[HI_PWR_LV] = X

In Standby mode, the internal VREF bandgap is enabled to generate an accurate 1.0 V output that you can trim by using UTRIM[VREFTRIM]. The bandgap requires time for startup and stabilization. Monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. When chop oscillator is used, the internal bandgap reference voltage settles within the chop oscillator startup time, Tchop_osc_stup.

The output buffer is disabled in this mode, and there is no buffered voltage output. VREF is in Standby mode. If you select this mode first and Low-Power or High-Power Buffer mode is subsequently enabled, there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

39.3.2.2 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 1

In High-Power buffer mode, the internal VREF bandgap is on, and the High-Power Buffer is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and can be adjusted in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can also be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate device data sheet.

If this mode is entered when VREF is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor is required to connect between the VREF_OUT pin and Analog Domain Power Supply Ground.

39.3.2.3 CSR[BUF21EN] = 1, CSR[HI_PWR_LV] = 0

In Low-Power buffer mode, the internal VREF bandgap is on, and the low-power buffer is enabled to generate a buffered voltage to VREF_OUT. The available voltage levels range from 1.0 to 2.1 V and you can adjust them in 0.1 V steps using UTRIM[TRIM2V1]. VREF bandgap can be used as a reference to internal analog peripherals such as an ADC channel or analog comparator input.

If this mode is entered from Standby mode (CSR[BUF21EN] = 0), there is a delay before the buffer output settles to its final value. This is the buffer startup delay (Tstup), as specified in the appropriate chip data sheet.

If this mode is entered when the VREF module is enabled, you must wait longer than Tstup or until CSR[VREFST] = 1 when the chop oscillator is not enabled. If the chop oscillator is being used, wait for the time specified by Tchop_osc_stup (chop oscillator startup time) to ensure that the VREF output has stabilized.

NOTE

In this mode, a 220-nF capacitor connects the VREF_OUT pin and Analog Domain Power Supply Ground.

39.3.3 Internal voltage regulator

VREF contains an internal voltage regulator that you can enable to provide additional supply noise rejection. The module also contains an internal chop oscillator to generate the chop clock. When possible, enable the internal regulator and chop oscillator to attain optimum VREF performance.

When using the chop function, you must also enable the internal voltage regulator. Perform the following procedure when enabling the internal regulator:

1. Enable the internal regulator by writing 1 to CSR[REGEN].
2. Enable the chop oscillator by writing 1 to CSR[CHOPEN].
3. Write 1 to CSR[LPBGEN] and CSR[HCBGEN].

39.3.4 Low-Power modes

VREF can run when the chip is in a low-power mode. To use the VREF regulator and/or the chop oscillator in a low-power mode, the system reference voltage (also known as the bandgap voltage reference) must also be enabled in these modes. See the chip-specific VREF information on how to enable the system reference voltage.

Having the VREF regulator enabled increases the current consumption. Depending on the requirements of the system application, consider disabling the VREF regulator to minimize the current consumption in low-power modes. However, not using the VREF regulator reduces the accuracy of the output voltage by as much as several mV.

39.3.5 Clocking

See the chip-specific VREF information for the required clocking.

39.3.6 Reset

System reset, VREF convert to initial state with buffer cleared and waiting to load new register.

39.3.7 Interrupts

This module has no interrupts.

39.4 External signals

Table 280. External signals

Signal	Description	I/O
VREF_OUT	Internally generated voltage reference output. When the VREF output buffer is disabled, the VREF_OUT signal state is high-impedance.	O

39.5 Initialization

VREF_OUT requires time for startup and stabilization. After writing 1 to CSR[HCBGEN], monitor CSR[VREFST] to determine whether the stabilization and startup are complete when the chop oscillator is not enabled. If the chop oscillator is enabled, Tchop_osc_stup defines the settling time of the internal bandgap reference. You must wait for this time (Tchop_osc_stup) after the internal bandgap is enabled to ensure that the VREF internal reference voltage is stabilized.

After VREF_OUT is enabled and stabilized, changing the value of CSR[HI_PWR_LV] temporarily destabilizes the output voltage at the VREF_OUT pin, even though CSR[VREFST] remains 1. The time it takes for VREF_OUT to settle again is the same as the buffer startup delay (Tstup), as specified in the appropriate device data sheet. Also, applying a step change of the load current to the VREF_OUT pin incurs some time delay to resettle.

To enable the internal 1.75 V VREF regulator, see Internal voltage regulator for the required sequence. When the internal regulator is disabled, the VREF_OUT voltage is more sensitive to supply voltage variation. Use the internal regulator to achieve optimum VREF_OUT performance.

NOTE

You must write 1 to CSR[CHOPEN], CSR[REGEN], and CSR[ICOMPEN] to achieve the performance stated in the device data sheet.

39.6 Register descriptions

39.6.1 VREF register descriptions

Register support 32-bit write and support 8-bit, 16-bit, and 32-bit read.

Signal multiplexing	Port control	Signal multiplexing

40.1.1 Module instances

- This device has one instance of the RTC module, RTC0.
- In this device, the supply of RTC OSC32K is internally tied to VDD_IO_D.
- Not all the tamper pins are available for each package, see Package pinout for details.

40.1.2 RTC_CLKOUT and RTC_WAKEUP_b

This device has no direct pinout for RTC_CLKOUT or RTC_WAKEUP_b, but the TAMPER pins can be configured to get these signals:

- CR[CPE] can be used to enable RTC_CLKOUT function on TAMPER1 or TAMPER2 if available
- CR[WPE] can be used to enable RTC_WAKEUP_b function on TAMPER0 if available.

40.2 Overview

40.2.1 Block diagram

The following figure is the block diagram of this module.

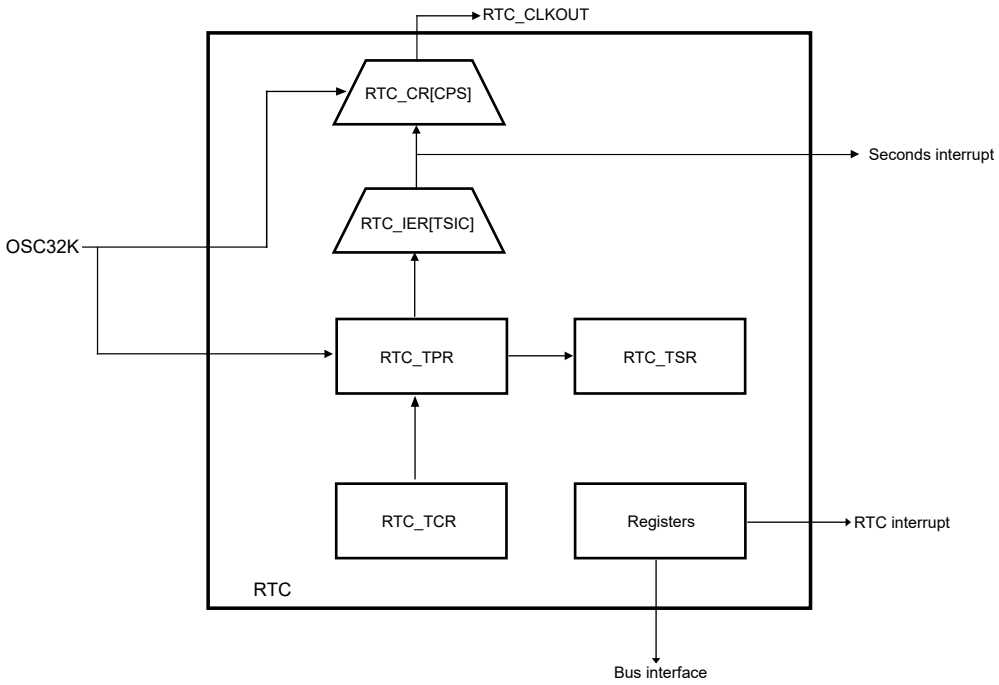

Figure 119. RTC module block diagram

40.2.2 Features

The RTC module features include:

- 32-bit seconds counter with roll-over protection and 32-bit alarm
- 16-bit prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm
- Register write protection
  - Lock register requires POR or software reset to enable write access
- Configurable 1, 2, 4, 8, 16, 32, 64 or 128 Hz square wave output with optional interrupt
- 64-bit monotonic counter with roll-over protection
- Up to 8 tamper input pins with optional interrupt and seconds timestamp when interrupt asserts

40.3 Functional description

40.3.1 Power

The RTC is an always powered block that remains active in all low power modes.

40.3.2 Time counter

The time counter consists of a 32-bit seconds counter that increments once every second and a 16-bit prescaler register that increments once every 32.768 kHz clock cycle.

Reading the time counter (either seconds or prescaler) while it is incrementing may return invalid data due to synchronization of the read data bus. If it is necessary for software to read the prescaler or seconds counter when they could be incrementing, it is recommended that two read accesses are performed and that software verifies that the same data was returned for both reads.

The time seconds register and time prescaler register can be written only when SR[TCE] is clear. Always write to the prescaler register before writing to the seconds register, because the seconds register increments on the falling edge of bit 14 of the prescaler register.

The time prescaler register increments provided SR[TCE] is set, SR[TIF] is clear, SR[TOF] is clear, and the 32.768 kHz (or 1 kHz) clock source is present. After enabling the oscillator, wait the oscillator startup time before setting SR[TCE] to allow time for the oscillator clock output to stabilize.

If the time seconds register overflows, SR[TOF] is set and the time prescaler register stops incrementing. Clear SR[TOF] by initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TOF] is set.

SR[TIF] is set on VBAT POR, software reset, and when an enabled tamper source is detected. It is cleared by clearing the enabled tamper detect flag and then initializing the time seconds register. The time seconds register and time prescaler register read as zero whenever SR[TIF] is set.

40.3.3 Compensation

The compensation logic provides an accurate and wide compensation range and can correct errors as high as 3906 ppm and as low as 0.12 ppm. The compensation factor must be calculated externally to the RTC and supplied by software to the compensation register. The RTC itself does not calculate the amount of compensation that is required, although the 1 Hz clock is output to an external pin in support of external calibration logic.

Crystal compensation can be supported by using firmware and crystal characteristics to determine the compensation amount. Temperature compensation can be supported by firmware that periodically measures the external temperature via ADC and updates the compensation register based on a look-up table that specifies the change in crystal frequency over temperature.

The compensation logic alters the number of 32.768 kHz clock cycles it takes for the prescaler register to overflow and increment the time seconds counter. The time compensation value is used to adjust the number of clock cycles between -127 and +128. Cycles are added or subtracted from the prescaler register when the prescaler register equals 0x3FFF and then increments. The compensation interval is used to adjust the frequency at which the time compensation value is used, that is, from once a second to once every 256 seconds.

Updates to the time compensation register do not take effect until the next time the time seconds register increments and provided the previous compensation interval has expired. When the compensation interval is set to other than once a second then the compensation is applied in the first second interval and the remaining second intervals receive no compensation.

Compensation is disabled by configuring the time compensation register to zero.

40.3.4 Time alarm

The Time Alarm register (TAR), SR[TAF], and IER[TAIE] allow the RTC to generate an interrupt at a predefined time. The 32-bit TAR is compared with the 32-bit Time Seconds register (TSR) each time it increments. SR[TAF] is set when TAR equals TSR and TSR increments.

SR[TAF] is cleared by writing TAR. This is usually the next alarm value, although writing a value that is less than TSR (such as 0) prevents SR[TAF] from setting again. SR[TAF] cannot otherwise be disabled, although the interrupt it generates is enabled or disabled by IER[TAIE].

40.3.5 Update mode

The Update Mode field in the Control register (CR[UM]) configures software write access to the Time Counter Enable (SR[TCE]) field. When CR[UM] is clear, SR[TCE] can be written only when LR[SRL] is set. When CR[UM] is set, SR[TCE] can also be written when SR[TCE] is clear or when SR[TIF] or SR[TOF] are set. This allows the time seconds and prescaler registers to be initialized whenever time is invalidated, while preventing the time seconds and prescaler registers from being changed on the fly. When LR[SRL] is set, CR[UM] has no effect on SR[TCE].

CR[UM] also configures software write access to the Monotonic Counter Enable (MER[MCE]) bit. When CR[UM] is clear, MER[MCE] can be written only when LR[MEL] is set. When CR[UM] is set, MER[MCE] can also be written when MER[MCE] is clear or when SR[TIF] or SR[MOF] are set. This allows the monotonic counter register to be initialized whenever the monotonic counter is invalid, while preventing the monotonic counter from being changed on the fly. When LR[MEL] is set, CR[UM] has no effect on MCR[MCE].

40.3.6 Monotonic counter

The 64-bit Monotonic Counter is a counter that cannot be exhausted or return to any previous value, once it has been initialized. If the monotonic overflow flag is set, the monotonic counter returns zero and does not increment.

Depending on the value of the monotonic counter enable bit, writing to the monotonic counter either initializes the register with the value written, or increments the register by one (and the value written is ignored).

When the monotonic counter is enabled, the monotonic counter high increments on either a write to the monotonic counter high register or if the monotonic counter low register overflows (due to a write to the monotonic counter low register). The monotonic overflow flag sets when the monotonic counter high register overflows and is cleared by writing the monotonic counter high register when the monotonic counter is disabled.

The monotonic counter is held in reset whenever the time invalid flag is set. Always clear the time invalid flag before initializing the monotonic counter.

40.3.7 Tamper detect

Each external tamper pin and internal tamper source can be configured to generate a tamper interrupt. The contents of the seconds register are latched in the tamper time seconds register when the tamper interrupt asserts. Read the tamper time seconds register before clearing the flag in the tamper detect register.

Writing the tamper time seconds register at any time will set the time invalid flag. Since this is a software initiated tamper, there is no status flag to indicate this tamper source. To disable the software initiated tamper, lock the tamper time seconds register to prevent write accesses to that register.

40.3.8 Register lock

The Lock register (LR) can be used to block write accesses to certain registers until the next POR or software reset. Locking the Control register (CR) disables the software reset. Locking LR blocks future updates to LR.

Write accesses to a locked register are ignored and do not generate a bus error.

40.3.9 Modes of operation

The RTC remains functional in all low power modes and can generate an interrupt to exit any low power mode.

40.3.10 Clocking

The time counter within the RTC is clocked by default from a 32.768 kHz clock.

The 32.768 kHz crystal oscillator is disabled at POR and must be enabled by software. After enabling the crystal oscillator, wait the oscillator startup time before setting SR[TCE] or using the oscillator clock external to the RTC.

The crystal oscillator includes tunable capacitors that can be configured by software. Do not change the capacitance unless the oscillator is disabled.

40.3.11 Reset

The power-on-reset signal initializes all RTC registers to their default state. A software reset bit can also initialize all RTC registers.

Writing 1 to CR[SWR] forces the equivalent of a POR to the rest of the RTC module. CR[SWR] is not affected by the software reset and must be cleared by software.

40.3.12 Interrupts

The RTC interrupt is asserted whenever a status flag and the corresponding interrupt enable bit are both set. It is always asserted on POR, and software reset. The RTC interrupt is enabled at the chip level by enabling the chip-specific RTC clock gate control bit. The RTC interrupt can be used to wakeup the chip from any low-power mode. If the RTC wakeup pin is enabled and the chip is powered down, the RTC interrupt causes the wakeup pin to assert.

The RTC interrupt is also asserted when a configured tamper flag asserts and the corresponding tamper interrupt enable bit is set. Both internal tamper events and external tamper pins can cause the tamper interrupt to assert. The contents of the seconds register are recorded in the tamper time seconds register when the tamper interrupt asserts.

The RTC seconds interrupt is an edge-sensitive interrupt with a dedicated interrupt vector that is generated once a second and requires no software overhead (there is no corresponding status flag to clear). It is enabled in the RTC by the time seconds interrupt enable bit and enabled at the chip level by setting the chip-specific RTC clock gate control bit. The frequency of the seconds interrupt defaults to 1 Hz, but can instead be configured to trigger every 2, 4, 8, 16, 32, 64 or 128 Hz. The RTC seconds interrupt does not cause the RTC wakeup pin to assert.

40.4 External signals

Table 282. RTC external signals description

Signal	Description	I/O
RTC_CLKOUT	Prescaler square-wave output or RTC 32.768 kHz clock	O
RTC_WAKEUP_b	Active low wakeup for external device	O
RTC_TAMPER[7:0]	Tamper pin input	I

40.4.1 RTC clock output

The RTC_CLKOUT signal can output either a square wave prescaler output (configurable to 1, 2, 4, 8, 16, 32, 64 or 128 Hz) or the RTC 32.768 kHz clock.

40.4.2 RTC wakeup pin

The RTC wakeup pin is an open drain, active low, output that allows the RTC to wakeup the chip via an external component. The wakeup pin asserts when the wakeup pin enable is set and either the RTC interrupt is asserted or the wakeup pin is turned on via a register bit. The wakeup pin does not assert from the RTC seconds interrupt.

NOTE

The wakeup pin is optional and may not be implemented on all devices.

40.4.3 RTC Tamper pins

The RTC tamper pins are input pins that can be used to generate an interrupt or invalidate the time counter. The first tamper pin to assert an interrupt will also capture a timestamp of the seconds register.

40.5 Initialization

To initialize the RTC time counter:

1. Enable the desired clock source for the RTC.
2. Initialize the time prescaler register by writing RTC_TPR[TPR] with the appropriate time value between 0x0 and 0x7FFF.
3. Initialize the time second register by writing RTC_TSR[TSR] with the appropriate time value that is greater than 0x0.
4. Enable the time counter by writing RTC_SR[SR]=0x10.

40.6 Register descriptions

All registers must be accessed using 32-bit writes and all register accesses incur three wait states.

When the supervisor access control bit is clear, only supervisor mode software can write to the RTC registers or read the RTC tamper and monotonic registers. Writes to the RTC registersor reads of the RTC tamper and monotonic registers by non-supervisor mode software generate a bus error. Both supervisor and non-supervisor mode software can always read the otherRTC registers.

Writing to a register protected by the lock register does not generate a bus error, but the writes can not be completed.

Offset

Register	Offset
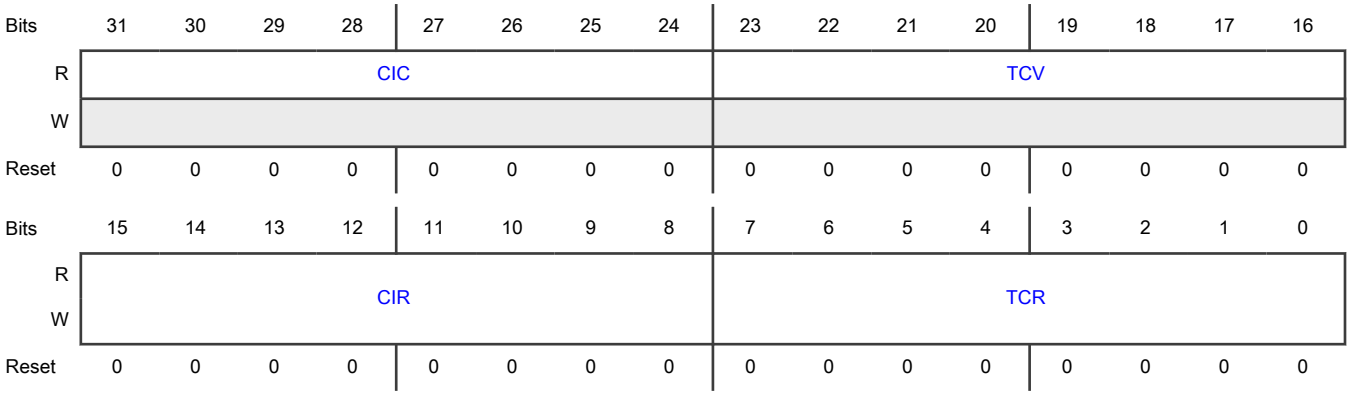
TCR	Ch

Diagram



Fields

Field	Function
31-24 CIC	Compensation Interval Counter Current value of the compensation interval counter. If the compensation interval counter equals zero then it is loaded with the contents of the CIR. If the CIC does not equal zero then it is decremented once a second. Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read.
23-16 TCV	Time Compensation Value Current value used by the compensation logic for the present second interval. Updated once a second if the CIC equals 0 with the contents of the TCR field. If the CIC does not equal zero then it is loaded with zero (compensation is not enabled for that second increment). Reading this register at the same time as the seconds counter is incrementing can result in an incorrect value being read.
15-8 CIR	Compensation Interval Register Configures the compensation interval in seconds from 1 to 256 to control how frequently the TCR should adjust the number of 32.768 kHz cycles in each second. The value written should be one less than the number of seconds. For example, write zero to configure for a compensation interval of one second. This register is double buffered and writes do not take effect until the end of the current compensation interval.
7-0 TCR	Time Compensation Register Configures the number of 32.768 kHz clock cycles in each second, equal to 32,768 - TCR (where TCR is a twos complement sign extended value). This register is double buffered and writes do not take effect until the end of the current compensation interval. Some example values are shown below.

Fields

Field	Function
31-8 —	Reserved
7 TIDF	Tamper Interrupt Detect Flag Indicates whether the tamper interrupt has asserted: • The Tamper Interrupt Detect Flag is set whenever the Tamper interrupt is asserted, as configured by the Tamper Status Register and Tamper Interrupt Enable Register. 0b - Tamper interrupt has not asserted. 1b - Tamper interrupt has asserted.
6-5 —	Reserved
4 TCE	Time Counter Enable Specifies whether to enable or disable time counter: 0b - Disables. When time counter is disabled the TSR register and TPR register are writeable, but do not increment. 1b - Enables. When time counter is enabled the TSR register and TPR register are not writeable, but increment.
3 MOF	Monotonic Overflow Flag Indicates whether monotonic overflow has occurred: • Monotonic overflow flag is set when the monotonic counter is enabled and the monotonic counter high overflows. The monotonic counter does not increment and will read as zero when this bit is set. • This bit is cleared by writing the monotonic counter high register when the monotonic counter is disabled. 0b - Monotonic counter overflow has not occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Monotonic counter overflow has occurred and monotonic counter is read as zero.
2 TAF	Time Alarm Flag • Is set when the TAR[TAR] equals the TSR[TSR] and the TSR[TSR] increments. • Is cleared by writing the TAR register. • Indicates whether time alarm has occured: 0b - Time alarm has not occurred. 1b - Time alarm has occurred.
1 TOF	Time Overflow Flag • Is set when the time counter is enabled and overflows. The TSR and TPR do not increment and read as zero when this bit is set. • Is cleared by writing the TSR register when the time counter is disabled. • Indicates whether time overflow has occured: 0b - Time overflow has not occurred. 1b - Time overflow has occurred and time counter reads as zero.
0 TIF	Time Invalid Flag • The time invalid flag is set on POR or software reset. • The TSR and TPR do not increment and read as zero when this bit is set. • This bit is cleared by writing the TSR register when the time counter is disabled. • The monotonic counter register is held in reset whenever the time invalid flag is set. • Indicates whether the time is valid or invalid: 0b - Time is valid. 1b - Time is invalid and time counter is read as zero.

Low-Power Timer (LPTMR)

41.1 Chip-specific LPTMR information

Table 283. Reference links to related information

Topic	Related module	Reference
Full description	LPTMR	LPTMR
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

41.1.1 Module instances

This device has three instances of the LPTMR module, LPTMR0, LPTMR1 and LPTMR2.

41.1.2 LPTMR clocks

The prescaler and glitch filter of the LPTMR module (the module functional clock) can be clocked from one of four sources determined by LPTMRx_PSR[PCS]. The following table shows the clock assignments for this field.

NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

The LPTMR allows the maximum clock frequency of 24 MHz.

Table 284. LPTMRn prescaler/glitch filter clocking options

LPTMRn_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
01	1	Reserved
10	2	32K_CLK - Selectable clock output from the Battery Backed domain produced by either the OSC-32K or the FRO-32K.
11	3	OSC_RF/2

41.1.3 LPTMR pulse counter input options

LPTMRn_CSR[TPS] configures the input source used in pulse counter mode. The following table shows the input assignments for this field.

Table 285. LPTMRn pulse counter input options

LPTMRn_CSR[TPS]	Pulse counter input number	Chip input
00	0	CMP0_OUT
01	1	CMP1_OUT
10	2	LPTMRn_Alt2
11	3	LPTMRn_Alt3

41.2 Overview

You can configure LPTMR to operate as a time counter with an optional prescaler, or as a pulse counter with an optional glitch filter, across all power modes, including low-power modes. It is reset only on Power on Reset (POR), allowing it to be used as a time-of-day counter.

41.2.1 Block diagram

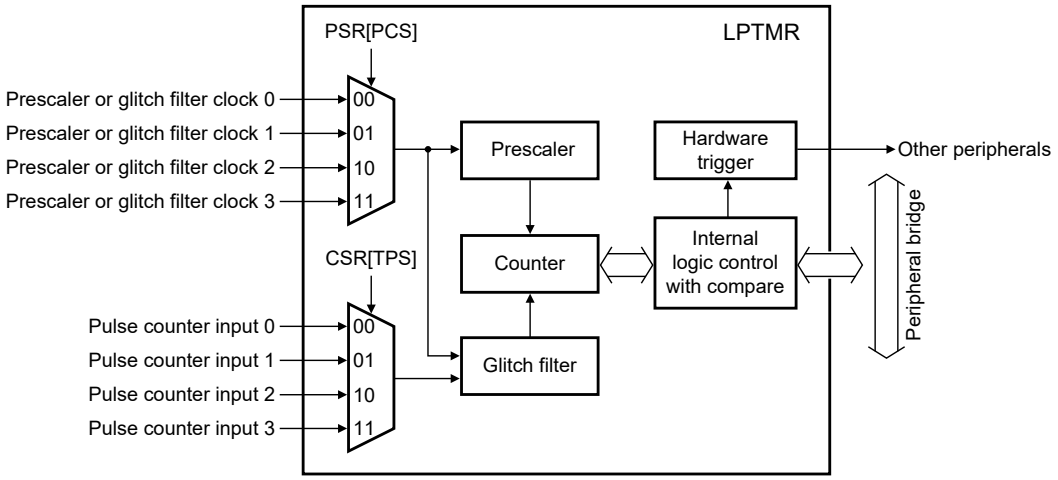

Figure 120. Block diagram

41.2.2 Features

- 32-bit time counter or pulse counter with compare:
  - Optional interrupt that can generate an asynchronous wake-up from any low-power mode
  - Hardware trigger output
  - Counter that supports a free-running mode or reset on compare
- Configurable clock source for prescaler and glitch filter
- Configurable input source for pulse counter (rising-edge or falling-edge)

41.3 Functional description

41.3.1 Low-power modes

In low-power modes, LPTMR continues to operate normally. You can configure LPTMR to exit a low-power mode by generating either an interrupt or a DMA request.

41.3.2 Clocks

The LPTMR prescaler and glitch filter can be clocked by one of the clocks that you configure by using PSR[PCS]. You must enable the clock source before you enable LPTMR.

In Pulse Counter mode, with the glitch filter bypassed, the selected input source directly clocks Counter (CNR), and no other clock source is required. To minimize power in this case, configure the glitch filter clock source for a clock that is disabled.

NOTE

- You may need to configure the clock source that you select in PSR[PCS] for it to remain enabled in low-power modes. Otherwise, LPTMR does not operate in low-power modes.
- The clock source or pulse input source selected for LPTMR must not exceed the maximum frequency of f_{LPTMR} defined in the chip data sheet.

41.3.3 Reset

LPTMR is reset only on Power on Reset (POR). When configuring LPTMR registers, you must initially write to Control Status (CSR) with LPTMR disabled, before configuring Prescaler and Glitch Filter (PSR) and Compare (CMR). Then, you must write 1 to CSR[TEN] as the last step in the initialization. Doing so ensures that LPTMR is configured correctly and the LPTMR counter is reset to zero following a Power on Reset (POR).

41.3.4 Prescaler and glitch filter

The LPTMR prescaler and glitch filter share the same logic, which operates as a prescaler in Time Counter mode and as a glitch filter in Pulse Counter mode.

NOTE

You must not alter the prescaler and glitch filter configuration when LPTMR is enabled.

41.3.4.1 Prescaler enabled

In Time Counter mode, when the prescaler is enabled, the output of the prescaler directly clocks Counter (CNR). When LPTMR is enabled, CNR increments every 2^1 to 2^{16} prescaler clock cycles. After LPTMR is enabled, the first increment of CNR takes an additional one or two prescaler clock cycles because of the synchronization logic.

41.3.4.2 Prescaler bypassed

In Time Counter mode, when the prescaler is bypassed, the selected prescaler clock increments Counter (CNR) on every clock cycle. When LPTMR is enabled, the first increment takes an additional one or two prescaler clock cycles because of the synchronization logic.

41.3.4.3 Glitch filter enabled

In Pulse Counter mode, when the glitch filter is enabled, the output of the glitch filter directly clocks Counter (CNR). When LPTMR is first enabled, the output of the glitch filter is asserted, that is, logic 1 for active-high and logic 0 for active-low. The following table shows the change in glitch filter output with the selected input source.

Table 286. Glitch filter output with the selected input source

If	Then
The selected input source remains deasserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also deasserts.
The selected input source remains asserted for at least 2^1 to 2^{15} consecutive prescaler clock rising edges	The glitch filter output also asserts.

NOTE

The input is sampled only on the rising clock edge.

The value of CNR increments each time the glitch filter output asserts. In Pulse Counter mode, the maximum rate at which CNR can increment is once every 2^2 to 2^{16} glitch filter clock edges. When first enabled, the glitch filter waits for an additional one or two glitch filter clock edges because of the synchronization logic.

41.3.4.4 Glitch filter bypassed

In Pulse Counter mode, when the glitch filter is bypassed, the selected input source increments the value of Counter (CNR) every time it asserts. Before LPTMR is first enabled, the selected input source is forced to be asserted. This prevents CNR from incrementing if the selected input source is already asserted when LPTMR is first enabled.

41.3.5 Counter

The value of Counter (CNR) increments by 1 on every:

- Prescaler clock in Time Counter mode, with prescaler bypassed.
- Prescaler output in Time Counter mode, with prescaler enabled.
- Input source assertion in Pulse Counter mode, with glitch filter bypassed.
- Glitch filter output in Pulse Counter mode, with glitch filter enabled.

CNR is reset when LPTMR is disabled or if the counter register overflows. If CSR[TFC] = 0, then CNR is also reset whenever CSR[TCF] = 1.

When the core is halted in Debug mode:

- CNR continues incrementing if configured for Pulse Counter mode.
- CNR stops incrementing if configured for Time Counter mode.

You cannot initialize CNR but can read it at any time. On each read of CNR, you must first write a value to it. This synchronizes and registers the current value of CNR into a temporary register. The contents of the temporary register are returned on each read of CNR.

When reading CNR, the bus clock must be at least two times faster than the rate at which the LPTMR counter is incrementing; otherwise, incorrect data may be returned.

41.3.6 Compare

After the next Counter (CNR) increment (when its value is equal to that of Compare (CMR)), the following events occur:

- CSR[TCF] is read as 1b.
- LPTMR generates an interrupt if CSR[TIE] is 1 as well.
- LPTMR generates a hardware trigger.
- LPTMR writes 0 to CNR if CSR[TFC] is 0.

When LPTMR is enabled, you can modify the value of CMR only when CSR[TCF] is 1. When updating CMR, you must write to it and clear CSR[TCF] before the LPTMR counter increments past the new LPTMR compare value.

NOTE

When LPTMR is enabled in Time Counter mode, the first increment takes an additional one or two clock cycles because of the synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster prescaler clock or larger prescaler value minimizes this impact.

41.3.7 Interrupt

LPTMR generates an interrupt whenever CSR[TIE] and CSR[TCF] are 1. CSR[TCF] is cleared by disabling LPTMR or writing a logic 1 to it.

You can modify the value of CSR[TIE] and write 1 to CSR[TCF] when LPTMR is enabled.

LPTMR generates an interrupt asynchronously to the system clock. The interrupt can be used to generate a wake-up from any low-power mode, provided LPTMR is enabled as a wake-up source.

41.3.8 Hardware trigger

The LPTMR hardware trigger asserts at the same time CSR[TCF] is set and can be used to trigger hardware events in other peripherals without your intervention. The hardware trigger is always enabled.

Table 287. Hardware trigger

When	Then
CMR[COMPARE] and CSR[TFC] are 0	The LPTMR hardware trigger asserts on the first compare and does not deassert.
CMR[COMPARE] is set to a nonzero value, or if CSR[TFC] = 1	The LPTMR hardware trigger asserts on each compare and deasserts on the following increment of Counter (CNR).

41.4 External signals

Table 288. External signals

Signal	Description		Direction
LPTMR_ALT*n*	Pulse Counter Input LPTMR can select one of the input pins to be used in Pulse Counter mode.		Input
	State meaning	Assertion—If configured for Pulse Counter mode with an active-high input, assertion causes Counter (CNR) to increment. Deassertion—If configured for Pulse Counter mode with an active-low input, deassertion causes CNR to increment.	
	Timing	Assertion or deassertion may occur at any time; input may assert asynchronously to the bus clock.	

41.5 Initialization

Perform the following procedure to initialize LPTMR:

1. Configure Control Status (CSR) for the selected mode and pin configuration, when CSR[TEN] is 0. This resets the counter and clears the flag.
2. Configure Prescaler and Glitch Filter (PSR) with the selected clock source and prescaler or glitch filter configuration.
3. Configure Compare (CMR) with the selected compare point.
4. Write 1 to CSR[TEN] to enable LPTMR.

41.6 Application information

41.6.1 Application 1: Generate an interrupt every 100 ms using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Bypass the prescaler and glitch filter by writing 1 to PSR[PBYP].
4. Assert an interrupt every 3277 cycles by configuring CMR[COMPARE] = 0CCCh.
5. Enable LPTMR by writing 1 to CSR[TEN].

6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific LPTMR information for the clocks supported on a given chip.

41.6.2 Application 2: Generate an interrupt once a minute using 32.768 kHz clock source

1. Disable LPTMR by writing 0 to CSR[TEN].
2. Select a 32.768 kHz clock source by configuring PSR[PCS].
3. Select the prescaler to divide the prescaler clock by 32768 to increment the counter once a second by configuring PSR[PRESCALE] = 0Eh.
4. Assert an interrupt every 60 seconds by configuring CMR[COMPARE] = 003Bh.
5. Enable LPTMR by writing 1 to CSR[TEN].
6. Enable the LPTMR interrupt by writing 1 to CSR[TIE].

NOTE

This is just an example. See the chip-specific LPTMR information for the clocks supported on a given chip.

41.7 Memory map and register definition

NOTE

The LPTMR registers are reset only on Power on Reset (POR). See Reset for more information.

Table continued from the previous page...

Field	Function
6 TIE	Timer Interrupt Enable Enables the timer interrupt. If TIE is 1, then LPTMR generates an interrupt if CSR[TCF] is 1 as well. 0b - Disable 1b - Enable
5-4 TPS	Timer Pin Select Configures the input source to be used in Pulse Counter mode. The input connections vary by chip. For details, see the chip configuration information about connections to these inputs. You must modify this field only when LPTMR is disabled. 00b - Input 0 01b - Input 1 10b - Input 2 11b - Input 3
3 TPP	Timer Pin Polarity Configures the polarity of the input source in Pulse Counter mode. If TPP is 0, then the pulse counter input source is active-high, and Counter (CNR) increments on the rising edge. If TPP is 1, then the pulse counter input source is active-low, and CNR increments on the falling edge. You must modify this field only when LPTMR is disabled. 0b - Active-high 1b - Active-low
2 TFC	Timer Free-Running Counter Specifies when the counter resets. If TFC is 0, Counter (CNR) resets on the count cycle following Counter (CNR) becoming equal to Compare (CMR). If TFC is 1, CNR resets on overflow. In both cases, CSR[TCF] sets to 1 on the cycle after CNR and CMR match. You must modify this field only when LPTMR is disabled. 0b - Reset when TCF asserts 1b - Reset on overflow
1 TMS	Timer Mode Select Configures the mode of LPTMR. You must modify this field only when LPTMR is disabled. 0b - Time Counter 1b - Pulse Counter
0 TEN	Timer Enable Enables the LPTMR timer. If TEN is 0, it resets the LPTMR internal logic, including CNR[COUNTER] and CSR[TCF]. If TEN is 1, LPTMR is enabled.

	Do not alter CSR[5:1] when writing 1 to this field. 0b - Disable 1b - Enable

41.7.1.3 Prescaler and Glitch Filter (PSR)

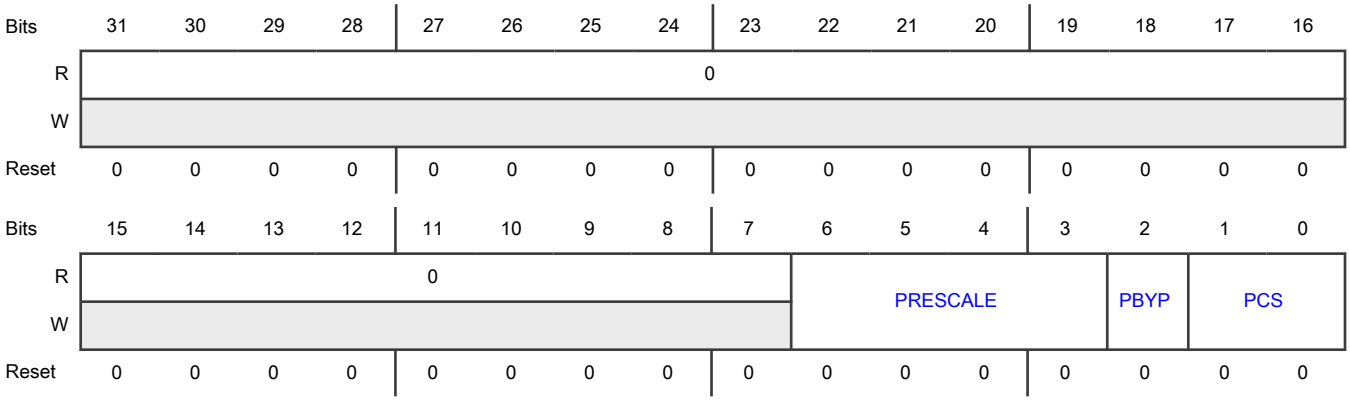
Offset

Register	Offset
PSR	4h

Function

Configures features related to the prescaler and glitch filter.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-3 PRESCALE	Prescaler and Glitch Filter Value Configures the size of the prescaler in Time Counter mode and the width of the glitch filter in Pulse Counter mode. The width of the glitch filter can vary by one cycle because of the pulse counter input synchronization. You must modify this field only when LPTMR is disabled. 0000b - Prescaler divides the prescaler clock by 2; glitch filter does not support this configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0001b - Prescaler divides the prescaler clock by 4; glitch filter recognizes change on input pin after two rising clock edges 0010b - Prescaler divides the prescaler clock by 8; glitch filter recognizes change on input pin after four rising clock edges 0011b - Prescaler divides the prescaler clock by 16; glitch filter recognizes change on input pin after eight rising clock edges 0100b - Prescaler divides the prescaler clock by 32; glitch filter recognizes change on input pin after 16 rising clock edges 0101b - Prescaler divides the prescaler clock by 64; glitch filter recognizes change on input pin after 32 rising clock edges 0110b - Prescaler divides the prescaler clock by 128; glitch filter recognizes change on input pin after 64 rising clock edges 0111b - Prescaler divides the prescaler clock by 256; glitch filter recognizes change on input pin after 128 rising clock edges 1000b - Prescaler divides the prescaler clock by 512; glitch filter recognizes change on input pin after 256 rising clock edges 1001b - Prescaler divides the prescaler clock by 1024; glitch filter recognizes change on input pin after 512 rising clock edges 1010b - Prescaler divides the prescaler clock by 2048; glitch filter recognizes change on input pin after 1024 rising clock edges 1011b - Prescaler divides the prescaler clock by 4096; glitch filter recognizes change on input pin after 2048 rising clock edges 1100b - Prescaler divides the prescaler clock by 8192; glitch filter recognizes change on input pin after 4096 rising clock edges 1101b - Prescaler divides the prescaler clock by 16,384; glitch filter recognizes change on input pin after 8192 rising clock edges 1110b - Prescaler divides the prescaler clock by 32,768; glitch filter recognizes change on input pin after 16,384 rising clock edges 1111b - Prescaler divides the prescaler clock by 65,536; glitch filter recognizes change on input pin after 32,768 rising clock edges
2 PBYP	Prescaler and Glitch Filter Bypass Controls the clocking of Counter (CNR). If PBYP is 0, the output of the prescaler or glitch filter clocks CNR. If PBYP is 1, the selected prescaler clock in Time Counter mode, or else the selected input source in Pulse Counter mode, directly clocks CNR. You must modify this field only when LPTMR is disabled. 0b - Prescaler and glitch filter enable 1b - Prescaler and glitch filter bypass
1-0	Prescaler and Glitch Filter Clock Select

Chapter 42
Low Power Periodic Interrupt Timer (LPIT)

42.1 Chip-specific LPIT information

Table 289. Reference links to related information

Topic	Related module	Reference
Full description	LPIT	LPIT
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

42.1.1 Module instances

This device has one instance of the LPIT module, LPIT0. The LPIT0 contains 4 channels.

42.1.2 External trigger source

If the TCTRLx[TRG_SRC] is set to 1, it selects to use external trigger source from TRGMUX, refer to TRGMUX0 outputs for more details.

42.2 Overview

LPIT is a low-power periodic interrupt timer with multiple timer channels. After a timer reaches a programmed count, the respective timer channels generate pre-trigger and trigger output signals, and these outputs can be used to trigger other modules on the chip.

42.2.1 Block diagram

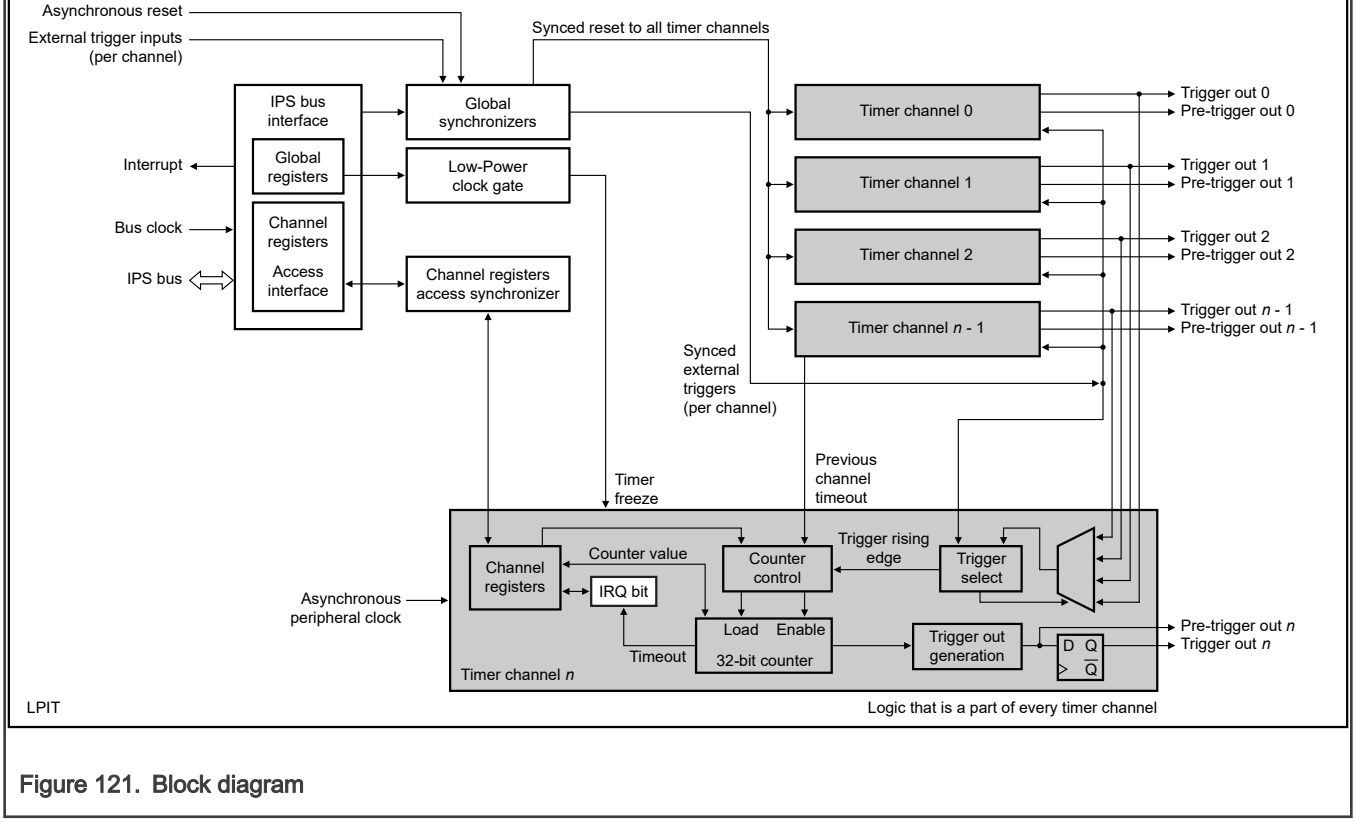

Figure 121. Block diagram

42.2.2 Features

LPIT allows you to configure timer channels in a way that they could be:

- Controlled using external triggers (triggers from outside LPIT).
- Controlled using internal triggers (triggers from other timer channels inside LPIT).
- Chained together, to form a larger width timer.
- Reloaded and counted again, or stopped after reaching the programmed count, depending on the timer modes used.

42.3 Functional description

42.3.1 Programming model

The LPIT programming model (see Figure 122) comprises:

- A global register set (common to all timer channels).
- Registers for each timer channel (that control their respective timer channels).

Access to these registers is synchronized with the asynchronous peripheral clock and then affects the timer channel registers:

- Each timer channel contains a 32-bit counter that loads the starting value and down counts after every peripheral clock's positive edge.
- After reaching a zero value (a channel timer timeout), a trigger output is generated.
- A timer enable register control field, external or internal triggers, or a previous channel timeout (when using timer chaining) control the counter enable.

- After a channel timer timeout, an interrupt flag is also set to tell the CPU about the timer timeout.

You must configure the following global registers only once:

- Module Control (MCR)
- Module Status (MSR)
- Module Interrupt Enable (MIER)
- Set Timer Enable (SETTEN)
- Clear Timer Enable (CLRTEN)

You must configure the following channel registers for each channel:

- Timer Value (TVAL0 - TVAL3)
- Timer Control (TCTRL0 - TCTRL3)

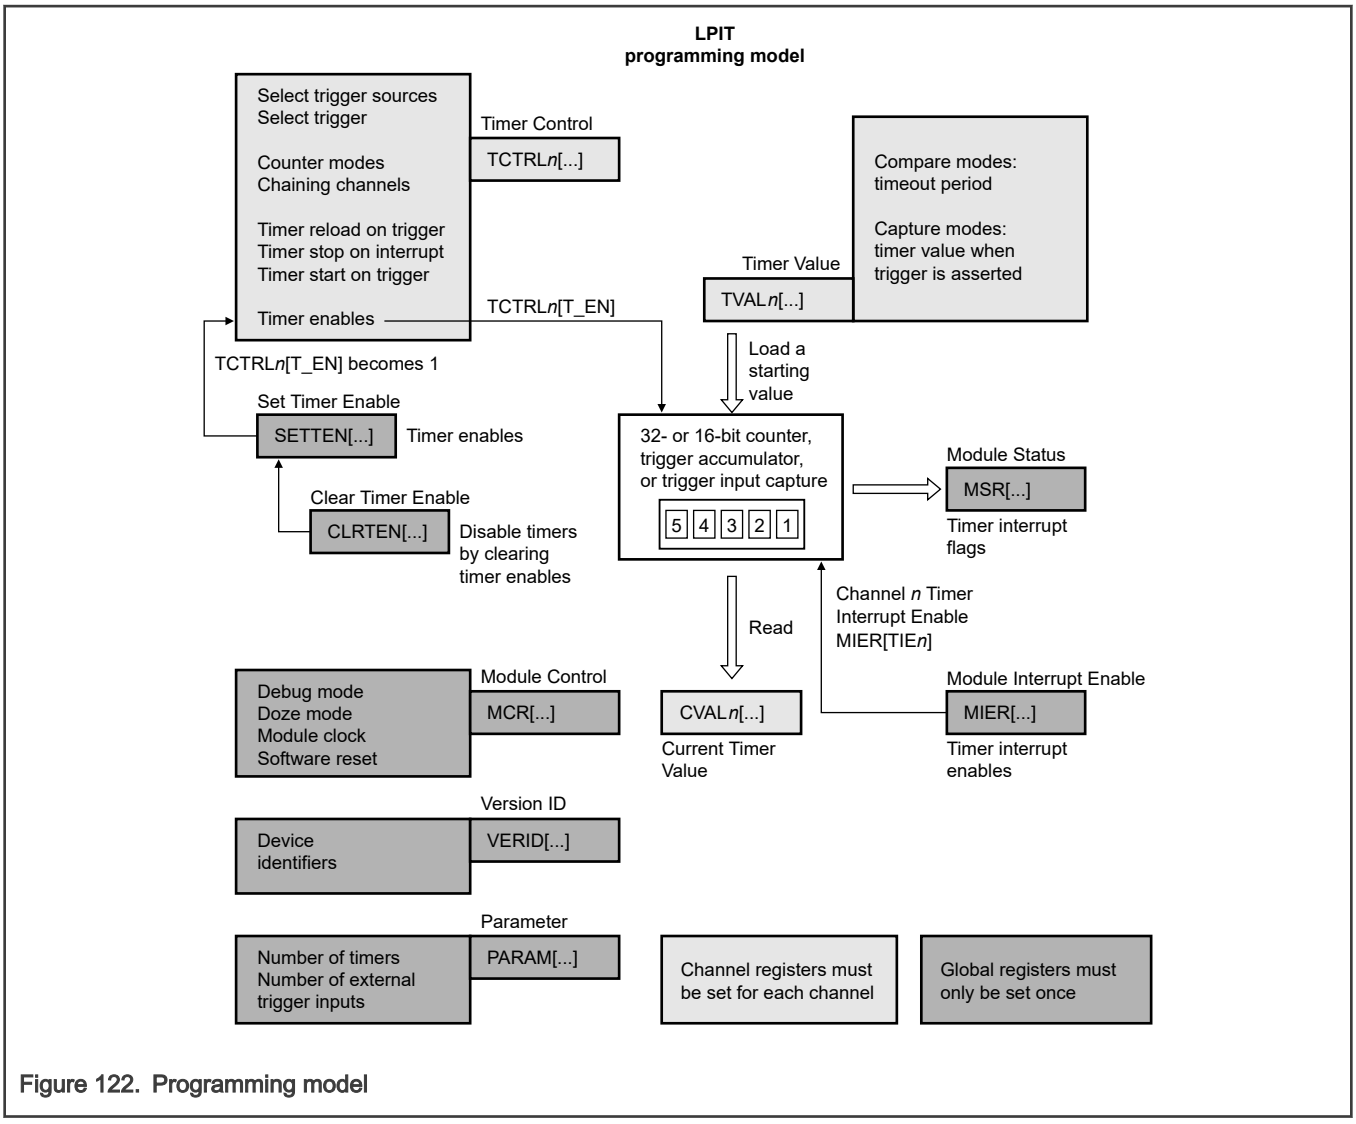

Figure 122. Programming model

42.3.2 Interfacing with other modules

The following figure shows the interface of an LPIT module with other modules on the chip:

- The CPU interface provides the clock, reset, and register read and write bus interface. It handles LPIT interrupts.

- The LPIT trigger output signals may trigger other modules on the chip.
- Similarly, other timer modules may provide trigger inputs to LPIT to control when an LPIT timer channel must start.

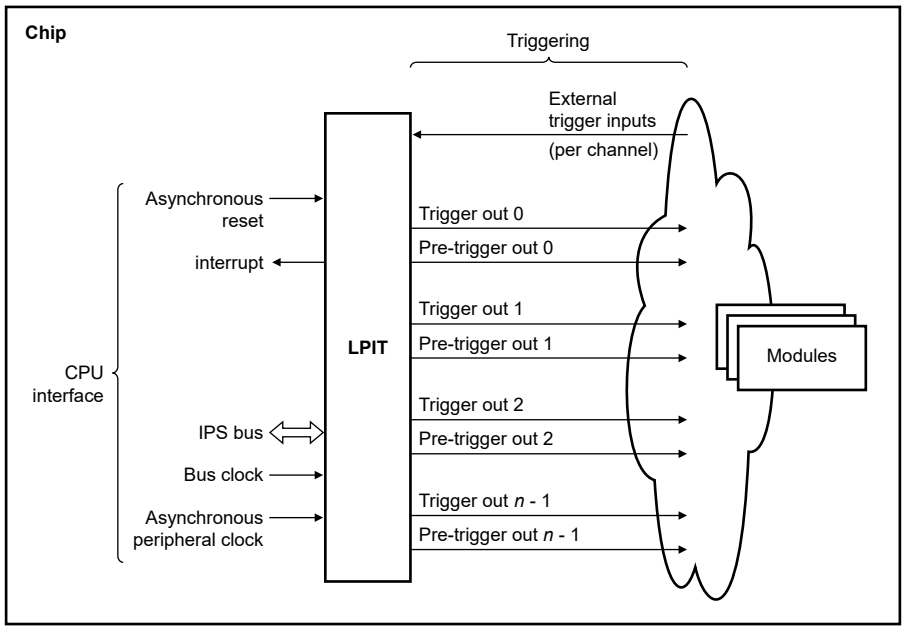

Figure 123. Interfacing with other modules

42.3.3 Chip power modes

LPIT supports the following chip power modes.

Table 290. Chip power modes

Chip mode	LPIT operation
Run	Normal operation
Sleep	Can continue operating in this mode if MCR[DOZE_EN] = 1 and LPIT is using an external or internal clock source that remains operational during Sleep mode
Low Power Stop (also called Deep Sleep)	The Doze Enable (MCR[DOZE_EN]) bit is ignored and the LPIT will be disabled for the duration of Low Power mode.
Debug	Can continue operating in this mode if MCR[DBG_EN] = 1

42.3.4 Supported timer modes

To configure a timer mode, you must select an appropriate value using TCTRL*n*[MODE].

Table 291. Supported timer modes

Timer mode	Operation
32-bit periodic counter	The counter loads and decrements down to 0, and this sets the timer interrupt flag and asserts the output pretrigger.

Table continues on the next page...

Table 291. Supported timer modes (continued)

Timer mode	Operation
Dual 16-bit periodic counter	• The counter loads and then the lower 16 bits decrement down to 0. This asserts the output pretrigger. • The upper 16 bits then decrement down to 0. This sets the timer interrupt flag and negates the output pretrigger.
32-bit trigger accumulator	The counter loads after the first trigger rising edge and then decrements down to 0 after each trigger rising edge. This sets the timer interrupt flag and asserts the output pretrigger.
32-bit trigger input capture	• The counter loads with a value of FFFF_FFFFh and then decrements down to 0. • If a trigger rising edge is detected, it stores the inverse of the current counter value in Timer Value (TVAL0 - TVAL3). This sets the timer interrupt flag and asserts the output pretrigger.

TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] control the timer operation. These fields control the timer load, reload, start, and restart of the timers.

NOTE

- The trigger output is asserted one peripheral timer clock cycle after the pre-trigger output. The trigger and pre-trigger outputs deassert at the same time.
- The pre-trigger output is asserted for two clock cycles and the trigger output is asserted for one clock cycle (except in 16-bit Periodic Counter mode, where both pre-trigger and trigger outputs are asserted for many cycles depending on the value of TVAL*n*[TMR_VAL][31:16]).
- Timer changes (that are based on external triggers) take effect after four peripheral clocks, after the actual external trigger assertion. This is because of clock synchronization, rise edge detection, and timer update.

42.3.5 Timer channel modes

You can configure each timer channel in LPIT to work in either compare modes or capture modes.

The timer channels operate on an asynchronous clock, which is independent of the register read and write access clock. Clock synchronization between clock domains ensures normal operations.

Table 292. Timer channel modes

Mode	Function
Compare	The timers decrement when enabled and generate an output pretrigger and trigger output. The trigger output is one clock cycle delayed of the pre-trigger pulse. You can configure certain control fields to control each timer channel's start, reload, and restart (see Trigger control for timers for more information). You can also configure the timer to always decrement from a programmed start value, on selected trigger inputs, or previous channel timeout (when channels are chained). By chaining timer channels, applications can achieve larger timeout durations.
Capture	You can use the timer to perform measurements by using Timer Value (TVAL0 - TVAL3), as the timer value is captured when a selected trigger input is asserted. The timer can support once-off or multiple measurements, such as frequency measurements.

42.3.6 Trigger control for timers

You can configure various LPIT register fields to control how trigger inputs and the timer operate:

- TCTRL*n*[TRG_SEL] helps you select the input trigger for the channel from all other channels' trigger outputs.
- TCTRL*n*[TRG_SRC] helps you select between the internal and external trigger inputs to the channel.

The selected trigger affects how the timer operates, using the configuration of TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] (see Table 293).

Table 293. Fields that control timer operations

If	=	Then
Timer stop on interrupt (TCTRL*n*[TSOI])	1	The counter stops after MSR[TIF*n*] assertion. To reload and decrement, it requires: • A trigger (if TCTRL*n*[TSOT] = 1). • A T_EN rising edge (if TCTRL*n*[TSOT] = 0).
	0	The counter does not stop after timeout.
Timer reload on trigger (TCTRL*n*[TROT])	1	The counter is loaded after each trigger.
	0	The counter is loaded after every T_EN rising edge or timeout rising edge (timeout is not used in Capture modes).
Timer start on trigger (TCTRL*n*[TSOT])	1	The counter starts decrementing after a trigger. Subsequent triggers are ignored until the counter times out.
	0	The counter decrements immediately after the next clock edge. When the channel is chained or is in Capture mode, TCTRL*n*[TSOT] has no effect.

In different timer modes, the programmable fields listed in Table 294 affect the timer operation differently.

Table 294. Timer modes and programmable fields

Mode (TCTRL*n*[MODE])	Fields affecting timer operations
32-bit periodic counter	TCTRL*n*[TSOT], TCTRL*n*[TSOI], and TCTRL*n*[TROT] affect the timer operation as described in Table 293.
Dual 16-bit periodic counter	
32-bit trigger accumulator	• Only TCTRL*n*[TSOI] controls the timer function. • TCTRL*n*[TROT] and TCTRL*n*[TSOT] have no effect on timer operations.
32-bit input trigger capture	• Only TCTRL*n*[TSOI] and TCTRL*n*[TROT] control the timer function. • TCTRL*n*[TSOT] has no effect on timer operations.

42.3.7 Channel chaining

You can chain individual timer channels together to achieve a larger value of timeout. Chaining enables these channels to work in a "nested loop" manner, thereby leading to an effective timeout value of $TVAL_{CHn} \times (TVAL_{CHn-1} + 1)$.

To chain the channels together, write 1 to TCTRL*n*[CHAIN] for the corresponding channel. When a channel is chained, that channel's timer decrements after the previous channel's timeout pulse, regardless of the timer mode that TCTRL*n*[MODE] defines.

TCTRL*n*[TSOT] does not have any effect if you chain the channel timer (channel *n*) to the previous channel's timer (channel *n* - 1).

42.3.8 Detailed timing

The following table represents various timing diagrams. The diagrams are not "cycle-accurate," which means, they may not show some of the cycles, but they do show the timer channel behavior across several clock cycles.

Table 295. Timing diagrams

Mode (TCTRL*n*[MODE]) setting		Timing diagram	TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	TCTRL*n*[CHAIN]
32-bit periodic counter (Compare mode)	00	Case 1: TCTRL*n*[MODE] = 0 • For a use case requiring repeated interrupts with reload • Trigger outputs have equal periods	0	0	0	0
		Case 2: TCTRL*n*[MODE] = 0 • Useful for One-Shot Trigger mode • Trigger starts again after TCTRL*n*[T_EN] becomes 1	0	0	1	0
		Case 3: TCTRL*n*[MODE] = 0 • For a use case requiring repeated interrupts with reload • Trigger outputs have unequal periods	0	1	0	0
		Case 4: TCTRL*n*[MODE] = 0 • For a one-shot timer with reload before timeout of Timer mode • Timer starts again after you write 1 to TCTRL*n*[T_EN]	0	1	1	0
		Case 5: TCTRL*n*[MODE] = 0 • Useful for generating periodic interrupts after a predefined event (input trigger) • Output triggers have equal periods	1	0	0	0
		Case 6: TCTRL*n*[MODE] = 0 • Triggers One-Shot Timer mode • Output trigger period depends on the input trigger	1	0	1	0
		Case 7: TCTRL*n*[MODE] = 0 • Repeated interrupts with Reload Timer mode • Outputs triggers have unequal periods	1	1	0	0
		Case 8: TCTRL*n*[MODE] = 0 • Case shown for a nonperiodic input trigger (might not be a use case)	1	1	1	0

Table continues on the next page...

Table 295. Timing diagrams (continued)

Mode (TCTRL*n*[MODE]) setting		Timing diagram	TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	TCTRL*n*[CHAIN]
		• If input trigger is periodic and greater than timer timeout, it is the same as TCTRL*n*[TROT] = 0 • If input trigger is periodic and less than timer timeout, the timer never times out and always reloads on the input trigger (not a valid use case)				
16-bit dual periodic counter (Compare mode)	01	Case 1: TCTRL*n*[MODE] = 1 • The effect of TCTRL*n*[TSOT], TCTRL*n*[TROT], and TCTRL*n*[TSOI] is the same as that of TCTRL*n*[MODE] = 0 (32-bit Counter Compare mode) • Both halves of the counter are affected in the same way	0	0	0	0
32-bit trigger accumulator mode	10	Case 1: TCTRL*n*[MODE] = 10 • Useful for a continuous pulse counting mode • Trigger and timeout generated after programmed number of pulses are accumulated	X	X	0	0
		Case 2: TCTRL*n*[MODE] = 10 • Useful for One-Shot Pulse Counting mode • Trigger and timeout generated after programmed number of pulses are accumulated	X	X	1	0
32-bit trigger capture mode	11	Case 1: TCTRL*n*[MODE] = 11 • Useful for determining the duration between pulses • Proper clock selection can ensure that the timer does not rollover more than once between two pulses	X	0	0	0
		Case 2: TCTRL*n*[MODE] = 11 • Useful for determining the duration between pulses • Selecting a fast timer clock provides accurate measurements but it can also cause timer rollover between pulses	X	1	0	0

Table continues on the next page...

Mode (TCTRL*n*[MODE]) setting		Timing diagram	TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	TCTRL*n*[CHAIN]
		Case 3: TCTRL*n*[MODE] = 11 • One-Shot Timer Count mode • You can enable it again by writing 1 to TCTRL*n*[T_EN]	X	0	1	0
Timer chaining: effects on timing operations	XX	Timer chaining	X	X	X	1

42.3.8.1 Case 1: TCTRL*n*[MODE] = 0

The following figure represents case 1 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

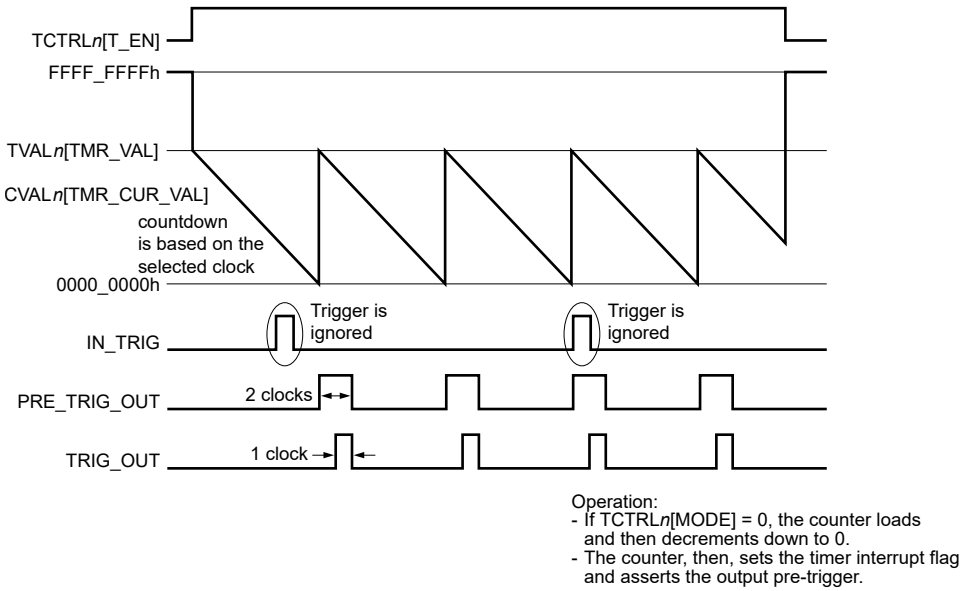

Figure 124. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

42.3.8.2 Case 2: TCTRL*n*[MODE] = 0

The following figure represents case 2 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

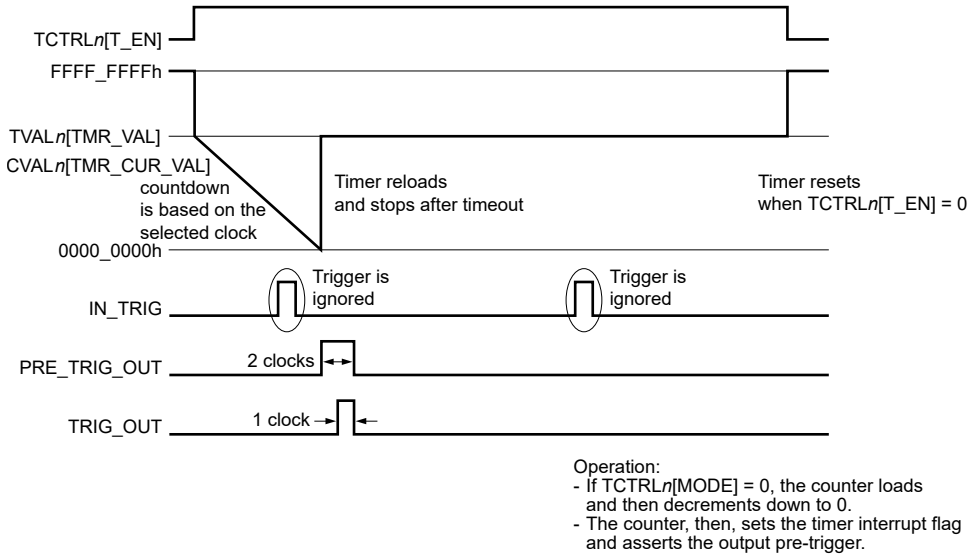

Figure 125. Case 2: TSOT = 0, TROT = 0, TSOI = 1, CHAIN = 0

42.3.8.3 Case 3: TCTRL*n*[MODE] = 0

The following figure represents case 3 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

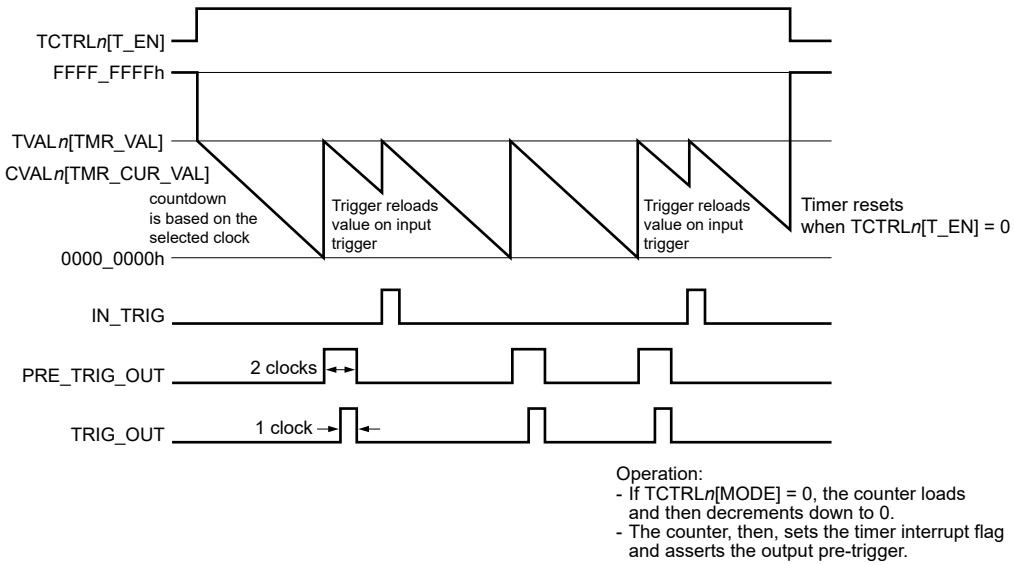

Figure 126. Case 3: TSOT = 0, TROT = 1, TSOI = 0, CHAIN = 0

42.3.8.4 Case 4: TCTRL*n*[MODE] = 0

The following figure represents case 4 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

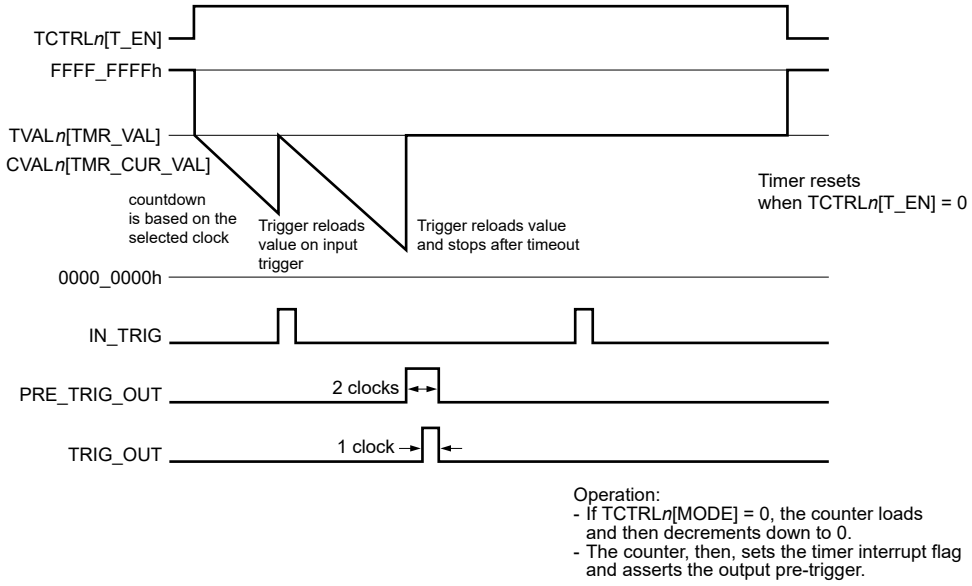

Figure 127. Case 4: TSOT = 0, TROT = 1, TSOI = 1, CHAIN = 0

42.3.8.5 Case 5: TCTRL*n*[MODE] = 0

The following figure represents case 5 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

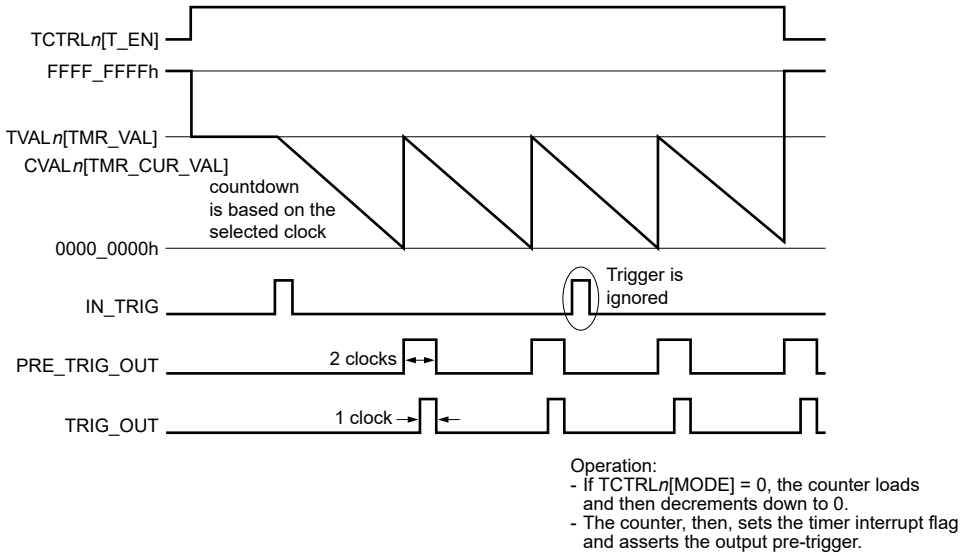

Figure 128. Case 5: TSOT = 1, TROT = 0, TSOI = 0, CHAIN = 0

42.3.8.6 Case 6: TCTRL*n*[MODE] = 0

The following figure represents case 6 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

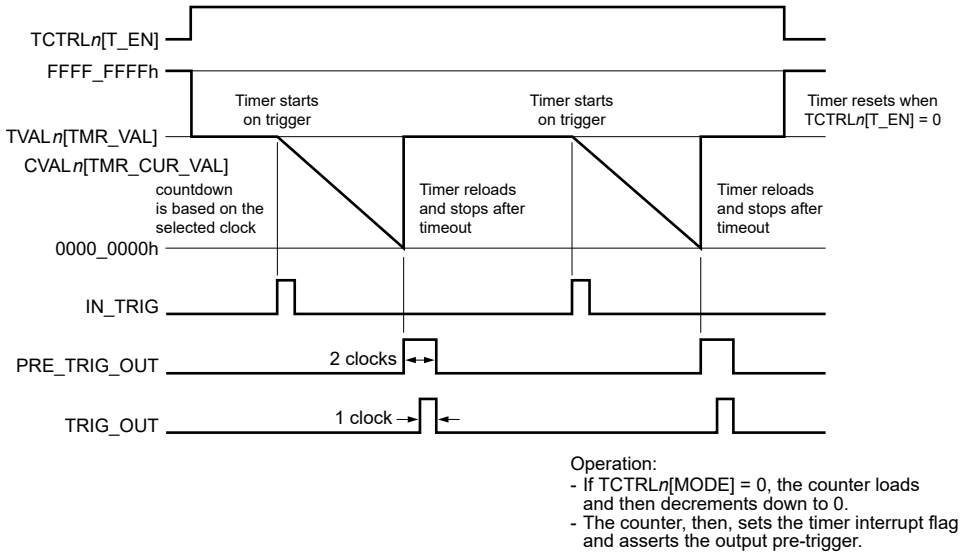

Figure 129. Case 6: TSOT = 1, TROT = 0, TSOI = 1, CHAIN = 0

42.3.8.7 Case 7: TCTRL*n*[MODE] = 0

The following figure represents case 7 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

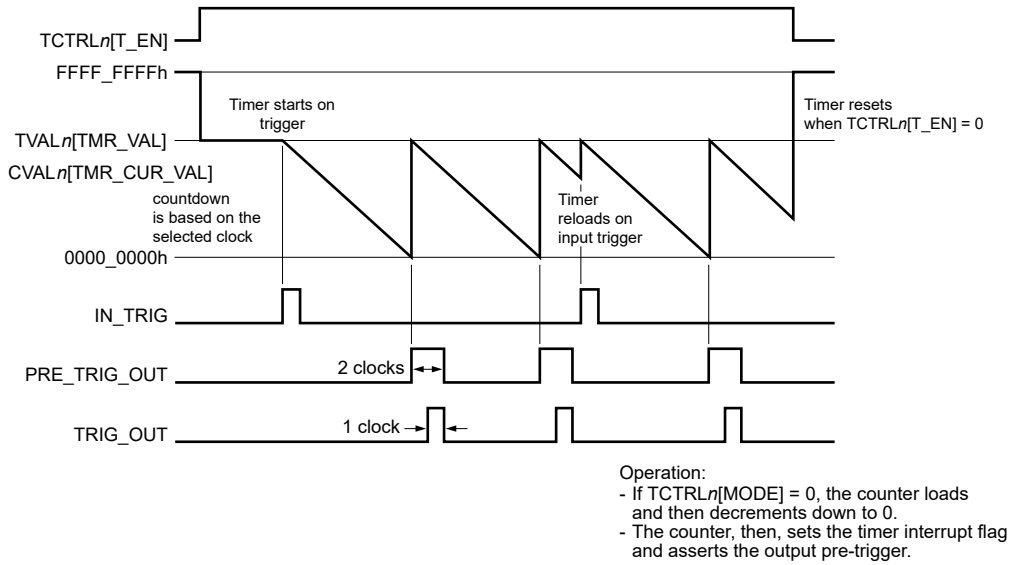

Figure 130. Case 7: TSOT = 1, TROT = 1, TSOI = 0, CHAIN = 0

42.3.8.8 Case 8: TCTRL*n*[MODE] = 0

The following figure represents case 8 in which TCTRL*n*[MODE] = 0 (32-bit periodic counter).

LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 1
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

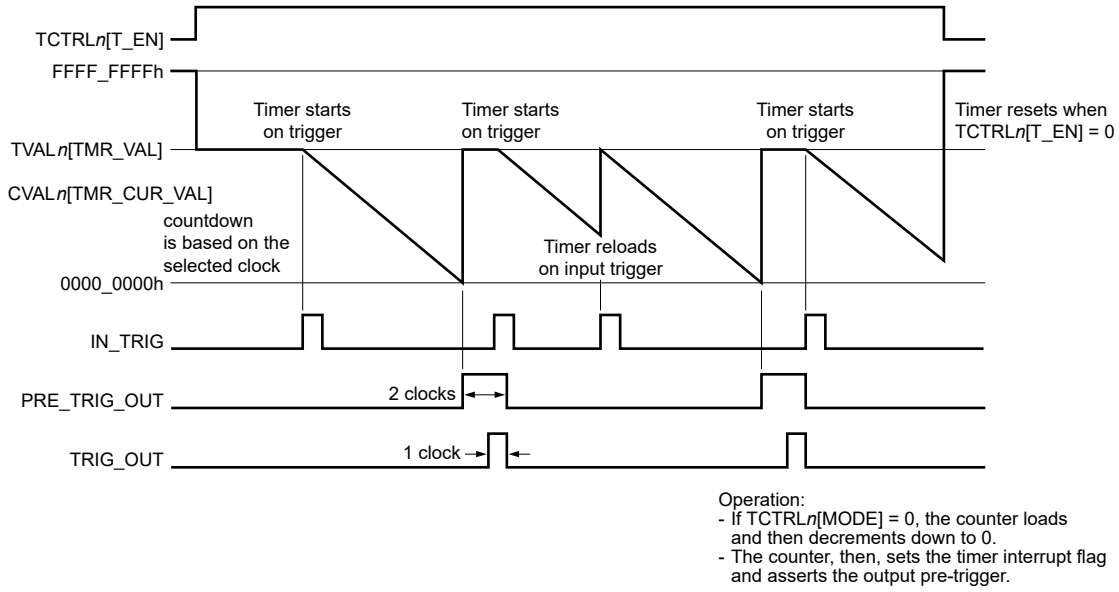

Figure 131. Case 8: TSOT = 1, TROT = 1, TSOI = 1, CHAIN = 0

42.3.8.9 Case 1: TCTRL*n*[MODE] = 1

The following figure represents case 1 in which TCTRL*n*[MODE] = 1 (16-bit dual periodic counter). LPIT works in Compare mode and is configured as follows:

- TCTRL*n*[TSOT] = 0
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

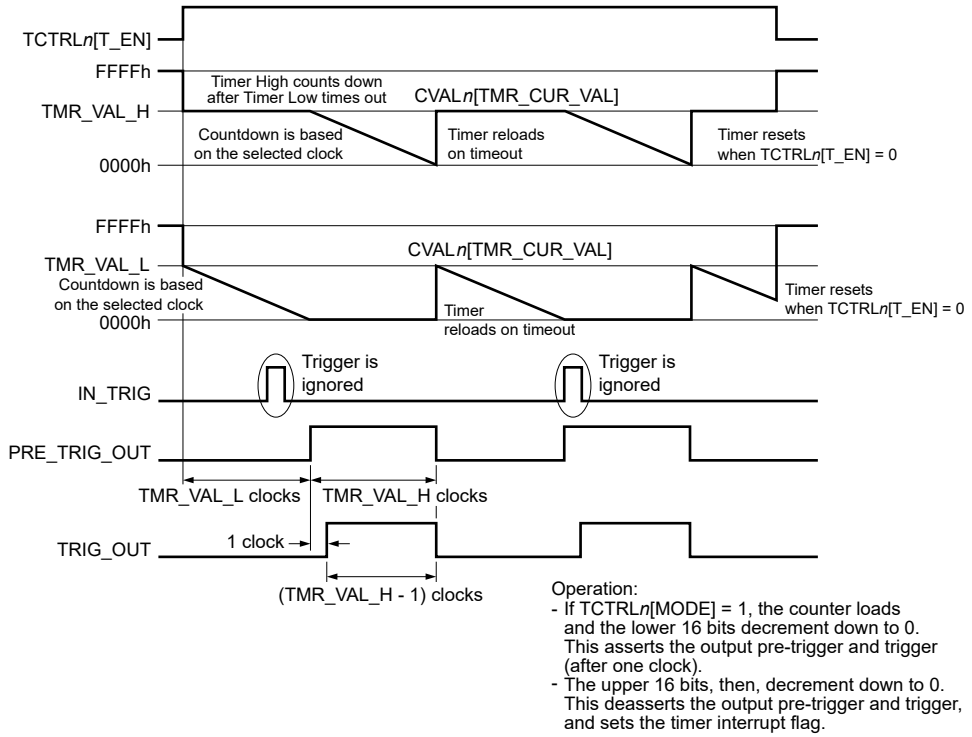

Figure 132. Case 1: TSOT = 0, TROT = 0, TSOI = 0, CHAIN = 0

If TCTRL*n*[MODE] = 1:

- The effect of timing control fields is similar to the effect of timer control fields when TCTRL*n*[MODE] = 0. See the individual timing diagrams for cases with TCTRL*n*[MODE] = 0 for more information.
- The timer interrupt (timeout) asserts when {TMR_H,TMR_L} = 0000_0000h.

See the following table for the behavior of timer control fields when TCTRL*n*[MODE] = 1.

Table 296. Timer control fields when TCTRL*n*[MODE] = 1

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
0	0	0	• For repeated interrupts with reload • Trigger outputs have equal periods	Similar to Case 1: TCTRL*n*[MODE] = 1.
0	0	1	One-shot mode	• Similar to Case 2: TCTRL*n*[MODE] = 0. • Both timers stop after first count down and then time out. • Timers do not count again until TCTRL*n*[T_EN] becomes 1.
0	1	0	• For repeated interrupts with reload • Trigger outputs have unequal periods	• Similar to Case 3: TCTRL*n*[MODE] = 0 . • Both timers reload the value of TVAL*n*[TMR_VAL] after the trigger rising edge.

Table continues on the next page...

Table 296. Timer control fields when TCTRL*n*[MODE] = 1 (continued)

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
				• Output triggers clear after reload, if asserted.
0	1	1	Reloadable one-shot mode	• Similar to Case 4: TCTRL*n*[MODE] = 0. • If a trigger occurs before timeout, then both timers reload and count down (as shown); the timers stop after timeout. • A trigger assertion after timeout reloads the value of TVAL*n*[TMR_VAL] into the timers. • The timers do not count again until TCTRL*n*[T_EN] becomes 1 again.
1	0	0	• For generating periodic interrupts after a predefined event (input trigger) • Output triggers have equal periods	• Similar to Case 5: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] rises, the timers do not start until after the first trigger's rising edge. • Subsequent triggers have no effect.
1	0	1	• Triggered one-shot timer mode • Output trigger period depends on the input trigger	• Similar to Case 6: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until after the first trigger's rising edge. • The timer stops counting after a timeout assertion. • The timer does not start counting again until a new trigger's rising edge is detected.
1	1	0	• For repeated interrupts with reload timer mode • Output triggers have unequal periods	• Similar to Case 7: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until the first trigger's rising edge. • Subsequent triggers cause the timer to reload the value of TVAL*n*[TMR_VAL] into both counters. • The output triggers clear after a reload, if asserted.
1	1	1	• For a nonperiodic input trigger • If input trigger is periodic and greater than timer timeout, then it is the	• Similar to Case 8: TCTRL*n*[MODE] = 0. • After TCTRL*n*[T_EN] becomes 1, the timers do not start until the first trigger's rising edge.

Table continues on the next page...

Table 296. Timer control fields when TCTRL*n*[MODE] = 1 (continued)

TCTRL*n*[TSOT]	TCTRL*n*[TROT]	TCTRL*n*[TSOI]	Function	Effect on timer
			same as TCTRL*n*[TROT] = 0 (which is triggered one-shot timer mode; output trigger period depends on the input trigger)	• The timers stop counting after a timeout assertion. • A trigger's rising edge causes the timers to reload and then count down.

42.3.8.10 Case 1: TCTRL*n*[MODE] = 10

The following figure represents case 1 in which TCTRL*n*[MODE] = 10. LPIT works in 32-bit trigger accumulator mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = X
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

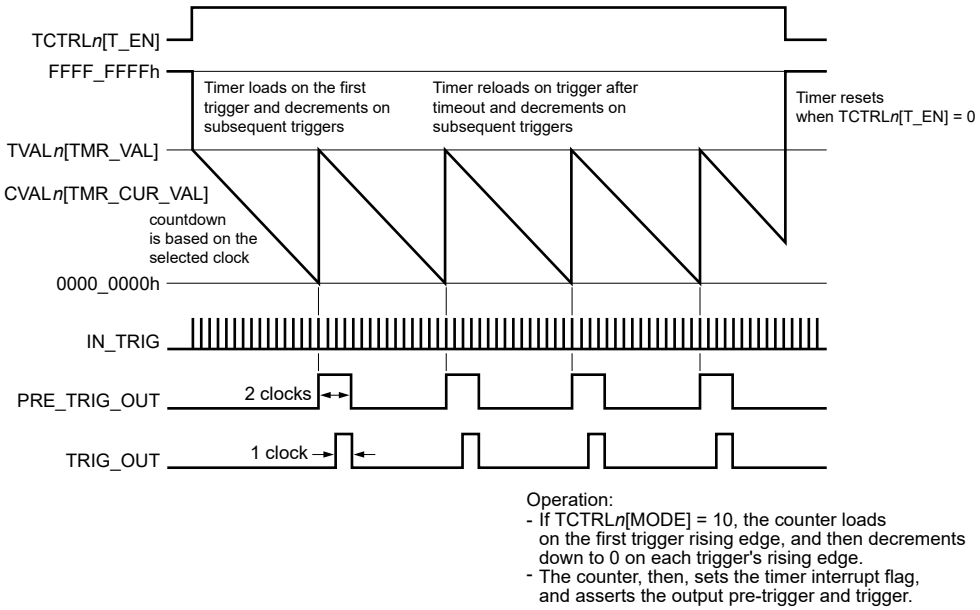

Figure 133. Case 1: TSOT = X, TROT = X, TSOI = 0, CHAIN = 0

42.3.8.11 Case 2: TCTRL*n*[MODE] = 10

The following figure represents case 2 in which TCTRL*n*[MODE] = 10. LPIT works in 32-bit trigger accumulator mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = X
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

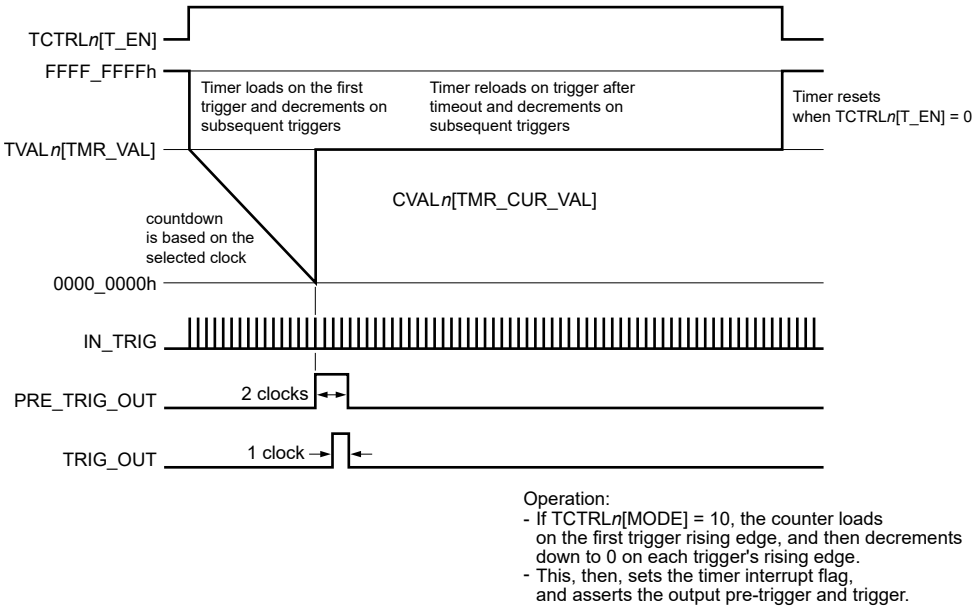

Figure 134. Case 2: TSOT = X, TROT = X, TSOI = 1, CHAIN = 0

42.3.8.12 Case 1: TCTRL*n*[MODE] = 11

The following figure represents case 1 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

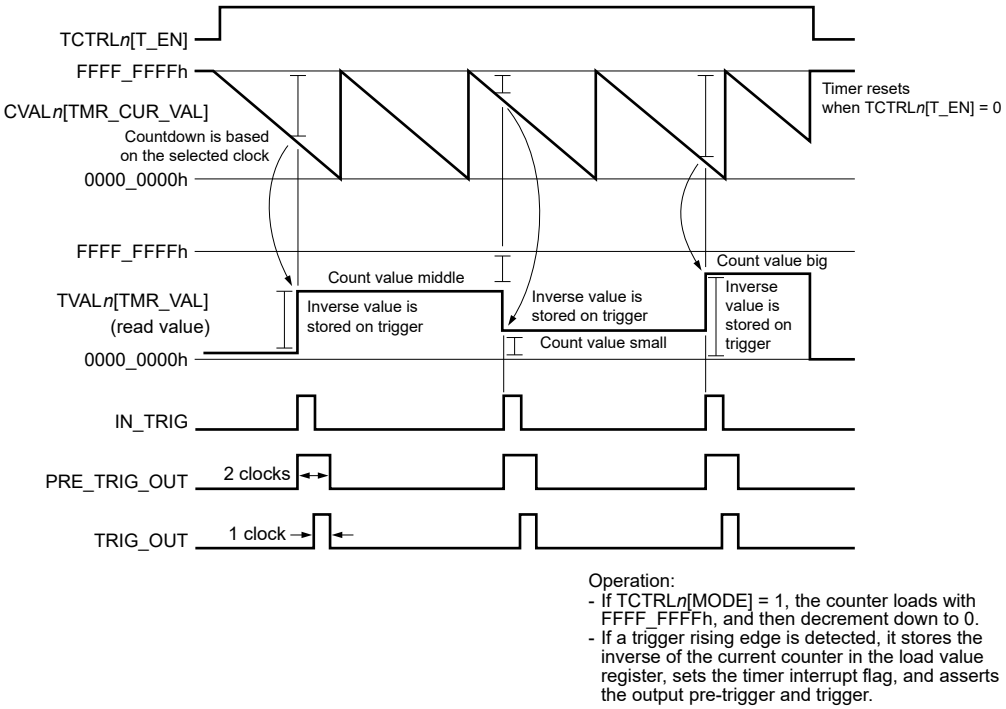

Figure 135. Case 1: TSOT = X, TROT = 0, TSOI = 0, CHAIN = 0

42.3.8.13 Case 2: TCTRL*n*[MODE] = 11

The following figure represents case 2 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 0
- TCTRL*n*[CHAIN] = 0

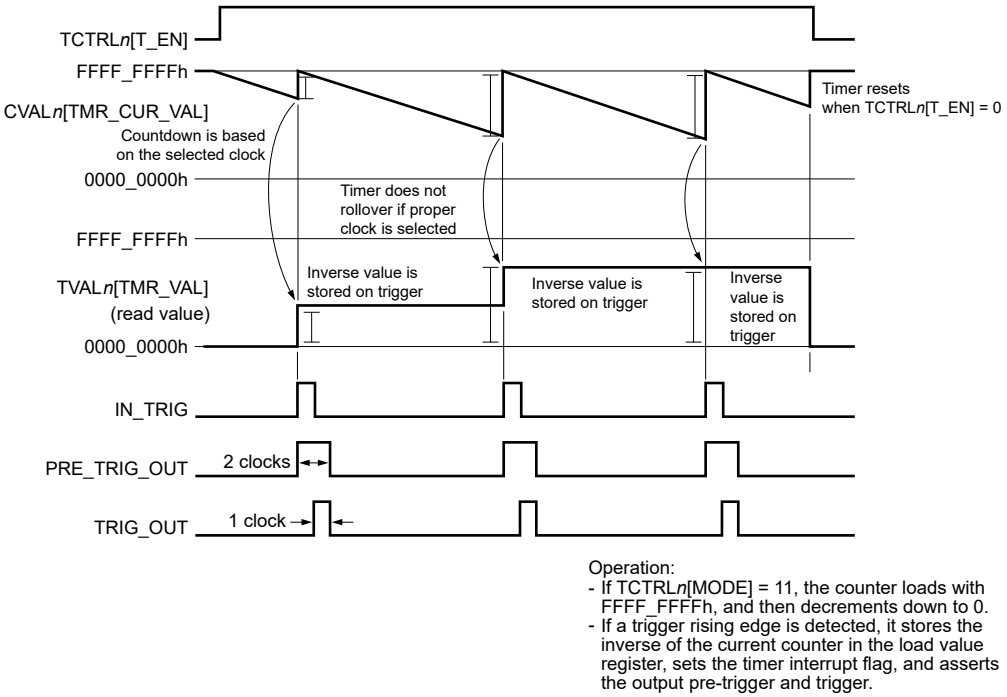

Figure 136. Case 2: TSOT = X, TROT = 1, TSOI = 0, CHAIN = 0

42.3.8.14 Case 3: TCTRL*n*[MODE] = 11

The following figure represents case 3 in which TCTRL*n*[MODE] = 11. LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 0
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

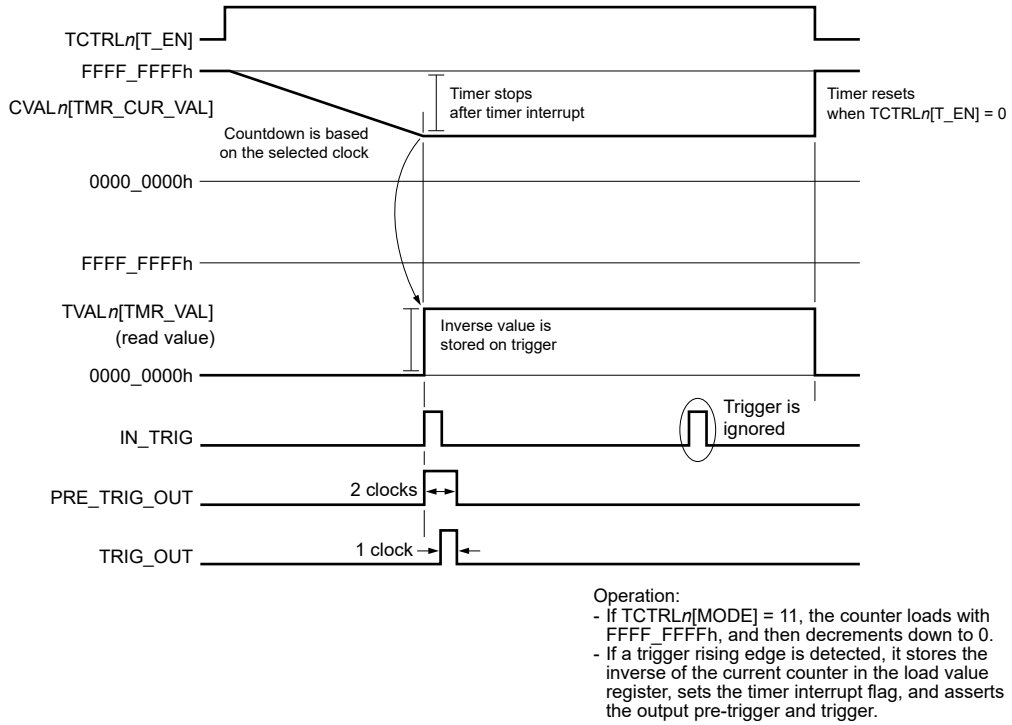

Figure 137. Case 3: TSOT = X, TROT = 0, TSOI = 1, CHAIN = 0

42.3.8.15 Case 4: TCTRL*n*[MODE] = 11

Case 4, in which TCTRL*n*[MODE] = 11, is the same as case 3, except that the timer reloads to FFFF_FFFFh and then stops. The timer does not start until TCTRL*n*[T_EN] becomes 1 again. In this case, LPIT works in 32-bit trigger capture mode and is configured as follows:

- TCTRL*n*[TSOT] = X
- TCTRL*n*[TROT] = 1
- TCTRL*n*[TSOI] = 1
- TCTRL*n*[CHAIN] = 0

42.3.9 Timer chaining

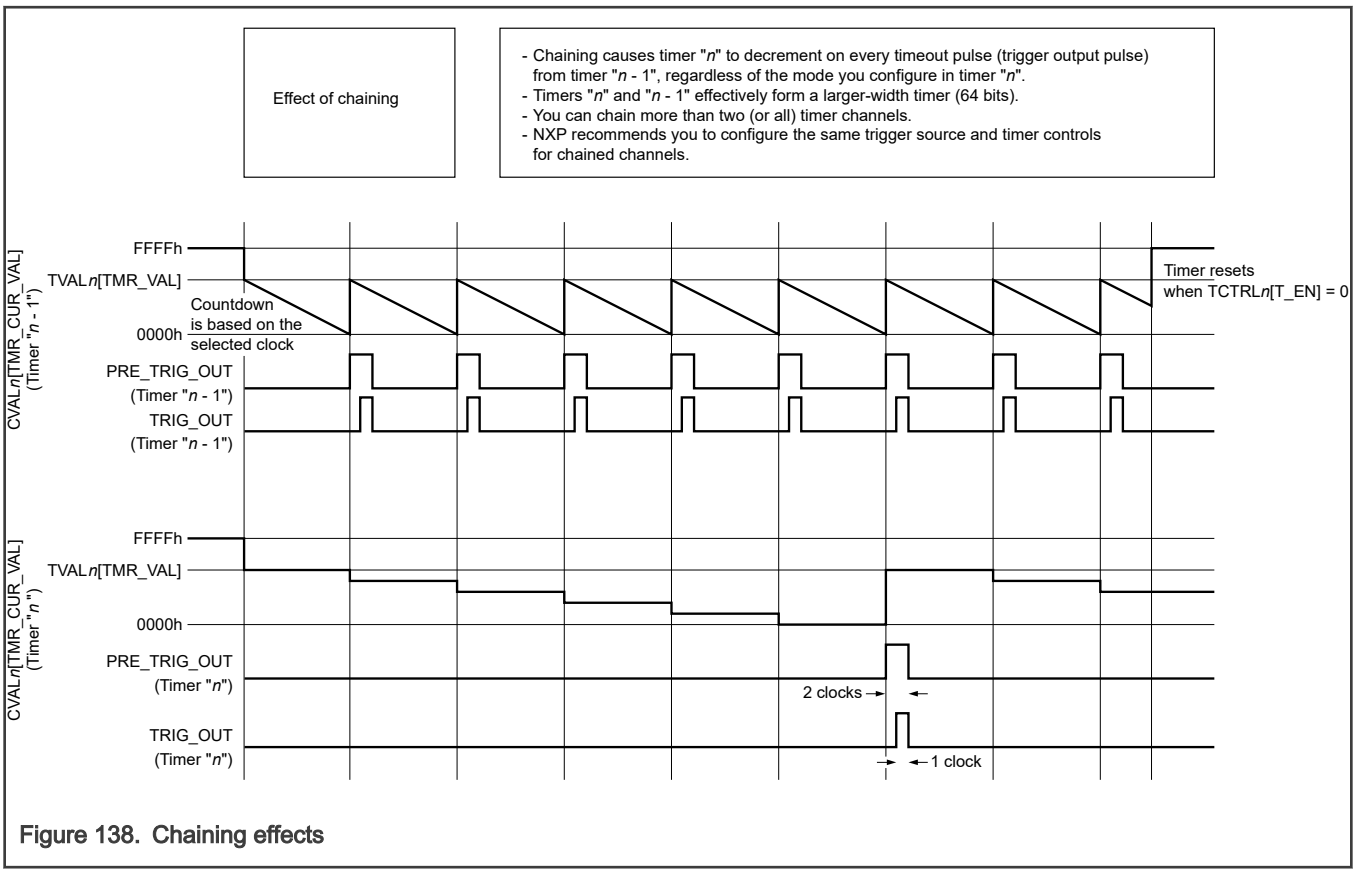

Figure 138. Chaining effects

42.4 Initialization

Table 297. Initializing LPIT

Step	Action	How or why to perform the step
1	Enable the peripheral clock	By writing 1 to MCR[M_CEN]. **NOTE** • Accessing certain registers (Module Status (MSR), Set Timer Enable (SETTEN), Clear Timer Enable (CLRTEN), Timer Value (TVAL0 - TVAL3), Current Timer Value (CVAL0 - CVAL3), and Timer Control (TCTRL0 - TCTRL3)) while MCR[M_CEN] = 0 leads to the assertion of a transfer error for that bus access. However, writing to CVAL*n* and reserved registers generates a transfer error. • There might be additional clock gating fields in the chip that gate the peripheral clock to this module. When enabling the clock to this module, you must configure those additional clock gating fields (in addition to configuring MCR[M_CEN]).
2	Wait for four peripheral clock cycles	To allow time for clock synchronization and reset deassertion.

Table continues on the next page...

Table 297. Initializing LPIT (continued)

Step	Action	How or why to perform the step
3	Configure timer control fields	For each timer channel that is to be enabled: • Timer mode of operation fields, TCTRL*n*[MODE] • Trigger source selection fields, TCTRL*n*[TRG_SEL] and TCTRL*n*[TRG_SRC] • Trigger control fields, TCTRL*n*[TROT], TCTRL*n*[TSOT], and TCTRL*n*[TSOI] **NOTE** You must not update timer control fields when the timer is disabled. You can disable a timer by using any one of the following methods: • Write 1 to the specific timer's CLRTEN[CLR_T_EN_*n*] field. • Write 0 to TCTRL*n*[T_EN] for that channel.
4	Configure the channels that are to be chained	By writing 1 to TCTRL*n*[CHAIN] in the corresponding channel's Timer Control (TCTRL0 - TCTRL3).
5	Set the timer timeout value	By programming an appropriate value in TVAL*n*[TMR_VAL] for the channels that you configure in Compare mode.
6	Configure MIER[TIE*n*]	For those channels that are required to generate interrupts after timer timeouts.
7	Configure the low-power modes of the module	By writing 1 to MCR[DBG_EN] and MCR[DOZE_EN]. This is common to all timer channels.
8	Enable the channel timers	By writing 1 to the corresponding TCTRL*n*[T_EN].

NOTE

When you enable a timer channel in Compare mode, the first decrement takes an additional one or two clock cycles because of synchronization logic. This results in the first compare (and therefore interrupt and hardware trigger) occurring slightly later. A faster counter clock minimizes this impact.

Additionally,

- For channels that you configure in Capture mode, you can read the timer value from Timer Value (TVAL0 - TVAL3) when a channel timeout occurs.
- At any time, you can read the current value of the timer for any channel by reading the corresponding channel's Current Timer Value (CVAL0 - CVAL3). Ensure that MCR[M_CEN] = 1 when doing so.
- MSR[TIF*n*] are asserted after timer timeout. To clear these timer interrupt flags, write 1 to them.

42.5 Memory map and registers

42.5.1 LPIT register descriptions

The LPIT memory map comprises 32-bit aligned registers, which you can access via 8-bit, 16-bit, or 32-bit accesses. Read and write accesses to reserved locations generate a transfer error, and the read bus shows all 0s.

NOTE

- The memory map and complete module are in big-endian (BE) format.
- LPIT does not check whether programmed values in these registers are correct—you must write the correct values.

42.5.1.1 LPIT memory map

LPIT0 base address: 4002_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0100_0000h

7-0 CHANNEL	Number of Timer Channels Specifies the number of timer channels implemented in this chip.

42.5.1.4 Module Control (MCR)

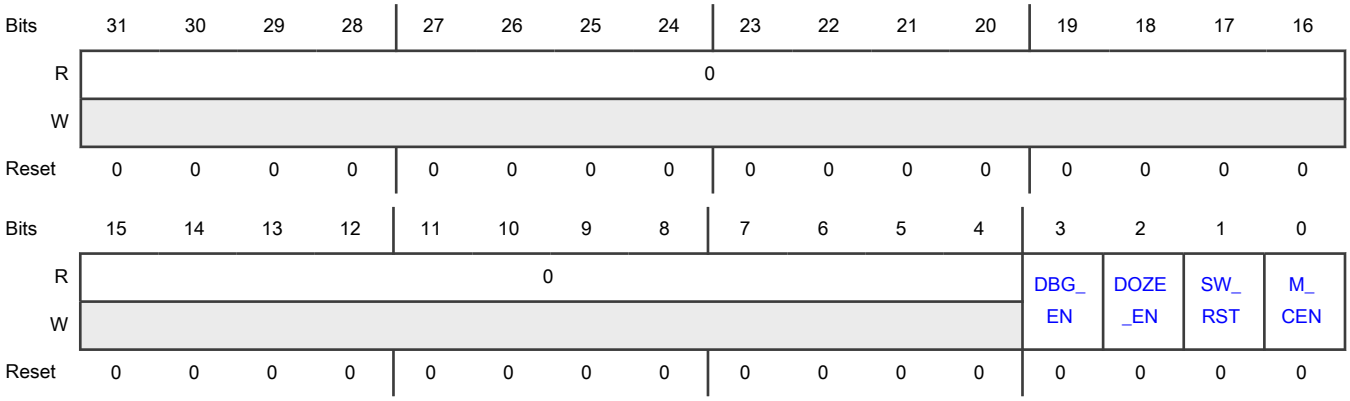
Offset

Register	Offset
MCR	8h

Function

Contains software reset, clock enable, and mode enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DBG_EN	Debug Mode Enable Stops the timer channels when the chip enters Debug mode. 0b - Stops timer channels 1b - Allows timer channels to continue running
2 DOZE_EN	DOZE Mode Enable Stops the timer channels when the chip enters Doze mode. 0b - Stops timer channels 1b - Allows timer channels to continue running
1 SW_RST	Software Reset Resets all timer channels and registers, except Module Status (MSR). This field remains 1 until software clears it. Before clearing this field, software must wait for four peripheral clocks (for clock synchronization and reset propagation). 0b - Does not reset 1b - Resets
0 M_CEN	Module Clock Enable Enables the peripheral clock to LPIT module timers. This field must become 1 when accessing the following registers: • Module Status (MSR) • Set Timer Enable (SETTEN) • Clear Timer Enable (CLRTEN)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Timer Value (TVAL0 - TVAL3) • Current Timer Value (CVAL0 - CVAL3) • Timer Control (TCTRL0 - TCTRL3) The following considerations apply when using this field: • You must enable both the bus and peripheral clocks to allow clock synchronization and update of the aforementioned registers. Accessing these registers when MCR[M_CEN] = 0 asserts a transfer error for that bus cycle. • Writing to Current Timer Value (CVAL0 - CVAL3) and reserved registers always generates a transfer error. **NOTE** There may be additional clock gating fields available in this chip that gate the peripheral clock to LPIT. You must configure those additional clock gating fields appropriately to enable the peripheral clock to LPIT. 0b - Disable 1b - Enable

42.5.1.5 Module Status (MSR)

Offset

Register	Offset
MSR	Ch

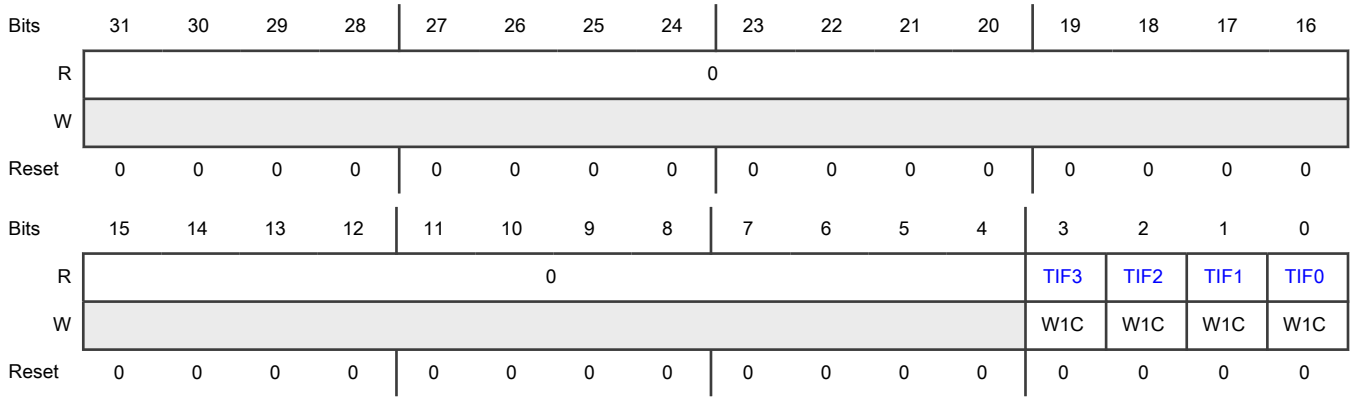
Function

Contains channel timer interrupt flags.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TIF3	Channel 3 Timer Interrupt Flag Specifies whether the channel 3 timer has timed out. In compare modes, at the end of the timer period, this flag becomes 1. In capture modes, when the trigger asserts, this flag becomes 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not timed out 1b - Timed out When writing 0b - No effect 1b - Clear the flag
2 TIF2	Channel 2 Timer Interrupt Flag Specifies whether the channel 2 timer has timed out. In compare modes, at the end of the timer period, this flag becomes 1. In capture modes, when the trigger asserts, this flag becomes 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not timed out

Table continues on the next page...

0 TIE0	Channel 0 Timer Interrupt Enable Enables interrupt generation when: • This field = 1. • The corresponding timer interrupt flag, MSR[TIF0] = 1. 0b - Disable 1b - Enable

42.5.1.7 Set Timer Enable (SETTEN)

Offset

Register	Offset
SETTEN	14h

Function

Allows the simultaneous enabling of timer channels.

You can enable timer channels by using either of the following ways:

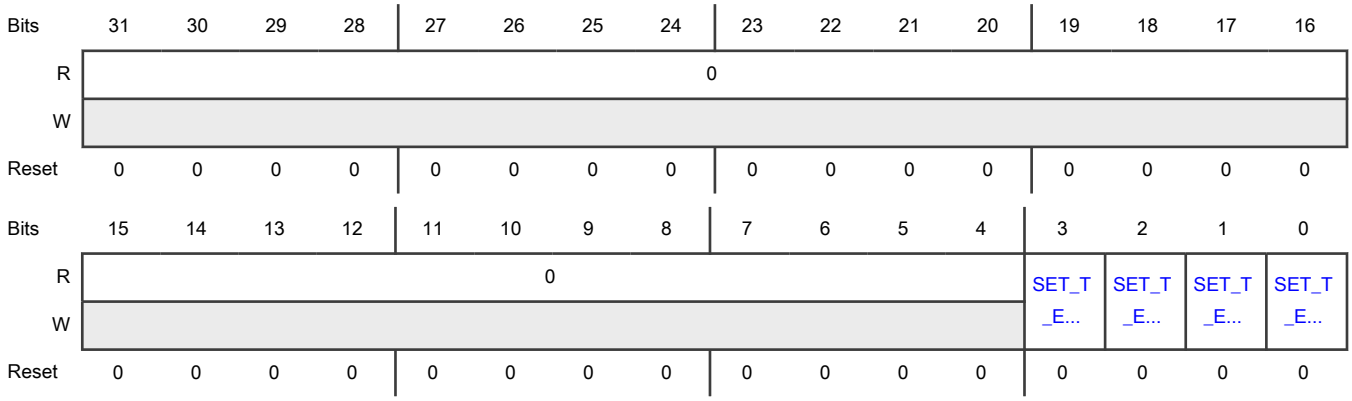
- Writing 1 to TCTRL*n*[T_EN] in the respective TCTRL*n* register.
- Writing 1 to the corresponding SETTEN[SET_T_EN_*n*] field.

To disable timer channels simultaneously, use Clear Timer Enable (CLRTEN). Writing 0 to the fields of this register has no effect.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 SET_T_EN_3	Set Timer 3 Enable Works with TCTRL3[T_EN] and enables timer channel 3. Writing 0 to this field does not disable the counter; rather it has no effect. This field becomes 0 if any of the following conditions is true: • TCTRL3[T_EN] = 0 • You write 1 to CLRTEN[CLR_T_EN_3] 0b - No effect 1b - Enables timer channel 3
2 SET_T_EN_2	Set Timer 2 Enable Works with TCTRL2[T_EN] and enables timer channel 2. Writing 0 to this field does not disable the counter; rather it has no effect. This field becomes 0 if any of the following conditions is true: • TCTRL2[T_EN] = 0 • You write 1 to CLRTEN[CLR_T_EN_2] 0b - No Effect 1b - Enables timer channel 2
1 SET_T_EN_1	Set Timer 1 Enable Works with TCTRL1[T_EN] and enables timer channel 1. Writing 0 to this field does not disable the counter; rather it has no effect. This field becomes 0 if any of the following conditions is true:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• TCTRL1[T_EN] = 0 • You write 1 to CLRTEN[CLR_T_EN_1] 0b - No Effect 1b - Enables timer channel 1
0 SET_T_EN_0	Set Timer 0 Enable Works with TCTRL0[T_EN] and enables timer channel 0. Writing 0 to this field does not disable the counter; rather it has no effect. This field becomes 0 if any of the following conditions is true: • TCTRL0[T_EN] = 0 • You write 1 to CLRTEN[CLR_T_EN_0] 0b - No effect 1b - Enables timer channel 0

42.5.1.8 Clear Timer Enable (CLRTEN)

Offset

Register	Offset
CLRTEN	18h

Function

Allows the simultaneous disabling of timer channels.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Field	Function
31-0 TMR_CUR_VAL	Current Timer Value Represents the current timer value, if the timer is enabled.

42.5.1.11 Timer Control (TCTRL0 - TCTRL3)

Offset

Register	Offset
TCTRL0	28h
TCTRL1	38h
TCTRL2	48h
TCTRL3	58h

Function

Contains control fields for each timer channel:

- TRG_SEL for trigger selection
- TRG_SRC for trigger source selection
- TROT for timer reload
- TSOI for timer stoppage
- TSOT for timer decrementing
- MODE for timer operation mode selection
- CHAIN for channel chaining

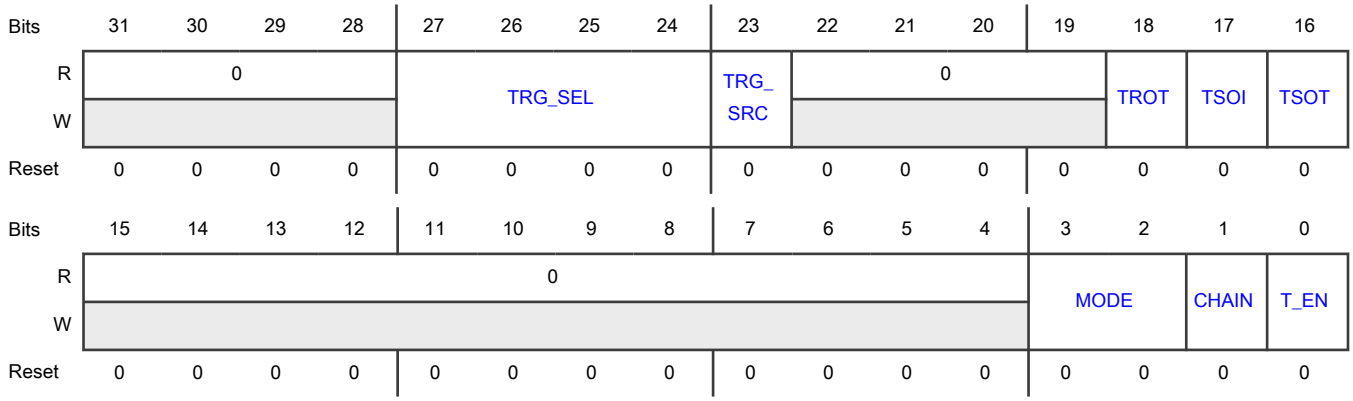
You must update timer controls when the timer is disabled, and use either of the following ways to disable a timer:

- By writing 1 to the specific timer's CLRTEN[CLR_T_EN_*n*] field.
- By writing 0 to T_EN for that channel.

NOTE

Unless the peripheral clock to the timers is enabled (MCR[M_CEN] = 1), reading or writing to this register generates a transfer error.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 TRG_SEL	Trigger Select Selects the trigger to use for starting and/or reloading the LPIT timer. This field selects one trigger from the set of internal or external triggers that TRG_SRC provides. TRG_SRC helps you make a choice between internal and external trigger signals for each channel. **NOTE** You must change the value of this field when the LPIT timer channel is disabled. 0000b-0011b - Timer channel 0–3 trigger source 0100b-1111b - Reserved
23 TRG_SRC	Trigger Source Selects whether to use internal or external trigger sources. You can select the trigger to be used by using this field or the TRG_SEL field. If a channel does not have an associated external trigger, write 1 to TRG_SRC. See LPIT chip-specific information for the available external trigger options. 0b - External 1b - Internal
22-19 —	Reserved
18 TROT	Timer Reload on Trigger Specifies whether the timer reloads after the selected trigger. If this field = 1, the LPIT timer reloads when a rising edge is detected on the selected trigger input. The trigger input is ignored if LPIT is disabled during Debug mode (MCR[DBG_EN] = 0) or Doze mode (MCR[DOZE_EN] = 0). 0b - Does not reload 1b - Reloads
17 TSOI	Timer Stop on Interrupt Controls whether the channel timer stops after being timed out. If this field = 0, the channel timer does not stop after timeout. If this field = 1, the channel timer stops after a timeout and then restarts based on the configuration of TSOT. If TSOT = 0, the channel timer restarts after a rising edge on T_EN is detected, which means that the timer channel is disabled and then enabled. If TSOT = 1, the channel timer restarts after a rising edge on the selected trigger is detected. 0b - Does not stop 1b - Stops

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 TSOT	Timer Start on Trigger Controls when the timer starts decrementing. If this field = 0, the timer starts decrementing immediately based on the restart condition (controlled by TSOI). If this field = 1, the timer starts decrementing when a rising edge on a selected trigger is detected. 0b - Immediately 1b - When a rising edge is detected
15-4 —	Reserved
3-2 MODE	Timer Operation Mode Configures the channel timer's mode of operation. This field controls how the timer decrements. 00b - 32-bit periodic counter 01b - Dual 16-bit periodic counter 10b - 32-bit trigger accumulator 11b - 32-bit trigger input capture
1 CHAIN	Chain Channel Specifies whether channel chaining is enabled. If channel chaining is enabled, the timer channel decrements after the previous channel's timeout (when timer channel N-1 trigger asserts). Timer channel 0 cannot be chained. If channel chaining is disabled, the channel timer runs independently. 0b - Disabled 1b - Enabled
0 T_EN	Timer Enable Enables the timer channel. 0b - Disable 1b - Enable

Chapter 43
Timer/PWM Module (TPM)

43.1 Chip-specific TPM information

Table 298. Reference links to related information

Topic	Related module	Reference
Full description	TPM	TPM
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

43.1.1 Module instances

This device has three instances of the TPM module, TPM0, TPM1, and TPM2.

43.1.2 Trigger options

Table 299. TPM trigger options

TPM2	0 = LPTMR0 trigger
	1 = LPTMR1 trigger
	2 = LPTMR2 trigger

43.2 Overview

TPM is a 6-channel timer that controls electric motor and power management applications by supporting:

- Input capture
- Output comparison
- Generation of PWM signals

An asynchronous clock that can remain enabled in low-power modes clocks the counter, compare, and capture registers.

43.2.1 Block diagram

TPM uses one input/output (I/O) pin per channel: CH*n* (TPM channel *n*) where *n* is the channel number.

The central component of TPM is a 32-bit counter with a programmable final value. Its counting can be up or up-down.

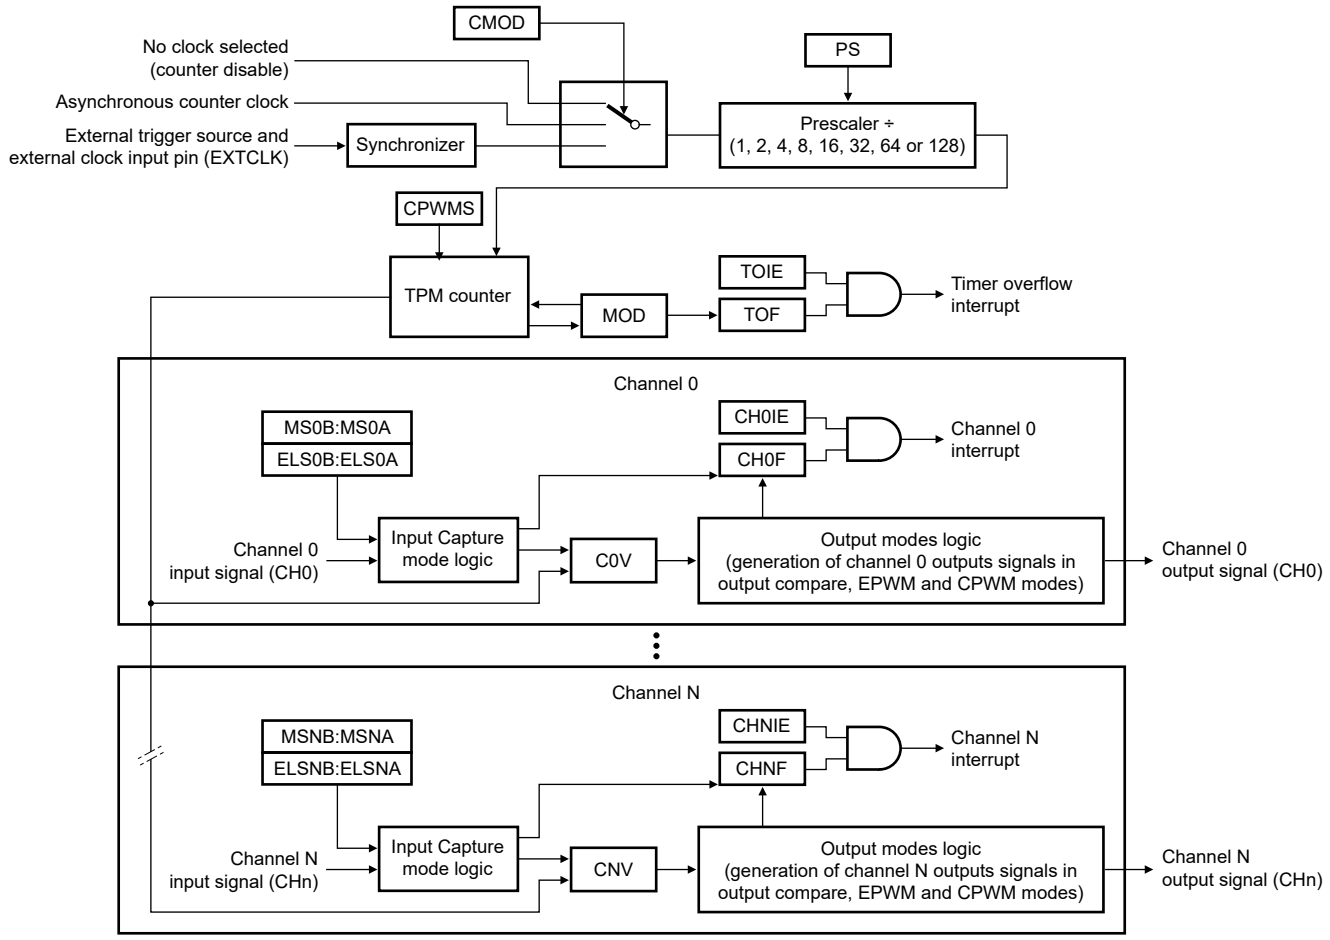


Figure 139. Block diagram

43.2.2 Features

- Supports selectable clock modes:
  - Can increment on every edge of the asynchronous counter clock
  - Can increment on the rising edge of an external clock input that is synchronized to the asynchronous counter clock
- Includes a prescaler divided by 1, 2, 4, 8, 16, 32, 64, or 128
- Includes a 32-bit TPM counter:
  - Can be a free-running counter or a modulo counter
  - The counting can be up or up-down
- Includes 6 channels that can be configured as follows:
  - Input Capture mode: the capture can occur on rising edges, falling edges, or both edges.
  - Output Compare mode: the output signal can be set, cleared, pulsed, or toggled on the match.
  - Edge-Aligned or Center-Aligned PWM mode for all channels.
- Supports the generation of an interrupt and DMA request per channel
- Supports the generation of an interrupt and DMA request when the counter overflows

- Supports selectable trigger input to either reset the counter to 0 or else cause the counter to start incrementing
  - The counter can also optionally stop incrementing on counter overflow.
- Supports the generation of hardware triggers per channel when the channel-interrupt-status flag is set
- Supports the generation of a hardware trigger when the counter overflows

43.3 Functional description

43.3.1 Counter

TPM has a 32-bit counter that the channels use for either input or output modes. The counter updates from the selected clock after it has been divided by the prescaler. The TPM counter can perform one of the following modes of operation:

- Up counting
- Up-down counting

43.3.1.1 Counter Clock mode

SC[CMOD] either disables the TPM counter or enables one of the three possible clock sources for the TPM counter. After any reset, SC[CMOD] becomes 0, which disables the TPM counter. You can configure SC[CMOD] for one of the following counter clock sources:

- Asynchronous counter clock
- External clock input pin
- External trigger source

You can read or write to SC[CMOD] at any time. Disabling the TPM counter by writing 0 to SC[CMOD] does not affect the TPM counter value or other registers, but the TPM counter clock domain must acknowledge this disabling action before SC[CMOD] becomes 0.

The external clock input and external trigger source pass through a synchronizer. The TPM counter clock clocks this synchronizer to ensure that counter transitions are properly aligned to counter clock transitions. Therefore, to meet Nyquist criteria, and also considering jitter, the frequency of the external clock source must be less than half of the counter clock frequency.

43.3.1.2 Prescaler

The counter clock source that you select passes through a prescaler that is a 7-bit counter. SC[PS] defines the value of the prescaler. The following figure shows an example of the prescaler counter and TPM counter.

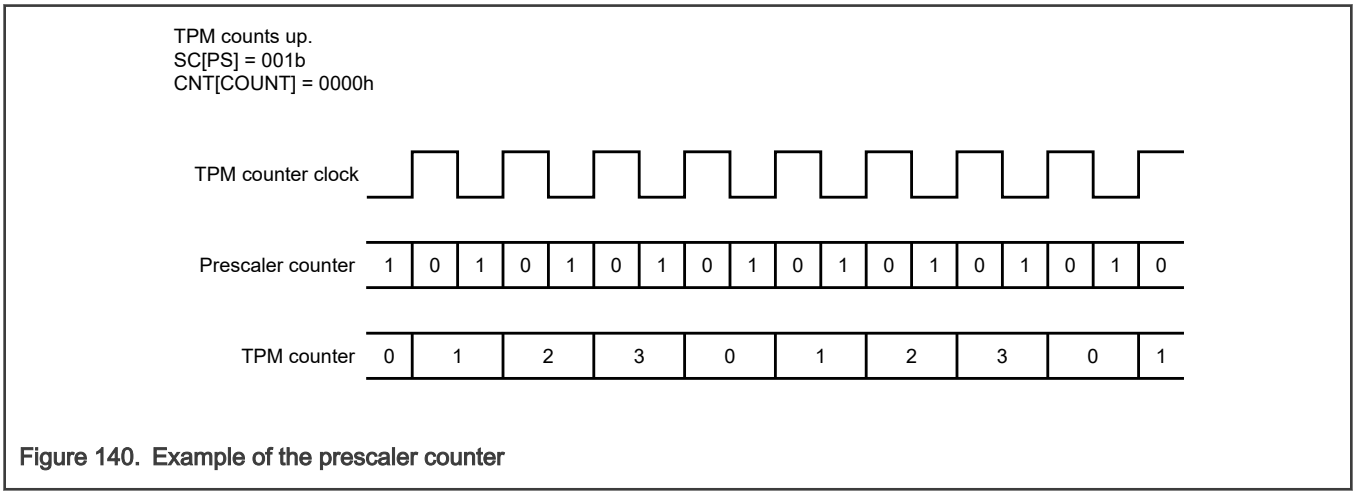

Figure 140. Example of the prescaler counter

43.3.1.3 Up counting

Up counting is enabled when you write 0 to SC[CPWMS].

In this mode, the TPM counter loads with value 0 and increments until it reaches the value defined in MOD[MOD], then the counter reloads with 0.

The TPM period when using up counting is (MOD[MOD] + 0001h) × period of the TPM counter clock.

SC[TOF] becomes 1 when the TPM counter changes from the value defined in MOD[MOD] to 0.

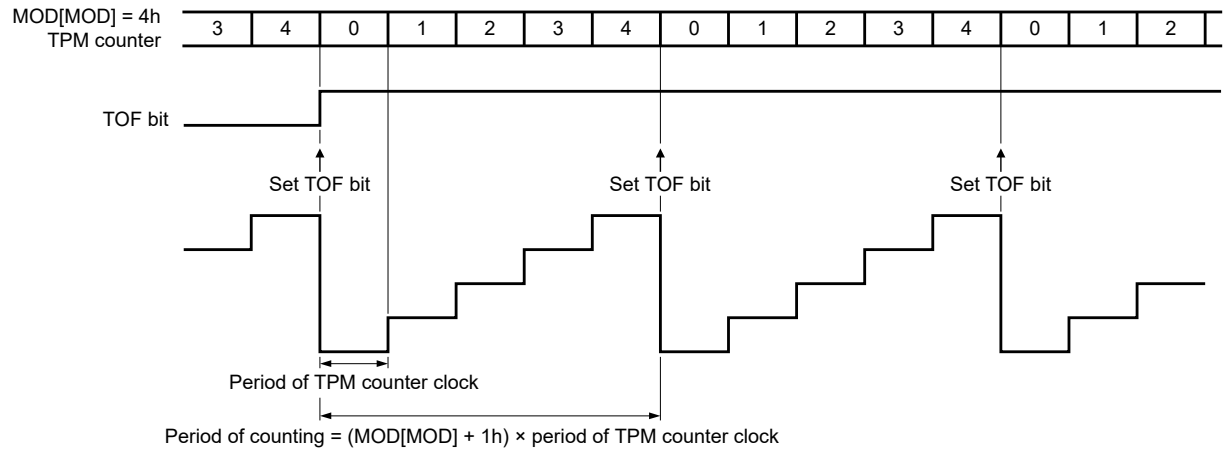

Figure 141. Example of TPM up counting

NOTE

- Configuring MOD[MOD] = 0 is a redundant condition. In this case, the TPM counter is always equal to the value of MOD[MOD], and SC[TOF] remains 1 for each rising edge of the TPM counter clock.
- Configuring MOD[MOD] = 1 and SC[PS] = 0 causes TPM to attempt to set SC[TOF] every second TPM counter clock. Because of synchronization delays between the TPM counter clock and the bus clock, you must write 1 to SC[TOF] to clear it two counter clock cycles before SC[TOF] can become 1 again.

43.3.1.4 Up-down counting

You enable up-down counting when you write 1 to SC[CPWMS]. This mode does not support configuring the value of Modulo (MOD) to be less than 2.

In this mode, the TPM counter loads with value 0 and increments until it reaches the value defined in MOD[MOD]. Then the counter starts decrementing until it returns to 0 and the up-down counting restarts.

The TPM period when using up-down counting is 2 × MOD[MOD] × period of the TPM counter clock.

TPM writes 1 to SC[TOF] when the TPM counter changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

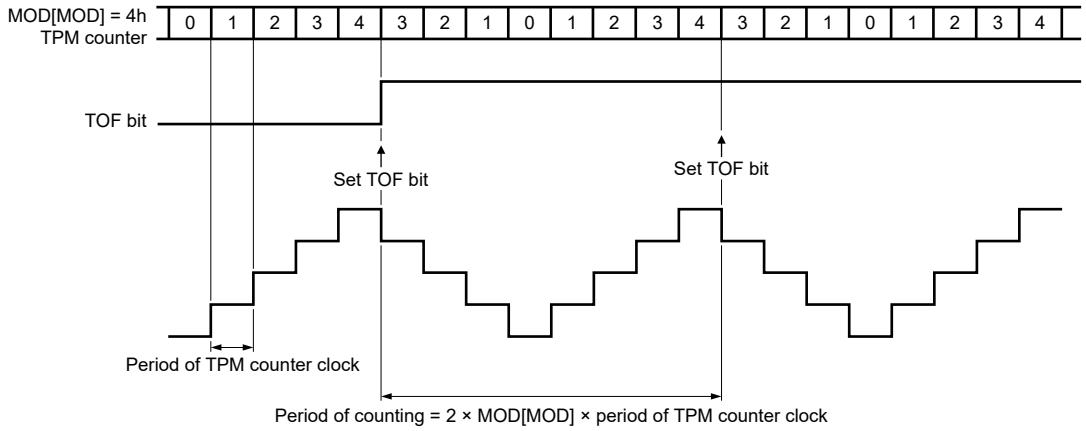

Figure 142. Example of up-down counting

43.3.1.5 Counter reset

Any write to CNT[COUNT] resets the TPM counter and forces the channel outputs to their initial values (except for channels in Output Compare mode).

43.3.1.6 Counter trigger

You can configure the TPM counter to start, stop, or reset in response to a hardware trigger input. The trigger input synchronizes with the asynchronous counter clock, so there is a three-counter-clock delay between the trigger assertion and counter response.

- When CONF[CSOT] = 1, the counter does not start incrementing until the trigger input detects a rising edge.
- When CONF[CSOO] = 1, the counter stops incrementing whenever SC[TOF] = 1. The counter does not increment again unless:
  - It is disabled.
  - CONF[CSOT] = 1 and the trigger input detects a rising edge.
- When CONF[CROT] = 1, the counter resets to 0, as if an overflow occurred, whenever the trigger input detects a rising edge. Any PWM channels are updated to their reload state.
- When CONF[CPOT] = 1, the counter pauses incrementing whenever you assert the trigger input. The counter continues incrementing when the trigger input negates. PWM output channels are forced to their default state.

You can configure the polarity of the external input trigger with CONF[TRGPOL].

When you enable an internal trigger source, the trigger input is selected from one or more channel input capture events. The input capture filters are used with the internal trigger sources. You can use POL[POL*n*] fields to invert the polarity of the input channels.

The following restrictions apply with input capture channel sources:

- When CONF[CSOT] = 1, the counter starts incrementing only on a rising edge on the channel input, if C*n*SC[ELS*n*A] = 1.
- When CONF[CROT] = 1, the counter resets to 0 on either edge of the channel input, as you configure it using C*n*SC[ELS*n*B] and C*n*SC[ELS*n*A].
- When CONF[CPOT] = 1, the counter pauses incrementing whenever you assert the channel input. PWM output channels are forced to their default state.

43.3.2 Registers updated from write buffers

43.3.2.1 MOD register update

If SC[CMOD] = 0, then Modulo (MOD) updates whenever you write to MOD[MOD].

If SC[CMOD] ≠ 0, then the MOD register updates accordingly as below:

- CPWM mode is disabled (SC[CPWMS] = 0), then the MOD register updates whenever you write to MOD[MOD], and the TPM counter value changes from the value defined in MOD[MOD] to 0.
- CPWM mode is enabled (SC[CPWMS] = 1), then the MOD register updates whenever you write to MOD[MOD], and the TPM counter value changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

43.3.2.2 C*n*V register update

If SC[CMOD] = 0, then the C*n*V register updates whenever you write to C*n*V[VAL].

If SC[CMOD] ≠ 0, then the C*n*V register updates according to the selected mode:

- If you select Output Compare mode, then the C*n*V register updates on the next TPM counter increment (end of the prescaler counting) after you write to C*n*V[VAL].
- If you select EPWM mode, then the C*n*V register updates after you write to C*n*V[VAL], and the TPM counter value changes from the value defined in MOD[MOD] to 0.
- If you select CPWM mode, then the C*n*V register updates after you write to C*n*V[VAL], and the TPM counter value changes from the value defined in MOD[MOD] to (MOD[MOD] – 1).

43.3.3 Peripheral triggers

See the chip-specific TPM information for more details.

43.3.3.1 Output triggers

TPM generates output triggers for the counter and for each channel that you can use to trigger events in other peripherals. The counter trigger asserts whenever SC[TOF] is 1 and remains asserted until the next increment.

Each TPM channel generates both a pre-trigger output and a trigger output.

1. The pre-trigger output asserts whenever C*n*SC[CH*n*F] sets.
2. The trigger output asserts on the first counter increment after the pre-trigger asserts.
3. Both the trigger and pre-trigger negate on the first counter increment after the trigger asserts.

When (COMBINE[COMBINE*n*] = 1) in Output Compare mode, the pre-trigger output for both channel *n* and channel *n* + 1 asserts when the CH*n*F flag is set and negates when the CH(*n* + 1)F flag is set. The trigger continues to assert on the first counter increment, after the pre-trigger asserts and negates at the same time as the pre-trigger negation.

43.3.3.2 Input trigger

You can configure the TPM input trigger to perform the following operations with configurable polarity:

- Increment the counter on trigger rising edge
- Start incrementing the counter on trigger rising edge
- Reset or reload the counter on trigger rising edge
- Pause the counter while trigger high

The TPM input trigger is synchronized and must remain asserted for at least two counter clock cycles, so that the input trigger can be detected.

43.3.4 Modes of operations

43.3.4.1 Input Capture mode

Input Capture mode is enabled when:

- (SC[CPWMS] = 0)
- (MS*n*B:MS*n*A = 0:0)
- (ELS*n*B:ELS*n*A ≠ 0:0)

When a selected edge occurs on the channel input:

- The C*n*V register captures the current value of the TPM counter.
- It also writes 1 to C*n*SC[CH*n*F] and generates a channel interrupt if C*n*SC[CH*n*IE] = 1 (see Figure 143).

When you configure a channel for input capture, the CH*n* pin is an edge-sensitive input. ELS*n*B:ELS*n*A control fields determine which edge, falling or rising, triggers the input-capture event. To detect the input signal correctly and to meet Nyquist criteria for signal sampling, the maximum frequency for the channel input signal is the counter clock divided by 4.

Input Capture mode ignores any writes to the C*n*V register.

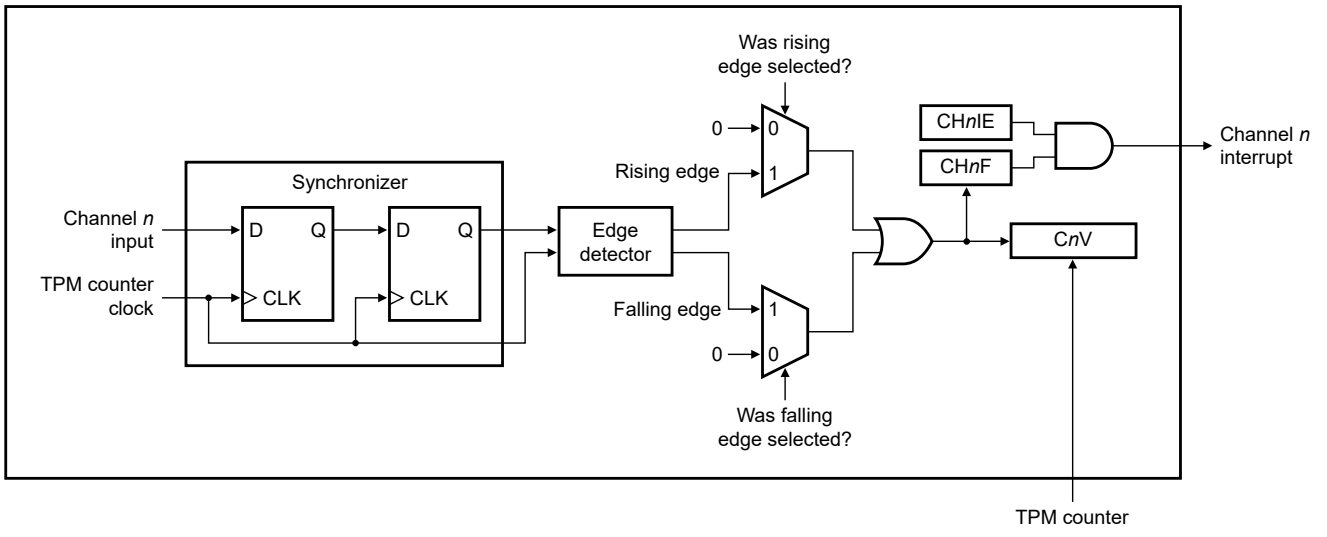

Figure 143. Input Capture mode

The CH*n*F flag is set on the third rising edge of the TPM counter clock after a valid edge occurs on the channel input.

43.3.4.1.1 Input capture filter

The input capture filter function is only available in Input Capture or Software Compare mode when Quadrature Decoder mode is enabled.

First, the TPM counter clock synchronizes the input signal. After synchronization, the input signal enters the filter block (see Figure 144).

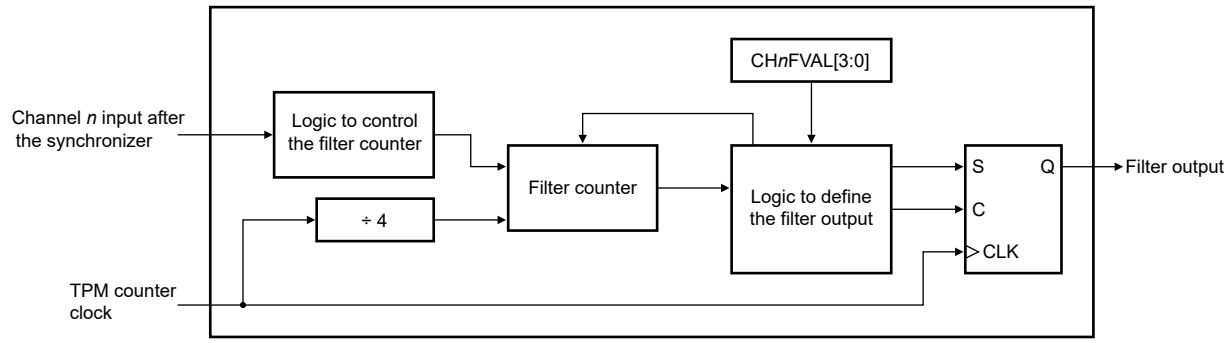

Figure 144. Channel input filter

When there is a state change in the input signal, TPM resets the counter, and it starts counting up. As long as the new state is stable on the input, the counter continues to increment. When the counter is equal to (CH*n*FVAL[3:0] × 4), the state change of the input signal is validated.

TPM resets the counter if the opposite edge appears on the input signal before it is validated. At the next input transition, the counter starts counting again. Any pulse that is less than the minimum value selected by (CH*n*FVAL[3:0] × 4 counter clocks) is considered as a glitch and does not pass through the filter. Figure 145 shows a timing diagram of the input filter.

The filter function is disabled when CH*n*FVAL[3:0] = 0. In this case, the input signal is delayed by 2 rising edges of the counter clock. If CH*n*FVAL[3:0] ≠ 0000, then the input signal is delayed by the minimum pulse width (CH*n*FVAL[3:0] × 4 system clocks) plus a further 3 rising edges of the system clock: two rising edges to the synchronizer, plus one more to the edge detector. In other words, the CH*n*F flag is set for (3 + (4 × CH*n*FVAL[3:0])) counter clock periods after a valid edge occurs on the channel input (see Figure 145).

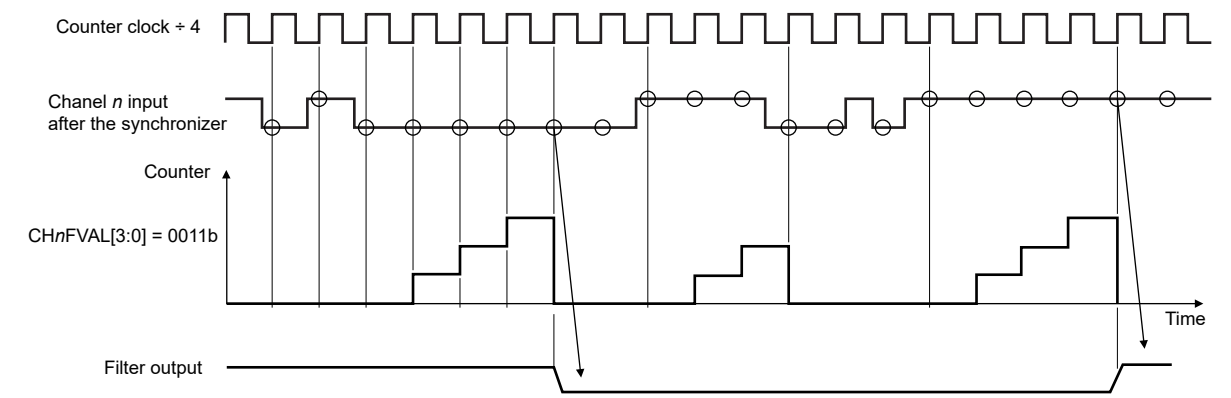

Figure 145. Channel input filter example

43.3.4.2 Output Compare mode

Output Compare mode is enabled when SC[CPWMS] = 0 and MS*n*B:MS*n*A = X:1.

In this mode, TPM can generate timed pulses with programmable:

- Position
- Polarity
- Duration
- Frequency

When the TPM counter matches the value defined in C*n*V[VAL] of an output compare channel, then channel *n* output can be set, cleared, or toggled if MS*n*B = 0. If MS*n*B = 1, then channel *n* output is pulsed high or low (as long as the TPM counter matches the value defined in C*n*V[VAL]).

When you initially configure a channel to Output Compare mode, the channel output is updated with its negated value (logic 0 for set/toggle/pulse high and logic 1 for clear/pulse low).

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1).

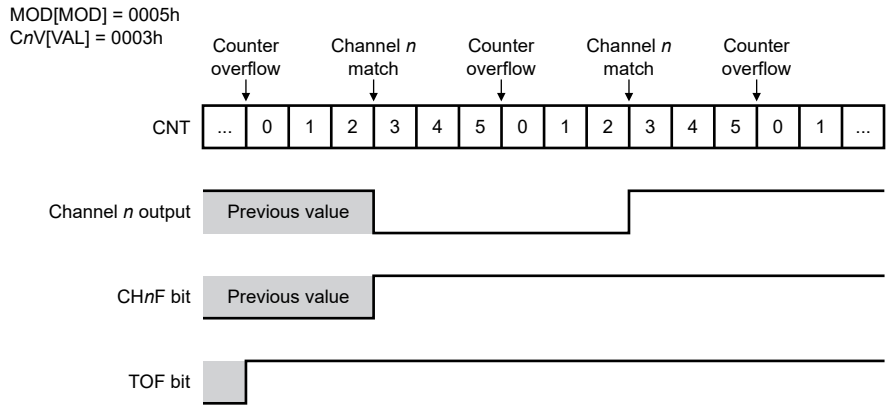

Figure 146. Example of Output Compare mode when a match toggles the channel output

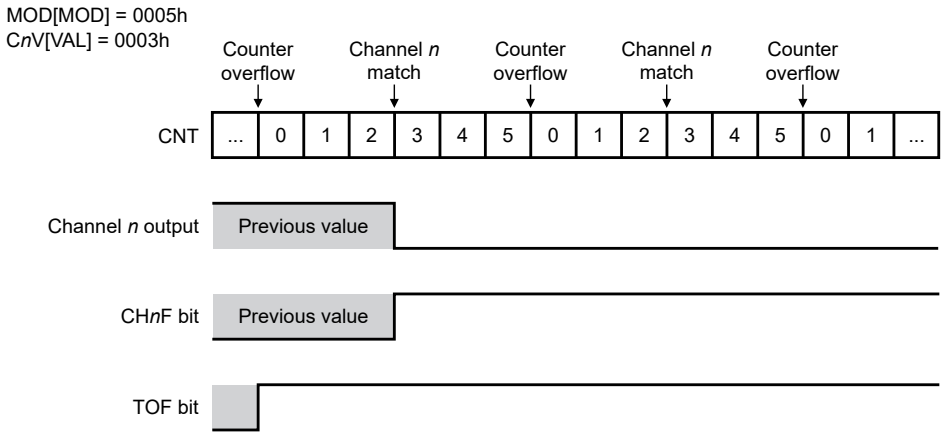

Figure 147. Example of Output Compare mode when a match clears the channel output

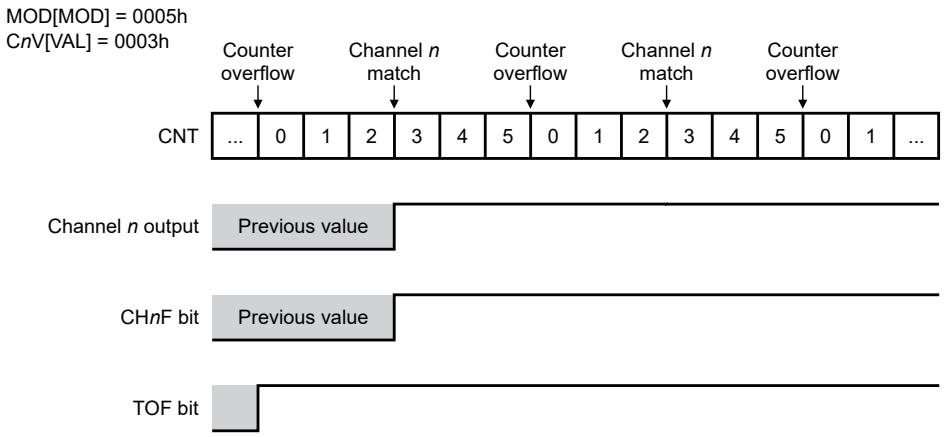

Figure 148. Example of Output Compare mode when a match sets the channel output

You can also use Output Compare mode with:

- SC[CPWMS] = 0 and MS*n*B:MS*n*A = 0:1
- SC[CPWMS] = 0 and ELS*n*B:ELS*n*A = 0:0

This condition is known as Software Compare mode. This mode sets the CH*n*F flag and generates a channel *n* interrupt (if CH*n*IE = 1) when the TPM counter reaches the value defined in the C*n*V register; however, TPM does not modify or control the channel *n* output.

43.3.4.3 Edge-Aligned PWM (EPWM) mode

EPWM mode is enabled when SC[CPWMS] = 0 and MS*n*B:MS*n*A = 1:0. The EPWM period is determined by (MOD[MOD] + 0001h) and the pulse width (duty cycle) is determined by C*n*V[VAL].

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1) at the end of the pulse width (see Figure 149).

This type of PWM signal is called edge-aligned because the leading edges of all PWM signals are aligned with the beginning of the period, which is the same for all channels within TPM.

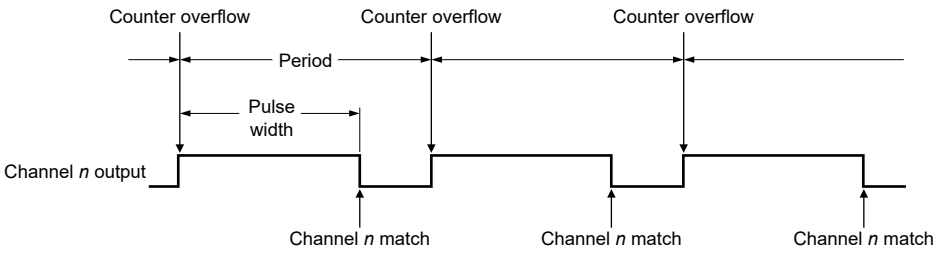

Figure 149. EPWM period and pulse width with ELS*n*B:ELS*n*A = 1:0

If ELS*n*B:ELS*n*A = 1:0, then the channel *n* output is forced high at the counter overflow or reload (when the TPM counter loads with 0), and it is forced low at the channel *n* match (TPM counter = C*n*V[VAL]). The channel *n* output is forced high when you first enable or whenever you pause the TPM counter (see Figure 150).

If ELS*n*B:ELS*n*A = 0:0, then the channel *n* output is forced high at the counter overflow or reload (when the TPM counter loads with 0), and it is forced low at the channel *n* match (TPM counter = C*n*V[VAL]). The channel *n* output is forced low when you first enable or whenever you pause the TPM counter.

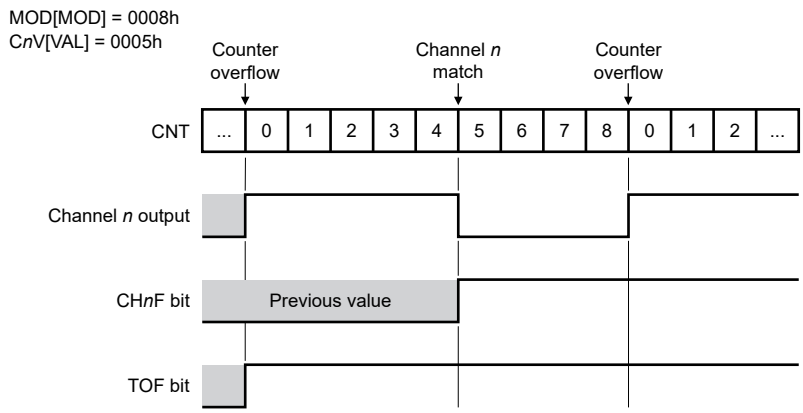

Figure 150. EPWM signal with ELS*n*B:ELS*n*A = 1:0

If ELS*n*B:ELS*n*A = 0:1, then the channel *n* output is forced low at the counter overflow or reload (when the TPM counter loads with 0), and it is forced high at channel *n* match (TPM counter = C*n*V[VAL]). Channel *n* output is forced low when you first enable or whenever you pause the TPM counter (see Figure 151).

If ELS*n*B:ELS*n*A = 1:1, then the channel *n* output is forced low at the counter overflow or reload (when the TPM counter loads with 0), and it is forced high at the channel *n* match (TPM counter = C*n*V[VAL]). Channel *n* output is forced high when you first enable or whenever you pause the TPM counter.

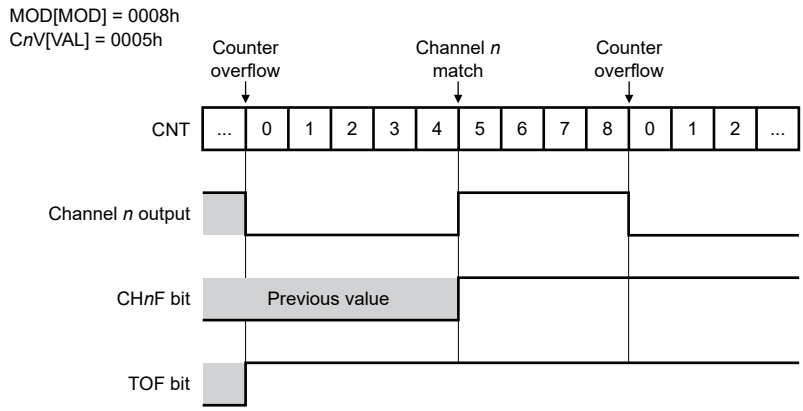

Figure 151. EPWM signal with ELS*n*B:ELS*n*A = 0:1

If C*n*V[VAL] = 0000h, then the channel *n* output is a 0% duty cycle EPWM signal.

If C*n*V[VAL] > MOD[MOD], then the channel *n* output is a 100% duty cycle EPWM signal and the CH*n*F flag is not set because there is never a channel *n* match. Therefore, MOD[MOD] must be less than FFFFFFFFh to get a 100% duty cycle EPWM signal.

43.3.4.4 Center-Aligned PWM (CPWM) mode

CPWM mode is enabled when (SC[CPWMS] = 1) and (MS*n*B:MS*n*A = 1:0).

The CPWM pulse width (duty cycle) is determined by 2 × C*n*V[VAL] and the period is determined by 2 × MOD[MOD] (see Figure 152). You must keep MOD[MOD] in the range of 0001h to 7FFFFFFF because values outside this range can produce ambiguous results.

In CPWM mode, the TPM counter counts up until it reaches the value defined in MOD[MOD], and then counts down until it reaches 0.

The channel *n* match (TPM counter = C*n*V[VAL]) sets C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1) when TPM is counting down (at the begin of the pulse width), and when TPM is counting up (at the end of the pulse width).

This type of PWM signal is called center-aligned because the pulse width centers for all channels are at the same place when the TPM counter is 0.

The other channel modes are not designed to be used with the up-down counter when SC[CPWMS] = 1. Therefore, you must use all TPM channels in CPWM mode when SC[CPWMS] = 1.

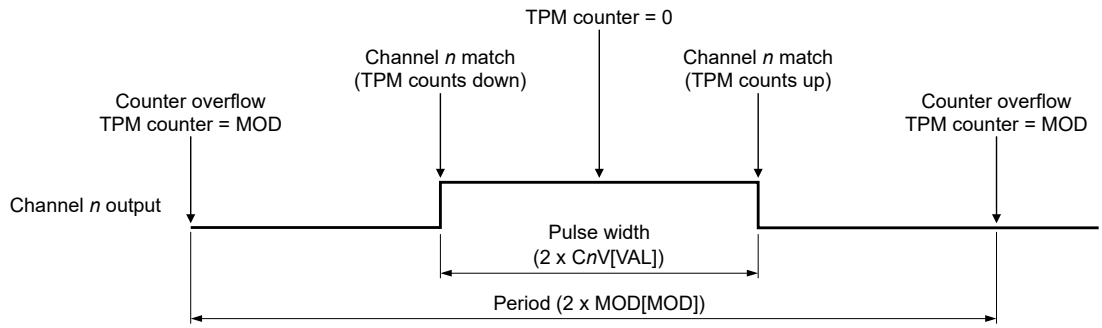

Figure 152. CPWM period and pulse width with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 1:0) then the channel *n* output is forced high at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced low at the channel *n* match when counting up. The channel *n* output is forced high when you first enable or reload the TPM counter, or whenever you pause it (see Figure 153).

If (ELS*n*B:ELS*n*A = 0:0) then the channel *n* output is forced high at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced low at the channel *n* match when counting up. The channel *n* output is forced low when you first enable or reload the TPM counter, or whenever you pause it.

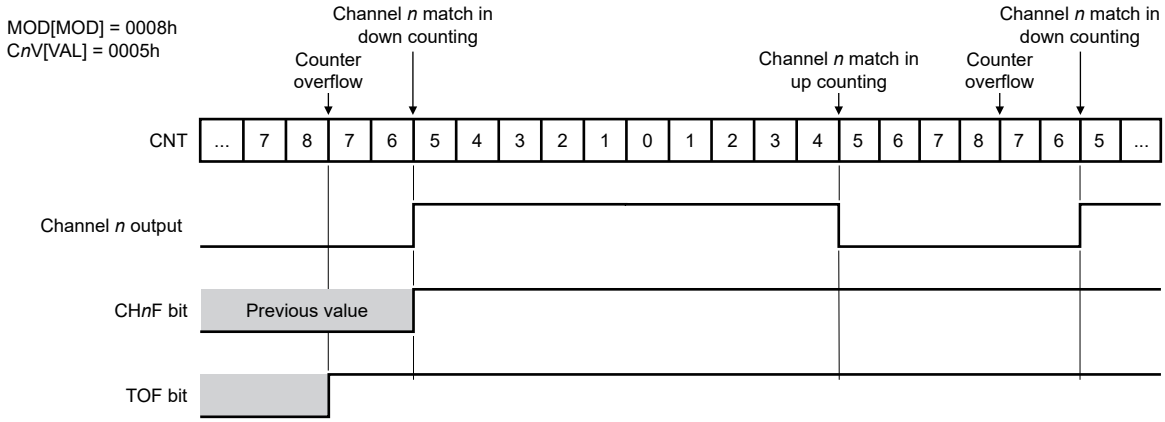

Figure 153. CPWM signal with ELS*n*B:ELS*n*A = 1:0

If (ELS*n*B:ELS*n*A = 0:1) then the channel *n* output is forced low at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced high at the channel *n* match when counting up. The channel *n* output is forced low when you first enable or reload the TPM counter, or whenever you pause it (see Figure 154).

If (ELS*n*B:ELS*n*A = 1:1) then the channel *n* output is forced low at the channel *n* match (TPM counter = C*n*V) when counting down, and it is forced high at the channel *n* match when counting up. The channel *n* output is forced high when you first enable or reload the TPM counter, or whenever you pause it.

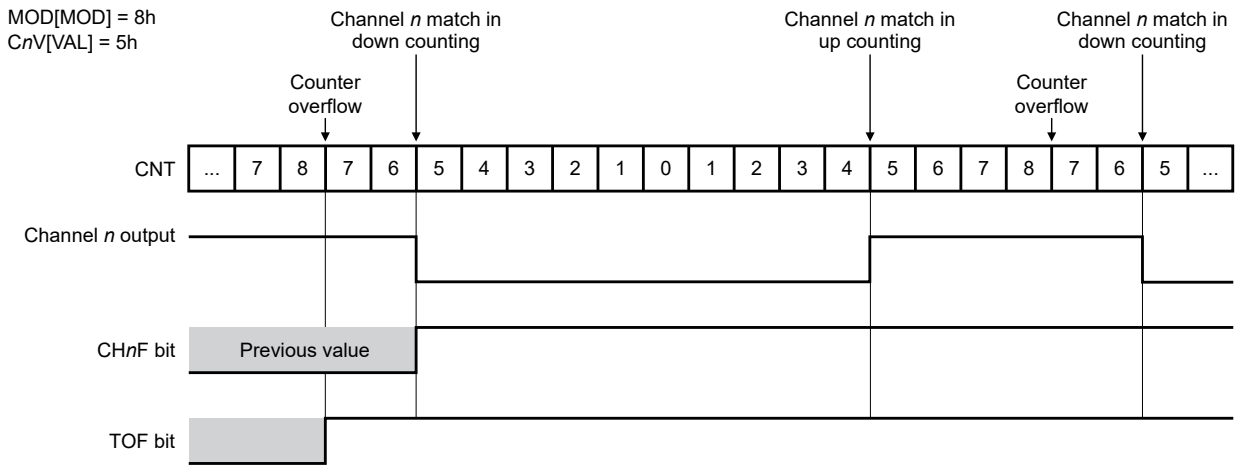

Figure 154. CPWM signal with ELS*n*B:ELS*n*A = 0:1

If (C*n*V[VAL] = 0000h) then the channel *n* output is a 0% duty cycle CPWM signal.

If (C*n*V[VAL] > MOD[MOD]) then the channel *n* output is a 100% duty cycle CPWM signal, although the CH*n*F flag is set when the counter changes from incrementing to decrementing. Therefore, MOD[MOD] must be less than 7FFFFFFF in order to get a 100% duty cycle CPWM signal.

43.3.4.5 Combine PWM mode

Combine PWM mode is enabled when:

- MS*n*B:MS*n*A = 1:0
- COMBINE[COMBINE*n*] = 1
- QDCTRL[QUADEN] = 0
- SC[CPWMS] = 0

In Combine PWM mode, an even channel *n* and adjacent odd channel *n* + 1 are combined to generate a PWM signal in the channel *n* output.

Determine the PWM period and pulse width according to Equation 4.

NOTE

Do not configure the second compare to a value that is lower than the first compare.

```
PWM period = MOD[MOD] + 0001h
PWM pulse width (duty cycle) = |C(n + 1)V[VAL] - CnV[VAL]|
```

Equation 4. PWM period and pulse width

- If (C*n*V[VAL] = C(*n* + 1)V[VAL] = 0000h), then the channel *n* output has a 0% duty cycle.
- If (C*n*V[VAL] = C(*n* + 1)V[VAL] > MOD[MOD]), then the channel *n* output has a 100% duty cycle. CH*n*F flag is not set because there is never a channel *n* match.

Therefore, MOD[MOD] must be less than FFFFh in order to get a 100% duty cycle signal.

The channel *n* match (TPM counter = C*n*V[VAL]) writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1). The channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]), sets the CH(*n* + 1)F flag and generates a channel *n* + 1 interrupt, if CH(*n* + 1)IE = 1.

If channel *n* (ELS*n*B:ELS*n*A = 0:1), then the channel *n* output is forced low at the beginning of the period (TPM counter = 0) and at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]). It is forced high at the channel *n* match (TPM counter = C*n*V[VAL]).

If channel *n* (ELS*n*B:ELS*n*A = 1:0), then the channel *n* output is forced high at the beginning of the period (TPM counter = 0) and at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]). It is forced low at the channel *n* match (TPM counter = C*n*V). See Figure 155 for pictorial representation.

When COMBINE[COMSWAP*n*] = 1, then the channel *n* output is forced low or high at the beginning of the period (TPM counter = 0) and at the channel *n* match (TPM counter = C*n*V[VAL]). It is forced high or low at the channel *n* + 1 match (TPM counter = C(*n* + 1)V[VAL]).

Channel *n* + 1 generates the same output as the channel *n* output, but the channel *n* + 1 (ELS*n*B:ELS*n*A) configuration controls the output polarity.

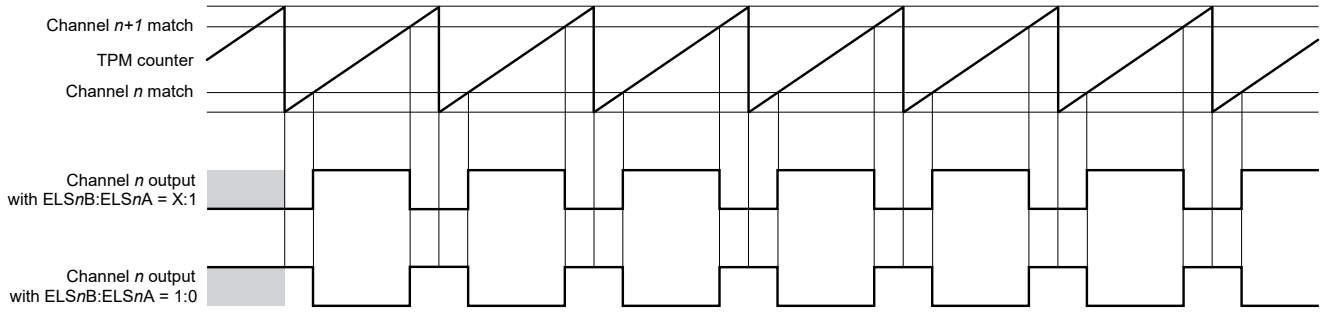

Figure 155. Combine mode

The following figures illustrate generation of PWM signals using the Combine mode.

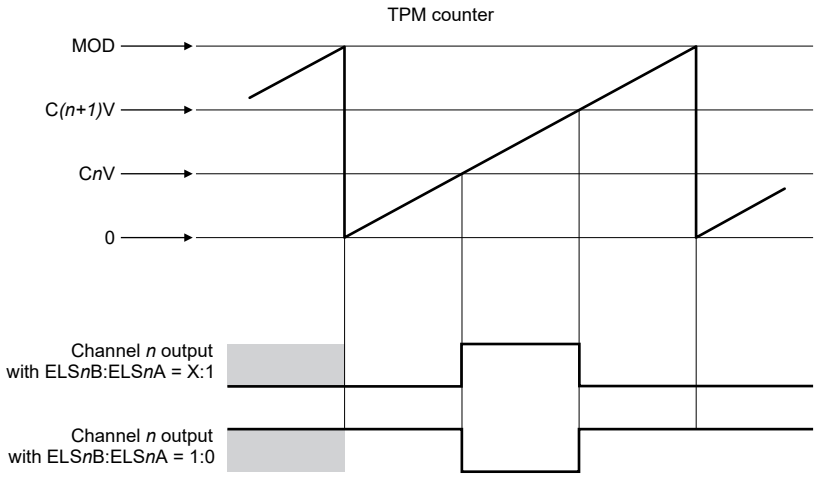

Figure 156. Channel *n* output if (C*n*V < MOD) and (C(*n* + 1)V < MOD) and (C*n*V < C(*n* + 1)V)

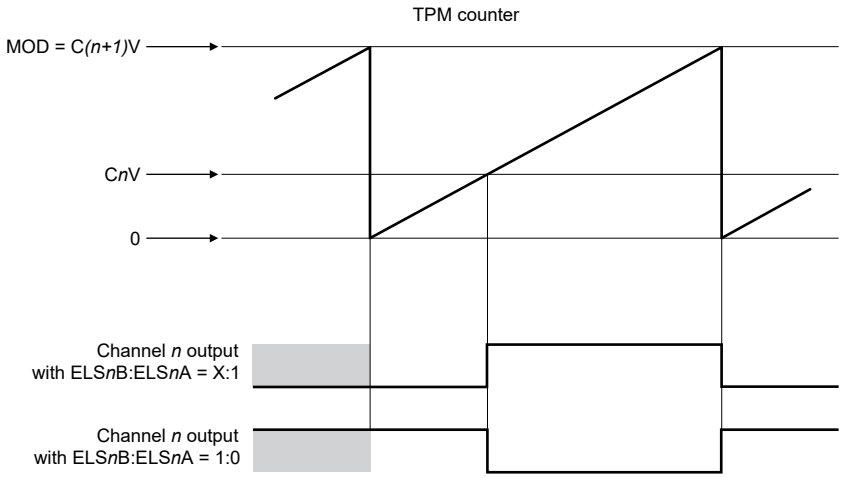

Figure 157. Channel *n* output if (C*n*V < MOD) and (C(*n* + 1)V = MOD)

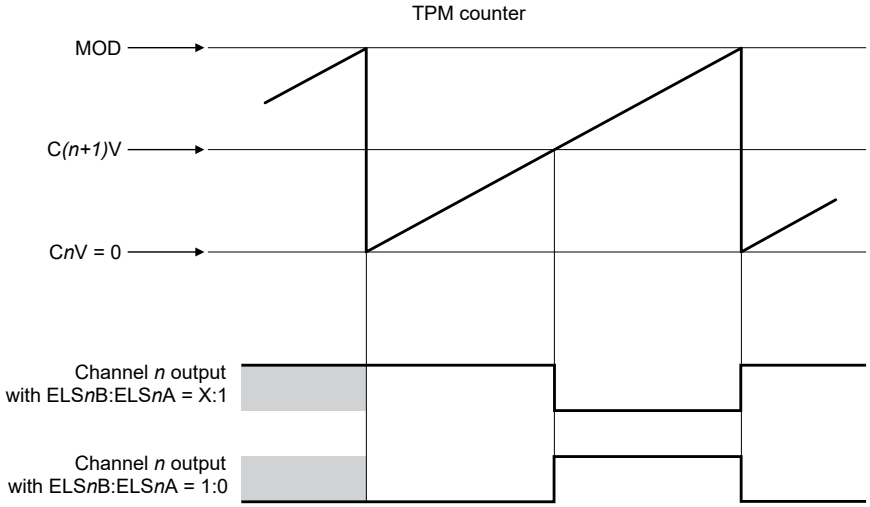

Figure 158. Channel *n* output if (C*n*V = 0) and (C(*n* + 1)V < MOD)

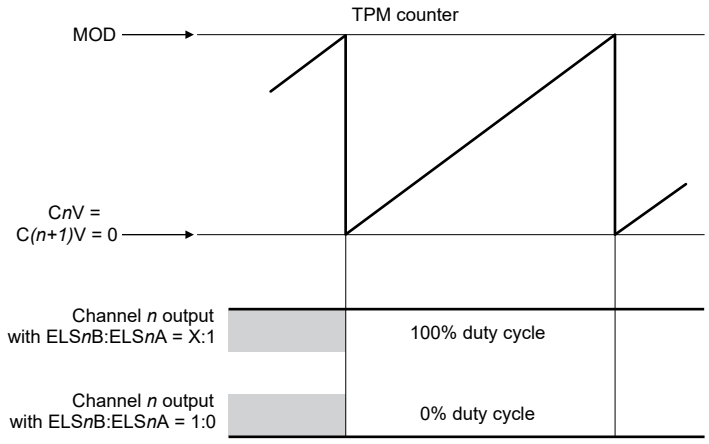

Figure 159. Channel (n) output if (C*n*V = C(*n* + 1)V = 0)

43.3.4.5.1 Dead time insertion

Dead time insertion is enabled in PWM Combine mode for each pair of channels when CH*n*FVAL and CH(*n* + 1)FVAL are non-zero. The dead time delay that is used for each TPM channel is defined as (CH(*n* + 1)FVAL[3:0] × 4) + (CH*n*FVAL[3:0] × 4).

The dead time delay insertion ensures that two complementary signals (even channel *n* and odd channel *n* + 1) do not drive the active state at the same time.

If ELS*n*B:ELS*n*A = 0:1, ELS(*n* + 1)B:ELS(*n* + 1)A = 1:0, COMBINE[COMSWAP*n*] = 0 and dead time is enabled, then:

- When a channel *n* match (TPM counter = C*n*V) occurs, the channel *n* output remains at the low value until the end of the dead time delay, when the channel *n* output is set.
- When a channel *n* + 1 match (TPM counter = C(*n* + 1)V) occurs, the channel *n* + 1 output remains at the low value until the end of the dead time delay, when the channel *n* + 1 output is set (see Figure 160).

If ELS*n*B:ELS*n*A = 1:0, ELS(*n*+1)B:ELS(*n*+1)A = 0:1, COMBINE[COMSWAP*n*] = 1, and dead time is enabled, then:

- When a channel *n* + 1 match (TPM counter = C(*n* + 1)V) occurs, the channel (*n* + 1) output remains at the low value until the end of the dead time delay, when channel *n* + 1 output is set.
- When a channel *n* match (TPM counter = C*n*V) occurs, the channel *n* output remains at the low value until the end of the dead time delay, when channel *n* output is set (see Figure 161).

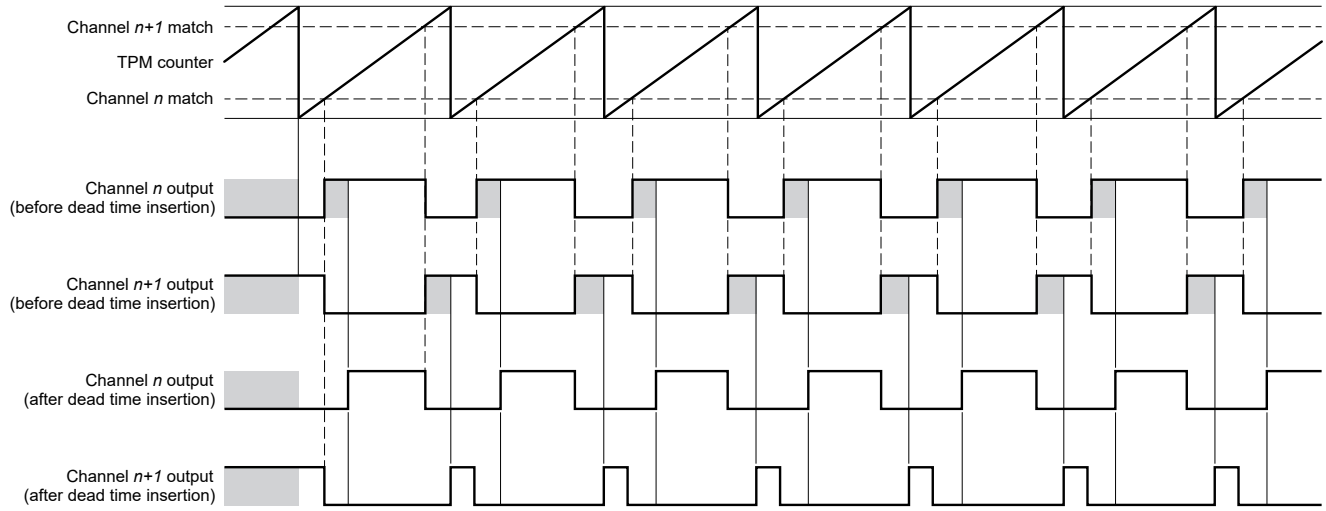

Figure 160. Dead time insertion with ELS*n*B:ELS*n*A = 0:1, ELS(*n* + 1)B:ELS(*n* + 1)A = 1:0, COMBINE[COMSWAP*n*] = 0

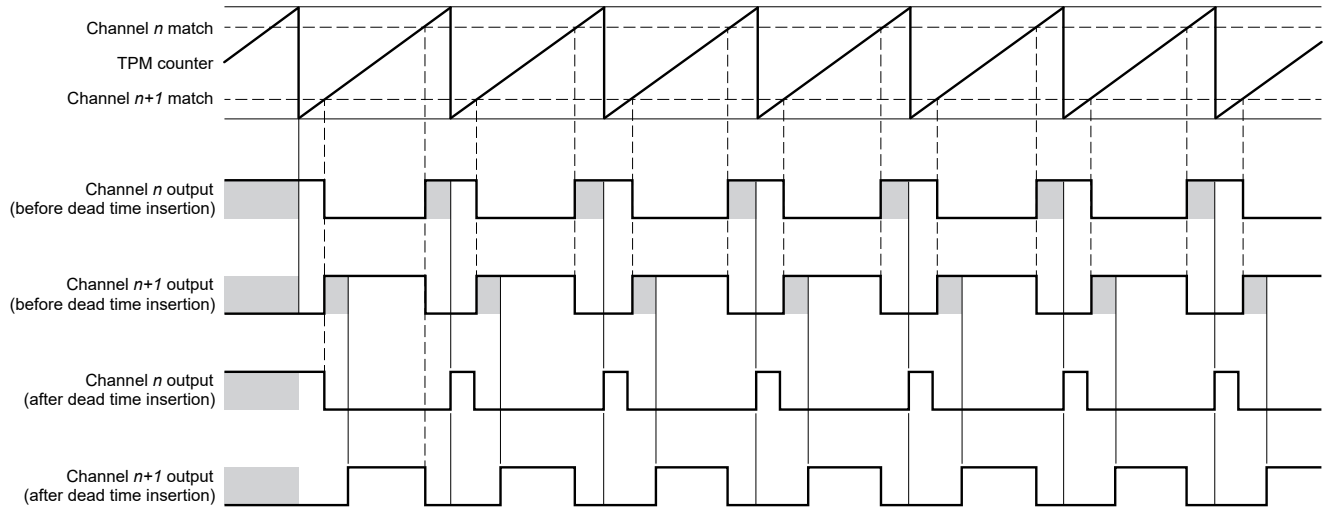

Figure 161. Dead time insertion with ELS*n*B:ELS*n*A = 1:0, ELS(*n* + 1)B:ELS(*n* + 1)A = 0:1, COMBINE[COMSWAP*n*] = 1

43.3.4.6 Combine Input Capture mode

Combine Input Capture mode is enabled if:

- (COMBINE[COMBINE*n*] = 1)
- (MS*n*B:MS*n*A = 0:0)
- (ELS*n*B:ELS*n*A ≠ 0:0)

This mode allows you to measure the pulse width of the signal at the input of channel *n* of a channel pair. The channel *n* filter can be active in this mode.

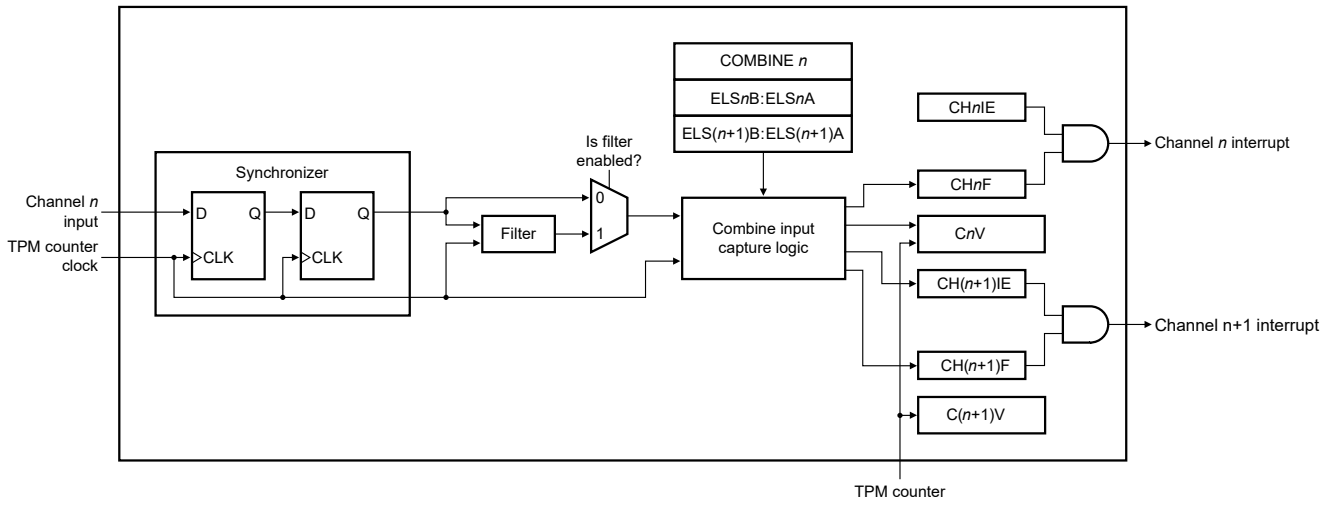

Figure 162. Block diagram

ELS*n*B:ELS*n*A fields select the edge that channel *n* captures. ELS(*n* + 1)B:ELS(*n* + 1)A fields select the edge that channel *n* + 1 captures.

This mode uses only the channel *n* input and ignores the channel *n* + 1 input. If COMBINE[COMSWAP*n*] = 1, then it uses only the channel *n* + 1 input and ignores the channel *n* input.

Detection of the edge selected by channel *n* fields at channel *n* input writes 1 to C*n*SC[CH*n*F] and generates a channel *n* interrupt (if C*n*SC[CH*n*IE] = 1). Detection of the edge selected by channel *n* + 1 fields at channel *n* input sets the CH(*n* + 1)F flag and generates the channel *n* + 1 interrupt (if CH(*n* + 1)IE = 1).

The C*n*V register stores the value of the TPM counter when the channel *n* input detects the edge selected by channel *n*. The C(*n* + 1)V register stores the value of the TPM counter when a channel *n* input detects the edge selected by channel *n* + 1.

NOTE

- Channel *n* fields are:
  - CH*n*F
  - CH*n*IE
  - MS*n*A
  - ELS*n*B
  - ELS*n*A
- Channel *n* + 1 fields are:
  - CH(*n* + 1)F
  - CH(*n* + 1)IE
  - MS(*n* + 1)A
  - ELS(*n* + 1)B
  - ELS(*n* + 1)A
- Use the Combine Input Capture mode with (ELS*n*B:ELS*n*A = 0:1 or 1:0) and (ELS(*n* + 1)B:ELS(*n* + 1)A = 0:1 or 1:0).

43.3.4.7 Quadrature Decoder mode

Quadrature Decoder mode is enabled if (QDCTRL[QUADEN] = 1). This mode uses channel 0 (phase A) and channel 1 (phase B) input signals to control the TPM counter increment and decrement (see Figure 163).

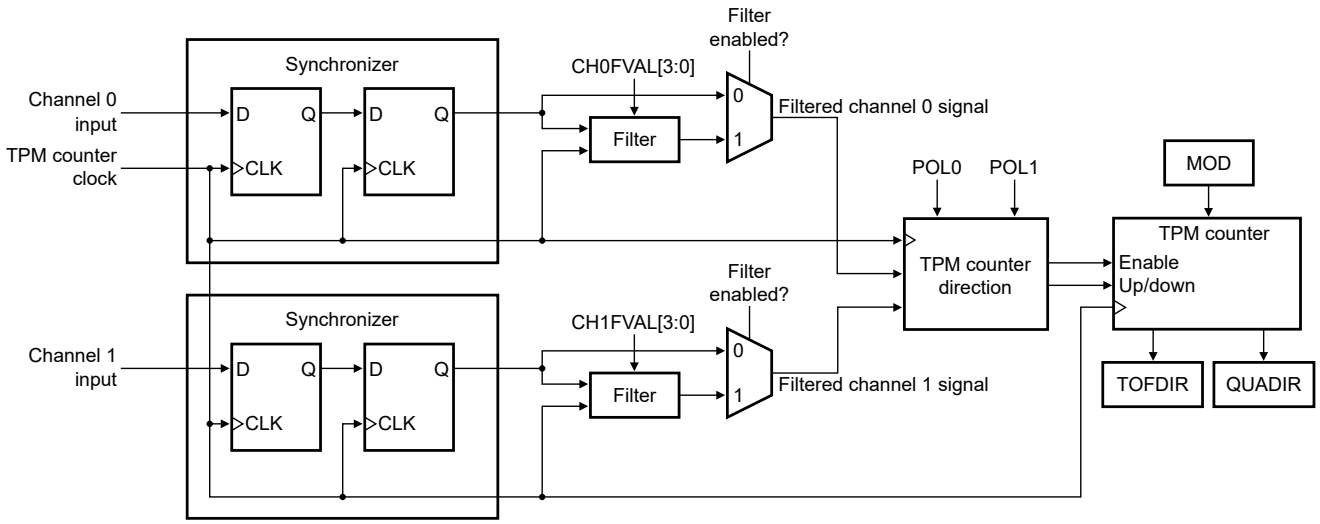

Figure 163. Block diagram

You can configure the input filter and polarity for channel 0 and channel 1 inputs in Quadrature Decode mode using Filter Control (FILTER) and Channel Polarity (POL).

NOTE

When Quadrature Decoder mode is enabled, then channel 0 and channel 1 input signals clock the TPM counter. Therefore, in this mode, you can only use Software Compare mode for channel 0 and channel 1, and you can only use Input Capture or Output Compare mode for other TPM channels.

QDCTRL[QUADMODE] defines the encoding mode that you use in Quadrature Decoder mode.

- If QDCTRL[QUADMODE] = 1, then count and direction encoding mode is enabled.
- If QDCTRL[QUADMODE] = 0, then phase encoding mode is enabled.

In count and direction encoding mode, the channel 1 input value indicates the counting direction, and the channel 0 input value defines the counting rate. A rising edge at the channel 0 input signal updates the TPM counter (see Figure 164).

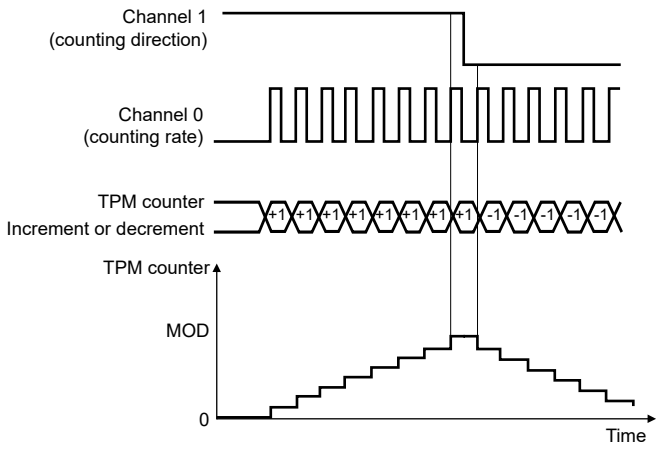

Figure 164. Quadrature Decoder—count and direction encoding mode

In phase encoding mode, the relationship between channel 0 and channel 1 signals indicates the counting direction, and channel 0 and channel 1 signals define the counting rate. An edge at either channel 0 or channel 1 signals updates the TPM counter (see Figure 165).

If POL[POL0] = 0 and POL[POL1] = 0, then:

- The TPM counter increment happens at:
  - A rising edge at channel 0 signal, and channel 1 signal is at logic 0
  - A rising edge at channel 1 signal, and channel 0 signal is at logic 1
  - A falling edge at channel 1 signal, and channel 0 signal is at logic 0
  - A falling edge at channel 0 signal, and channel 1 signal is at logic 1
- The TPM counter decrement happens at:
  - A falling edge at channel 0 signal, and channel 1 signal is at logic 0
  - A falling edge at channel 1 signal, and channel 0 signal is at logic 1
  - A rising edge at channel 1 signal, and channel 0 signal is at logic 0
  - A rising edge at channel 0 signal, and channel 1 signal is at logic 1

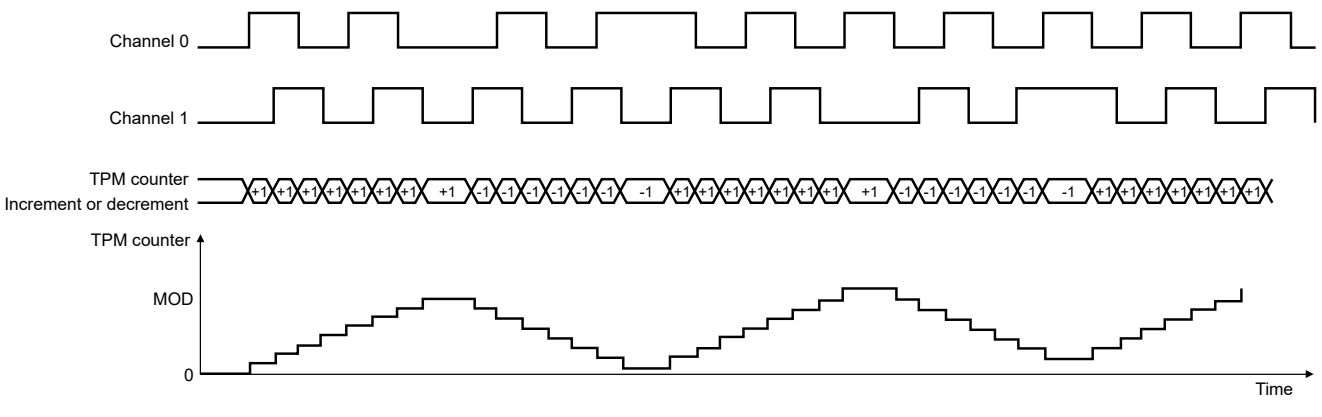

Figure 165. Quadrature Decoder—phase encoding mode

In Figure 166, when the TPM counter changes from the value defined in MOD[MOD] to 0, then SC[TOF] is 1 and QDCTRL[TOFDIR] becomes 1. SC[TOF] indicates that a TPM counter overflow has occurred. QDCTRL[TOFDIR] indicates that TPM was counting up when the TPM counter overflow occurred.

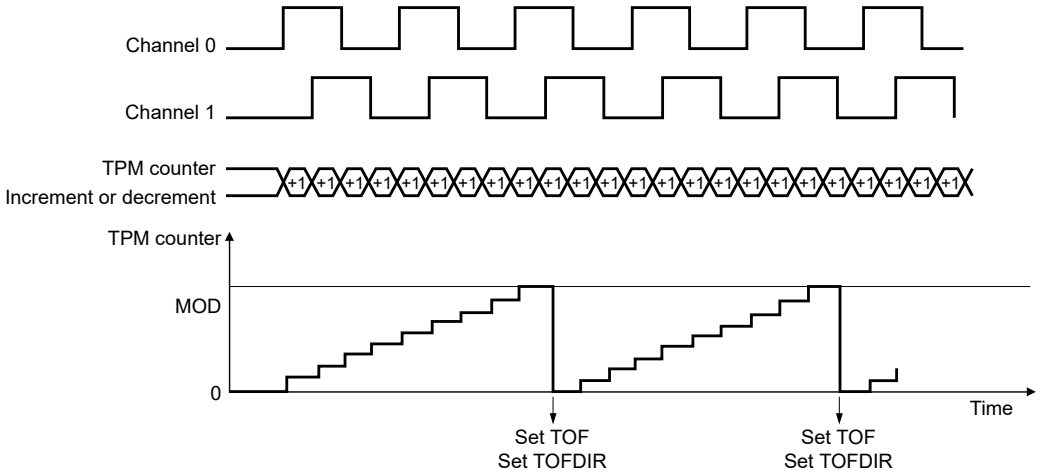

Figure 166. TPM counter overflow in up counting for Quadrature Decoder mode

In Figure 167, when the TPM counter changes from 0 to MOD[MOD], then SC[TOF] is 1 and QDCTRL[TOFDIR] becomes 0. SC[TOF] indicates that a TPM counter overflow has occurred. QDCTRL[TOFDIR] indicates that TPM was counting down when the TPM counter overflow occurred.

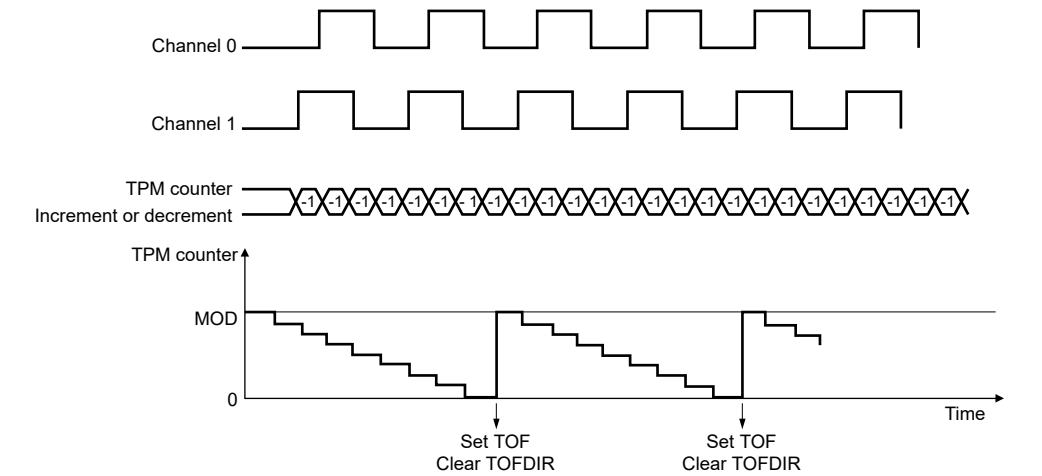

Figure 167. TPM counter overflow in down counting for Quadrature Decoder mode

43.3.5 Low-Power mode

During chip Low-Power mode, you can configure TPM to operate normally or to pause all counting.

Chip mode	TPM operation
Low-Power mode	• When CONF[DOZEEN] = 0, and TPM uses an external or internal clock source that remains functional, then counting continues. TPM can generate an asynchronous interrupt to exit the chip from Low-Power mode. • When CONF[DOZEEN] = 1, then counting pauses during Low-Power mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state.

43.3.6 Debug mode

During chip Debug mode, you can configure TPM to operate normally or to pause all counting temporarily.

Chip mode	TPM operation
Debug (core is in Debug or Halted mode)	• When CONF[DBGMODE] = 00b, then counting pauses until the core returns to normal user operating mode. Trigger inputs and input capture events are ignored, and PWM outputs are forced to their initial state. • When CONF[DBGMODE] = 11b, then counting continues.

43.3.7 Clocking

TPM supports two clock domains.

The bus clock domain is used by the register interface and for synchronizing interrupts and DMA requests.

The TPM counter clock domain clocks the counter and prescaler along with the output compare and input capture logic. The TPM counter clock is considered asynchronous to the bus clock. It can be a higher or lower frequency than the bus clock. It can optionally remain operational in low-power modes. When the global timebase feature is enabled, you must clock any TPM instance that is sharing the global timebase by the same TPM counter clock.

43.3.8 Reset

TPM resets whenever any chip reset occurs.

When TPM exits from reset:

- The TPM counter and the prescaler counter are 0 and are stopped (SC[CMOD] = 0).
- The timer overflow interrupt is 0.
- The channel interrupts are 0.
- The channels are in Input Capture mode.
- The channel outputs are 0.
- TPM does not control the channel pins (ELS*n*B:ELS*n*A = 0:0).

43.3.9 Interrupts

43.3.9.1 Timer overflow interrupt

TPM generates the timer overflow interrupt when (SC[TOIE] = 1) and (SC[TOF] = 1).

43.3.9.2 Channel *n* interrupt

TPM generates the channel *n* interrupt when (C*n*SC[CH*n*IE] = 1) and (C*n*SC[CH*n*F] = 1).

43.3.10 DMA

The channel and overflow flags generate a DMA transfer request according to SC[DMA] and C*n*SC[CH*n*IE]/SC[TOIE] fields. See the following table for more information.

Table 300. DMA transfer request

DMA	CH*n*IE/ TOIE	Channel and overflow DMA transfer request	Channel and overflow interrupt
0	0	Not generated	Not generated
0	1	Not generated	Generated if (CH*n*F/TOF = 1)
1	0	Generated if (CH*n*F/TOF = 1)	Not generated
1	1	Generated if (CH*n*F/TOF = 1)	Generated if (CH*n*F/TOF = 1)

If DMA = 1, the CH*n*F/TOF field can be cleared either by completion of the DMA transfer or by writing 1 to CH*n*F/TOF (see Table 301).

Table 301. Clear CH*n*F/TOF field

DMA	How to clear CH*n*F/TOF
0	CH*n*F/TOF field is cleared by writing 1 to it.
1	CH*n*F/TOF field is cleared either when the DMA transfer is completed or by writing 1 to it.

43.4 External signals

Table 302 shows the user-accessible signals for TPM.

Table 302. TPM signal descriptions

Signal	Description	Direction
EXTCLK	External clock If selected in SC[CMOD], EXTCLK increments the TPM counter on every rising edge synchronized to the TPM counter clock. EXTCLK must be less than half of the TPM counter clock frequency. The TPM counter prescaler selection and settings are also used when EXTCLK is selected.	I
CH*n*	Channel *n* I/O pin (where *n* = 5 to 0) You can configure each CH*n* to operate either as input or output. CH*n* is an output when configured in Output Compare or PWM mode and the TPM counter is enabled; otherwise, CH*n* is an input.	I/O

43.5 Initialization

To initialize TPM:

1. Write to the following registers, in any order, to configure the counter mode of operation:
   - Configuration (CONF)
   - Quadrature Decoder Control and Status (QDCTRL)
   - Modulo (MOD)
2. Write to the following registers, in any order, to configure the mode of operation for each channel:
   - Channel n Value (C0V - C5V)
   - Combine Channel (COMBINE)
   - Channel Trigger (TRIG)
   - Channel Polarity (POL)
   - Filter Control (FILTER)
3. Use Channel n Status and Control (C0SC - C5SC) to configure the mode of operation for each channel and to enable the channel.
4. Use Status and Control (SC) to configure the counter mode of operation and to enable the TPM (TPM is enabled and counting when SC[CMOD] ≠ 00).

43.6 Application information

To configure TPM counter to generate an overflow interrupt every 64,000 cycles:

1. Write any data to CNT to reset the counter.
2. Write MOD[MOD] = F9FFh to configure counter overflow.
3. Write SC = 48h to enable the counter and overflow interrupt.
4. Write STATUS = 100h to clear the flag during the interrupt routine.

To configure TPM channel 0 for input capture on either edge generating an interrupt:

1. Write C0SC = 4Ch to configure channel 0.
2. Optionally, write CONF = 840000h to configure counter to reset on each channel 0 input capture. Write CONF = 850000h to delay starting the counter until the first edge.
3. Write any data to CNT to reset the counter.
4. Write MOD[MOD] = FFFFFFFFh to configure the counter overflow to maximum.
5. Write SC = 48h to enable the counter and overflow interrupt.
6. During the interrupt routine, first check the setting for the STATUS flag:
   - If STATUS[TOF] is set, clear flag by writing STATUS = 100h. Note that software is responsible for tracking number of overflows between consecutive input capture events.
   - If STATUS[CH0F] is set, first read C0V to obtain the input capture value and then clear flag by writing STATUS = 0001h.

To configure TPM channel 0 for output compare to toggle the output pin using an array of counter values:

1. Write C0SC = 54h for interrupt or write C0SC = 15h for DMA.
2. Write C0V = array[0] to configure initial compare value.
3. Write any data to CNT to reset the counter.
4. Write MOD[MOD] = FFFFFFFFh to configure the counter overflow to maximum.
5. Write SC = 08h to enable the counter.
6. Write the next compare value C0V = array[N] during the interrupt routine and then write STATUS = 0001h to clear the flag.

7. Write the next compare value C0V = array[N] during the DMA transfer. DMA transfer will automatically clear the channel flag.

The array is an array of counter values where the first output compare occurs at “array[0]” cycles after the counter is enabled and subsequent output compares occur at “array[N] – array[N-1]” cycles after the last compare. If the output waveform repeats, then MOD can be set to an output compare value where the waveform starts to repeat.

An example of using TPM with the asynchronous DMA is described in AN4631:Using the Asynchronous DMA features of the Kinetis L Series.

43.7 Memory map and register definition

This section provides a detailed description of all TPM registers.

An attempt to access a reserved register location in the TPM memory map generates a bus error.

43.7.1 TPM register descriptions

43.7.1.1 TPM memory map

TPM0 base address: 4003_1000h

Fields

Field	Function
31-24 —	Reserved
23-16 WIDTH	Counter Width Specifies the width of the counter and timer channels.
15-8 TRIG	Trigger Count Specifies the number of trigger inputs that TPM implements.
7-0 CHAN	Channel Count Specifies the number of timer channels that TPM implements.

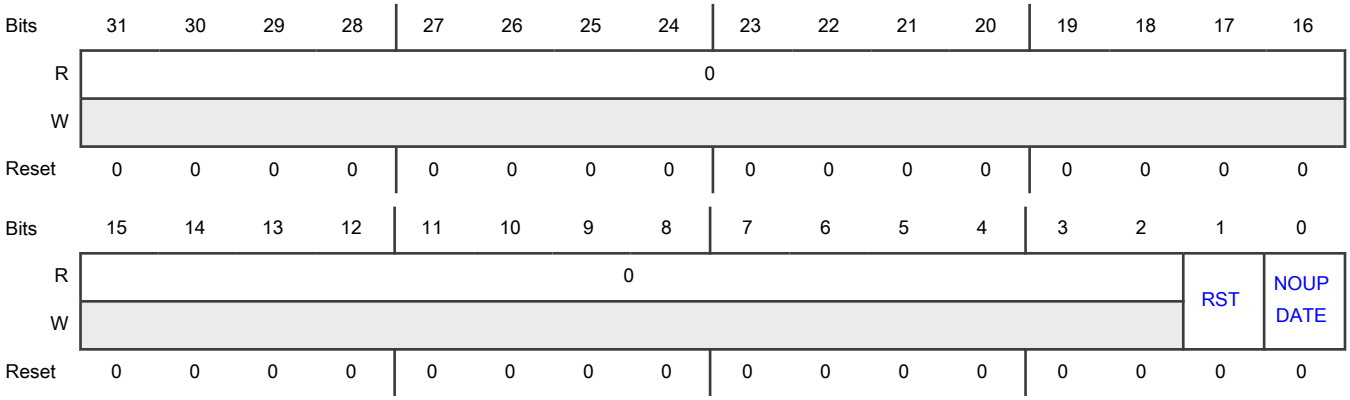
43.7.1.4 TPM Global (GLOBAL)

Offset

Register	Offset
GLOBAL	8h

Function
Includes the software reset control field.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RST	Software Reset Resets all internal logic and registers, except TPM Global (GLOBAL). This field remains 1 until you write 0 to it. 0b - Module is not reset 1b - Module is reset
0 NOUPDATE	No Update Blocks updates to all internal double-buffered registers while this field remains 1. You can still update the software visible registers, but changes cannot take effect until you write 0 to this field. At that point they update as normal. 0b - Internal double-buffered registers update as normal 1b - Internal double-buffered registers do not update

43.7.1.5 Status and Control (SC)

Offset

Register	Offset
SC	10h

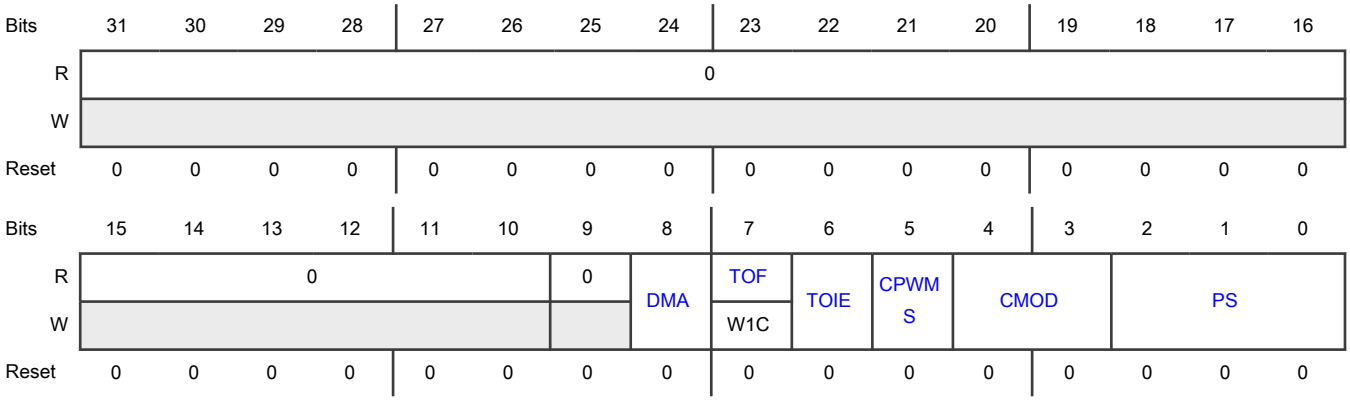
Function

Contains the overflow status flag and control fields that you can use to configure:

- Interrupt enable
- Module configuration
- Prescaler factor

These controls relate to all channels within this module.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 —	Reserved
8 DMA	DMA Enable Enables DMA transfers for the overflow flag. 0b - Disable 1b - Enable
7 TOF	Timer Overflow Flag Indicates whether a TPM overflow has occurred. Hardware sets this flag when the TPM counter value is equal to the value defined in MOD[MOD], and increments after this value. If another TPM overflow occurs between the flag setting and the flag clearing, then the write operation has no effect. Therefore, TOF remains set, which indicates that another overflow has occurred. In this case, a TOF interrupt request is not lost due to a delay in clearing the previous TOF. 0b - No overflow 1b - Overflow
6 TOIE	Timer Overflow Interrupt Enable Enables TPM overflow interrupts. A TOF interrupt is generated when SC[TOF] = 1. If TOIE = 0, use software polling or DMA request. 0b - Disable 1b - Enable
5 CPWMS	Center-Aligned PWM Select Enables CPWM mode. This mode configures TPM to operate in up-down counting mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is write-protected. Disable the TPM counter before you write to this field. 0b - Up counting mode 1b - Up-down counting mode
4-3 CMOD	Clock Mode Selection Selects the TPM counter clock modes. When disabling the counter, this field remains 1 until acknowledged in the TPM clock domain. 00b - TPM counter is disabled 01b - TPM counter increments on every TPM counter clock 10b - TPM counter increments on the rising edge of EXTCLK synchronized to the TPM counter clock 11b - TPM counter increments on the rising edge of the selected external input trigger
2-0 PS	Prescale Factor Selection Selects one of 8 division factors for the clock mode selected by SC[CMOD]. This field is write-protected. Disable the TPM counter before you write to this field. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

43.7.1.6 Counter (CNT)

Offset

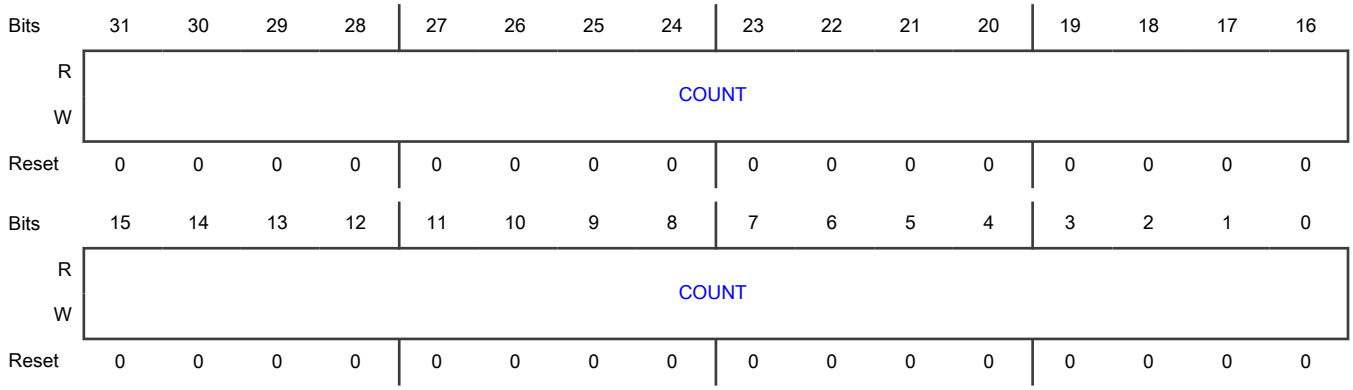
Register	Offset
CNT	14h

Function

Contains the TPM counter value. You can write 0 to this register with reset. Writing any value to CNT[COUNT] triggers a reload of the counter and forces PWM outputs to their reload state.

When debug is active, the TPM counter does not increment unless you configure it otherwise. Reading this register adds two wait states to the register access, because of synchronization delays.

Diagram



Fields

Field	Function
31-0 COUNT	Counter Value Specifies the TPM counter value.

43.7.1.7 Modulo (MOD)

Offset

Register	Offset
MOD	18h

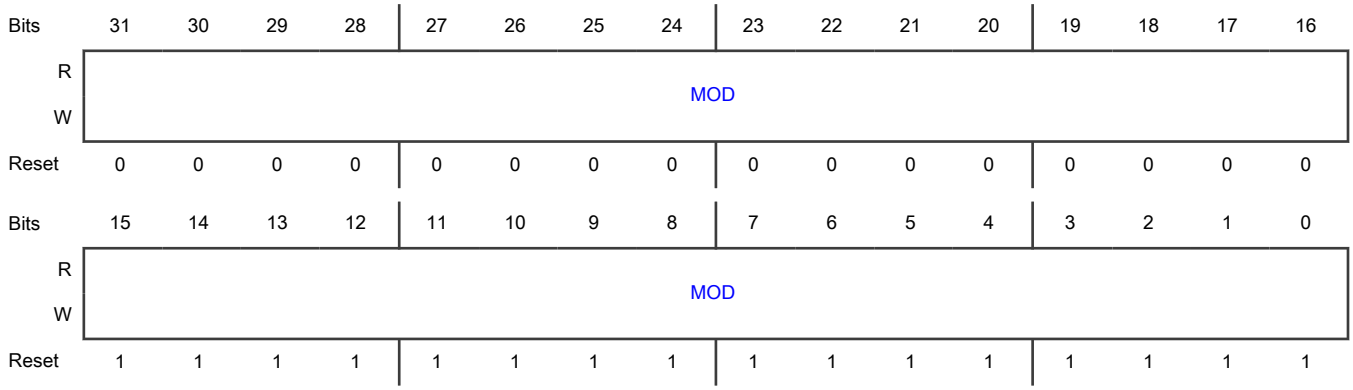
Function

Contains the modulo value for the TPM counter. When the TPM counter reaches the modulo value and increments, SC[TOF] sets and the next value of the TPM counter depends on the selected counting method (see Counter).

Writing to the MOD register latches the value into a buffer. This register updates with the value of its write buffer according to MOD register update. Additional writes to the MOD write buffer are ignored until the register has been updated.

To avoid confusion about occurrence of the first counter overflow, initialize the TPM counter (write to CNT[COUNT]) before writing to the MOD register.

Diagram



Fields

Field	Function
31-0 MOD	Modulo Value Specifies the modulo value for the TPM counter. Write a single 16-bit or 32-bit access value to this field.

43.7.1.8 Capture and Compare Status (STATUS)

Offset

Register	Offset
STATUS	1Ch

Function

Contains a copy of the status flag (C*n*SC[CHF]) for each TPM channel, as well as SC[TOF], for software convenience. Each CH*n*F field in STATUS is a mirror of the corresponding C*n*SC[CHF]. You can check all C*n*SC[CHF] fields using only one read of STATUS. Writing all ones to STATUS writes 0 to all C*n*SC[CHF] fields.

Hardware sets the individual channel flags when an event occurs on the channel. If another event occurs between the flag setting and the write operation, the write operation has no effect; therefore, CHF remains set, which indicates that another event has occurred. In this case, a CHF interrupt request is not lost because of the clearing sequence for a previous CHF.

43.7.1.10 Channel n Value (C0V - C5V)

Offset

Register	Offset
C0V	24h
C1V	2Ch
C2V	34h
C3V	3Ch
C4V	44h
C5V	4Ch

Function

Contains the captured TPM counter value for the input modes or the match value for the output modes.

Input Capture mode ignores any write to a C*n*V register. In compare modes, writing to a C*n*V register latches the value into a buffer. A C*n*V register updates with the value of its write buffer according to C*n*V register update.

NOTE

Additional writes to the C*n*V write buffer are ignored until the register has been updated.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
TPM0	C0V–C5V	—
TPM1	C0V–C5V	—
TPM2	C0V–C1V	C2V–C5V

Diagram

43.7.1.12 Channel Trigger (TRIG)

Offset

Register	Offset
TRIG	6Ch

Function

Configures the trigger input that is used by the channel to capture the counter value in Input Capture mode. In Output Compare or PWM mode, configures the trigger input used to modulate the channel output. When modulating the output, the

output is forced to the channel initial value whenever the trigger is not asserted. The even-numbered channels share the first input trigger source, and the odd-numbered channels share the second input trigger source.

Fields

Field	Function
31-26 —	Reserved
25-24 TRGSEL	Trigger Select Selects the input trigger that you use to start, reload, and pause the counter. You can configure the source of the trigger (external or internal to TPM) by CONF[TRGSRC]. Disable the TPM counter before you change this field. See the chip-specific TPM information for available external trigger options.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The below list shows available internal trigger sources. 01b - Channel 0 pin input capture 10b - Channel 1 pin input capture 11b - Channel 0 or channel 1 pin input capture
23 TRGSRC	Trigger Source Selects between internal (channel pin input capture) or external trigger sources. CONF[TRGSEL] selects this trigger source. When selecting an internal trigger, configure the selected channel for input captures as follows: • CONF[CSOT] enables you to start the counter initially using only a rising edge input capture. • CONF[CROT] enables you to reload the counter using either a rising edge or falling edge input capture. • CONF[CPOT] enables you to pause the counter using the state of the channel input pin. You can use Channel Polarity (POL) to invert the polarity of the channel input pins. Disable the TPM counter before you change this field. 0b - External 1b - Internal (channel pin input capture)
22 TRGPOL	Trigger Polarity Selects the polarity of the external trigger source. Disable the TPM counter before you change this field. 0b - Active high 1b - Active low
21-20 —	Reserved
19 CPOT	Counter Pause on Trigger Specifies that while the trigger remains asserted (level sensitive), and this field is 1, the counter pauses incrementing. While being paused, the counter ignores the input capture events and forces PWM outputs to their default state. If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field. 0b - TPM counter continues 1b - TPM counter pauses
18 CROT	Counter Reload on Trigger Specifies that when you detect a rising edge on the selected trigger input and this field is 1, then the TPM counter reloads with 0 (and sets PWM outputs to their reload state). If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No reload 1b - Reload
17 CSOO	Counter Stop on Overflow Specifies that the TPM counter pauses when SC[TOF] = 1 and this field is 1. Reloading the counter with 0 by writing to Counter (CNT), or by a trigger input, does not cause the counter to stop incrementing. When stopped, the counter does not start incrementing unless you first disable and then enable it, or if you detect a rising edge on the selected trigger input when CONF[CSOT] is 1. While the counter is paused, it ignores the input capture events and forces PWM outputs to their default state. Disable the TPM counter before you change this field. 0b - TPM counter continues 1b - TPM counter stops
16 CSOT	Counter Start on Trigger Specifies that until you detect a rising edge on the selected trigger input, and this field is 1, the TPM counter pauses incrementing when it is enabled. If the TPM counter pauses due to an overflow, a rising edge on the selected trigger input also causes the TPM counter to start incrementing again. While being paused, the counter ignores the input capture events, and forces PWM outputs to their default state. If the TPM counter pauses during Debug mode or Low-Power mode, then the counter ignores the trigger input. Disable the TPM counter before you change this field. 0b - Counter starts immediately 1b - Counter starts after detection of a rising edge on the selected input trigger
15-10 —	Reserved
9 GTBEEN	GTB Enable Configures TPM to use an externally generated GTB counter. When you use an externally generated timebase, the channels do not use the internal TPM counter, but you can use the internal TPM counter to generate a periodic interrupt or DMA request using Modulo (MOD) and SC[TOF]. 0b - Internally generated TPM counter 1b - Externally generated GTB counter
8 GTBSYNC	GTB Synchronization Enables the TPM counter to synchronize with GTB. It uses the GTB enable, trigger, paused state and overflow to ensure that the TPM counter starts incrementing, stops incrementing, and resets at the same time as GTB. Disable the TPM counter before you change this field. 0b - Disable 1b - Enable
7-6	Debug Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
DBGMODE	Configures the TPM behavior in Debug mode (see Debug mode). All other configurations are reserved. 00b - TPM counter pauses 11b - TPM counter continues
5 DOZEEN	Doze Enable Configures the TPM behavior in Low-Power mode (see Low-Power mode). 0b - TPM counter continues 1b - TPM counter pauses
4-0 —	Reserved

Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

44.1.1 Module instances

This device has two instances of the LPI2C module, LPI2C0, and LPI2C1.

44.1.2 Host request configuration

Both of the LPI2C0 and LPI2C1 support host request feature.

The input trigger that can be used as host request input is from TRGMUX, refer to Trigger multiplexer (TRGMUX) for more details.

44.2 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, Ultra Fast, and High-Speed (HS) modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses
- Continues operating in Sleep modes if an appropriate clock is available

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit (I^2C) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I^2C-bus specification, Rev. 7.0, as shown in Table 305.

Table 305. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

44.2.1 Block diagram

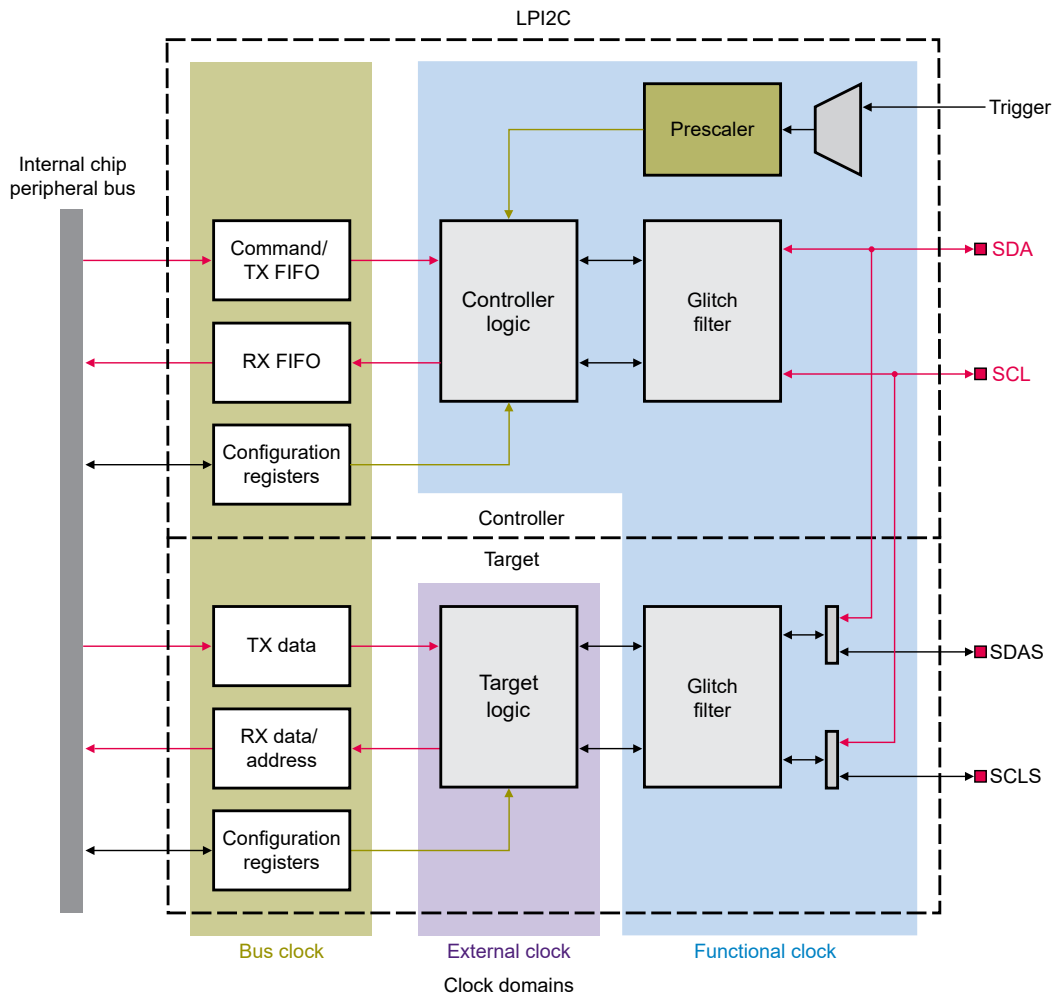

Figure 168. Block diagram

44.2.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes
- HS mode in target mode and controller mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).
- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 4 words (8-bit transmit data + 3-bit command)

- Receive FIFO of 4 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

44.3 Functional description

44.3.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

44.3.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.
- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

44.3.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. It also relaxes some restrictions on the order of FIFO commands. For example, it allows a Stop command when it is idle to generate a Start condition, followed by one SCL clock pulse, and then a Stop condition.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

The LPI2C controller aborts the existing transfer when MCFGR0[ABORT] becomes 1. This action causes the LPI2C controller to complete the existing word and then transmit a Stop condition. If the receive FIFO is full when the receive operation is aborted, the last received data is discarded. A new transfer does not start while MCFGR0[ABORT] is 1.

44.3.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last (repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

44.3.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 306. You must configure these parameters to meet the I2C timing specification for the required mode.

Table 306. Timing parameters

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE)
Hold time (repeated) Start condition	tHD:STA	(SETHOLD +1) × (2 ^ PRESCALE)
Low period of the SCL clock	tLOW	(CLKLO + 1) × (2 ^ PRESCALE)
High period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Setup time for a repeated Start condition or Stop condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Data hold time	tHD:DAT	(DATAVD + 1) × (2 ^ PRESCALE)
Data setup time	tSU:DAT	(SDA_LATENCY + 1) × (2 ^ PRESCALE)
Bus free time between a Stop and Start condition	tBUF	(CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE)
Data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) × (2 ^ PRESCALE)

Table 307 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 307. Synchronization latency

Timing parameter	Timing definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

Table 308. LPI2C timing parameter restrictions

Timing parameter	Minimum	Maximum	Comment
CLKLO	03h	—	CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	—	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	—	SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY

Table continues on the next page...

Table 308. LPI2C timing parameter restrictions (continued)

Timing parameter	Minimum	Maximum	Comment
DATAVD	01h	CLKLO – SDA_LATENCY – 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO × (2 ^ PRESCALE)] – 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO × (2 ^ PRESCALE)] – 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO + SETHOLD + 2) × 2	—	Must also be greater than (CLKHI + 1)

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

44.3.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1). LPI2C controller stops driving SDA immediately, but continues to drive SCL for the remainder of the byte.
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1). This restriction is ignored when MCFGR0[RELAX] is 1.
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR0[RELAX] to attempt to recover a target with SDA stuck low. If MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. Initiating a Start command with address FFh, then the Stop condition, should generate sufficient SCL clock edges to cause the target to release SDA.

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

44.3.1.6 Pin configuration

Configuration	Description
Open-drain support	The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
HS mode support	Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification.
Ultra-Fast mode support	The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1.
Push-pull two-wire support	A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the first clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration.
Push-pull four-wire support	The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses.

44.3.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

44.3.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.
- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

When SCFGR1[RXALL] is 1, the LPI2C target receives all addresses and data on the I2C bus. Unless the address is matched, it never drives the SDA pin. Configure the LPI2C target to match only on 7-bit address mode when this feature is enabled. Software can support 10-bit address mode. This option is intended for debugging the contents of an I2C transfer between another controller

and target. Likewise, SCFGR1[SDCFG] and SCFGR1[RSCFG] configure the Stop or repeated Start flags to assert on all Stop or repeated Start conditions, even when there is no address match.

44.3.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

44.3.2.3 Read request

The LPI2C target generates a read request when the I2C bus is idle and you write 1 to SCFGR0[RDREQ]. This occurrence causes the LPI2C target to pull the SDA pin low until either the first SCL falling edge or SCFGR0[RDREQ] becomes 0. Following the next Stop condition or a software timeout, you can proceed as follows:

- If the LPI2C target is accessed at the correct address, the read request is acknowledged, and you must write 0 to SCFGR0[RDREQ].
- If SCFGR0[RDACK] is 1, the read request is acknowledged by a Start followed by one SCL pulse followed by a STOP condition. You must write 0 to SCFGR0[RDREQ].
- If neither of the first two cases occurred, the read request is not acknowledged. You must write 0 and then 1 to SCFGR0[RDREQ] after an appropriate delay, provided the I2C bus is idle.
- If a software timeout occurs, the read request is not acknowledged, and you should write 0 to SCFGR0[RDREQ]. Another request can be generated after an appropriate delay.

Writing to SCFGR0[RDREQ] when the I2C bus is busy results in a logic 0 being written. Write 1 to SCFGR0[RDREQ], then confirm that the register is written to correctly. If the register does not update correctly, the I2C bus is no longer idle and the read request must be attempted later.

44.3.2.4 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.
- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

44.3.2.5 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

44.3.2.6 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on a receive data overrun.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on an address overrun regardless of the value of SCFGR1[RXCFG].

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

44.3.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

NOTE

See the chip-specific information for low-power modes available on your chip.

44.3.4 Debug mode

Table 309. Debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in Debug mode.

44.3.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

Table 310. LPI2C triggers

Trigger	Description
Controller output trigger	Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target output trigger	Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input trigger	Controls the start of a LPI2C bus transfer. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE].

44.3.6 Clocking

Table 311. LPI2C clocks

Clock	Description
LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time.
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For chip-specific clocking information, see the Clocking chapter.

44.3.7 Reset

Table 312. LPI2C resets

Reset	Description
Chip reset	The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset.
Software reset	The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself. The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself.

Table continues on the next page...

Table 312. LPI2C resets (continued)

Reset	Description
FIFO reset	The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

44.3.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

44.3.8.1 Controller mode

Table 313 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 313. Controller interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (MSR[TDF])	Data can be written to transmit FIFO, as configured by MFCR[TXWATER].	Y	TX	Y
Receive Data Flag (MSR[RDF])	Data can be read from the receive FIFO, as configured by MFCR[RXWATER].	Y	RX	Y
End Packet Flag (MSR[EPF])	Controller has transmitted a repeated Start or Stop condition.	Y	N	Y
Stop Detect Flag (MSR[SDF])	Controller has transmitted a Stop condition (and the LPI2C controller is idle, if MCFGR1[STOPCFG] = 1) .	Y	N	Y
NACK Detect Flag (MSR[NDF])	During an address byte, the controller expects an ACK but detects a NACK. During an address byte, the controller expects a NACK but detects an ACK. During a controller-transmitter data byte, the controller detects a NACK.	Y	N	Y
Arbitration Lost Flag (MSR[ALF])	The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y

Table continues on the next page...

Table 313. Controller interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
FIFO Error Flag (MSR[FEF])	The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition.	Y	N	Y
Pin Low Timeout Flag (MSR[PLTF])	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
Data Match Flag (MSR[DMF])	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
Start Detect Flag (MSR[STF])	A Start condition is detected on the I2C bus (and the LPI2C controller is idle, if MCFGR1[STARTCFG] = 1).	Y	N	Y
Controller Busy Flag (MSR[MBF])	LPI2C controller is busy transmitting or receiving data.	N	N	N
Bus Busy Flag (MSR[BBF])	LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

44.3.8.2 Target mode

Table 314 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 314. Target interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (SSR[TDF])	Data can be written to Target Transmit Data (STDR).	Y	TX	Y
Receive Data Flag (SSR[RDF])	Data can be read from Target Receive Data (SRDR).	Y	RX	Y
Address Valid Flag (SSR[AVF])	Address can be read from Target Address Status (SASR).	Y	RX	Y
Transmit ACK Flag (SSR[TAF])	ACK or NACK can be written to Target Transmit ACK (STAR).	Y	N	Y
Repeated Start Flag (SSR[RSF])	Target has detected an address match followed by a repeated Start condition.	Y	RX	Y
Stop Detect Flag (SSR[SDF])	Target has detected an address match followed by a Stop condition.	Y	RX	Y

Table continues on the next page...

Table 314. Target interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Bit Error Flag (SSR[BEF])	Target was transmitting data, but received data is different from what was transmitted.	Y	N	Y
FIFO Error Flag (SSR[FEF])	This flag is set by: • Transmit data underrun • Receive data overrun • Address status overrun when SCFGR1[RXCFG] = 1 This flag can only be set when clock stretching is disabled.	Y	N	Y
Address Match 0 Flag (SSR[AM0F])	Target detected an address match SAMR[ADDR0].	Y	N	N
Address Match 1 Flag (SSR[AM1F])	Target detected an address match with SAMR[ADDR1] or using an address range.	Y	N	N
General Call Flag (SSR[GCF])	Target detected an address match with the general call address.	Y	N	N
SMBus Alert Response Flag (SSR[SARF])	Target detected an address match with the SMBus alert address.	Y	N	N
Target Busy Flag (SSR[SBF])	LPI2C target is busy receiving an address byte or is transmitting or receiving data.	N	N	N
Bus Busy Flag (SSR[BBF])	LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected.	N	N	N

44.3.8.3 End-of-packet DMA transfer

End-of-packet functionality serves serial interfaces where the transfer size may not be known in advance and the data is pushed by an external device. Examples include UART receive, I2C Target mode, and SPI Target mode. End-of-packet processing is intended to ensure that data does not become stranded in either the receive FIFO or DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet differs for each serial interface but is processed by the serial peripheral and DMA in the same way. For example:

- UART end of packet is signaled by an idle line condition.
- I2C end of packet is signaled by Stop or repeated Start condition.
- SPI end of packet is signaled by PCS negation.

When the serial peripheral is configured to signal an end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO regardless of the watermark configuration. For larger watermark configurations, this behavior ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.

- If the receive FIFO is not empty, but the first word in the FIFO starts a new packet, data is not pulled from the receive FIFO. Also, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO does not start a new packet, the DMA transfers data as normal.

Because the DMA may transfer multiple words per request, the end-of-packet condition persists until the DMA minor loop finishes and no additional data is pulled from the FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes after the end of packet is signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into system memory. It also saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. The final destination address can be saved to system memory or is available in the destination address register.

Because the DMA terminates the major loop, the receive FIFO is not serviced until the DMA is reconfigured. You can perform this reconfiguration through software or hardware (for example, channel linking or scatter-gather). Minimize this delay to avoid receiver FIFO overrun. Automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. In this case, the DMA spends more time processing the end of packet than transferring the data. For example, to avoid an excessive number of idle conditions, increase the UART idle line length as needed.

44.4 External signals

Table 315. External signals

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
SCL	LPI2C clock line	SCL	In Four-Wire mode, this pin is the SCL input pin.	Input or output
SDA	LPI2C data line	SDA	In Four-Wire mode, this pin is the SDA input pin.	Input or output
SCLS	Secondary I2C clock line	Not used	In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	Input or output
SDAS	Secondary I2C data line	Not used	In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SDA pin.	Input or output

Figure 169 shows the two-signal connection.

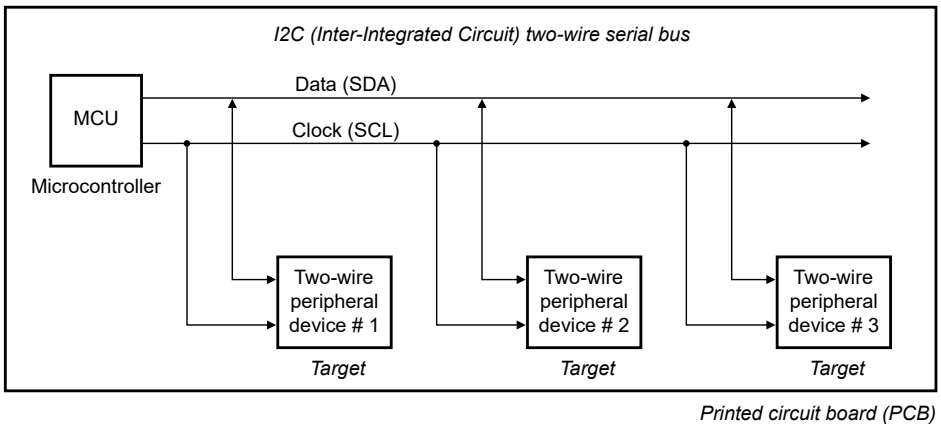

Figure 169. I²C two-wire serial bus

Figure 170 shows a possible four-signal connection.

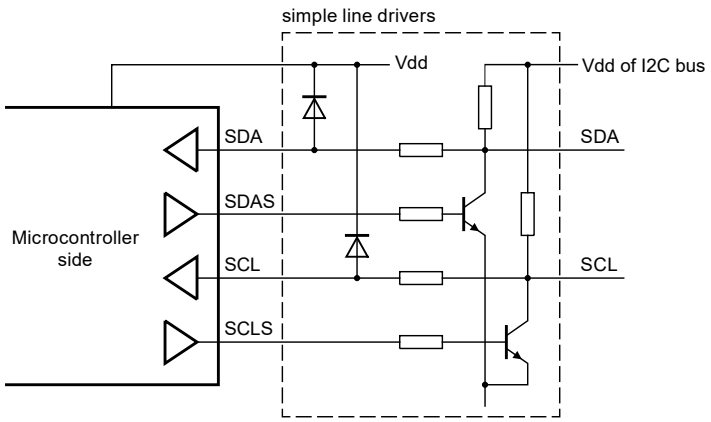

Figure 170. I²C four-wire serial bus

44.5 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.
2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.
4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 0 (SCFGR0) and Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

44.6 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 316. Example timing configurations

I2C mode	Clock frequency	Baud rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Standard	8 MHz	100 kbit/s	0h	0h/0h	24h	28h	24h	02h
Standard	48 MHz	100 kbit/s	2h	1h/1h	37h	3Fh	37h	03h
Standard	60 MHz	100 kbit/s	2h	1h/1h	45h	50h	44h	04h
Fast	8 MHz	400 kbit/s	0h	0h/0h	04h	0Bh	05h	02h
Fast+	8 MHz	1 Mbit/s	0h	0h/0h	02h	03h	01h	01h
Fast	48 MHz	400 kbit/s	0h	1h/1h	1Dh	3Eh	35h	0Fh
Fast	48 MHz	400 kbit/s	2h	1h/1h	07h	11h	0Bh	03h
Fast+	48 MHz	1 Mbit/s	2h	1h/1h	03h	06h	04h	04h
HS	48 MHz	3.2 Mbit/s	0h	0h/0h	07h	08h	03h	01h
Fast	60 MHz	400 kbit/s	1h	2h/2h	11h	28h	1Fh	08h
Fast+	60 MHz	1 Mbit/s	1h	2h/2h	07h	0Fh	0Bh	01h
HS	60 MHz	3.33 Mbit/s	1h	0h/0h	04h	04h	02h	01h

44.7 Memory map and registers

44.7.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

44.7.1.1 LPI2C memory map

LPI2C0 base address: 4003_3000h

LPI2C1 base address: 4003_4000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0103_0003h
4h	Parameter (PARAM)	32	R	0000_0202h

Fields

Field	Function
31-16 —	Reserved
15-12 —	Reserved
11-8 MRXFIFO	Controller Receive FIFO Size Configures the number of words in the controller receive FIFO to $2^{MRXFIFO}$.
7-4 —	Reserved
3-0 MTXFIFO	Controller Transmit FIFO Size Configures the number of words in the controller transmit FIFO to $2^{MTXFIFO}$.

44.7.1.4 Controller Control (MCR)

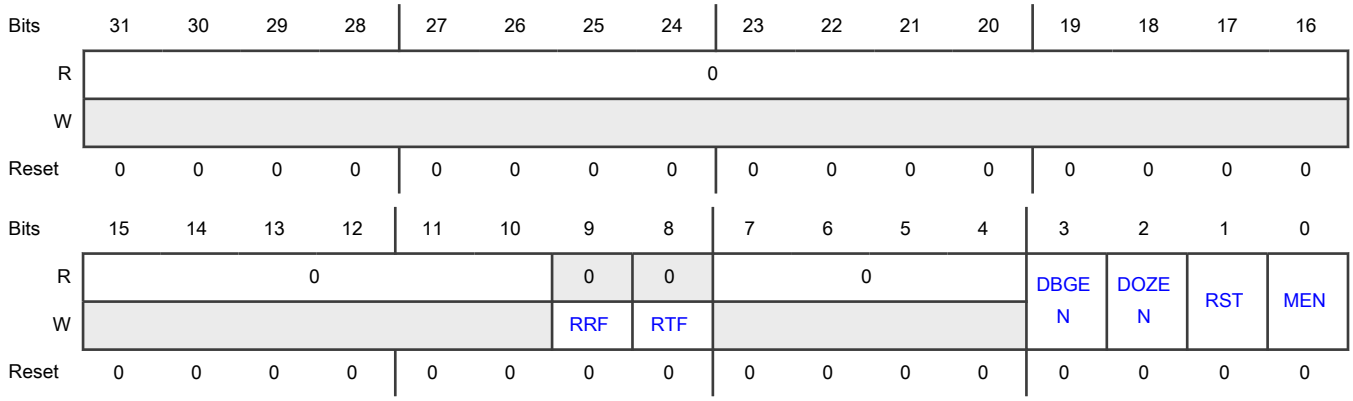
Offset

Register	Offset
MCR	10h

Function

Contains resets, debug enable, and other controller control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the receive FIFO in Controller Receive Data (MRDR). 0b - No effect 1b - Reset receive FIFO
8 RTF	Reset Transmit FIFO Resets the transmit FIFO in Controller Transmit Data (MTDR). 0b - No effect 1b - Reset transmit FIFO
7-4 —	Reserved
3 DBGEN	Debug Enable Enables the controller in Debug mode. 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables the controller in Doze mode. 0b - Enable 1b - Disable
1	Software Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
RST	Resets all internal controller logic and registers except Controller Control (MCR). This field remains 1 (enabled) until you write 0 to it. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - No effect 1b - Reset
0 MEN	Controller Enable Enables the controller logic. 0b - Disable 1b - Enable

44.7.1.5 Controller Status (MSR)

Offset

Register	Offset
MSR	14h

Function

Contains status flags for transmit and receive data, for start and stop conditions, and for bus and controller busy or idle status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 BBF	Bus Busy Flag Specifies whether the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Specifies whether the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 STF	Start Flag Specifies whether a Start condition is detected on the bus when the bus is idle. When MCFGR1[STARTCFG] is 0, this field becomes 1 only if the LPI2C controller is also idle. When MCFGR1[STARTCFG] is 1, STF becomes 1 for any Start condition when the I2C bus is idle. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Start condition not detected 1b - Start condition detected When writing 0b - No effect 1b - Clear the flag
14 DMF	Data Match Flag Indicates whether the received data matches MDMR[MATCH0] or MDMR[MATCH1] (as configured by MCFGR1[MATCFG]). Received data discarded due to MTDR[CMD] does not cause this flag to set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Matching data not received 1b - Matching data received When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 PLTF	Pin Low Timeout Flag Indicates whether pin low timeout has occurred. Sets when the SCL or SDA input is low for more than the number of PINLOW cycles defined by MCFGR3[PINLOW], even when the LPI2C controller is idle. You must resolve the pin low condition via software. PLTF cannot be cleared as long as the pin low timeout continues. Before LPI2C can initiate a Start condition, you must clear this flag. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Pin low timeout did not occur 1b - Pin low timeout occurred When writing 0b - No effect 1b - Clear the flag
12 FEF	FIFO Error Flag Detects the LPI2C controller's attempt to send or receive data without first generating a (repeated) Start condition. This error can occur when the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When this flag is set, the LPI2C controller sends a Stop condition (if busy). The controller does not initiate a new Start condition until the flag is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
11 ALF	Arbitration Lost Flag Indicates whether arbitration is lost. Either of these conditions sets this flag: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus. • The LPI2C controller detects a Start or Stop condition when the LPI2C controller is transmitting data. When ALF is set, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new Start condition until the ALF is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Controller did not lose arbitration 1b - Controller lost arbitration When writing 0b - No effect 1b - Clear the flag
10 NDF	NACK Detect Flag Indicates whether an unexpected NACK has been detected. This flag is set when the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When set, the controller does not initiate a new Start condition until this flag is cleared. If a NACK is expected for a given address (as configured by the command word), this flag is set if a NACK is not generated. When this flag is set, the LPI2C controller automatically transmits a Stop condition if MCFGR1[AUTOSTOP] = 1, or if the transmit FIFO is not empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unexpected NACK detected 1b - Unexpected NACK detected When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C controller has generated a Stop condition. When MCFGR1[STOPCFG] = 0, this flag is set for any Stop condition. When MCFGR1[STOPCFG] = 1, this flag is set only when the LPI2C controller is also idle (transmit FIFO is empty). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop condition generated 1b - Stop condition generated When writing 0b - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clear the flag
8 EPF	End Packet Flag Indicates whether the LPI2C controller has generated a repeated Start condition or a Stop condition. When the controller first generates a Start condition, this flag is not set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop or repeated Start generated 1b - Stop or repeated Start generated When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the receive data is ready. This flag is set when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether transmit data is requested. This flag is set when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

44.7.1.6 Controller Interrupt Enable (MIER)

Offset

Register	Offset
MIER	18h

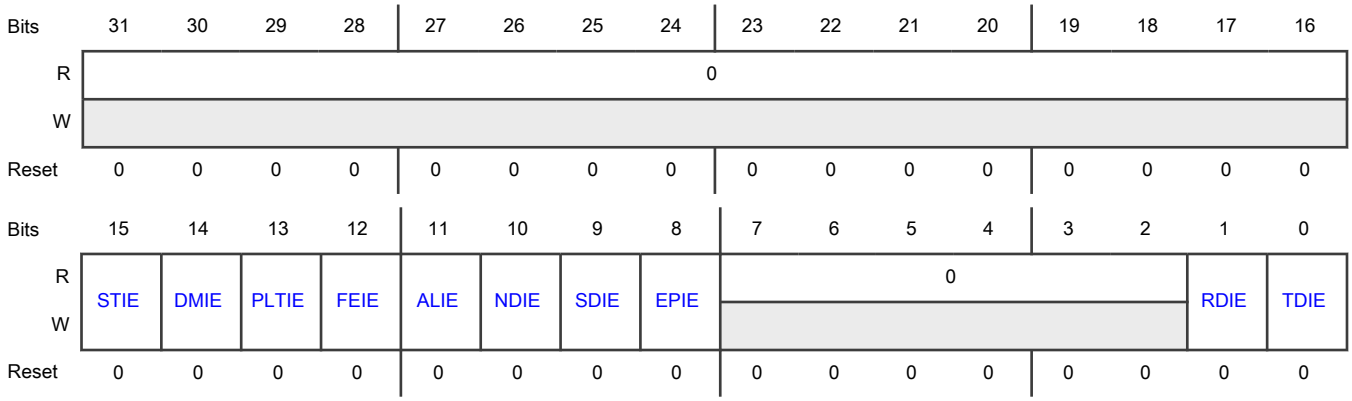
Function

Contains enables for:

- Transmit and receive data interrupts

- Start, Stop, and NACK detection interrupts
- DMA interrupts

Diagram



Fields

Field	Function
31-16 —	Reserved
15 STIE	Start Interrupt Enable Enables interrupt for Start condition. 0b - Disable 1b - Enable
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match. 0b - Disable 1b - Enable
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin-low timeout. 0b - Disable 1b - Enable
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable
11	Arbitration Lost Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ALIE	Enables interrupt for arbitration lost. 0b - Disable 1b - Enable
10 NDIE	NACK Detect Interrupt Enable Enables interrupt for NACK detection. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

44.7.1.7 Controller DMA Enable (MDER)

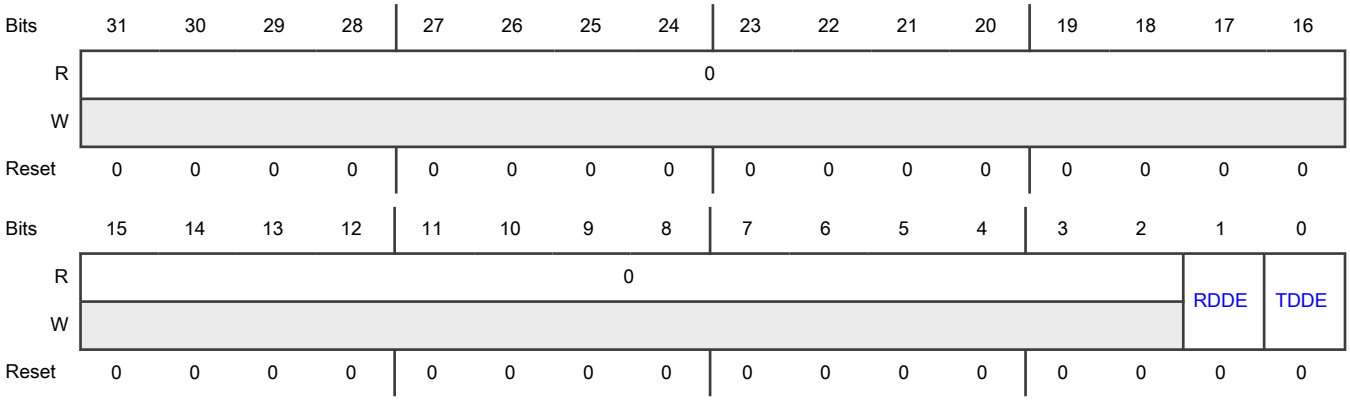
Offset

Register	Offset
MDER	1Ch

Function

Contains DMA transmit, request, and receive enables.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data. 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0b - Disable 1b - Enable

44.7.1.8 Controller Configuration 0 (MCFGR0)

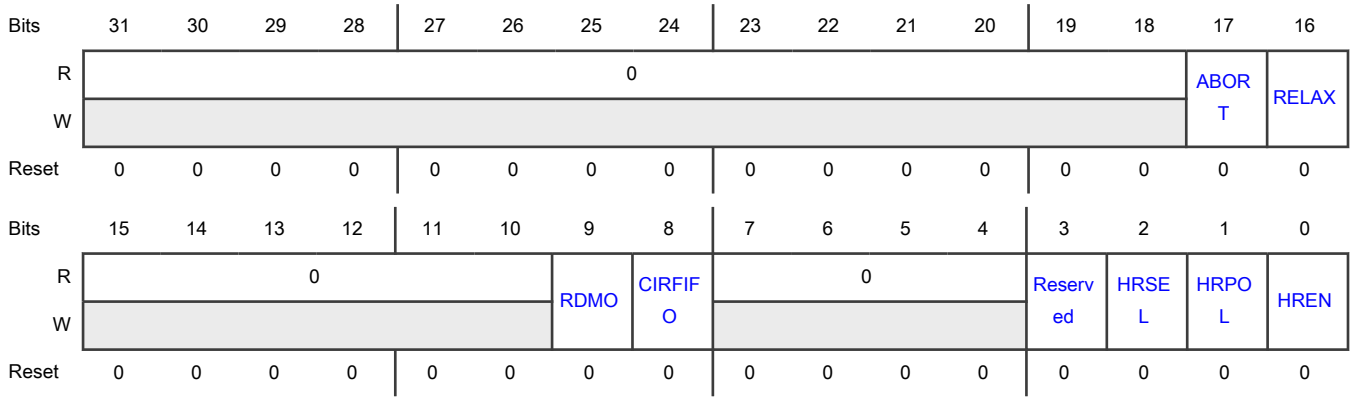
Offset

Register	Offset
MCFGR0	20h

Function

Contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 ABORT	Abort Transfer Determines whether the LPI2C controller completes the existing byte and then sends a Stop condition. A new transfer does not start while this field is 1. 0b - Normal transfer 1b - Abort existing transfer and do not start a new one
16 RELAX	Relaxed Mode Specifies the type of transfer. If this field is 1, the LPI2C controller relaxes several transfer restrictions. Transfers start when the bus is busy and FIFO commands are not checked for errors. You can use this mode to attempt recovery of a stuck I2C target by toggling the SCL pin. 0b - Normal transfer 1b - Relaxed transfer
15-10 —	Reserved
9 RDMO	Receive Data Match Only Determines whether all received data that does not set MSR[DMF] is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, write 0 to this field before writing 0 to MSR[DMF] to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless MSR[DMF] is set
8 CIRFIFO	Circular FIFO Enable Enables the transmit FIFO read pointer to be saved to a temporary register. The transmit FIFO empties as normal. After the LPI2C controller is idle and the transmit FIFO is empty, the read pointer value is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a Stop condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Disable 1b - Enable
7-4 —	Reserved
3 —	Reserved
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, this field must not change. 0b - Reserved 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, this field must not change. HRPOL sets the polarity for both the HREQ pin and the input trigger. • When HRPOL=0, the polarity is configured for active low, so host request is asserted if the HREQ pin or input trigger are logic 0. • When HRPOL=1, the polarity is configured for active high, so host request is asserted if the HREQ pin or input trigger are logic 1. 0b - Active low 1b - Active high
0 HREN	Host Request Enable Enables host request. When enabled, the LPI2C controller only initiates a Start condition if the host request input is asserted and the bus is idle. A repeated Start condition is not affected by the host request. 0b - Disable 1b - Enable

44.7.1.9 Controller Configuration 1 (MCFGR1)

Offset

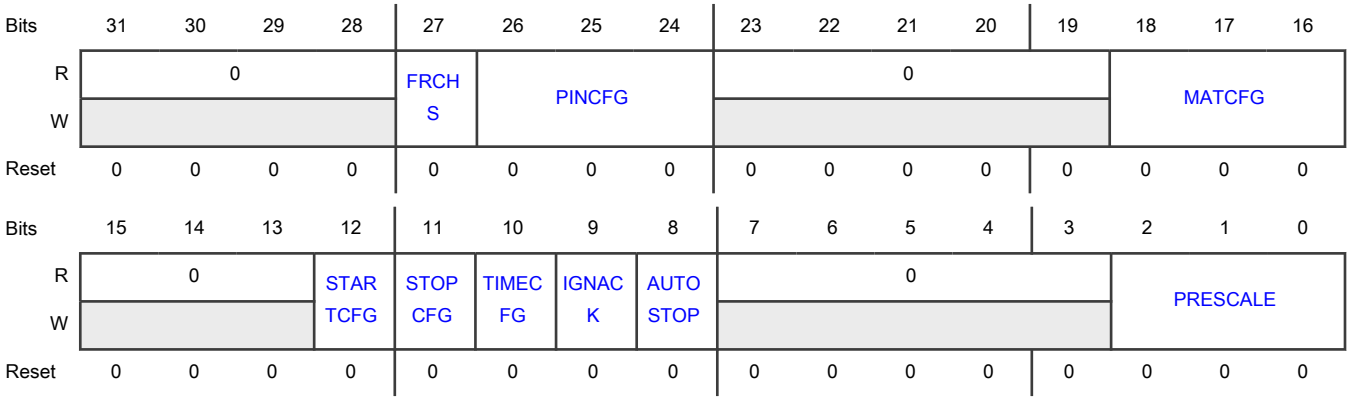
Register	Offset
MCFGR1	24h

Function

Contains controls for pin configuration, clock prescaler, and various other control settings.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS Mode Forces the LPI2C pin state into HS mode. Writing 1 to this field does not impact the digital filter configuration or digital timing parameters. 0b - No effect 1b - LPI2C pin state forced into HS mode
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (Ultra-Fast mode). SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller and target. SCLS/SDAS pins: Not used. 010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target. 100b - Two-pin open-drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	101b - Two-pin output only mode (Ultra-Fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that sets MSR[DMF]. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled: first data word equals MDMR[MATCH0] OR MDMR[MATCH1] 011b - Match is enabled: any data word equals MDMR[MATCH0] OR MDMR[MATCH1] 100b - Match is enabled: (first data word equals MDMR[MATCH0]) AND (second data word equals MDMR[MATCH1) 101b - Match is enabled: (any data word equals MDMR[MATCH0]) AND (next data word equals MDMR[MATCH1) 110b - Match is enabled: (first data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled: (any data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12 STARTCFG	Start Configuration Configures the conditions that set MSR[STF] when a Start condition occurs. When this field is 0, MSR[STF] is set on a Start condition when both the I2C bus and LPI2C are idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus except the LPI2C controller. When this field is 1, MSR[STF] is set on a Start condition when the I2C bus is idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus including the LPI2C controller. 0b - Sets when both I2C bus and LPI2C controller are idle 1b - Sets when I2C bus is idle
11 STOPCFG	Stop Configuration Configures the conditions that set MSR[SDF].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 0, any Stop condition generated by the LPI2C controller sets SDF. When this field is 1, the last Stop condition before the LPI2C controller is idle sets SDF. In this case, the transmit FIFO is empty at the time of the Stop condition. 0b - Any Stop condition 1b - Last Stop condition
10 TIMECFG	Timeout Configuration Configures which signals must be low for longer than the configured timeout to set MSR[PLTF]. When this field is 0, MSR[PLTF] is set when SCL is low for longer than the configured timeout. 0b - SCL 1b - SCL or SDA
9 IGNACK	Ignore NACK Determines whether the LPI2C controller ignores a received NACK and treats it as an ACK. In this case, MSR[NDF] is never set. This field must be 1 in Ultra-Fast mode. 0b - No effect 1b - Treat a received NACK as an ACK
8 AUTOSTOP	Automatic Stop Generation Determines whether a Stop condition is generated when the LPI2C controller is busy and the transmit FIFO is empty. A Stop condition can also be generated using a transmit FIFO command. When this field is 1, a Stop condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy. 0b - No effect 1b - Stop automatically generated
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic except the digital glitch filters. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64

Table continues on the next page...

Table continued from the previous page...

Field	Function
	111b - Divide by 128

44.7.1.10 Controller Configuration 2 (MCFGR2)

Offset

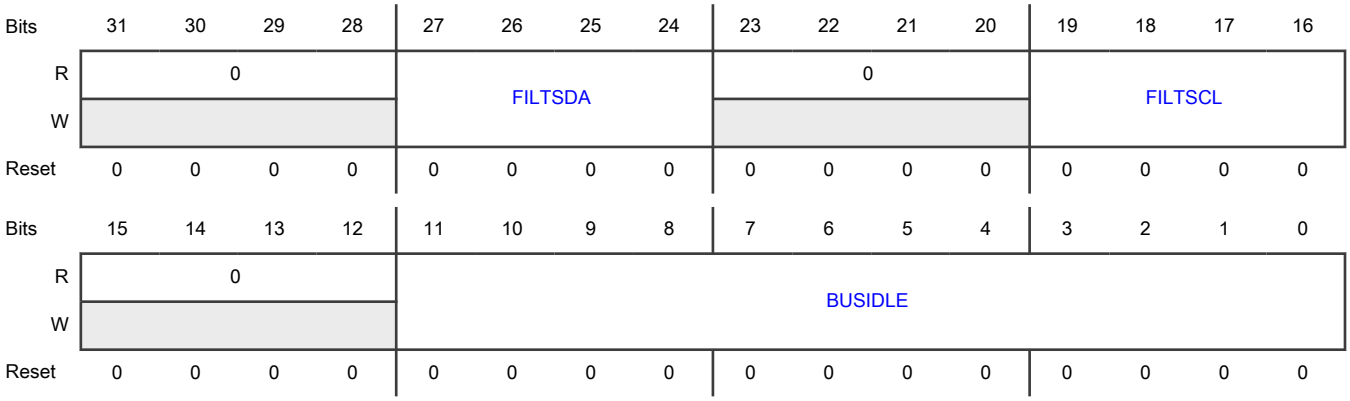
Register	Offset
MCFGR2	28h

Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C controller digital glitch filters for the SDA input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C controller digital glitch filters for SCL input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
15-12 —	Reserved
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period, in clock cycles. If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition. Writing 0 to this field disables the bus idle timeout.

44.7.1.11 Controller Configuration 3 (MCFGR3)

Offset

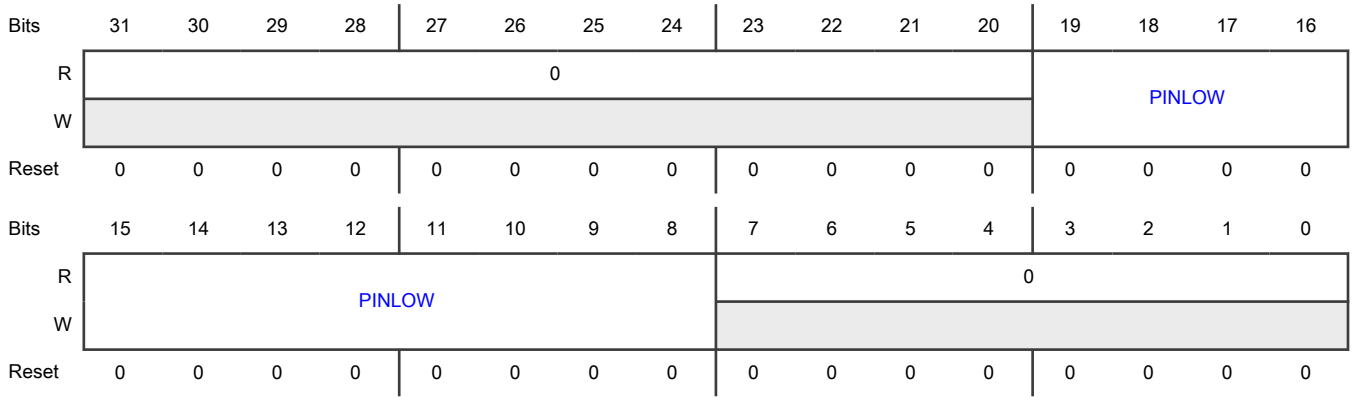
Register	Offset
MCFGR3	2Ch

Function

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the threshold value, in clock cycles, that sets MSR[PLTF]. If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set. When this field is 0, the pin low timeout feature is disabled.
7-0 —	Reserved

44.7.1.12 Controller Data Match (MDMR)

Offset

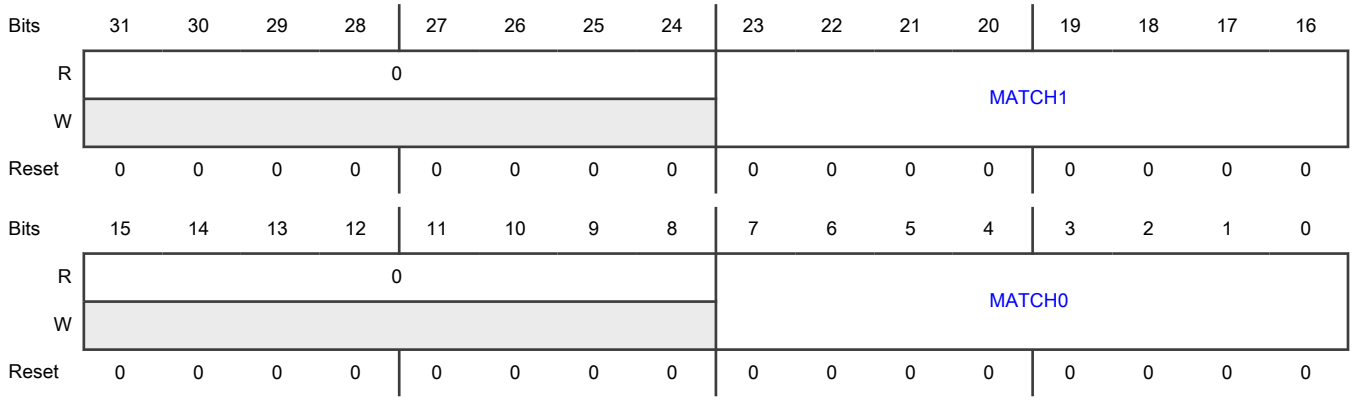
Register	Offset
MDMR	40h

Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 MATCH1	Match 1 Value Specifies match 1 value that is compared to the received data when receive data match is enabled.
15-8 —	Reserved
7-0 MATCH0	Match 0 Value Specifies match 0 value that is compared to the received data when receive data match is enabled.

44.7.1.13 Controller Clock Configuration 0 (MCCR0)

Offset

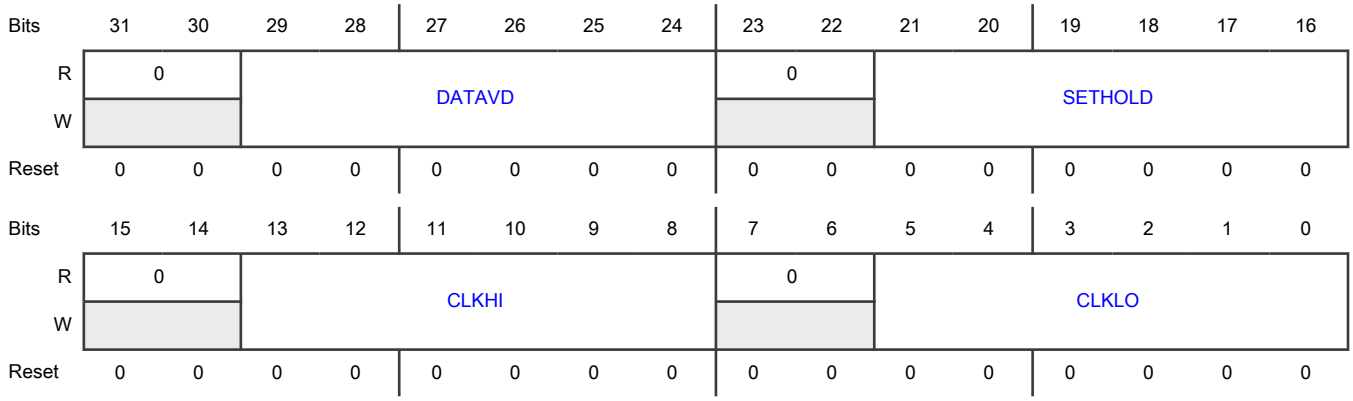
Register	Offset
MCCR0	48h

Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start • Setup and hold time for a repeated Start • Setup time for a Stop The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

44.7.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start condition • Setup and hold time for a repeated Start condition • Setup time for a Stop condition The setup time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

44.7.1.15 Controller FIFO Control (MFCR)

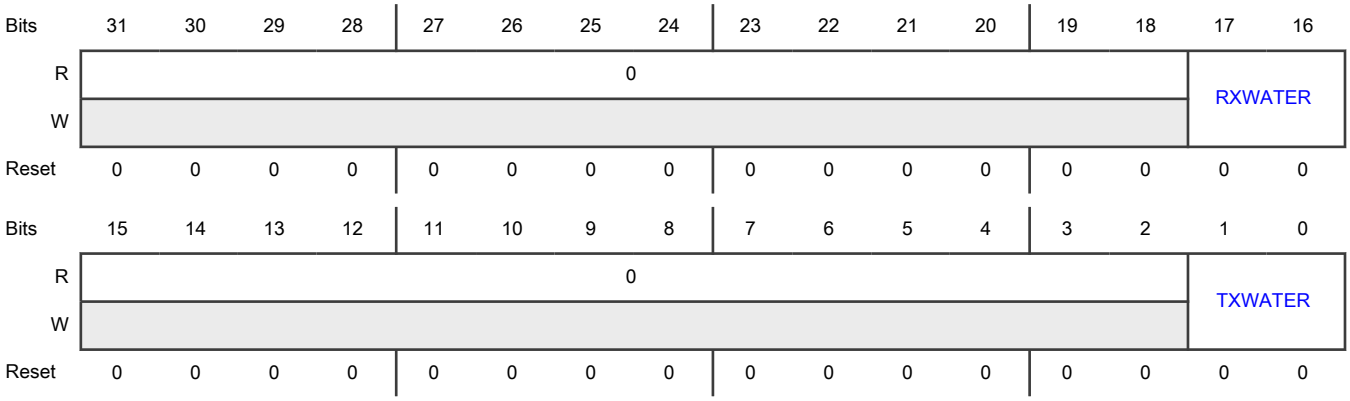
Offset

Register	Offset
MFCR	58h

Function

Controls the receive and transmit FIFO watermark values.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 RXWATER	Receive FIFO Watermark Determines the watermark for setting SSR[RDF]. That flag is set when the number of words in the receive FIFO is greater than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.
15-2 —	Reserved
1-0 TXWATER	Transmit FIFO Watermark Determines the watermark for setting SSR[TDF]. That flag is set when the number of words in the transmit FIFO is equal or less than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.

44.7.1.16 Controller FIFO Status (MFSR)

Offset

Register	Offset
MFSR	5Ch

Function

Specifies the number of words in the transmit and receive FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-19 —	Reserved
18-16 RXCOUNT	Receive FIFO Count Specifies the number of words in the receive FIFO.
15-3 —	Reserved
2-0 TXCOUNT	Transmit FIFO Count Specifies the number of words in the transmit FIFO.

44.7.1.17 Controller Transmit Data (MTDR)

Offset

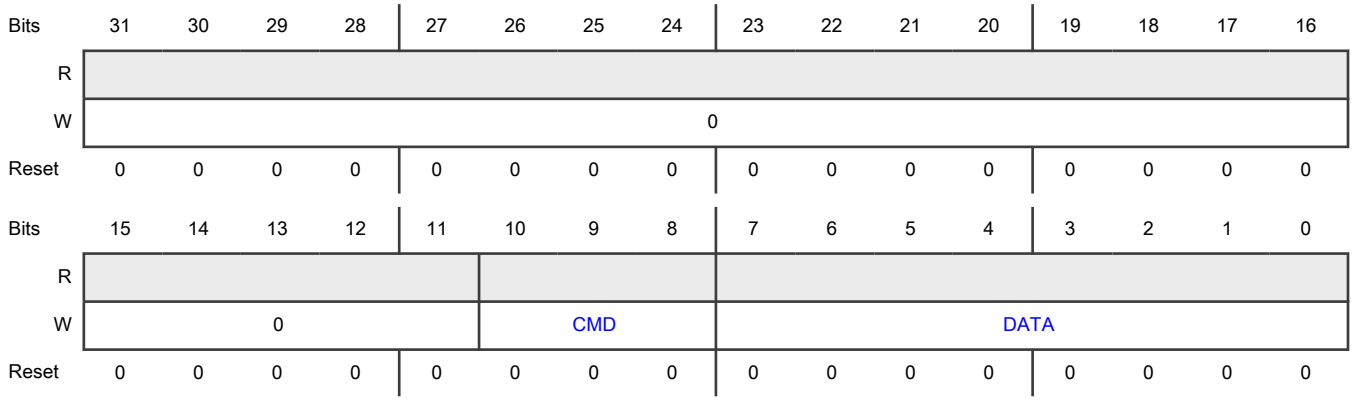
Register	Offset
MTDR	60h

Function

Configures transmit data:

- An 8-bit write to MTDR[CMD] is ignored and does not increment the FIFO write pointer.
- An 8-bit write to MTDR[DATA] zero-extends the value of MTDR[CMD] and increments the FIFO write pointer.
- A 16-bit or 32-bit write operation writes to both MTDR[CMD] and MTDR[DATA] and increments the FIFO write pointer.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-8 CMD	Command Data Selects command transmitted by controller. 000b - Transmit the value in DATA[7:0] 001b - Receive (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes and check each for a data match (if configured) before storing the received data in the receive FIFO. 010b - Generate Stop condition on I2C bus 011b - Receive and discard (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes but do not check for a data match or store those bytes in the receive FIFO. 100b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] 101b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] (this transfer expects a NACK to be returned) 110b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode 111b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode (this transfer expects a NACK to be returned)
7-0 DATA	Transmit Data Contains data used by the commands listed in MTDR[CMD]. Performing an 8-bit write to this field zero-extends the value of MTDR[CMD].

44.7.1.18 Controller Receive Data (MRDR)

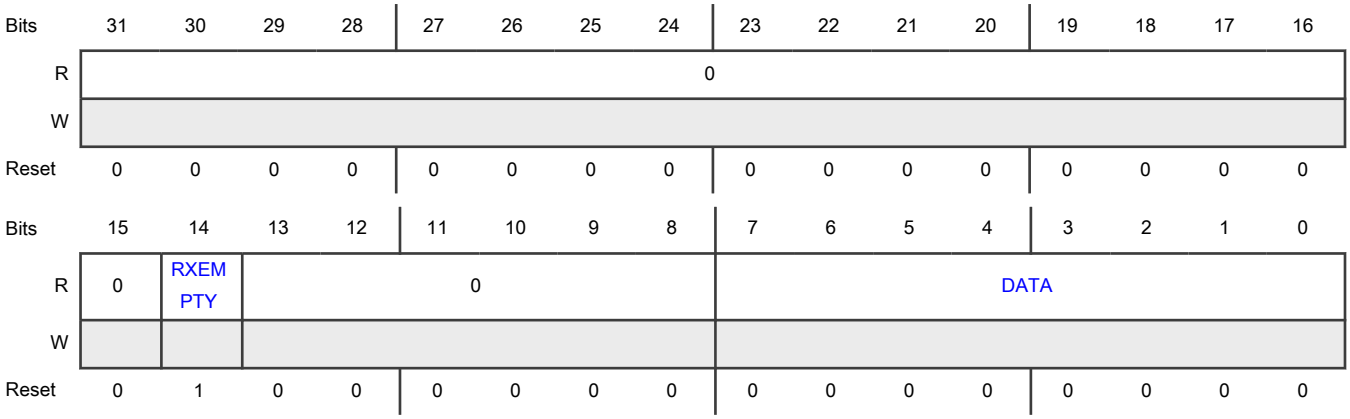
Offset

Register	Offset
MRDR	70h

Function

Contains the status of the receive FIFO and the data received by the I2C controller that has not been discarded.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 RXEMPTY	Receive Empty Indicates whether the controller receive data FIFO is empty. 0b - Not empty 1b - Empty
13-8 —	Reserved
7-0 DATA	Receive Data Contains data received by the I2C controller that has not been discarded. Received data can be discarded due to the command in MTDR[CMD], or the controller can be configured to discard nonmatching data.

44.7.1.19 Controller Receive Data Read Only (MRDROR)

Offset

Register	Offset
MRDROR	78h

Function

Contains the status of the receive FIFO and returns the data received by the I2C controller, but does not pull the data from the FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13-8 —	Reserved
7-0 DATA	Receive Data

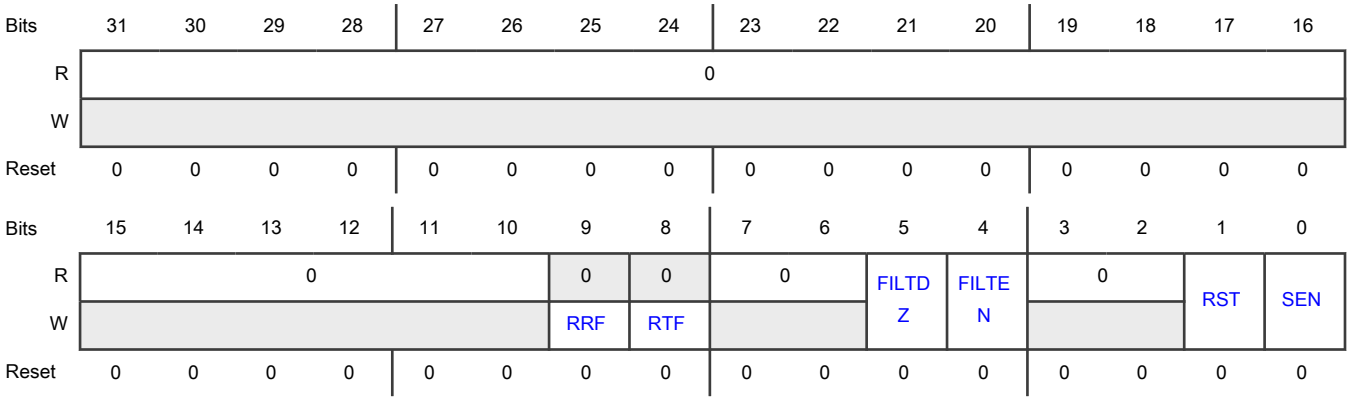
44.7.1.20 Target Control (SCR)

Offset

Register	Offset
SCR	110h

Function
Contains resets and other target control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Empties the receive FIFO in Target Receive Data (SRDR). 0b - No effect 1b - SRDR is now empty
8 RTF	Reset Transmit FIFO Empties the transmit FIFO in Target Transmit Data (STDR). 0b - No effect 1b - STDR is now empty
7-6 —	Reserved
5	Filter Doze Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FILTDZ	Enables filter in Doze mode. Update this field only when the I2C target is disabled. 0b - Enable 1b - Disable
4 FILTEN	Filter Enable Enables digital filter and output delay counter for target mode. Update this field only when the I2C target is disabled. 0b - Disable 1b - Enable
3-2 —	Reserved
1 RST	Software Reset Resets target mode logic. The reset takes effect immediately. The value of this field remains 1 until you write 0 to it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 SEN	Target Enable Enables I2C Target mode. 0b - Disable 1b - Enable

44.7.1.21 Target Status (SSR)

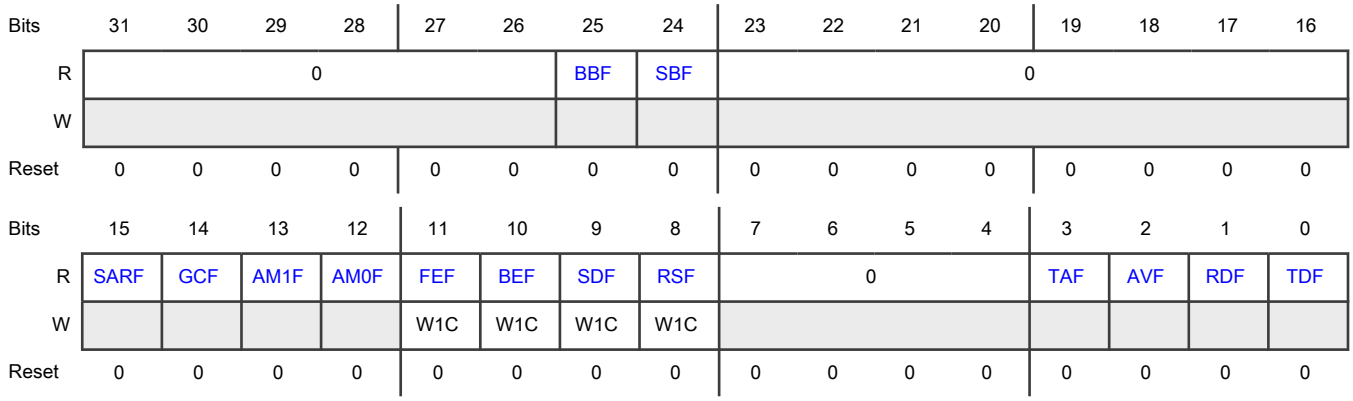
Offset

Register	Offset
SSR	114h

Function

Contains status flags for transmit and receive data, for error conditions, and for bus and target busy or idle status.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates whether an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target Busy Flag Indicates whether an I2C target is idle or busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag Indicates whether an SMBus alert response has been detected. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Disabled or not detected 1b - Enabled and detected
14 GCF	General Call Flag Indicates whether a target has detected the general call address. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - General call address disabled or not detected 1b - General call address detected
13 AM1F	Address Match 1 Flag Indicates whether the received address matches the value in ADDR1, or it falls within the ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Matching address not received 1b - Matching address received
12 AM0F	Address Match 0 Flag Indicates whether the received address matches the ADDR0 field, as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO Error Flag Indicates whether there is a FIFO error. This flag can only be set when clock stretching is disabled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
10 BEF	Bit Error Flag Indicates whether the LPI2C target has transmitted a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit error occurred

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Bit error occurred When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C target detects a Stop condition, and if the LPI2C target matched the last address byte. When SCFGR1[SDCFG] = 1, this flag is set on any Stop condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop detected 1b - Stop detected When writing 0b - No effect 1b - Clear the flag
8 RSF	Repeated Start Flag Indicates whether the LPI2C target detects a repeated Start condition and if the LPI2C target matched the last address byte. When SCFGR1[RSCFG] = 1, this flag is set on any repeated Start condition. This flag is not set when the target first detects a Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No repeated Start detected 1b - Repeated Start detected When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 TAF	Transmit ACK Flag Indicates whether a transmit ACK or NACK is required. You can clear this flag by writing to Target Transmit ACK (STAR). 0b - Not required

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Required
2 AVF	Address Valid Flag Indicates whether the contents of Target Address Status (SASR) are valid. You can clear this flag by reading SASR. When SCFGR1[RXCFG] = 1, this flag is also cleared by reading Target Receive Data (SRDR). 0b - Not valid 1b - Valid
1 RDF	Receive Data Flag Indicates whether receive data is ready. You can clear this flag by reading Target Receive Data (SRDR). When SCFGR1[RXCFG] = 1, this flag is not cleared when reading Target Receive Data (SRDR) if SSR[AVF] = 1. 0b - Not ready 1b - Ready
0 TDF	Transmit Data Flag Indicates whether transmit data has been requested. This flag is cleared by writing to Target Transmit Data (STDR). When SCFGR1[TXCFG] = 0, if a NACK, repeated Start, or Stop condition is detected, this flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

44.7.1.22 Target Interrupt Enable (SIER)

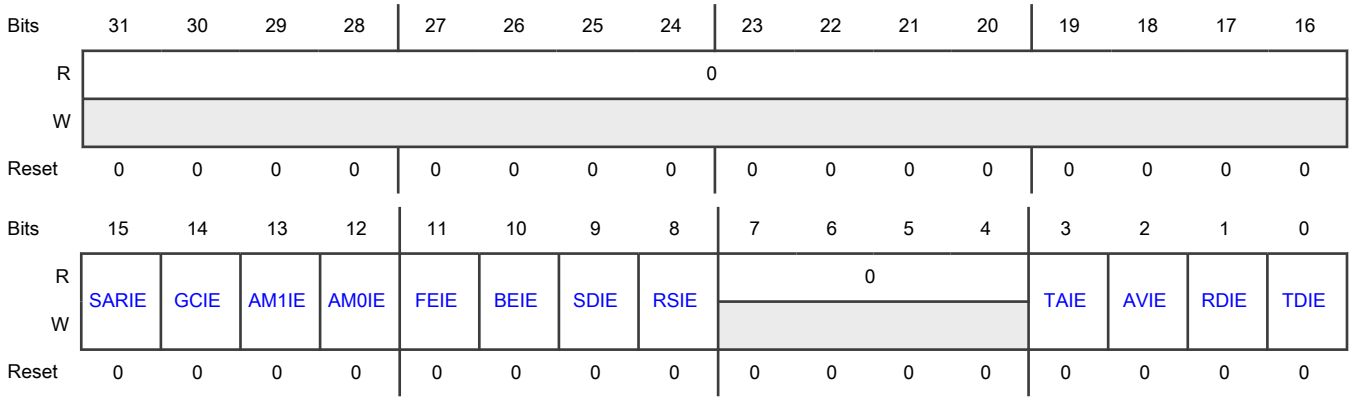
Offset

Register	Offset
SIER	118h

Function

Contains transmit and receive data interrupt enables, start and stop detect interrupt enables, and other target interrupt enables.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 SARIE	SMBus Alert Response Interrupt Enable Enables interrupt for SMBus alert response. 0b - Disable 1b - Enable
14 GCIE	General Call Interrupt Enable Enables interrupt for general call. 0b - Disabled 1b - Enabled
13 AM1IE	Address Match 1 Interrupt Enable Enables interrupt for address match 1. 0b - Disable 1b - Enable
12 AM0IE	Address Match 0 Interrupt Enable Enables interrupt for address match 0. 0b - Disable 1b - Enable
11 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 BEIE	Bit Error Interrupt Enable Enables interrupt for bit error. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 RSIE	Repeated Start Interrupt Enable Enables interrupt for repeated start. 0b - Disable 1b - Enable
7-4 —	Reserved
3 TAIE	Transmit ACK Interrupt Enable Enables interrupt for transmit ACK. 0b - Disable 1b - Enable
2 AVIE	Address Valid Interrupt Enable Enables interrupt for valid address. 0b - Disable 1b - Enable
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

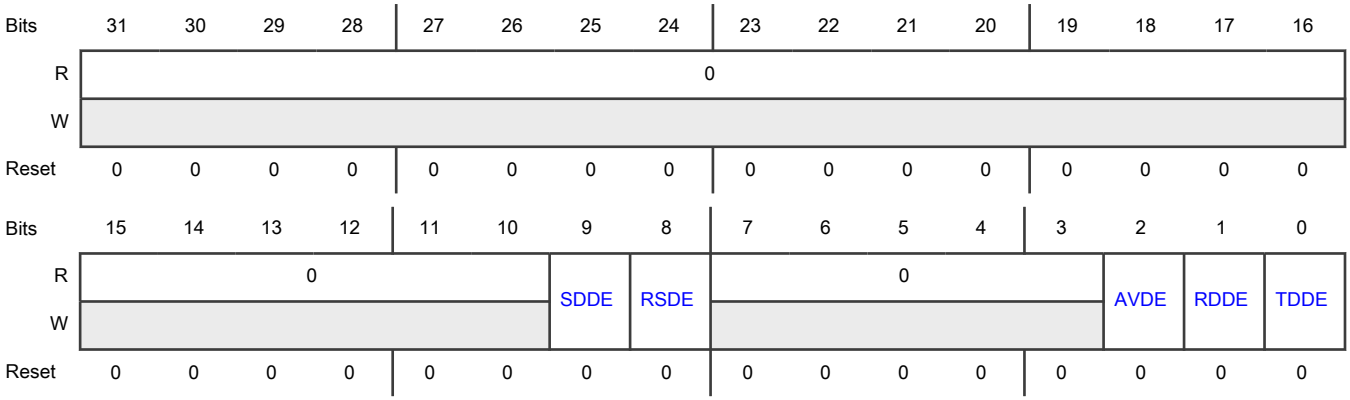
44.7.1.23 Target DMA Enable (SDER)

Offset

Register	Offset
SDER	11Ch

Function
Contains the transmit, request, and receive enables for DMA.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 SDDE	Stop Detect DMA Enable Enables DMA end-of-packet processing on stop detection. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response. • Returns 0000_40FFh. • Writes 0 to SSR[SDF]. 0b - Disable 1b - Enable
8 RSDE	Repeated Start DMA Enable Enables DMA end-of-packet processing on repeated start. Reading Target Receive Data (SRDR) when it is empty: • Generates a DMA end-of-packet response.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Returns 0000_40FFh. • Writes 0 to SSR[RDF]. 0b - Disable 1b - Enable
7-3 —	Reserved
2 AVDE	Address Valid DMA Enable Enables address valid DMA request. The address valid DMA request is shared with the receive data DMA request. If both are enabled, write 1 to SCFGR1[RXCFG] to allow the DMA to read the address from Target Receive Data (SRDR). 0b - Disable 1b - Enable
1 RDDE	Receive Data DMA Enable Enables receive data for DMA. 0b - Disable DMA request 1b - Enable DMA request
0 TDDE	Transmit Data DMA Enable Enables transmit data for DMA. 0b - Disable 1b - Enable

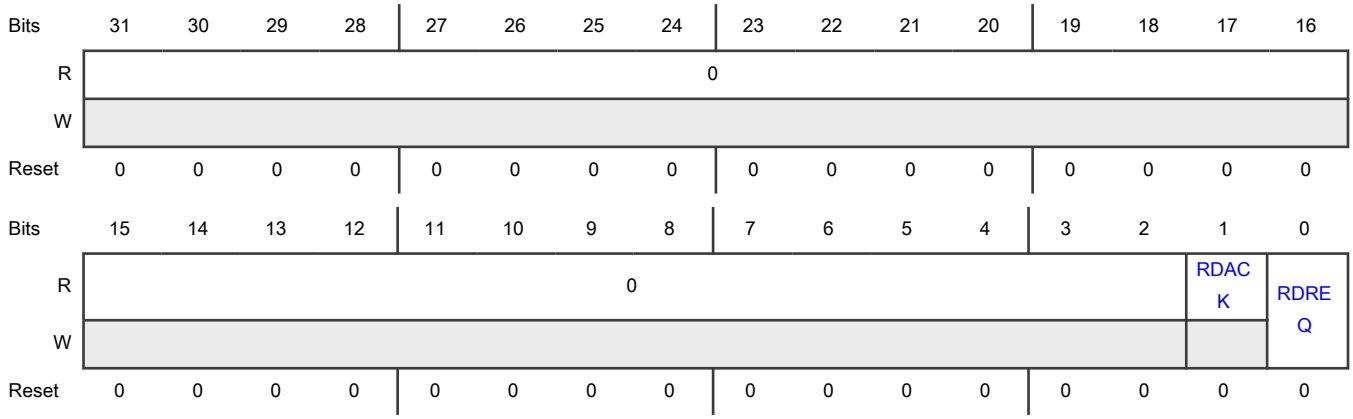
44.7.1.24 Target Configuration 0 (SCFGR0)

Offset

Register	Offset
SCFGR0	120h

Function
Configures the read request feature.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDACK	Read Acknowledge Flag Indicates whether a Start then Stop sequence with one SCL pulse between them acknowledged the read request while SCFGR0[RDREQ] = 1. You can clear this flag by writing 0 to SCFGR0[RDREQ]. 0b - Read Request not acknowledged 1b - Read Request acknowledged
0 RDREQ	Read Request Enables read request. When the I2C bus is idle, writing 1 to this field causes the LPI2C target to drive SDA low, triggering a Start condition. The LPI2C target releases SDA on the next falling edge of SCL or when you write 0 to this field. To initiate a second read request (for example, following I2C bus activity that did not acknowledge the request), write 0 then 1 to this field. When the I2C bus is busy, writing to this register always writes 0 to this field. 0b - Disable 1b - Enable

44.7.1.25 Target Configuration 1 (SCFGR1)

Offset

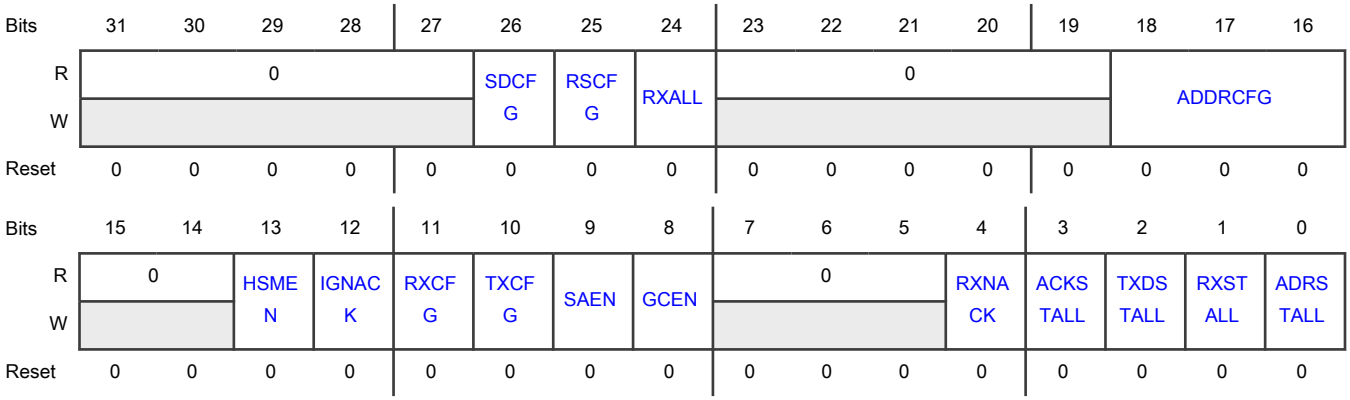
Register	Offset
SCFGR1	124h

Function

Configures various aspects of the target.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 SDCFG	Stop Detect Configuration Configures the conditions that set SSR[SDF]. 0b - Any Stop condition following an address match 1b - Any Stop condition
25 RSCFG	Repeated Start Configuration Configures the conditions that set SSR[RSF]. 0b - Any repeated Start condition following an address match 1b - Any repeated Start condition
24 RXALL	Receive All Enables receive-all functionality. When enabled, the LPI2C target stores all addresses on the I2C bus in Target Address Status (SASR) and all data on the I2C bus in Target Receive Data (SRDR). However, the LPI2C target does not drive SDA (for ACK or target-transmit transfer) unless there is an address match. The LPI2C target can drive SCL if clock stretching is enabled. When this field is 1, the LPI2C target only supports 7-bit addressing modes (you must configure SCFGR1[ADDRCFG] for 7-bit address match). Software can support 10-bit addresses, however. The first byte of a 10-bit address is saved to Target Address Match (SAMR). The second byte is saved as the first data byte in Target Receive Data (SRDR).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Use this field to aid debugging of the I2C bus by saving all data on the bus without altering the state of the bus. When this field is 1, it is recommended to also write 1 to SCFGR1[RSCFG] and SCFGR1[SDCFG] so you can track the full state of the I2C bus. 0b - Disable 1b - Enable
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or address match 1 (7-bit) 011b - Address match 0 (10-bit) or address match 1 (10-bit) 100b - Address match 0 (7-bit) or address match 1 (10-bit) 101b - Address match 0 (10-bit) or address match 1 (7-bit) 110b - From address match 0 (7-bit) to address match 1 (7-bit) 111b - From address match 0 (10-bit) to address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	HS Mode Enable Enables detection of the HS mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any HS mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] are ignored until the next Stop condition is detected. 0b - Disable 1b - Enable
12 IGNACK	Ignore NACK Determines whether the target ends transfer when a NACK condition is detected. When this field is 1, the LPI2C target continues transfers after a NACK is detected. This field is required to be 1 in Ultra-Fast mode. 0b - End transfer on NACK 1b - Do not end transfer on NACK
11 RXCFG	Receive Data Configuration Configures which data is returned and which flags are cleared when reading Target Receive Data (SRDR).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 0, reading SRDR returns received data and clears SSR[RDF]. When this field is 1, reading SRDR: • Returns the value of Target Address Status (SASR) and clears SSR[AVF] when SSR[AVF] is set. • Returns received data and clears SSR[RDF] when SSR[AVF] is not set. 0b - Return received data, clear SSR[RDF] 1b - Return SASR and clear SSR[AVF] when SSR[AVF] is set, return received data and clear SSR[RDF] when SSR[AFV] is not set
10 TXCFG	Transmit Flag Configuration Determines which conditions set SSR[TDF]. This field always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. When this field is 0, Target Transmit Data (STDR) is automatically emptied when a target-transmit transfer is detected. SSR[TDF] is set when a target-transmit transfer is detected, and SSR[TDF] is cleared at the end of the target-transmit transfer. When this field is 1, SSR[TDF] is set when STDR is empty, and SSR[TDF] is cleared when STDR is full. This setting allows STDR to be filled before a target-transmit transfer is detected. However, it can cause STDR to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - SSR[TDF] is set only during a target-transmit transfer when STDR is empty 1b - SSR[TDF] is set whenever STDR is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disable 1b - Enable
8 GCEN	General Call Enable Enables a general call address. 0b - Disable 1b - Enable
7-5 —	Reserved
4 RXNACK	Receive NACK Determines whether to override the setting of STAR[TXNACK] when the LPI2C receives a matching address during an overrun. When this field is 1, the LPI2C target responds with a NACK under the following conditions:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• SSR[AVF] would be set due to matching an address, but that flag is already 1 (address overrun). • SSR[RDF] would be set due to receiving data, but that flag is already 1 (receive data overrun). 0b - ACK or NACK always determined by STAR[TXNACK] 1b - NACK always generated on address overrun or receive data overrun, otherwise ACK or NACK is determined by STAR[TXNACK]
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during target-transmit address bytes and target-receiver address and data bytes, so you can write to Target Transmit ACK (STAR) before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with HS mode. If this field is 1: • You do not need to write 1 to SCFGR1[RXSTALL] or SCFGR1[ADRSTALL]. • When there is an address match on the first byte of a 10-bit address, SSR[AVF] is set, allowing you to read the received address before writing to Target Transmit ACK (STAR). 0b - Disable 1b - Enable
2 TXDSTALL	Transmit Data SCL Stall Enables SCL clock stretching when SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable

44.7.1.26 Target Configuration 2 (SCFGR2)

Offset

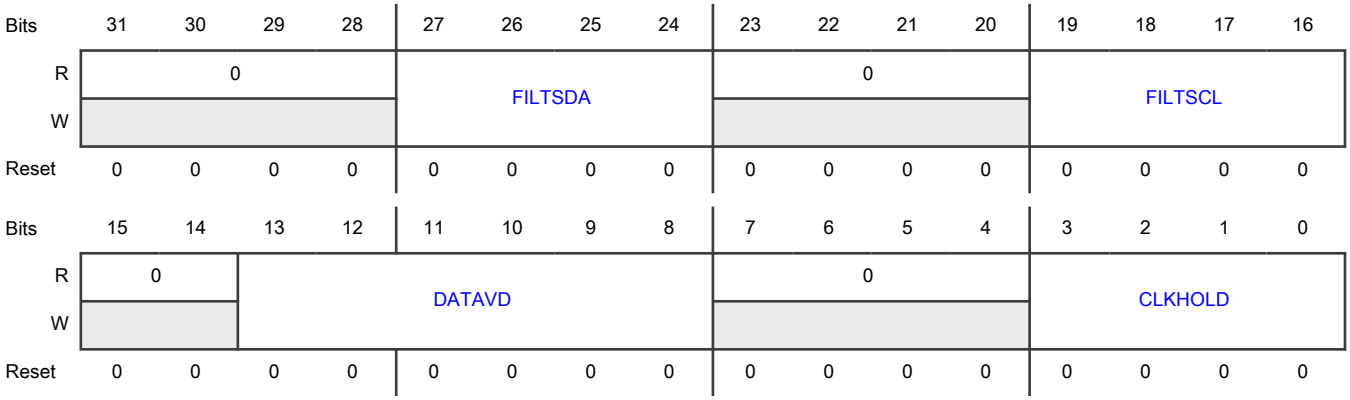
Register	Offset
SCFGR2	128h

Function

Configures data valid delay, clock hold time, and glitch filters for SDA and SCL.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C target digital glitch filters for SDA input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
23-20 —	Reserved
19-16	Glitch Filter SCL

Table continues on the next page...

Table continued from the previous page...

Field	Function
FILTSCL	Configures the I2C target digital glitch filters for SCL input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
15-14 —	Reserved
13-8 DATAVD	Data Valid Delay Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL + DATAVD + 3 cycles. The data valid delay must be configured to be less than the minimum SCL low period. MCFGR1[PRESCALE] does not affect the I2C target data valid delay time, and the I2C target data valid delay time is disabled in HS mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. The minimum hold time is equal to the number of cycles defined by this field + 3. MCFGR1[PRESCALE] does not affect the I2C target clock hold time, and the I2C target clock hold time is disabled in HS mode.

44.7.1.27 Target Address Match (SAMR)

Offset

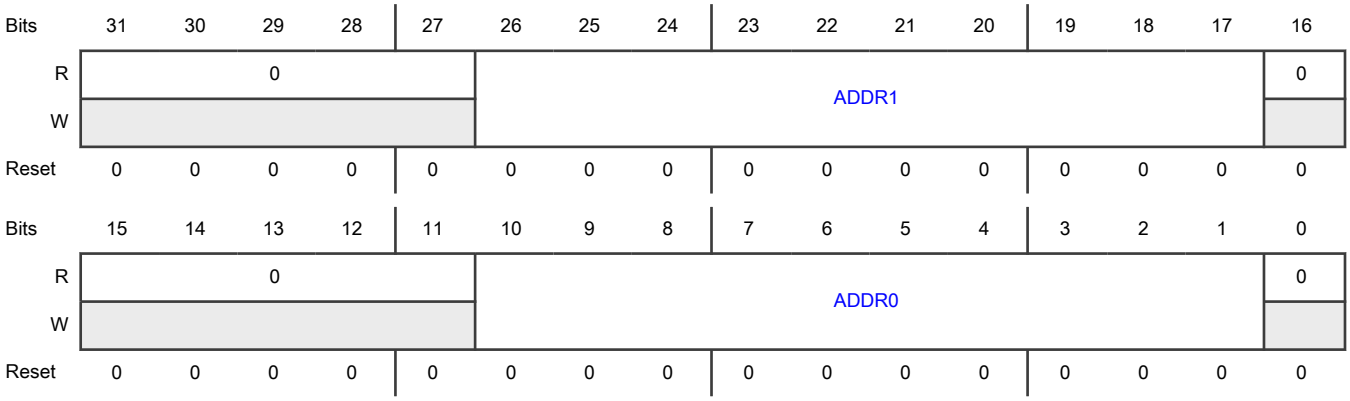
Register	Offset
SAMR	140h

Function

Contains address values for received target match comparison.

Write to this register only when the I2C target is disabled.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-17 ADDR1	Address 1 Value Contains the value of address 1, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR1[26:25]} and the second address byte is compared to ADDR1[24:17]. In 7-bit mode, the address is compared to ADDR1[23:17].
16-11 —	Reserved
10-1 ADDR0	Address 0 Value Contains the value of address 0, which is compared to the received address to detect the target address. In 10-bit mode, the first address byte is compared to {11110, ADDR0[10:9]} and the second address byte is compared to ADDR0[8:1]. In 7-bit mode, the address is compared to ADDR0[7:1].
0 —	Reserved

44.7.1.28 Target Address Status (SASR)

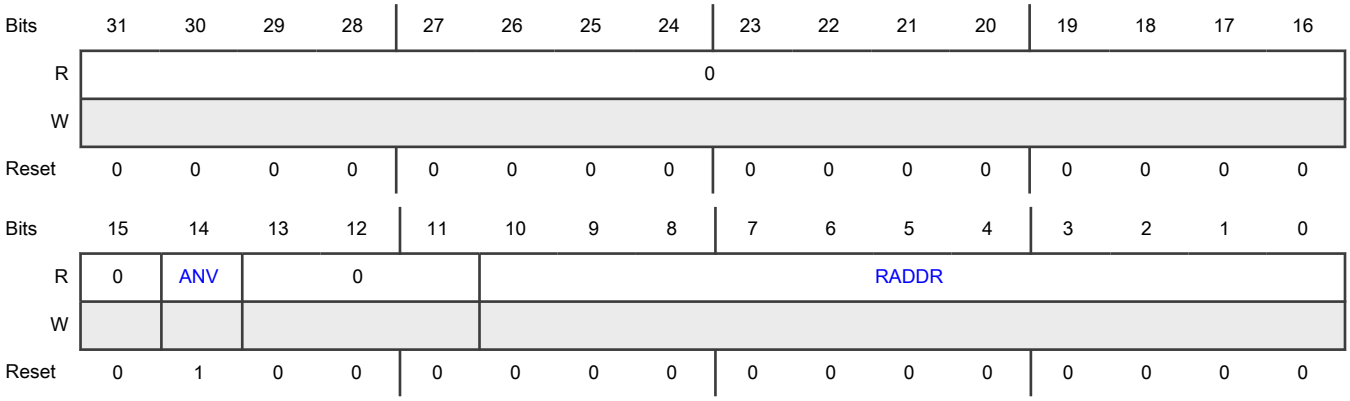
Offset

Register	Offset
SASR	150h

Function

Contains the received address and its validity.

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid Indicates whether SASR[RADDR] is valid. 0b - Valid 1b - Not valid
13-11 —	Reserved
10-0 RADDR	Received Address Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F]. In 7-bit mode, the address byte is stored in RADDR[7:0]. In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0]. When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address.

44.7.1.29 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Configures choice of ACK or NACK on each received word.

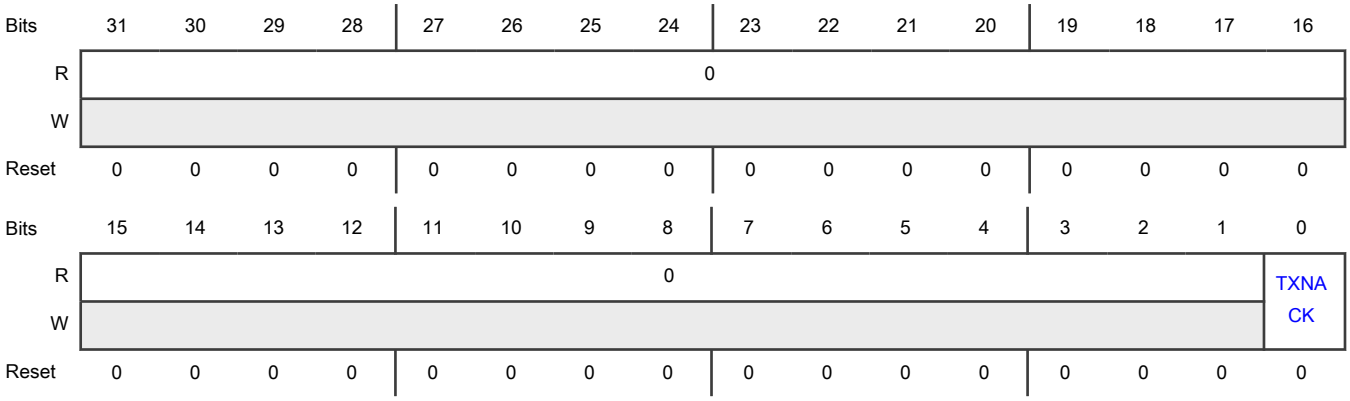
You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word. • When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK). • To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle. 0b - Transmit ACK 1b - Transmit NACK

44.7.1.30 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

Signal multiplexing	Port control	Signal multiplexing

45.1.1 Module instances

This device has one instance of the I3C module, I3C0.

45.1.2 PORT module configuration for I3C mode pull-up resistor control

In order to work in the I3C mode, the PV (pull value), PE (pull enable) and PS (pull select) values in the corresponding PORT_PCR registers should be correctly configured in advance.

The following table lists the required PORT_PCR register bit fields configuration of corresponding I3C pins to support I3C pull-up resistor control.

Table 318. PORT module configuration to support different I3C pull-up resistor control

I3C pins	Weak pull-up resistor enable	Strong pull-up resistor enable
I3C0_SDA	Corresponding PCRx[PE] = 1, PCRx[PV] = 0, PCRx[PS] = 1	Corresponding PCRx[PE] = 1, PCRx[PV] = 1, PCRx[PS] = 1
I3C0_SCL	Corresponding PCRx[PE] = 1, PCRx[PS] = 1	–

45.1.3 DMA wake-up support in I3C mode

In order to support I3C mode DMA wake-up, the CMC_CKCTRL[CKMODE] should be configured as 0x0 (No clock gating), 0x1 (Core clock is gated), or 0x3 (Core and platform clocks are gated).

45.2 Overview

I3C is a communications processor that improves upon the use and power of I2C, and provides an alternative to SPI for mid-speed applications.

The I3C bus protocol supports:

- In-band interrupts (IBI): these interrupts move from target to controller without extra wires, and the controller knows which target sent the interrupt
- Common command codes (CCC)
- Dynamic addressing
- Multi-controller and multi-drop
- Hot-Join (HJ)
- I2C compatibility

I3C supports all required and many optional features of the MIPI Alliance Specification for I3C, v1.0 and v1.1, except for ternary data rates (HDR-TSP and HDR-TSL). See Features, Target Capabilities (SCAPABILITIES), and Target Capabilities 2 (SCAPABILITIES2) for more information.

45.2.1 Block diagram

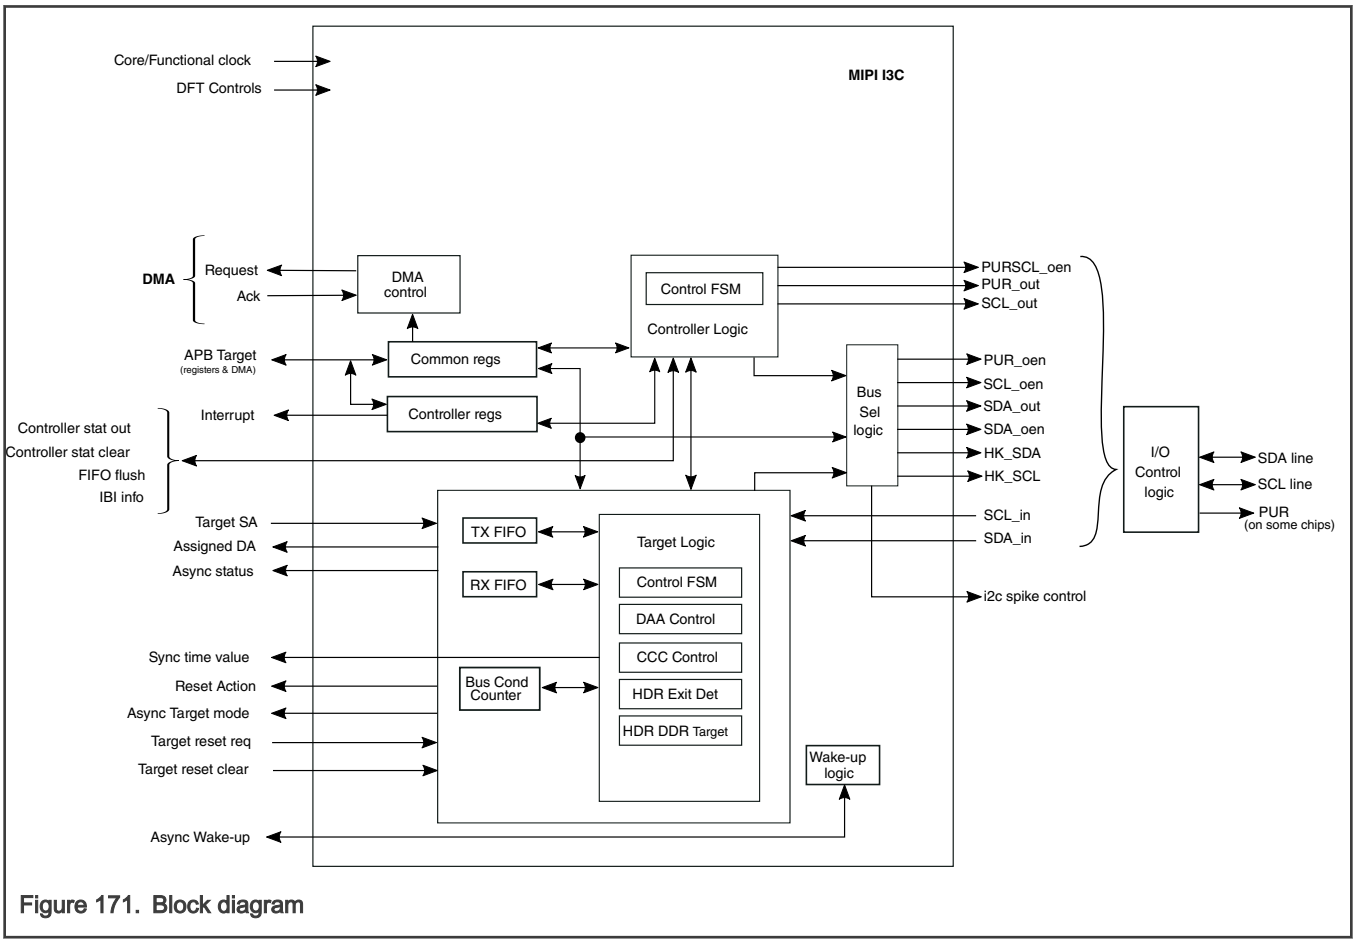

Figure 171. Block diagram

45.2.2 Features

- Two-wire multidrop bus that is capable of up to 12.5 MHz clock speeds with up to 11 devices:
  - Uses standard pads with 4 mA drive.
  - Dynamically assigns target addresses, and targets do not require static addresses (SAs). However, targets can have an I2C static address assigned at startup, so the target can operate on an I2C bus. By default, I3C supports 7-bit I2C-style addresses.
  - Allows targets to use the inbound SCL clock as the peripheral clock (instead of the clock from the controller) so that devices can have slow or inaccurate clocks internally.
  - Allows simple targets, such as temperature sensors, to have no internal clock.
  - I3C controller supports handoff from Open-Drain to Push-Pull mode for ACK to data transfer.
  - Generally, the controller terminates the read, but for I3C, the target can also end the read.
- IBIs that allow targets to send notifications to a controller:
  - Can be equivalent to a separate GPIO, but can also be directly data-bearing.

  - Can be prioritized. When multiple targets send interrupts to a controller at the same time, the order is resolved. Dynamic addresses (DAs) establish the priority of the targets, so the controller controls the priority of the targets.

    Targets with lower-value DAs are higher-priority level IBIs.
  - Can start interrupts even when the controller is not active on the bus. A free-running clock is not required, but starting an interrupt requires a Bus Available condition.
  - Can resolve an initial event via a time-stamping option, not requiring an interrupt.
- Built-in commands for applications created in software or firmware by using the register interface maintained in a separate space. These commands do not collide with normal controller-to-target messages and:
  - Control bus behavior, modes and states, low-power state, inquiries, and more.
  - Have an extra room for new built-in commands for other groups.
- Organized forms of multicontroller modes that are secondary controllers using clean handoffs between different controllers.
- Hot-Join onto I3C bus allows devices to connect to the bus later than when the bus starts. This:
  - Enables a device or module to access the I3C bus after power up or when physically inserted onto the I3C bus.
  - Provides a clean method for notification when new devices or modules access the I3C bus.
- I3C can use both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus.
  - I3C target devices can operate on I2C buses.
  - In I2C controller mode, it supports only Push-Pull mode on the SCL line.
  - A reset output is available for I2C mode SW reset for application usage. Asserted when the module is an I2C target and gets a I2C software General command from a controller. See the chip-specific section, for usage if this is available.
- Higher data rate modes are available:
  - I3C has a high data rate: double data rate (HDR-DDR) mode, which is double the data rate of SDR .
  - Only the controller and the specific targets, which are capable and configured to work with HDR-DDR, support the higher data rate (the other targets can ignore it).

I3C supports most of the I3C features (see Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2)), except for the ternary data rates (HDR-TSP and HDR-TSL), HDR-BT modes, and peer-to-peer messaging.

45.3 Functional description

45.3.1 Operating modes

This section describes all functional operation modes of the I3C module.

45.3.1.1 Target and controller roles for I3C

The I3C protocol defines these roles for devices on the I3C bus:

- Main controller: initially configures the I3C bus and serves as the first active controller
- Secondary controller: accepts the controller role from any active controller to become the new active controller (the secondary controller may then pass the controller role along: either back to the previous active controller, or on to any other controller-capable device)
- Target: responds to commands from any I3C controller
- I2C target: responds to compatible commands from any I3C controller

The I3C peripheral contains both controller and target components and can be configured to be either controller or target, or as target with secondary controller capability. However, if I3C is chosen to be a controller, then the I3C peripheral supports Target mode to facilitate handoffs to multiple controllers.

In general, any I3C controller can be a controller or a target because a controller becomes a target when giving over control to another controller. The only exceptions to this rule occur when using point-to-point communication or when using a controller that never shares controllership.

45.3.1.1.1 Controller requirements

Controller mode uses software that supports the requirements of the controller (including as a secondary controller):

- Managing the enter dynamic address assignment (ENTDAA) assigning dynamic addresses (DAs) to each target. The I3C peripheral supports this process but requires you to make choices.
- Driving the serial data (SDA) signal in both Open-Drain and Push-Pull modes. After START command, SDA is in Open-Drain mode and after Repeated START command, it is in Push-Pull mode:
  - SDA is subject to arbitration because both controller and target can drive the SDA line (arbitration is also useful for handoff from controller to target).
  - The ninth bit of SDA controller write data is an odd parity bit.
- Building a table of targets and their capabilities to control which actions and commands may be sent to the targets.
- Managing requests such as IBI and controller requests (handoff).
- Adjusting clock speed or write-to-read timing to match the limitations of the target. This adjustment can be done in hardware using dividers and uneven duty cycles, but you must decide how.
- Adjusting the maximum data length.
- Being a target after the controller role handoff to another controller-capable device.

The controller needs an accurate clock capable of running at a frequency that is the multiple of a frequency between 11 MHz and 12.5 MHz. For example:

- 24 MHz (multiple of 12 MHz)

If required to use a lower I3C SCL value, for example as small as 5 MHz (although the lower value does not support a mixed bus system):

- The controller clock can be a multiplier of that value.
- A lower SCL can also be achieved using a higher PPBAUD value.

45.3.1.1.2 I3C target acts like I2C target on I3C buses

If the target is assigned an I2C static address, the I3C target acts like an I2C device when it first powers on. If the I3C target is placed on an I2C bus with an I2C controller, then the I3C target stays in I2C mode and operates normally. The software is aware that the I3C target is in I2C mode because:

- There has not been an interrupt (see SSTATUS[DACHG]) indicating that a dynamic address was assigned.

For full I2C support of Fast mode (Fm) and Fast-mode Plus (Fm+), the pads must support a 50-ns spike filter. This filter must be turned off when the I3C 7Eh broadcast address is received (indicating an I3C controller). You can turn off the spike filters via hardware using the raw net indicating that the address was received, or via software. I3C does not need a 50-ns spike filter to operate on an I2C bus. Therefore, the spike filter is not a requirement for the I3C peripheral.

Depending on the configuration, the module supports most I2C features. See Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2) for more information.

45.3.1.1.3 How a target rejoins the I3C bus

When a target tries to rejoin the I3C bus following a power-up or hard reset, the target needs a new dynamic address (DA). The target can rejoin the I3C bus in these ways:

- If the DA is lost, Hot-Join is used.
- If the DA is retained in the peripheral (for example, with state retention flip-flops), SCONFIG[OFFLINE] is used.

When SCONFIG[SLVENA] is 1, SCONFIG[OFFLINE] may become 1. This setting causes the peripheral to rejoin the bus safely. It does so by ensuring that the I3C bus is not in HDR mode, using the same approach as TE0 or TE1 exit. The peripheral waits for the HDR exit pattern from the controller, or for 60 µs of SCL and SDA lines not changing, whichever occurs first.

After using SCONFIG[OFFLINE], the I3C peripheral cannot safely use IBI until SSTATUS[STOP] becomes 1. This status ensures that the next START is safe to use for IBI.

If the application has to perform an IBI, it must wait for SSTATUS[STOP] to become 1, or for SCL and SDA lines to remain high for 200 µs. You can perform this process using the SSTATUS and SINTSET controls:

- If Target Status (SSTATUS) indicates that the bus is not busy and the peripheral interrupts on START or STOP, use a timer to measure 200 µs. If the timer finishes with no START or STOP, it is safe to use IBI.
- If a START causes an interrupt, then the timer must be turned off and the application must wait for a STOP.
- If a STOP causes an interrupt, it is safe to use IBI.

45.3.1.2 Using the I3C controller for I2C and I3C

The I3C controller operates with the following set of built-in capabilities with the application flow:

- Built-in enter dynamic address assignment (ENTDAA) mechanism to simplify the assignment of dynamic addresses to targets. This feature is used when set dynamic address from static address (SETDASA) is not available.

  NOTE

  When SETDASA CCC is available, use SETDASA CCC before using ENTDAA CCC; all targets without assigned dynamic addresses respond to ENTDAA CCC.

- Request for START + address with IBI support, including both I2C and I3C modes.
- SDR write flow via FIFO, with automatic parity in I3C and ACK or NACK detection in I2C.
- SDR read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C.
- Request for Repeated START + address or STOP when finished with the previous request, including both I2C and I3C.
- Auto-IBI mode, which responds immediately to a target-initiated IBI and can be used when in Sleep or Deep Sleep mode.
- Special message mode for SDR and DDR to simplify DMA use.
- Automated SCL, SDA, pullup, and High-Keeper controls.
- I2C and I3C frequency and duty cycle configurations from functional clock.

  NOTE

  You must configure Controller Configuration (MCONFIG) and Controller In-band Interrupt Registry and Rules (MIBIRULES) before using the controller.

45.3.1.3 Protocol modes and states

The following modes are activated in I3C:

- I2C mode is the default mode on startup:
  - If no I2C static address is used, this mode has no effect other than to track frames looking for I3C transitional frames.
  - If an I2C static address is used, the device can interact with the I2C bus controller using the address.
- When in I2C mode, I3C Transitory Frame mode occurs whenever the I3C broadcast address is received (7Eh). In particular:

- This mode occurs when 7Eh is broadcast followed by SETDASA from the controller. If there is a static address match, the target is assigned a dynamic address and it enters I3C SDR mode.
- This mode occurs when 7Eh is broadcast followed by ENTDAA from the controller. If the target can send a 48-bit provisioned ID (48b ID), a dynamic address is assigned, and the target enters I3C SDR mode.
- If a Hot-Join arbitrated event occurs (sending 02h when the controller generates another address such as 7Eh), there is a conceptual Hot-Join mode. ENTDAA or SETDASA sets a dynamic address to resolve the event, and the target enters I3C SDR mode.

NOTE

An I3C target can operate as a normal I2C target only when it has a static address. Otherwise, it matches nothing in I2C and waits for the aforementioned events.

- I3C SDR mode is the standard mode after I3C activates, which is defined by a dynamic address being assigned. This mode is the resting mode of I3C, and all devices are normally in SDR mode:
  - RSTDAA CCC causes an exit from SDR mode and a return to I2C mode. This transition is not normally used.

    RSTDAA can be issued to ensure that all I3C targets participate in an upcoming dynamic address assignment process, before the I3C controller starts assigning the target address.
  - SETNEWDA does not affect the SDR mode; it only changes the dynamic address of an I3C device that already had a dynamic address assigned.
  - When in SDR mode, the device ignores messages to or from its original I2C static address.
- The I3C CCC command submode of type Direct or Broadcast. Following are the options to exit the CCC:
  - Exit the Broadcast CCC submode by a Repeated START or by a STOP.
  - Exit the Direct CCC submode by a 7Eh broadcast address after a Repeated START or by a STOP.
  - I3C dynamic address assignment (DAA) CCC command enters DAA mode. This mode is a special mode for dynamic addressing. Use STOP to exit. If a target has a dynamic address, the command is ignored.
- I3C SETDASA CCC command enters Static Address Match submode, which allows matching the static address of the device (if any). The command is ignored when a target has a dynamic address, or when the target in I2C mode has no static address.

NOTE

The special point-to-point address is also matched.

- I3C HDR modes are activated by ENTHDR*n* CCC commands, where *n* represents the type of HDR (0 to 7). This mode is valid until an HDR exit pattern is detected, irrespective of whether HDR mode for a target is supported.

  Exit-pattern detection must always be on to prevent errors. Alternatively, you could set it to be activated only on ENTHDR.
- A special HDR-DDR syntax is used for transmitting CCC in the HDR-DDR protocol.
- Internal states such as IBI or no-IBI and Low-Power mode are flagged internally (see SSTATUS[EVDET] for more information). These states are exported to the application and affect the engine to restrain it from performing a prohibited operation.

45.3.1.4 Address match

For an address match to occur, the target matches the I3C broadcast address and either the I2C-style static address or I3C dynamic address (see Table 319).

The address match is inactive (just listening) for all Repeated START commands and also for the START command, unless an IBI, CR, or Hot-Join has been activated. If inactive, it simply tries to match. If not matched, it waits for a Repeated START or STOP command. If an IBI, CR, or Hot-Join has been activated, the arbitration mechanism is used for START (but never for a Repeated START).

When matching the 7Eh broadcast address, it looks for a CCC until the next Repeated START or STOP command.

Table 319. Address match conditions

For	Match condition occurs when	Notes
I3C broadcast address	The address is 111 1110b (written as 7Eh).	
I2C-style static address	• The device has a static address. • The device is not in I3C mode.	When in I3C mode, the address matches only until the ENTDAA, SETDASA, or SETAASA command has a dynamic address assigned. SETDASA matches the static address or the special one-controller-to-one-target point-to-point address.
I3C dynamic address	ENTDAA or SETDASA assigns it, or SETNEWDA modifies it.	

45.3.1.5 I3C from low power mode and wake-up

A wake-up interrupt is available to bring the I3C module out of low power mode.

This interrupt works in both Controller and Target mode of operation as described below.

45.3.1.5.1 Controller mode

In Controller mode, I3C works with 2 clocks.

- Host interface clock for accessing registers and DMA
- Functional clock (FCLK) for controller logic operation and generating SCL

The Functional clock can be switched off to keep the I3C controller in low power mode if there is no data to be sent by the host and the i3C bus is in idle state (SDA = 1).

Before switching off the clock, take the below steps.

- Ensure that you enable the Controller mode MCONFIG[MSTENA] = 01b.
- Ensure that the bus is in the idle state.
- Switch off the Functional Clock.

If any agent on the bus pulls the SDA line low and at the SoC level the ENABLE bit of the I3C SDA interrupt is set to 1, then the interrupt goes high to inform the SoC logic to switch on the FCLK again.

45.3.1.5.2 Target mode

In Target mode, I3C works with only the Host interface clock (for accessing registers and DMA)

The main target control logic works on the external SCL clock.

The Host interface clock can be switched off to keep the I3C Target in low-power mode.

Before switching off the clock, take these steps.

- Ensure that you configure the Target mode, MCONFIG[MSTENA] = 00b along with all other normal target configuration as required.
- Clear the interrupts in Target Status (SSTATUS) after handling them.
- Enable DA matched interrupt in SINTSET[MATCHED].

- The host can now stop the Host interface clock to enter low power mode.

The interrupt asserts when any address match happens, either DA or SA or group address with this target.

The host then resumes the Host interface clock to serve and clear the interrupt.

45.3.2 Operations

This section describes the operations of the module.

45.3.2.1 Reading and writing I2C messages using the normal method

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to read out data.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to supply data.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure the following fields in Controller Control (MCTRL) simultaneously:
   a. Write 1 to REQUEST (EmitStartAddr).
   b. Write 1 to TYPE (I2C).
   c. Configure IBIRESP to respond to IBIs in your chosen manner.
   d. Write 1 to DIR for read, or write 0 for write.
   e. Write the static address of the I2C target to ADDR.
   f. Configure RDTERM to the maximum length for read operations, to auto-terminate, or set it to STOP as the data is read out. For example, write 1 (with MCTRL[REQUEST] = 0) to stop after the next character.
3. Write or read the data.
   - For write operations, write to Controller Write Data Byte (MWDATAB) for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte:
     — You can perform or start this operation before setting up interrupts.
     — If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.
   - For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB). DMA may also be used.
4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may end with a STOP condition, or a new message may start with a Repeated START condition:
   a. Write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion. (When sending STOP in I2C mode, MCONFIG[ODSTOP] and MCTRL[TYPE] must be 1.)
   b. Write 1 to MCTRL[REQUEST] (EmitStartAddr to restart). IBI is not possible in this case.

NOTE

I2C Fm and I2C Fm+ modes are supported for legacy I2C devices as per the I3C standard specifications. See I2C configuration to meet timing requirements for Fm and Fm+ modes for more information.

45.3.2.2 Reading and writing I3C messages using the normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as the method for I2C with a few differences:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the I3C module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to read out bytes.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to supply bytes.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Set up Controller Control (MCTRL).
   - Option 1: Configure the following fields of Controller Control (MCTRL) simultaneously in this way:
     a. Write 1 to REQUEST (EmitStartAddr).
     b. Write 0 to TYPE for I3C Single Data Rate (SDR) mode or write 2 for Double Data Rate (DDR) mode.
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 1 to DIR for read, or write 0 for write.
     e. Write the dynamic address of the I3C target to ADDR.
     f. For read operations, you can configure RDTERM to the maximum length to terminate automatically.
     g. For write operations, prewriting the data (MWDATAB or MWDATAH) is preferred to ensure that there are no time delays waiting for the data.

        For DMA with MCTRL, use either Controller Write Byte Data 1 (to Bus) (MWDATAB1) or Controller Write Halfword Data (to Bus) (MWDATAH1).

     NOTE

     HDR-DDR mode requires writing an 8-bit command value for read or write. This value must be written into the TX FIFO via Controller Write Data Byte (MWDATAB). The END field is not used for this byte.

   - Option 2: This option is preferred when stopped (bus free condition) in SDR mode, and not in HDR-DDR mode. It allows any target to issue an IBI and avoids collisions with an IBI address. Also, it is faster (when the MSB of the dynamic address is always 0).

     Configure the following fields of Controller Control (MCTRL) in this way:
     a. Write 1 to REQUEST (EmitStartAddr). No prewritten transmit data can be in the FIFO.
     b. Write 0 to TYPE (I3C).
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 0 to DIR.
     e. Write 7Eh to ADDR.
     f. Wait for MCTRLDONE (via interrupt, for example), then proceed as in option 1. The option 2 method has advantages for IBIs when 7Eh is sent on START (but not on Repeated START conditions).
3. Write or read the data.
   - For write operations, write to MWDATAB for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte. For HDR-DDR, the byte with END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs:

— You can perform or start this operation before step 1 (REQUEST = 1) of the option 1 method, but not before the option 2 method.

— If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.

- For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB) or Controller Read Data Halfword (MRDATAH). DMA may also be used. When using DMA, read using the same registers.

4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may be ended with STOP (or EXIT in HDR mode). Alternatively, a new message may be started with a Repeated START (or HDR-Restart in HDR mode):
   - In SDR mode, write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion.
   - For HDR mode, write 6 to MCTRL[REQUEST] (ForceExit) to end HDR mode. Then wait for the MCTRLDONE status to be asserted for its completion. When sending the HDR exit pattern, MCONFIG[ODSTOP] must be 0.
   - Write 1 to MCTRL[REQUEST] (EmitStartAddr to start another message). IBI is not possible in this case.

45.3.2.3 Determining bus types and modes

The settings of MCTRL[TYPE] and MCTRL[REQUEST] determine bus types and modes.

Table 320. Determining bus types and modes

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
0	SDR mode of I3C	SDR mode of I3C	Exit pattern
1	Standard I2C protocol	Standard I2C protocol	Reserved
2	The bus enters DDR mode (7E and then ENTHDR0), if the module is not in DDR mode already. The first byte written to the transmit FIFO must be a command and already in the FIFO. To end DDR mode, use ForceExit.	Reserved	Target reset
3	If not already in HDR-BT, the bus automatically enters BT mode (7E and then ENTHDR3). You must also configure the MHDRBTCFG register for multilane and CMD rules.	Reserved	Reserved

Table 321. Deriving the dynamic address

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 4 (ProcessDAA)
0	The dynamic address is derived from MWDATAB[VALUE]; in case of a NACK, ProcessDAA continues to the next 7E/R request.
1	Reserved
2	The dynamic address is derived from MWDATAB[VALUE]; in case of a NACK, a STOP condition is sent after the assignment.
3	Reserved

45.3.2.4 Sending a CCC to I3C targets

The normal common command code (CCC) method uses an I3C write operation with an address of 7Eh (the CCC is the first byte):

- For broadcast type, any remaining bytes are sent with the CCC. This operation ends with a STOP or a Repeated START and 7Eh.
- For direct type, only the CCC byte is sent (or by a CCC and a defining byte, if required by the CCC).

  These bytes are followed by a Repeated START and the address of the I3C target (for SETDASA, this address is its I2C static address). This sequence may be repeated with more Repeated START conditions and addresses until done. It may end in STOP or a Repeated START and 7Eh. After the Repeated START and target address, the values are read or written depending on the CCC.
- I3C provides interrupts (by hardware) for unhandled and handled CCC when received by the target. Its state is reflected in Target Status (SSTATUS).

I3C controllers require to emit a single START, 7E/W sequence with both SCL high and SCL low half periods at full open-drain timing (for example, 200 ns). This sequence allows I3C targets acting as I2C legacy devices to turn off their I2C 50-ns spike filters, if they have them.

NOTE

START, 7E/W is a notation indicating a START command, followed by the 7Eh broadcast address and then by a write command.

After that sequence, addresses following START may be sent with Open-Drain Low (for example, 200 ns) but high of Push-Pull timing (for example, 40 ns). The I3C controller must emit this START, 7E/W sequence with MCONFIG[ODHPP] = 0. ODHPP is Open-Drain High period at Push-Pull speeds, and MCONFIG[ODHPP] is usually 1.

NOTE

- MCONFIG[ODHPP] is ignored when sending a message to an I2C legacy device on an I3C bus.
- Each Repeated START is a new EmitStart request. This request can be chained by an interrupt or pushed by a message model using DMA.

45.3.2.5 IBI handling

An IBI occurs when a target sends its address after a START, and that address is numerically the lowest. That is, it is lower than the address sent by the controller and addresses sent by any other targets. When the controller sends 7Eh, the controller always loses the arbitration.

The IBI can occur unexpectedly when any new START (not a Repeated START) is sent. The IBI can also occur in response to a target pulling SDA low. This condition can occur in one of these ways:

- The controller has set the request to AutoIBI mode, so the IBI occurs automatically. The controller sends 7Eh to allow the target to win the arbitration.
- The application receives the SLVSTART (target START request) interrupt, so it sends 7Eh.

The IBI response is configured by MCTRL[IBIRESP], which can be set to:

- NACK (always reject the IBI).
- ACK (always accept the IBI):
  - You must configure Controller In-band Interrupt Registry and Rules (MIBIRULES) so that the engine knows whether IBI bytes follow.
  - If IBI bytes follow (also known as IBI mandatory byte), then the COMPLETE field does not become 1 when IBIWON becomes 1. RXPEND becomes 1 for one or more bytes in the receive FIFO. When the last byte is received, then the COMPLETE field becomes 1. The controller automatically stops IBI data after 9 bytes (including the mandatory data byte). MCTRL[RDTERM] can be used with MCTRL[REQUEST] = 0 to end the process of receiving data sooner. I3C

supports address ACK to mandatory byte transition during IBI from Open_Drain (controller acknowledges the target address) to Push Pull (target sends SDR data).

— I3C target supports up to 7 bytes (maximum limit is defined by IBIEXT1[MAX]) of extended IBI data following a mandatory data byte. Extended data to send, if any, is present in Extended IBI Data 1 (IBIEXT1) and Extended IBI Data 2 (IBIEXT2).

- Manual (allow the decision to be made by the application on a case-by-case basis):
  — The application rewrites it when stopped, pending an IBI.
  — The application can ACK or NACK the IBI based on the IBI address defined in MSTATUS.
  — This mode selects whether there is an IBI byte when accepting the IBI request from targets.

Accurate timestamping of I3C target data is supported in I3C though Async mode 0. In I3C Asynchronous Timing Control mode, a target device timestamp event occurs within that target. The target notifies the controller about the event by generating an IBI.

45.3.2.6 Assigning dynamic addresses to I3C devices

If dynamic addresses (DAs) are all assigned below 40h (7-bit values from 3Fh down to 03h, except where not allowed), then MIBIRULES[MSB0] can be 1. This setting optimizes the START timing. When dynamic addresses are assigned, you must program Controller In-band Interrupt Registry and Rules (MIBIRULES) based on which I3C target uses IBI bytes (present in SIDEXT[BCR]).

Any SETDASA assignments can be performed via the normal CCC model. These assignments cannot be performed when using the static address for the directed part.

There is a built-in mechanism to process ENTDAA mode:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when a target has sent its ID and BCR or DCR, and a new DA is needed.
   - COMPLETE: Indicates when DAA is done (NACKed by all targets).
   - RXPEND: Indicates the reading of the IDs of the targets. You can also use this field to allow DMA to read out bytes.
   - IBIWON: Indicates when an IBI has occurred (normally there are no IBI conditions when assigning dynamic addresses to the I3C device).
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure Controller Control (MCTRL):
   a. Write 4 to MCTRL[REQUEST] (ProcessDAA).
   b. Set MCTRL[IBIRESP] to IBI response, if possible. If not possible, set to the first target assignment.
3. Wait for the MCTRLDONE interrupt when reading ID using the RXPEND interrupt. If MSTATUS[STATE] = 5 (DAA mode) and MSTATUS[BETWEEN] = 1, it is waiting to write a dynamic address:
   a. Write the dynamic address into Controller Write Data Byte (MWDATAB) using bits 6:0, such as 14h for DA = 7'h14.
   b. Write 4 to MSTATUS[STATE] (ProcessDAA again). This option writes the DA, then moves to the next DA.
   c. If MSTATUS[COMPLETE] = 1 and MSTATUS[STATE] = 0, then all targets are assigned.
   d. If MSTATUS indicates NACK after writing a new DA, the DA is not accepted by the target. The next step is to write 2 to MCTRL[REQUEST] (EmitStop) and start over. It is also acceptable to write 4 to MCTRL[REQUEST] (ProcessDAA again).

45.3.2.7 Using Controller Message mode

Controller Message mode is intended for use with DMA although Message mode can also be used by the processor. In Message mode, all writes are to the same location, including control and data. Reads occur from an associated location.

NOTE

The data writes for Message mode work in the same way as the halfword access registers, Controller Write Data Halfword (MWDATAH) and Controller Read Data Halfword (MRDATAH).

To send a message via Single Data Rate (SDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL). This request includes the following items:
   - The address.
   - I2C or I3C.
   - Read or write.
   - The count of bytes to process.
   - How to end (on STOP or ready for Repeated START).
2. Process the data:
   - For write operations, write the rest of the data to Controller Write Message Data in SDR mode (MWMSG_SDR_DATA). Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when it has already consumed the number of bytes configured in the LEN field.
   - For read operations, a DMA trigger (or interrupt) indicates when the RX FIFO is ready to be read out via Controller Read Message in SDR mode (MRMSG_SDR).
3. Select the in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
4. Use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using Controller Control (MCTRL). To exit Message mode with the original message, use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using the MCTRL register.

To send a message via Double Data Rate (DDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL). This request includes:
   - The count of byte pairs.
   - How to end the message (through HDR exit or to wait for HDR restart).
2. Write the second control data to MWMSG_DDR_CONTROL. This second write includes:
   - The address.
   - Read or write.
   - The 7-bit command value.
3. Process the data:
   - For write operations, write the rest of the data to MWMSG_DDR_DATA. Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when the program count MWMSG_DDR_CONTROL register reaches 0.
   - For read operations, a DMA trigger (or interrupt) indicates when the receive FIFO is ready to be read out.
4. Select in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
5. Use END type exit (MCTRL[REQUEST] = 6) with a zero-length message or by using the MCTRL register to exit DDR Message mode with the original message.

45.3.2.8 Handing off controllership to another target and getting it back

To hand off controllership, the controller can perform either of the following actions:

- Wait for a controller request (CR) (that is, MSTATUS[IBIWON] = 1 interrupt), indicating that the CR is using MSTATUS[IBITYPE].
- Push the request manually.

In either case, the controller sends a GETACCMST request, which is a directed GET informing the target that it is being assigned controllership. If the target accepts this request, it returns its dynamic address in bits 7:1 and the negative parity of its dynamic address in bit 0. A STOP must be issued, and MCONFIG[MSTENA] must be set to 2 (switching to Target mode).

To gain controllership, the target sends a CR using Target Control (SCTRL):

- If MCONFIG[MSTENA] is 2, the GETACCCR CCC is ACKed.
- If MCONFIG[MSTENA] is not 2, the GETACCCR CCC is NACKed.

After controllership is granted, MSTATUS[NOWMASTER] becomes 1. The application must enable MINTSET[NOWMASTER], so the application is interrupted when a controllership transfer occurs.

45.3.2.9 Controller engine flow diagram

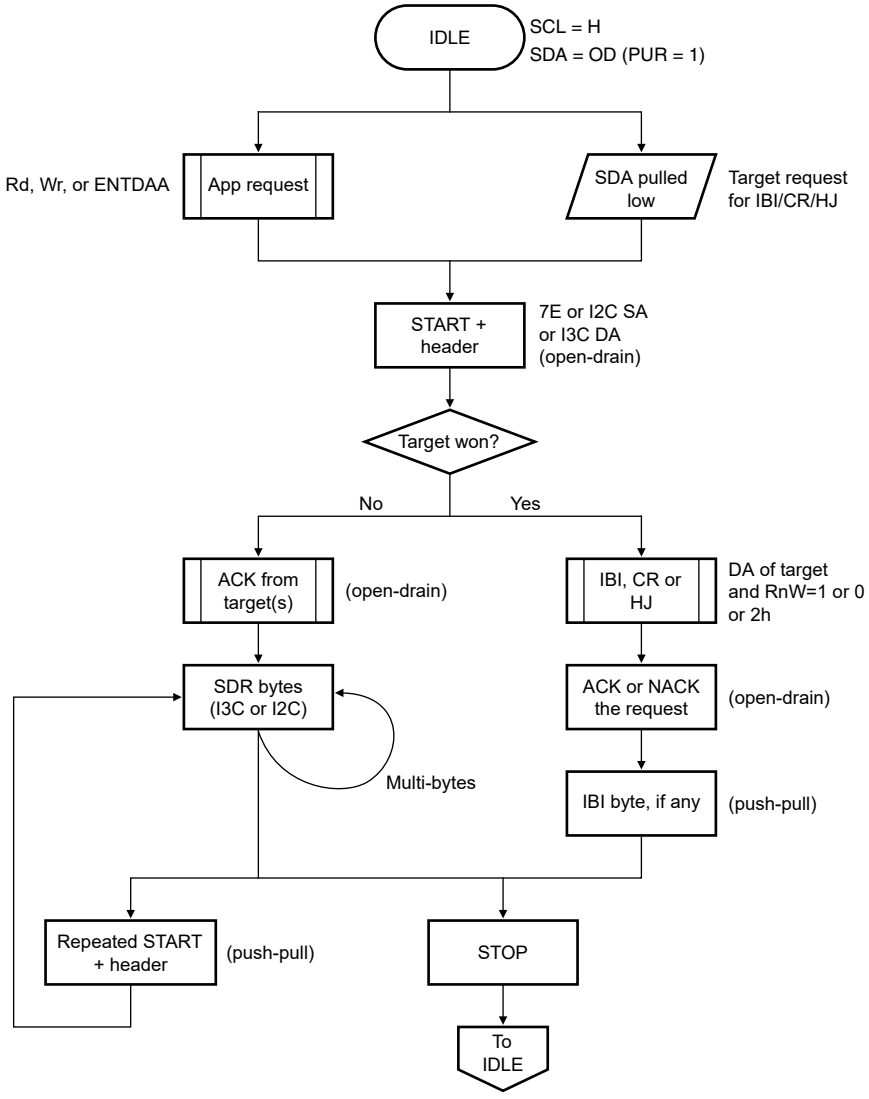

Figure 172. Controller engine flow diagram for SDR (HDR flow progresses from SDR bytes)

45.3.2.10 Target receives data from controller

When the address match is valid for the target dynamic address and the type is W (write from controller), the target ACKs the address. It does so unless some condition prevents it, such as a full buffer. On ACK, the Write state is entered. Once ACKed, it waits for each complete data byte. This process occurs in two steps:

1. Eight bits are clocked in and stored in the next buffer location when in the Write state.
2. On the ninth bit:
   - In I3C mode, the W9TH state (in I3C, the ninth data bit written by the controller is the parity of the preceding eight data bits) is used and the parity is checked. The buffer is marked as complete with or without a parity error.
   - In I2C mode, the W9TH state (in I2C, the ninth data bit written by the controller is an ACK by the target) is used and the data is ACKed and stored.

When the address match is valid for the 7Eh broadcast address, the target acknowledges it. After first data completion, it sets the in_ccc broadcast or direct flag (based on bit 7 of the command). If recognized, it parses the command, setting that bit as well. The recognized commands are for dynamic address work and modes. The CCC and DAA blocks handle the workload afterward. If not supported, then the commands are passed up to the system.

45.3.2.11 Target sends data to controller

When the address match is valid for the target dynamic address, and the type is R (read by controller), the target ACKs the address. The target does so unless there is no data waiting for the read. On ACK, the Read state is entered.

After being ACKed, it emits the data byte at a time, with the ninth bit using the R9TH state. In I2C, the ninth data bit from target to controller is an ACK by the controller. In I3C, this bit allows the target to end a read, and allows the controller to abort a read:

- In I3C mode, the T bit is emitted to allow the device to indicate whether this byte is the last. If it is not the last byte, the controller may terminate the read via the T bit.
- In I2C mode, the ninth bit allows the controller to terminate via NACK, or else it allows the read to continue via ACK. On completion of each byte read, the "done" signal is pulsed to get the next byte.

If the read is terminated by the controller unexpectedly (abort in I3C, NACK before END marked), the application is notified.

45.3.3 Clocking

The controller works on the following primary clocks:

- The system clock, which controls access to the memory-mapped registers.
- A functional clock (FCLK), which is used to generate the SCL clock rate on the I2C or I3C bus.

I3C supports adjusting clock frequency and accuracy via Target Time Control Clock (STCCLOCK).

FCLK is used to check conditions such as bus availability, bus free for IBI, or HJ:

- To determine the Bus Available condition for IBI, the target needs a clock to generate the ~1 µs timing. To support this requirement, a slow clock (CLK_SLOW) is provided to save on power.
- I3C supports a counter field, SCONFIG[BAMATCH], to calculate the Bus Available condition. BAMATCH provides the count of the slow clock . This field counts 1 µs or more to allow an IBI to drive SDA low when the controller is free. The I3C module controls the maximum width and maximum values.

I3C supports a timeout when stalled for too long in a frame. This timeout occurs when:

- The transmit FIFO or receive FIFO is not handled and the bus is stuck in the middle of a message.
- No STOP is issued and the bus is between messages.
- IBI manual is used and no decision is made.

45.3.4 Reset

- Global or system reset fed into the module: Everything is reset by this global or system reset. Release is assumed to be synchronized with the system clock. It is not synchronized with SCL or SDA. These signals must not be active when the reset is released; otherwise, I3C enters Hot-Join mode and remains inactive.
- Software reset

45.3.5 Interrupts

This section describes all the interrupts (IRQs) that this module generates. All status interrupts are updated in Controller Status (MSTATUS) and Target Status (SSTATUS).

Supported interrupts occur:

- For pending IBI, CR, or Hot-Join that have been sent by a target.
- When a CCC is received and is handled by the module (SSTATUS[CHANDLED]).
- When an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR, or CRC error.

A wake-up interrupt is also available to bring the I3C module out of low power mode. See I3C from low power mode and wake-up .

45.4 External signals

Table 322. External signals

Signal	Description	Direction
SCL	Serial clock	Input or output
SDA	Serial data	Input or output
PUR	Pull up resistance. There is an internal pullup resistance on SDA, which the I3C controls. If the internal pullup is not enough, PUR can control an external pullup resistance on SDA actively. See the chip-specific I3C information on whether this external pullup is available on your chip.	Output

45.5 Initialization

45.5.1 Controller configuration

Certain configuration is performed when initializing this module. Controller Configuration (MCONFIG) controls the frequencies, duty cycle, optimizations for performance, and other parameters.

Table 323. Configuration for module initialization

Configuration parameter		Description
MSTENA	Controller enable	Determines whether the peripheral starts in Controller mode (main controller in I3C terms) or starts in Target mode (and switches to Controller mode later).
HKEEP	High-Keeper	Determines how the high-keeper (weak pullup) is implemented, depending on the device capabilities.
PPBAUD	Push-Pull baud	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This frequency sets the SCL half-clock period baseline (used at least for the high time of SCL).

Table continues on the next page...

Table 323. Configuration for module initialization (continued)

Configuration parameter		Description
		The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is 0, then SCL high = SCL low (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) Examples: • If FCLK = 24 MHz, then PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then PPBAUD = 1 yields 12.5 MHz (20 + 20 = 40 ns per half period)
PPLOW	Push-Pull low	Changes the duty cycle for Push-Pull. It indicates how many more FCLK cycles to use for low. The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is a nonzero value, then: • SCL high (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) • SCL low (in ns) = (1 + PPBAUD + PPLOW) × 1000 ÷ FCLK (in MHz) For example, when FCLK is 50 MHz, PPBAUD is 1, and PPLOW is 1, then the periods are: • (1 + 1) × 1000 ÷ 50 = 20 + 20 = 40 ns high • (1 + 1 + 1) × 1000 ÷ 50 = 20 + 20 + 20 = 60 ns low This timing is equivalent to 10 MHz SCL, but this timing maintains the 40 ns high needed; therefore, I2C devices do not see the high periods. **NOTE** The PPLOW value does not have any impact on Open-Drain mode and I2C mode SCL rate calculations.
ODBAUD	Open-Drain baud	Determines the number of PPBAUD periods to make up one I3C Open-Drain half-clock baseline. If ODHPP is 0, the ODBAUD half-clock time period = (ODBAUD + 1) × PPBAUD high period. If ODHPP is 0, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (2 + 2 × PPBAUD) × (ODBAUD + 1) Target to get open-drain half-clock period is 200 ns. For example: • If PPBAUD yields 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 can be used to get 200 ns. See ODHPP for details on short high and long low. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (2 + 2 × 1) × 5 = 2.5 MHz.
ODHPP	Open-Drain High Push-Pull	Optional field that allows the I3C open drain to be long low and short high. The high period of SCL is the PPBAUD period. This period leaves enough time for the pullup resistor to pull the SDA high when SCL is low. It is also quick when SCL is high and there are no changes happening. ODBAUD low half-clock time period = (ODBAUD + 1) × PPBAUD high period.

Table continues on the next page...

Table 323. Configuration for module initialization (continued)

Configuration parameter		Description
		ODBAUD high half-clock time period = PPBAUD high period If ODHPP is 1, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (1 + PPBAUD) × (ODBAUD + 1) + (1 + PBAUD) For example: • If PPBAUD produces 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 and ODHPP = 1. These settings provide a high period of 40 ns and a low period of 200 ns. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (1 + 1) × 5 + (1 + 1) = 4.16 MHz.
I2CBAUD	I2C Baud	Indicates the number of ODBAUD periods that are required to communicate with I2C devices (MCTRL[TYPE] = 2 or MWMSG_SDR_CONTROL[I2C] = 1). For example, if ODBAUD gives 200 ns, and the goal is Fm+ (Fast Mode, 1 MHz), then the sum must be 1 µs. I2CBAUD acts differently for odd and even values. For example: • If I2CBAUD = 3, it gives three ODBAUD periods low and two ODBAUD periods high. • If I2CBAUD = 4, it gives three ODBAUD periods for low and three ODBAUD periods for high. • Also, if I2CBAUD = 3, this yields 200 × 3 = 600 ns and 200 × 2 = 400 ns, with the sum 600 + 400 = 1000 ns = 1 µs.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and return. This time is normally 2 ns to 5 ns (or sometimes more). If the skew is too fast, then add more delay. The skew allows specifying the number of FCLK to insert.

Additional optimizations:

- Use MIBIRULES[MSB0] to obtain faster start header times. If the controller application assigns all I3C dynamic addresses to be less than 40h (it does not have MSB set), you can write 1 to MIBIRULES[MSB0]. When the controller emits 7Eh (broadcast) and a target does not drive the first bit low, the rest of the header can be at push-pull speeds. This speed is two times faster or more, depending on optimizations.
- Auto-emit 7Eh speeds up the frame when used with MIBIRULES[MSB0]. It allows the processor to sleep when the frame starts automatically (in response to a target).

45.5.2 Interrupt service flow

Set up interrupts for Controller Status (MSTATUS) in Controller Interrupt Set (MINTSET).

Set up interrupts for Target Status (SSTATUS) in Target Interrupt Set (SINTSET).

45.6 Application information

45.6.1 I2C configuration to meet timing requirements for Fm and Fm+ modes

I2C Fm and I2C Fm+ modes are supported according to the I3C standard specifications.

Table 324 shows the configuration for Fm mode, where frequency is close to 400 kHz but timing requirement is not met (T_{SU_STA} is not met) because the actual value is 600 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 325 shows the configuration for Fm mode, where all timing requirements are met.

Table 324. Configuration for Fm mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	11	370 kHz	T_{SU_STA} - 353 ns

Table 325. Configuration for Fm mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	1	2	9	363 kHz	All requirements met per the I2C specifications in the chip data sheet

Table 326 shows the configuration for Fm+ mode, where the frequency is close to 1 MHz. In this case, the T_{SU_STA} timing requirement is not met because the actual value is 260 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 327 shows the configuration for Fm+ mode, where all timing requirements are met. To meet all the timing specifications, frequency may differ from 1 MHz. Use the configurations listed in Table 327.

Table 326. Configuration for Fm+ mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	3	960 kHz	T_{SU_STA} - 228 ns

Table 327. Configuration for Fm+ mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	3	6	749 kHz	All requirements met per the I2C specifications in the chip data sheet

NOTE

The controller module provides an option to slow down the clock for standard speed mode to support legacy I2C standard targets as well (although this option may not necessarily meet the exact timing requirement of the standard mode according to the standard I2C timing specification).

For the timing requirements under consideration, see the "I3C timing requirements when communicating with I2C legacy devices" table in the MIPI I3C v1.1.1 specification available on www.mipi.org.

45.7 I3C register descriptions

Writing to a read-only (RO) register, except to Controller Interrupt Mask (MINTMASKED), causes bus errors. This module does not verify whether programmed values in the registers are correct. You must ensure that valid programmed values are written.

However, the peripheral ignores writes to RO registers and returns 0 for reads from WO or nonexistent registers. It requires all 32-bit registers to be read and written as 32-bit and aligned to 32 bits. The peripheral uses the advanced peripheral bus (APB: AMBA 3 APB Protocol Specification v1.0); therefore, the peripheral does not know whether partial read or write operations (less than 32 bits) are used.

45.7.1 I3C memory map

I3C0 base address: 4003_5000h

45.7.2 Controller Configuration (MCONFIG)

Offset

Register	Offset
MCONFIG	0h

Function

Controls all controller states when the controller operation is enabled. You must not change this register during an active transaction.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	I2CBAUD				SKEW			ODHPP	ODBAUD

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PPLOW				PPBAUD				Reserved	ODSTOP	HKEEP		DISTO	0	MSTENA	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 I2CBAUD	I2C Baud Rate Specifies the I2C low and high times in ODBAUD counts. See I2CBAUD in Controller configuration.
27-25 SKEW	Skew Specifies the number of FCLK counts for an SDA change after SCL for I3C push-pull. This skew is in addition to the roundtrip of the SCL line from the pad back to the module (6 ns or more): • SKEW is normally not needed, so assign SKEW = 0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules. Use the following values: • In I2C Controller mode (MCONFIG[MSTENA] = 11b) — SKEW > 0 when clock stretching feature is not required. — SKEW = 0 when clock stretching feature is required. • In I3C Controller mode, use SKEW = 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 ODHPP	Open-drain High Push-Pull Enables ODHPP. If you write 0 to this field, open-drain SCL high half-clock period is the same as the open-drain low SCL half period. If you write 1 to this field, open-drain high SCL half-lock period is one PPBAUD count for I3C messages. This setting is faster and works for I3C devices. Any legacy I2C devices on the bus do not see the SCL high level at all (less than the spike filter period). For open-drain timing, check upon the first 7Eh broadcast allowing I3C peripherals acting as I2C legacy devices to turn off their I2C 50-ns spike filters. See Sending a CCC to I3C targets for more information. 0b - Disable 1b - Enable
23-16 ODBAUD	Open-drain Baud Rate Specifies the open-drain baud rate. ODBAUD is configured in terms of number of PPBAUD counts - 1. This field must not be 0; this setting is not the same as push-pull. See Controller configuration for more information. The open-drain baud rate is usually 200 ns (see I2CBAUD for I2C counts). When used with MCONFIG[ODHPP], this setting produces 250 ns per clock in I3C. In this case, if MCONFIG[PPBAUD] provides 12 MHz, then one PPBAUD count is half of 12 MHz, or 41.67 ns. To obtain a rate around 200 ns, use a value of 5 - 1 = 4 for ODBAUD.
15-12 PPLOW	Push-Pull Low Acts as an adder for push-pull low to create a duty cycle with a longer low period, with up to 15 more FCLK cycles low than high. PPLOW = 0 produces a 50/50 duty cycle.
11-8 PPBAUD	Push-Pull Baud Rate Specifies the push-pull baud rate. The number of FCLK counts makes each push-pull low and normally high period. PPBAUD = 0 when run at 1/2 input FCLK speed. For example, a 24 MHz FCLK produces a 12 MHz SCL because each FCLK is SCL low or SCL high. MCONFIG[PPLOW] has an effect on the duty cycle. For example, 24 MHz with 50/50 duty cycle is 12 MHz. However, when PPLOW adds three more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz or 5 beats).
7 —	Reserved
6 ODSTOP	Open-drain Stop Enables open-drain stop. If you write 0 to this field, open-drain stop is disabled. ODSTOP must be disabled when sending an HDR exit pattern. If you write 1 to this field, open-drain stop is enabled. STOP condition is emitted at open-drain speeds even for I3C messages. In legacy devices, this feature can ensure that the legacy devices see the STOP condition. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
5-4 HKEEP	High-Keeper Indicates how High-Keeper is supported. If this field is 00b, use pull-up resistor (PUR). No separate pin_HK_SDA or pin_HK_SCL is used. Only pin_PUR_oena is used for SDA. The pin_SCL_oena pin is held high in this mode, SCL clock is push-pull, and pin_SCL_out toggles, which is the actual clock. If this field is 01b, High-Keeper controls are in place; pin_HK_SDA or pin_HK_SCL (High-Keeper) controls are used. SCL may use an HK or that signal (pin_HK_SCL) may only OR into pin_SCL_oena. The pin_HK_SDA pin is used as well for SDA high keeper, along with pin_PUR_oena. Use HKEEP = 10b or 11b for I2C modes. Use HKEEP = 00b or 01b for I3C modes. **NOTE** Your chip may not support any or all High-Keeper methods. You must check the availability of High-Keeper methods. 00b - None 01b - WIRED_IN 10b - PASSIVE_SDA (I2C mode, no clock stretches mode). SDA is open drain, and will be Hi-Z (high-impedance) for Bus Free (IDLE) and hold. The pin pin_HK_SDA is not used in this option, only a combination of SDA_oena and pin_PUR_oena are used. SCL is push-pull. The pin pin_HK_SCL is not used in this option, only pin_SCL_oena is used. Since the controller does not support multi-controller mode, there is no need to have open-drain SCL for I2C. For a single controller application, the controller's SCL output can be a push-pull driver design if there are no devices on the bus which would stretch the clock. 11b - PASSIVE_ON_SDA_SCL. For I2C clock stretching mode, where both SCL and SDA are open-drain. Open-Drain on both SDA and SCL, can Hi-Z (high-impedance) both for Bus Free (IDLE), and can Hi-Z SDA for hold. Does not support multi-controller mode, SCL open-drain is only to support clock stretching.
3 DISTO	Disable Timeout Disables the timeout that produces application errors. If the controller is left in a state other than Stopped for more than 100 µs (because 10 kHz is the slowest allowed I3C speed), the timeout sends a MERRWARN interrupt. To prevent the MERRWARN interrupt during development or testing, write 1 to DISTO to disable the timeout. In systems that support timeouts, timeout is disabled automatically during debug. To obtain a clock configuration with 100 µs timeout, see SCONFIG[BAMATCH]. 0b - Enabled 1b - Disabled
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 MSTENA	Controller Enable Indicates whether the controller is enabled and the states it can use. If this field is 0b, the controller is disabled. The module can only use Target mode. If this field is 1b, the controller is enabled. When used upon start-up, this module is the main controller by default. I3C controls the bus unless the controller is handed off. When this happens, MSTENA must become 2 so that it has the capability to become the controller again. Performing the handoff means emitting the GETACCMST CCC command. If the command is accepted, I3C emits a STOP condition and sets this field to 2 (or 0). If this field is 10b, I3C is controller-capable, but is operating as a target now. When used from the start, I3C starts as a target, but is prepared to switch to Controller mode. To switch to this mode, the target emits a controller request (CR) or receives a GETACCMST CCC command and accepts it (to switch on the STOP condition). Legacy I2C—if this field is 11b, I2C Controller mode uses an open-drain clock (to allow clock stretching) and relies on passive pull-up resistors (PURs) on both SCL and SDA. This mode uses only I2CBAUD. START requests can only be made for I2C type, and I3C requests are not accepted. If there are only I2C targets on the bus and no clock stretching, use type 1 instead. Type 1 has a push-pull SCL clock, which is faster and uses less power. 00b - CONTROLLER_OFF 01b - CONTROLLER_ON 10b - CONTROLLER_CAPABLE 11b - I2C_CONTROLLER_MODE

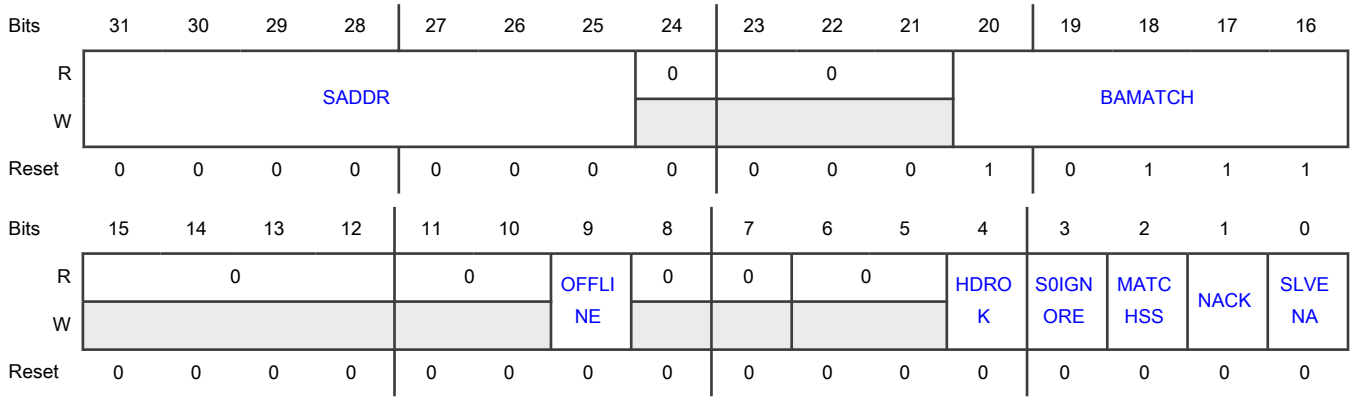
45.7.3 Target Configuration (SCONFIG)

Offset

Register	Offset
SCONFIG	4h

Function
Contains fields that must be configured before the module is activated.

Diagram



Fields

Field	Function
31-25 SADDR	Static Address Sets the I2C 7-bit static address, which otherwise must be 0.
24 —	Reserved
23-21 —	Reserved
20-16 BAMATCH	Bus Available Match Specifies the bus available condition match value for the current slow clock. BAMATCH provides the count of the slow clock to count out 1 µs (or more). The BAMATCH should be set as (slowClk(MHz) - 1) to generate a 1 µs clock cycle. Use BAMATCH = 1 to generate 1 µs clock cycle if slow clock is 1 MHz. A value of 0 would not give a correct match indication. The default value applies to the default slow clock setting of the chip. If the I3C slow clock is updated to a new value, BAMATCH must be updated, too. When I3C operates in Controller mode, BAMATCH is used to generate a 1 µs clock cycle basic time to count 100 µs timeout. When I3C operates in Target mode, BAMATCH allows the IBI to drive SDA low when the controller is not doing so.
15-12 —	Reserved
11-10 —	Reserved
9	Offline

Table continues on the next page...

Table continued from the previous page...

Field	Function
OFFLINE	Enables wait to ensure that the bus is not in HDR mode. If this field is 1 when SCONFIG[SLVENA] is 1, then I3C waits for either 60 µs of bus quiet or an HDR exit pattern. This waiting ensures that the bus is not in HDR mode, and so can safely monitor the next activity in Single Data Rate (SDR) mode. 0b - Disable 1b - Enable
8 —	Reserved
7 —	Reserved
6-5 —	Reserved
4 HDROK	HDR OK Enables HDR OK. If you write 1 to this field, it allows HDR-DDR and/or HDR-BT messaging, if available, by writing 1 to the corresponding SIDEXT[BCR] field to indicate HDR is available, and the corresponding GETCAPS field for DDR and/or BT bit permitting use. This is a deprecated field; use the SIDEXT[BCR] field instead. 0b - Disable HDR OK 1b - Enable HDR OK
3 S0IGNORE	Ignore TE0 or TE1 Errors Ignores TE0 or TE1 errors. If you write 1 to this field, the target does not detect TE0 or TE1 errors, so it does not lock up waiting on an exit pattern. You must not use this setting when the bus does not use HDR mode. 0b - Do not ignore TE0 or TE1 errors 1b - Ignore TE0 or TE1 errors
2 MATCHSS	Match Start or Stop Enables matched START, that is Repeated START, or STOP condition. If you write 1 to this field, SINTSET[START] and SINTSET[STOP] become 1 only when SSTATUS[MATCHED] is 1. This setting allows the START and STOP fields to be used to detect the end of a message to or from this target. **NOTE** SSTATUS[START] does not assert for START of transaction if SCONFIG[MATCHSS] = 1. SSTATUS[START] only asserts for Repeated Start within that transaction, because SSTATUS[START] only asserts after SSTATUS[MATCHED] occurs, which is after START of transaction.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
1 NACK	Not Acknowledge Controls the ACK or NACK capability. If you write 1 to this field, the target rejects all requests, except for a CCC broadcast. NACK = 1 must be used with caution because the controller may decide that the target is missing, if NACK is overused. 0b - Always disable NACK mode 1b - Always enable NACK mode (works normally)
0 SLVENA	Target Enable Enables the target. If you write 0 to this field, the target ignores the I2C or I3C bus. If you write 1 to this field, the target can operate on the I2C or I3C bus. You must not write 1 to this field before registers such as Target Configuration (SCONFIG), Target ID Part Number (SIDPARTNO), Target ID Extension (SIDEXT), and others are configured because these registers affect the data to and from the controller. Target enable is configured just once before the bus comes up. If target enable is used at other times, SCAPABILITIES[IBI_MR_HJ] must be 1 before writing 1 to SLVENA so that the device does not see a START or STOP condition incorrectly. 0b - Disable 1b - Enable

45.7.4 Target Status (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Indicates the sticky status for interrupts, states, and modes related to the I3C bus. Not all fields of the register are used if the module only acts as a target. The fields are divided into current activity, interrupt maskable actions, and then states and modes on the bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 TIMECTRL	Time Control Indicates whether time control is enabled, and in which mode. 00b - NO_TIME_CONTROL (no time control is enabled) 01b - SYNC_MODE (Synchronous mode is enabled) 10b - ASYNC_MODE (Asynchronous standard mode (0 or 1) is enabled) 11b - BOTHSYNCASYNC (both Synchronous and Asynchronous modes are enabled)
29-28 ACTSTATE	Activity State from Common Command Codes (CCC) Indicates the activity state from CCC. 00b - NO_LATENCY (normal bus operations) 01b - LATENCY_1MS (1 ms of latency) 10b - LATENCY_100MS (100 ms of latency) 11b - LATENCY_10S (10 seconds of latency)
27 HJDIS	Hot-Join Disabled Indicates whether hot-join is disabled. When hot-join is disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
26 —	Reserved
25 MRDIS	Controller Requests Disable Indicates whether controller requests are disabled. When controller requests are disabled, CTRL requests are not responded to.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
24 IBIDIS	In-Band Interrupts Disable Indicates whether in-band interrupts are disabled. When in-band interrupts are disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
23-22 —	Reserved
21-20 EVDET	Event Details Indicates current details of the last (EVENT = 1) or pending event. 00b - NONE (no event or no pending event) 01b - NO_REQUEST (request is not sent yet; either there is no START condition yet, or is waiting for Bus-Available or Bus-Idle (HJ)) 10b - NACKed (not acknowledged, request sent and rejected); I3C tries again 11b - ACKed (acknowledged; request sent and accepted), so done (unless the time control data is still being sent)
19 —	Reserved
18 EVENT	Event Flag Indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. See the upper status register fields for details. This field becomes 1 only when acknowledged by a controller. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No event occurred 1b - IBI, CR, or HJ occurred When writing 0b - No effect 1b - Clear the flag
17 CHANDLED	Common Command Code Handled Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether an HDRMATCH CCC is being handled by I3C. This field is for notification only, but it may result in updates to this register. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC handling not in progress 1b - CCC handling in progress When writing 0b - No effect 1b - Clear the flag
16 HDRMATCH	High Data Rate Command Match Flag Indicates whether the HDR command matched the I3C dynamic address of this device. The HDR command is available as the first byte, with RXPEND = 1. The MSB of the command byte indicates whether it is a read or a write command. If the HDR command is a read, and there are to-bus bytes waiting, then the command is ACKed and the data is sent back. Otherwise, the HDR command is NACKed. **NOTE** When this field is 1, you must check SSTATUS[ERRWARN] because the HPAR error may occur after signaling this HDR command. The parity occurs after the destination address and command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not match 1b - Matched the I3C dynamic address When writing 0b - No effect 1b - Clear the flag
15 ERRWARN	Error Warning Indicates that an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition (see Target Errors and Warnings (SERRWARN) for more information).
14 CCC	Common Command Code Flag Indicates whether a CCC has been received, and is not handled by I3C. There are two types of common command codes: • Broadcast CCC, which corresponds with RXPEND, and the first byte is the CCC (command).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Direct CCC, which may never be directed to this device. If the direct CCC is directed to this device, then TXSEND or RXPEND are triggered, and RXPEND contains the command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC not received 1b - CCC received When writing 0b - No effect 1b - Clear the flag
13 DACHG	Dynamic Address Change Flag Indicates an occurrence of dynamic address (DA) change. Actual DA can be seen in the DYNADDR register. If this field is 1, DA change is detected. The target DA has been assigned, reassigned, or reset (lost) and is now in the state of being valid or none. This field is also used when the MAP auto feature is configured, changing one or more MAP items. See DYNADDR and MAPCTRL*n* for more information. DYNAADDR for the main DA (0) indicates whether the last change was because of Auto-MAP. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No DA change detected 1b - DA change detected When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	Transmit Buffer Not Full Indicates that the transmit buffer is not full. If DMA is enabled for transmitting, then it is also signaled to provide more data. To-bus buffer or FIFO can accept more data to be transmitted. For all but external FIFOs, this process uses SDATACTRL[TXTRIG], which defaults to "not full". 0b - Transmit buffer full 1b - Transmit buffer not full
11 RX_PEND	Received Message Pending Indicates whether a received message is pending. The field indicates when a message from the controller that is not being handled by I3C (not a CCC message) is received. I3C processes such messages internally. For all but external FIFOs, this process uses SDATACTRL[RXTRIG], which

Table continues on the next page...

Table continued from the previous page...

Field	Function
	defaults to "not empty". If DMA is enabled for receiving, then DMA is signaled as well. This field automatically becomes 0 if data is read (from FIFO and non-FIFO sources). 0b - No received message pending 1b - Received message pending
10 STOP	Stop Flag Indicates whether the Stopped state is detected. The STNOTSTOP state also indicates when the module is in Stop mode. A fast STOP and START combination may not trigger the Stop status. In that case, the Start status is always set. If this field is 1, it indicates that the Stop state was present on the bus since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stopped state detected 1b - Stopped state detected When writing 0b - No effect 1b - Clear the flag
9 MATCHED	Matched Flag Indicates whether an incoming header matched the I3C dynamic or I2C static address (if any) of this device since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Header not matched 1b - Header matched When writing 0b - No effect 1b - Clear the flag
8 START	Start Flag Indicates whether a START or Repeated START was detected after this flag was last cleared. This flag is not usually needed, but can be used for wake events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 STHDR	Status High Data Rate Indicates whether the I3C bus is in HDR-DDR mode, regardless of whether HDR mode is supported by this module, and regardless of whether the message is intended for this module or some other module. 0b - I3C bus not in HDR-DDR mode 1b - I3C bus in HDR-DDR mode
5 STDAA	Status Dynamic Address Assignment Indicates whether the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus target has a dynamic address. 0b - Not in ENTDAA mode 1b - In ENTDAA mode
4 STREQWR	Status Request Write Indicates whether the REQ in process is SDR write data from the controller to this bus target (or all targets), but not in ENTDAA mode. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR write 1b - SDR write data from the controller, but not in ENTDAA mode
3 STREQRD	Status Request Read Indicates whether the REQ in process is an SDR read from this target. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR read 1b - SDR read from this target or an IBI is being pushed out
2	Status Common Command Code Handler

Table continues on the next page...

Table continued from the previous page...

Field	Function
STCCCH	Indicates whether a CCC message is being handled automatically. 0b - No CCC message handled 1b - Handled automatically
1 STMSG	Status Message Indicates whether the bus target is busy (listening to the bus traffic or responding). If STNOSTOP = 1, STMSG is 0 when a nonmatching address is seen, until the next Repeated START or STOP condition occurs. 0b - Idle 1b - Busy
0 STNOTSTOP	Status not Stop Indicates the status of the bus. If this field is 0, I3C is in a STOP condition. If this field is 1, the bus is busy (has activity). Other fields of this register may also be set when busy. STNOTSTOP can also become 1 after a TE0 or TE1 error, when I3C is waiting for an exit pattern. 0b - In STOP condition 1b - Busy

45.7.5 Target Control (SCTRL)

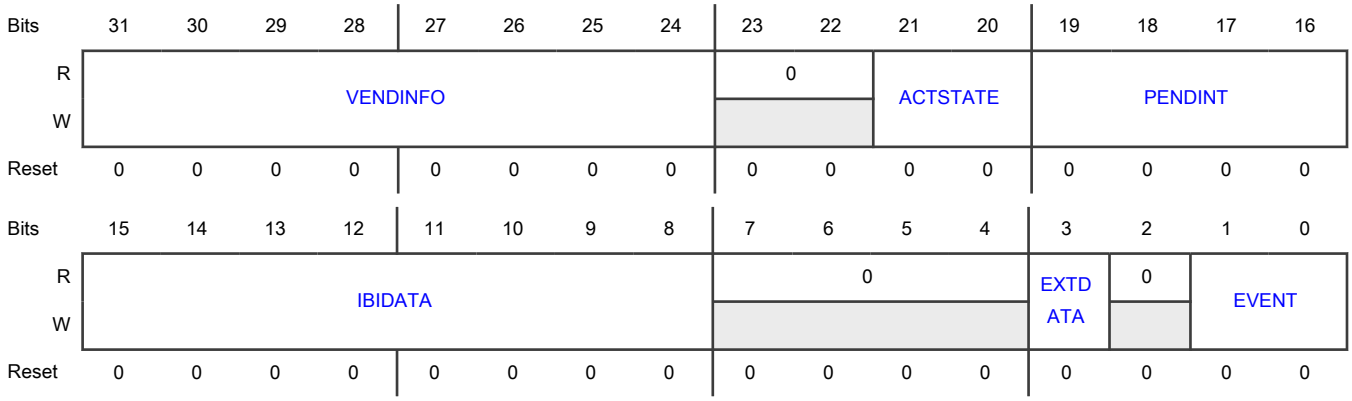
Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus (for example, event generation such as interrupts to the controller). Only if I3C is configured to support various special operations for the target, this register is used to activate those operations. These events include IBI and GETSTATUS fields (except the protocol error, which is automatically set).

Diagram



Fields

Field	Function
31-24 VENDINFO	Vendor Information Controls vendor information that the GETSTATUS CCC returns. You must set this field to the Vendor Reserved field that the GETSTATUS CCC returns. The application must maintain the vendor information because the controller reads this field. If this field is not configured, then the GETSTATUS field always returns 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity State of Target Controls the activity state of the target. You must set this field to the activity state of the target that the GETSTATUS CCC command returns as activity mode. The application must maintain the activity state because the controller reads this field. If you do not configure the activity state, then the GETSTATUS command always returns 0.
19-16 PENDINT	Pending Interrupt Specifies whether an IBI interrupt is pending. You must set this field to the pending interrupt that the GETSTATUS CCC command returns. The application must maintain the pending interrupt because the controller reads this field. If PENDINT = 0: • The GETSTATUS command returns 1 if an IBI interrupt is pending. • The GETSTATUS field returns 0 if an IBI interrupt is not pending.
15-8 IBIDATA	In-Band Interrupt Data Controls the data byte accompanying the IBI, if the module is enabled for IBI. If SCTRL[IBIDATA] is enabled, then IBI is required.
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 EXTDATA	Extended Data Enables extended data. After IBIDATA is emitted, extended data is acquired from IBIEXT1 and IBIEXT2, if configured. If extended data is used with time control, the data follows the time information. See IBIEXT1[MAX] for more information. 0b - Disable 1b - Enable
2 —	Reserved
1-0 EVENT	Event Requests an event. If this field is 0b, it indicates Normal mode, in which if this field becomes 0 from a nonzero value and event processing has not yet started, the event processing is canceled. However, event processing is not canceled if it has already started. If this field is 1b, an IBI is pushed onto the I3C bus. If there is data associated with the IBI, the data is read from SCTRL[IBIDATA]. If time control is enabled, this data includes any time-control-related bytes. Additionally, SCTRL[IBIDATA][7] becomes 1 automatically (as is required for time control). The IBI interrupt occurs after the first (mandatory) IBIDATA, if any. If this field is 10b, a controller request is started; the meaning depends on SIDEXT[BCR] configured in I3C. If this field is 11b, a hot-join (HJ) request is started, which is used when the device is powered on after the I3C bus is already powered up. It is also used when the device is connected using hot-insertion methods (the device is powered up when it is physically inserted in the powered-up I3C bus). The HJ waits for Bus Idle, and SCTRL[EVENT] = HOT_JOIN_REQUEST must be set before the target enable (SCONFIG[SLVENA]). If this field is a nonzero value, it requests an event. After the request, SSTATUS[EVENT] and SSTATUS[EVDET] show the status as it progresses. After completion, this field automatically returns to 0. After this field becomes a nonzero value, you can write only 0 it (to cancel) until the event processing is finished. 00b - NORMAL_MODE 01b - IBI 10b - CONTROLLER_REQUEST 11b - HOT_JOIN_REQUEST

45.7.6 Target Interrupt Set (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

Sets interrupt enables for select Target Status (SSTATUS) fields. Reading this register (SINTSET) returns the status of the interrupt enable:

- To activate an interrupt enable, write 1 to its corresponding field in this register (SINTSET).
- To disable an interrupt, write 1 to its corresponding field in Target Interrupt Clear (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow the masking of interrupt sources. They also allow the checking of which interrupts are activated. The normal method is to enable an interrupt, and then after the interrupt occurs, clear the interrupt either by writing to Target Status (SSTATUS) or by performing an action on the corresponding data register. The interrupt is level-held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races; if a new event occurs, that new event is not lost:

- SINTSET sets interrupt enables for Target Status (SSTATUS) fields. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for the SSTATUS fields.
- SINTMASKED returns the value of the SSTATUS fields ANDed with their interrupt enables.

Fields

Field	Function
31-20 —	Reserved
19 —	Reserved
18 EVENT	Event Interrupt Enable Enables event interrupts. This field indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. The field is configured to support events. See SSTATUS[EVDET] for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
17 CHANDLED	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field specifies whether CCC is being handled by I3C. Target Status (SSTATUS) shows new results. You can use this field to track when activity states and masks on events (for example, IBIs) occur. The field is used for CCCs that are enabled. 0b - Disable 1b - Enable
16 DDRMATCHED	Double Data Rate Interrupt Enable Enables DDR match for read or write command. This field indicates when DDR matches for read or write command, and the field is used only if HDR is enabled. 0b - Disable 1b - Enable
15 ERRWARN	Error or Warning Interrupt Enable Enables error or warning interrupts. This field indicates whether an error or warning has occurred, such as data underrun, data overrun, parity error, or HDR-DDR CRC error, or any other error or warning condition. See Target Errors and Warnings (SERRWARN) for cause of error. Only available for errors related to configured features. 0b - Disable 1b - Enable
14 CCC	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field indicates whether a CCC has been received, and is not handled by I3C. For CCCs that the block does not handle, RXPEND also interrupts, and SSTATUS[STREQRD] indicates that it is a CCC sending a read request. 0b - Disable 1b - Enable
13 DACHG	Dynamic Address Change Interrupt Enable Enables dynamic address change interrupts: interrupt on dynamic address defined (SETDASA or ENTDAA) or lost (RSTDAA). See Controller Dynamic Address (MDYNADDR) for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 TXSEND	Transmit Interrupt Enable Enables transmit interrupts. This field indicates whether to-bus buffer or FIFO can accept more data to be transmitted. The corresponding interrupt occurs when the controller requests data to read from this target. This interrupt occurs on the first request (header) as well as when it is ready for more data. The corresponding interrupt occurs when the controller requests data to be read from this target. If this interrupt is for a FIFO, it triggers on the transmit emptiness trigger. If this interrupt is for DMA, then it indicates message end (DMA end or termination). 0b - Disable 1b - Enable
11 RXPEND	Receive Interrupt Enable Enables receive interrupts. This field specifies when a message from the controller that is not being handled by the module is received. For example, where data is consumed by hardware directly when it goes into the FIFO (excludes CCCs being handled automatically). If this interrupt is for a FIFO, it indicates a receive fullness trigger. If this interrupt is for DMA, then it indicates message end. 0b - Disable 1b - Enable
10 STOP	Stop Interrupt Enable Enables stop interrupts. This field detects the Stopped state present on the bus since the bus was last cleared. Use SINTSET[START] as the preferred interrupt when needed. This interrupt may not trigger for a quick STOP and START combination because it relates to the state of being stopped. 0b - Disable 1b - Enable
9 MATCHED	Match Interrupt Enable Enables match interrupts. Incoming header matched the I3C dynamic or I2C static address of this device since the bus was last cleared. If configured and if no dynamic address is set, this interrupt is also for matching a header on an I2C static address. See Controller Dynamic Address (MDYNADDR) for related information. 0b - Disable 1b - Enable
8	Start Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
START	Enables start interrupts. A START or Repeated START (such as wakeup) is seen after this field last became 0. See SINTSET[STOP] for related information. 0b - Disable 1b - Enable
7-0 —	Reserved

45.7.7 Target Interrupt Clear (SINTCLR)

Offset

Register	Offset
SINTCLR	14h

Function

Clears interrupt enables for select Target Status (SSTATUS) fields. To clear an interrupt enable, write 1 to the corresponding field in this register (SINTCLR). Writing 0 has no effect.

45.7.9 Target Errors and Warnings (SERRWARN)

Offset

Register	Offset
SERRWARN	1Ch

Function

Contains errors and warnings from I3C and I2C protocols. This includes internal issues such as overrun and underrun, detected errors and conditions like parity errors, CRC errors, and read terminations by the controller. See SSTATUS[ERRWARN] and SINTSET[ERRWARN] for related information.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20-18 —	Reserved
17 OWRITE	Over-Write Error Flag Indicates that Target Write Data Byte (SWDATAB) or Target Write Data Byte End (SWDATABE) was written to when full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overwrite error 1b - Overwrite error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Over-Read Error Flag Indicates that Target Read Data Byte (SRDATAB) was read for more bytes than were available, by the application. This field also indicates over-read errors for Target Read Data Halfword (SRDATAH), if it is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No over-read error 1b - Over-read error When writing 0b - No effect 1b - Clear the flag
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 S0S1	TE0 or TE1 Error Flag Indicates whether a TE0 or TE1 error occurred and the target is locked and waiting for an HDR exit pattern. Writing 1 to S0S1 causes I3C to release the lock, but this method must be used with great care. S0S1 becomes 0 automatically when an exit pattern is detected, so writing 1 to S0S1 must be used under controlled circumstances to avoid problems. Before starting to operate normally after this error, I3C waits for a START (or Repeated START) or STOP state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No TE0 or TE1 error occurred 1b - TE0 or TE1 error occurred When writing 0b - No effect 1b - Clear the flag
10 HCRC	HDR-DDR CRC Error Flag Indicates whether an HDR-DDR CRC error occurred on a message from the controller. Error reasons include an HDR restart and an exit being issued before an HDR-DDR message from the controller has finished. This error calls into question the data from the entire DDR command frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No HDR-DDR CRC error occurred 1b - HDR-DDR CRC error occurred When writing 0b - No effect 1b - Clear the flag
9 HPAR	HDR Parity Error Flag Indicates when an HDR parity error or framing error on a message from the controller occurs. The corresponding command or data that has the error is usually in the RX buffer, which can be read using Target Read Data Byte (SRDATAB). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No HDR parity error 1b - HDR parity error When writing 0b - No effect 1b - Clear the flag
8 SPAR	SDR Parity Error Flag Indicates when an SDR parity error on a message from the controller occurs. This error also sets the GETSTATUS protocol error field (which becomes 0 after a GETSTATUS read). For read operations, this field becomes 1 when a read abort (timeout) occurs because of the controller not driving clock for more than 100 µs during an SDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No SDR parity error 1b - SDR parity error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 INVSTART	Invalid Start Error Flag Indicates an invalid condition with SCL falling before SDA falls, so there is no start. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No invalid start error 1b - Invalid start error When writing 0b - No effect 1b - Clear the flag
3 TERM	Terminated Error Flag Indicates when the controller terminates a read from a target, if an END is not set by the target (on the same read or the previous read). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No terminated error 1b - Terminated error When writing 0b - No effect 1b - Clear the flag
2 URUNNACK	Underrun and Not Acknowledged (NACKed) Error Flag Indicates when the internal to-bus buffer or FIFO is underrun in the read header and so the module NACKed the header. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun; not acknowledged error 1b - Underrun; not acknowledged error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Flag Indicates when the internal to-bus buffer or FIFO is underrun during data read (the application is not providing the data fast enough). The END field or register must be used if the read was the last one. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun error 1b - Underrun error When writing 0b - No effect 1b - Clear the flag
0 ORUN	Overrun Error Flag Indicates when the internal from-bus buffer or FIFO has overrun (arrival of too many characters that you cannot process fast enough). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun error 1b - Overrun error When writing 0b - No effect 1b - Clear the flag

45.7.10 Target DMA Control (SDMACTRL)

Offset

Register	Offset
SDMACTRL	20h

Function

Allows DMA to be used for inbound and outbound messages. This register is limited in value for target use because the target must be reactive. These are the two common use case models:

- To avoid an overrun in from-bus collection: if SCONFIG[MATCHSS] becomes 1, then the processor enables the interrupts for START and STOP and enables the DMA to collect the data. The START or STOP interrupt only occurs after a message is directed to the target (MATCHED is 1). The DMA copied data can then be examined.
- To perform larger reads from the to-bus: I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the target). Because of this process, the DMA can be used to push through the data:
  - For I3C, the processor must manage the last value, unless the DMA moves wider words and is able to write 1 to the END field. These values are 16-bit values when in Byte mode or 32-bit values when in Halfword mode.
  - For I2C, the controller determines the last value, so the DMA may end early or run out when the controller expects more values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								0		DMAWIDTH		DMATB		DMAFB	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	Width of DMA Operations Indicates the width of DMA operations, if configured to allow halfword data accesses. 00b,01b - Byte 10b - Halfword (16 bits) (this value ensures that two bytes are available in the FIFO) 11b - Reserved
3-2 DMATB	DMA Write (To-Bus) Trigger Enables DMA writes. If this field is enabled, it starts a request DMA on a transmit trigger (see Target Data Control (SDATACTRL)). DMATB requests until full, unless the DMA is set up as a trigger. DMATB becomes 0 when MSTATUS[ERRWARN] becomes 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you write 1b to this field, DMA is enabled for one frame (ended by DMA or terminated). DMATB automatically becomes 0 after a STOP or repeated START. See SCONFIG[MATCHSS] for more information. If you write 10b to this field, DMA is enabled until turned off. The value must only be used with Controller Message mode. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved
1-0 DMAFB	DMA Read (From-Bus) Trigger Enables DMA reads. If this field is enabled, DMAFB requests DMA on receive trigger (see SDATACTRL). It requests until empty, unless the DMA is set up as a trigger. This field becomes 0 when SSTATUS[ERRWARN] becomes 1. If this field is 1b (DMA is enabled for one frame), it automatically becomes 0 on STOP or repeated START. See SCONFIG[MATCHSS] for more information. **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the target and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved

45.7.11 Target Data Control (SDATACTRL)

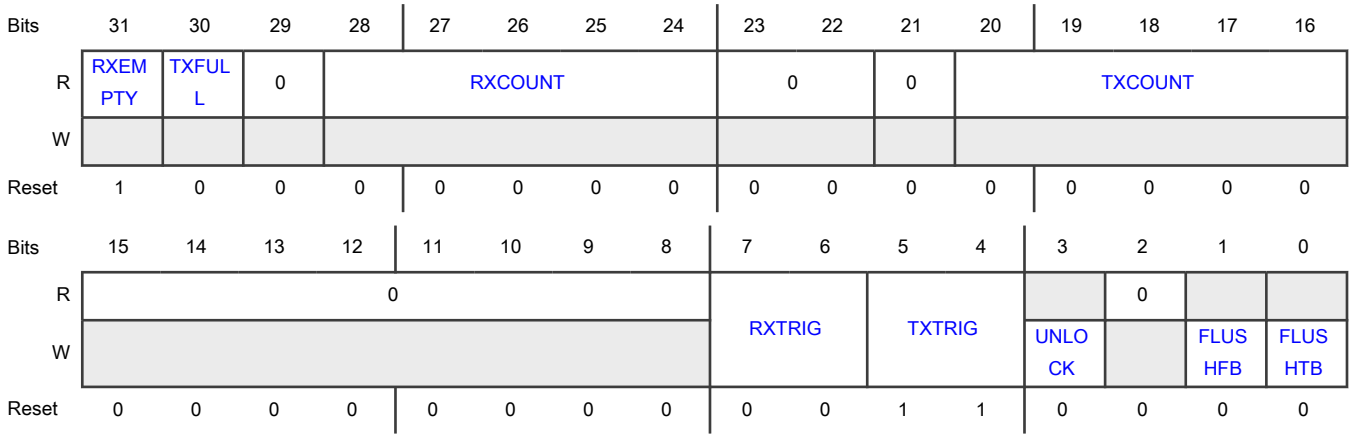
Offset

Register	Offset
SDATACTRL	2Ch

Function

Assists in data control when no FIFO is used. Also assists in data control of FIFO when the FIFO is available (regardless of size) allowing some control over the FIFO behavior. This register controls when to interrupt based on fullness or emptiness of a buffer or FIFO. It also controls behavior related to width, when the buffer or FIFO is not 1 byte wide.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Count of Entries in Receive Contains the count of entries in the receive FIFO or buffer. Entry size for SDR and HDR-DDR is in bytes.
23-22 —	Reserved
21 —	Reserved
20-16 TXCOUNT	Count of Entries in Transmit Contains the count of entries waiting in the TXFIFO. This count is the number of entries that the application has written to the transmit FIFO that have not yet gone onto the bus. Entry size for SDR and HDR-DDR is in bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. The field affects the RXPEND interrupt. 00b - Trigger when not empty (default) 01b - Trigger when 1/4 or more full 10b - Trigger when 1/2 or more full 11b - Trigger when 3/4 or more full
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. The field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Default (trigger when 1 less than full or less)
3 UNLOCK	Unlock Indicates whether the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 in the same cycle while writing to TXTRIG or RXTRIG. 0b - Cannot be changed 1b - Can be changed
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Not normally used. **NOTE** Before using FLUSHFB, disable the DMA (SDMACTRL[DMAFB] = 0). Then use FLUSHFB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer
0 FLUSHTB	Flush To-Bus Buffer or FIFO Indicates when the controller terminates a to-bus (read) message prematurely.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Before using FLUSHTB, disable the DMA (SDMACTRL[DMATB] = 0). Then use FLUSHTB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer

45.7.12 Target Write Data Byte (SWDATAB)

Offset

Register	Offset
SWDATAB	30h

Function
