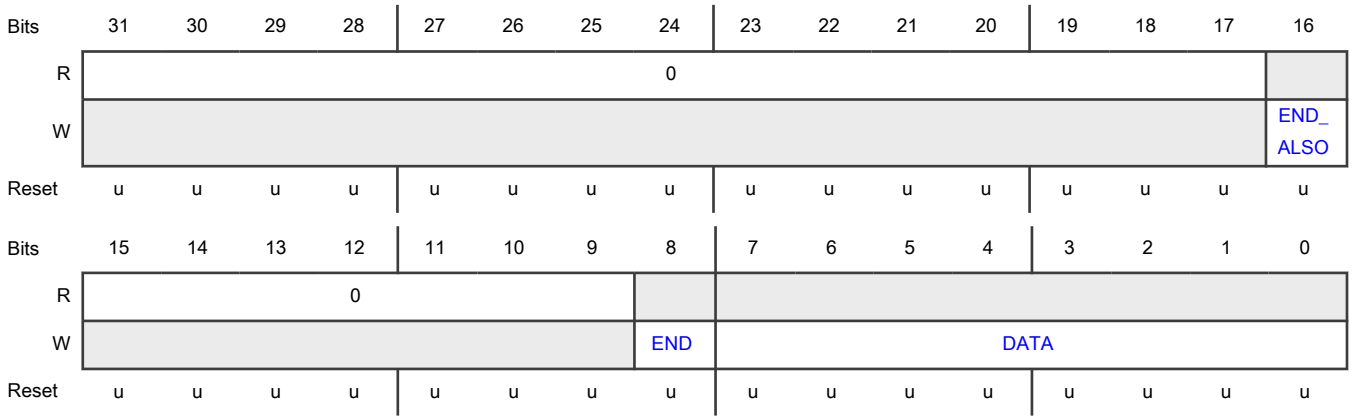
Allows writing a byte to the bus (to the controller) unless an external FIFO is used. Writing a byte requires a byte plus an end-of-data (last) marker bit. A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End Also Marks the last byte of the message. This field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End Marks the last byte of the message. If this field is 0, it indicates that there are more bytes in the message. This field is required for I3C, but is optional for I2C. For HDR-DDR, the byte with END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
7-0 DATA	Data Indicates the data byte to be sent to the controller.

45.7.13 Target Write Data Byte End (SWDATABE)

Offset

Register	Offset
SWDATABE	34h

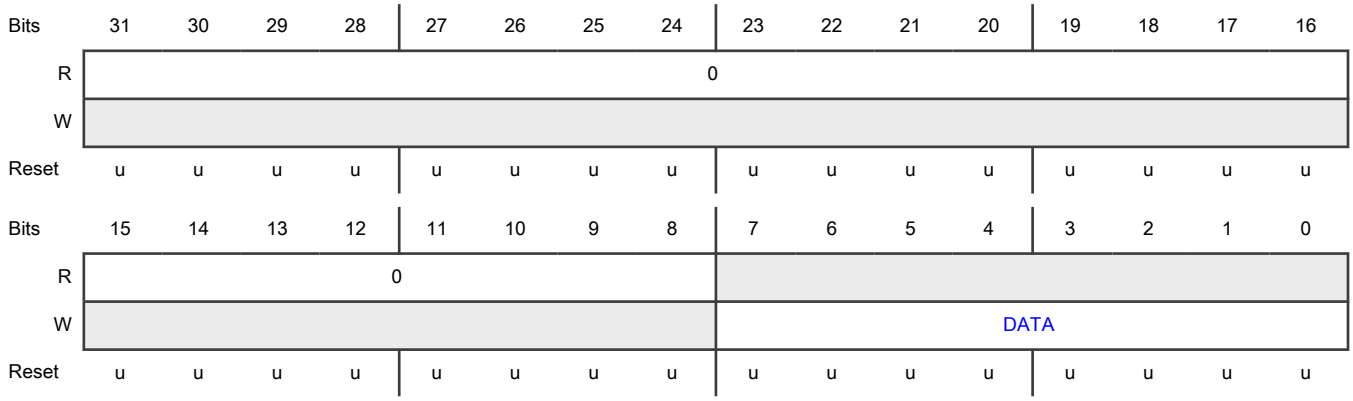
Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used.

Unlike Target Write Data Byte (SWDATAB), writing a byte only requires the byte itself, and is marked as end-of-data (last byte). A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the data byte to be sent to the controller.

45.7.14 Target Write Data Halfword (SWDATAH)

Offset

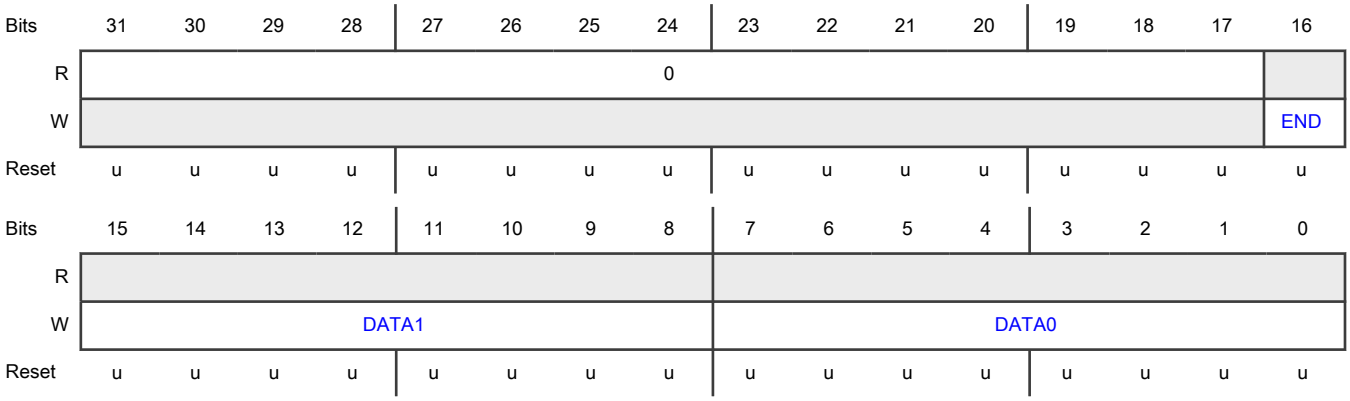
Register	Offset
SWDATAH	38h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used. The low byte is followed by the high byte. The 16th bit marks the end; that is, the last byte of the halfword is the end.

An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Marks the last byte of the message. This field always marks DATA1 as the end. The field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

45.7.15 Target Write Data Halfword End (SWDATAHE)

Offset

Register	Offset
SWDATAHE	3Ch

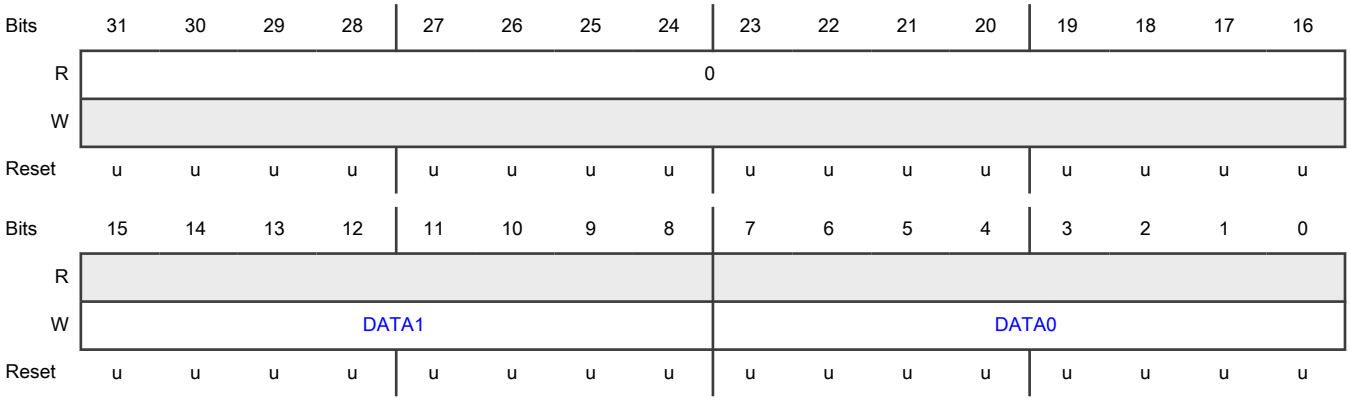
Function

Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way it writes to Target Write Data Halfword (SWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

45.7.16 Target Read Data Byte (SRDATAB)

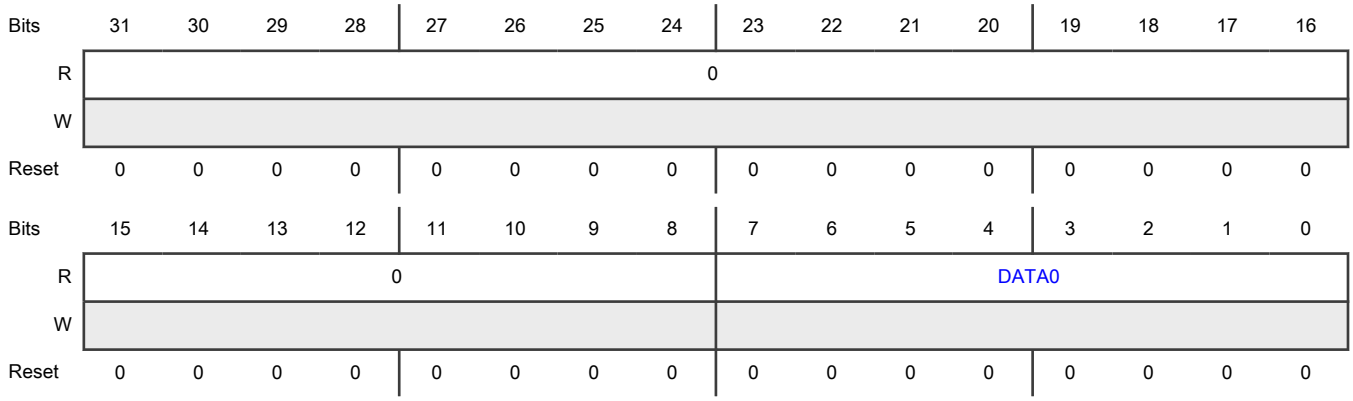
Offset

Register	Offset
SRDATAB	40h

Function

Allows reading a byte from the bus (controller). A byte must not be read unless there is data waiting, as indicated by SSTATUS[RX_PEND] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Data 0 Indicates the byte read from the controller.

45.7.17 Target Read Data Halfword (SRDATAH)

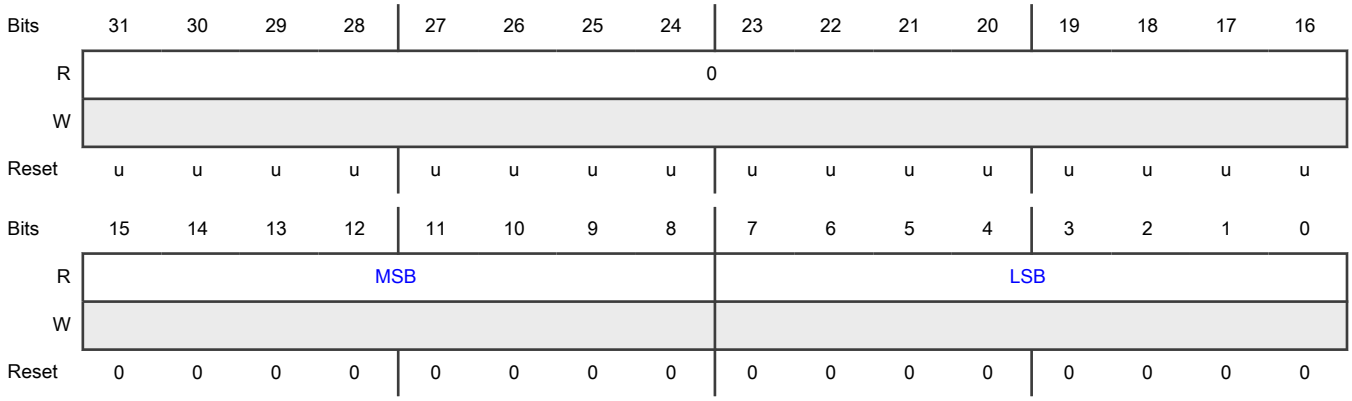
Offset

Register	Offset
SRDATAH	48h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the use of receive FIFO level trigger or SDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Indicates the second byte read from the target.
7-0 LSB	Low Byte Indicates the first byte read from the target.

45.7.18 Target Write Data Byte (SWDATAB1)

Offset

Register	Offset
SWDATAB1	54h

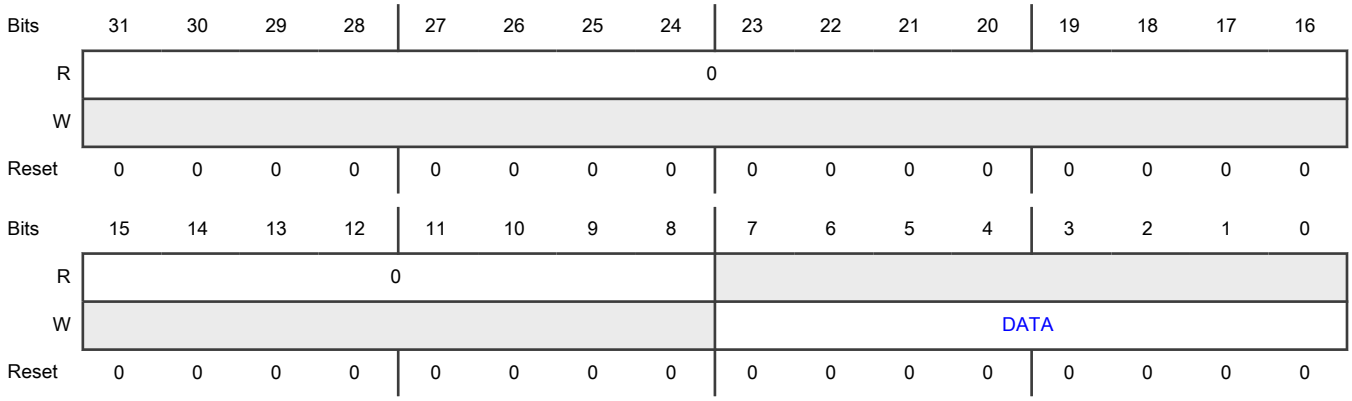
Function

Allows writing a single byte to the bus (to the controller) in a way that only bits 7:0 are used.

This register is intended to be used by DMAs (the upper bytes of the APB word are ignored).

A byte must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the byte to be sent to the controller.

45.7.19 Target Write Data Halfword (SWDATAH1)

Offset

Register	Offset
SWDATAH1	54h

Function

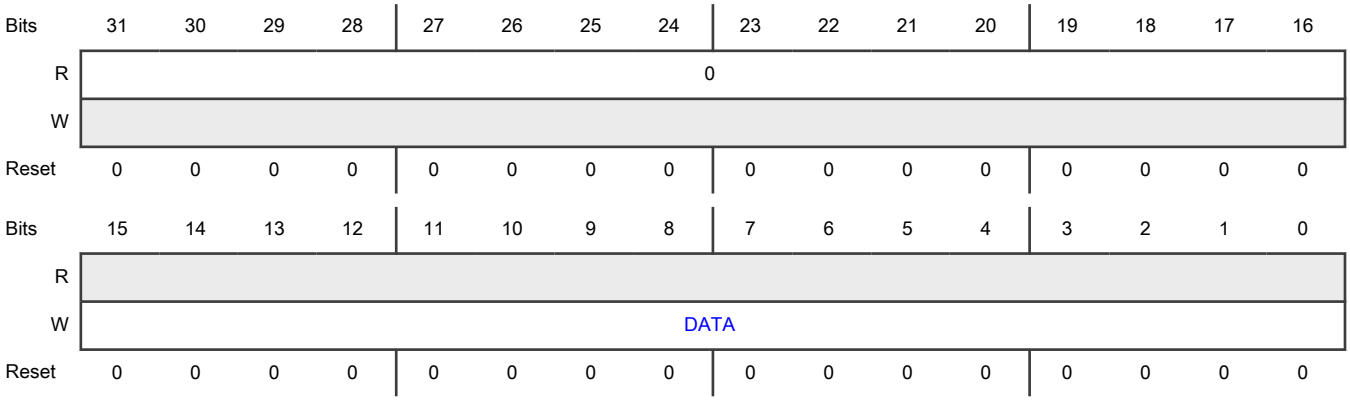
Shares the same address as Target Write Data Byte (SWDATAB1), and SDMACTRL[DMAWIDTH] determines which one is set.

This register allows writing a single-byte pair (halfword) to the bus (to the controller) in a way that only bits 15:0 are used.

This register is intended for use by DMAs, which do not format the upper part of the APB word.

A halfword must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Indicates the byte pair (halfword) to be sent to the controller.

45.7.20 Target Capabilities 2 (SCAPABILITIES2)

Offset

Register	Offset
SCAPABILITIES2	5Ch

Function

Indicates which features are available and supported in this module, including controller and target capabilities, HDR modes, and others.

Field	Function
31 DMA	Direct Memory Access Indicates whether DMA is supported. 0b - Not supported 1b - Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 INT	Interrupts Indicates whether interrupts are supported. 0b - Not supported 1b - Supported
29-28 FIFORX	FIFO Receive Indicates the size of receive (from-bus) FIFO. **NOTE** Controller and target use the same receive FIFO, so size is the same for the controller receive FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two or three 01b - Four 10b - Eight 11b - 16 or larger
27-26 FIFOTX	FIFO Transmit Indicates the size of transmit (to-bus) FIFO. **NOTE** Controller and target use the same transmit FIFO, so size is the same for the controller transmit FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two 01b - Four 10b - Eight 11b - 16 or larger
25-23 EXTFIFO	External FIFO Indicates whether external FIFOs are enabled. If they are not enabled, then check FIFOTX and FIFORX for the internal FIFO. 000b - No external FIFO available 001b - Standard available or free external FIFO 010b - Request track external FIFO All other values are reserved.
22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 TIMECTRL	Time Control Specifies whether any time-control type is supported. 0b - No time control supported 1b - At least one time-control type supported
20-16 IBI_MR_HJ	In-Band Interrupts, Controller Requests, Hot-Join Events Indicates which events (IBI, CR, and HJ) are allowed. For example, if this field is 00011b, IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. 0_0000b - Application cannot generate IBI, CR, or HJ 1_xxxxb - Application can use SCONFIG[BAMATCH] for bus-available timing x_1xxxb - Application can generate a Hot-Join event x_x1xxb - Application can generate a controller request for a secondary controller x_xx1xb - When bit 0 = 1, the IBI has data from the SCTRL register x_xxx1b - Application can generate an IBI
15-12 CCCHANDLE	Common Command Codes Handling Indicates what manages CCC between I3C and the application. 0000b - All handling features disabled 1xxxb - GETSTATUS CCC returns the value of SCTRL[VENDINFO] x1xxb - GETSTATUS CCC returns the values of SCTRL[PENDINT] and SCTRL[ACTSTATE] xx1xb - The I3C module manages maximum read and write lengths, and max data speed xxx1b - The I3C module manages events, activities, status, HDR, and if enabled for it, ID and static-address-related items
11-10 SADDR	Static Address Indicates how the static address is managed. 00b - No static address 01b - Static address is fixed in hardware 10b - Hardware controls the static address dynamically (for example, from the pin strap) 11b - SCONFIG register supplies the static address
9 MASTER	Controller Specifies whether controller capability is supported. 0b - Not supported 1b - Supported
8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 HDRSUPP	High Data Rate Support Indicates which HDR modes are supported. 00b - No HDR modes supported 01b - DDR mode supported All other values are reserved.
5-2 IDREG	ID Register Indicates which ID features are available in the configurable registers. 0000b - All ID register features disabled 1xxxb - A Bus Characteristics Register (BCR) is available x1xxb - A Device Characteristic Register (DCR) is available xx1xb - An ID Random field is available xxx1b - ID Instance is a register; used if there is no PARTNO register
1-0 IDENA	ID 48b Handler Indicates what handles the 48-bit ID value. 00b - Application 01b - Hardware 10b - Hardware, but the I3C module instance handles ID 48b 11b - A part number register (PARTNO)

45.7.22 Target Dynamic Address (SDYNADDR)

Offset

Register	Offset
SDYNADDR	64h

Function

Fills with the assigned address after the controller has assigned it via SETDASA or ENTDAA CCC commands. It clears if the RESETDAA CCC is used. The current validity state is also indicated through SSTATUS[DAVALID], which can be used to interrupt the processor. The DCAUSE field can be used to determine the changes, if enabled.

NOTE

If mapped addresses are enabled, you can access them through the SMAPCTRL*n* registers.

The first dynamic address (DA[0]) may be written irrespective of whether the mapping is enabled, if configured to allow writes used to restore the DA after a power-down (an ultra-low power state that loses power to peripherals but retains the DA somewhere else). This is not required if state-retention flops are used for the DA. This mechanism only allows writes when target is disabled

(and is ignored otherwise). If the controller uses RSTDAA or SETNEWDA, then it overrides this mechanism and yields to the controller-assigned DA. When enabling the target, SCONFIG[OFFLINE] must be 1. This waits for evidence that the bus is not in I3C HDR mode and exits when an HDR exit pattern is seen or when 60 µs has expired. This makes it safe to monitor START and STOP. If the application needs to do an IBI, then the application must either wait for a STOP (see STATUS) or make sure that 200 µs have gone by with no activity (no START or STOP) before the application emits the IBI.

The MAPIDX or MAPSA model allows writing additional DAs (and SAs) into a list (the number in the list is preconfigured); any DA or SA with DAVALID = 0 are never matched. The additional DAs may be based on the bridge target CCC or done by a move (read current DA and then copy into the upper map, and then invalidate the 0 map) when matching ENTDAA over and over. Any mapped location can be invalidated by writing MAPIDX and DAVALID = 0. The mapped ones are not reset by the RSTDA CCC (see Target Message Map Address (SMSGMAPADDR)).

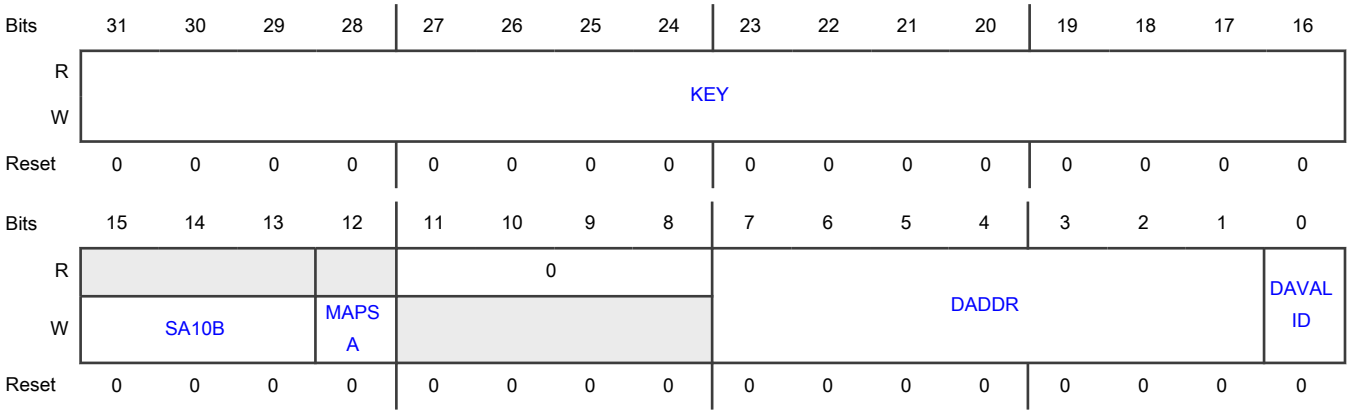
To copy the base DA to the mapped set, you must perform the configuration to allow it; otherwise it leads to distinct mechanisms:

- If used in I3C mode, a base DA is required, so the last one must not be cleared (or writing a dynamic address with DAVALID = 1 is necessary).

NACK/ACK of mapped DAs/SAs: The register also permits specific DAs (above the base) to NACK or ACK writes or reads, such as for bridges when the endpoint is busy. The NACK must not be set for too long, or the controller may consider the target in an error state. The model is to write with KEY = A731h and the MAPIDX and DAVALID to select ACK or NACK.

Mapping: If MAPIDX ≠ 0 and KEY = 0, then the next read returns details on the static or dynamic address at that location. If the read does not have MAPIDX ≠ 0, then it is not an acceptable location.

Diagram



Fields

Field	Function
31-16 KEY	Key Specifies the value of KEY. Must be set to A4D9h to write to the DADDR field (and 1 to the DAVALID field). Write only when a target is not enabled (for restoring after power-down sleep with auto-restore). The mapped locations and base may be written when a target is enabled, but do not write when there are transactions on the I3C bus. KEY reads back 1 if overwritten, else KEY is 0 if assigned by the controller including when the controller changes it. If address mapping is allowed, then writing with KEY = CB19h is used to clear the base DA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If mapping is allowed, then writing with the key of A731h means that MAPIDX indicates which mapped address to set to ACK or NACK, such that DAVALID = 1 if ACK, DAVALID = 0 if NACK. This allows having the address refuse write and read requests when NACK. When using read back from map index (write with MAPIDX ≠ 0, KEY = 0, read) bit [16] = 1 if NACK, else 0.
15-13 SA10B	10-Bit Static Address Stores a 10-bit static address composed of {SA10B,DADDR}, if not 0 when MAPSA is set. Only one static address may be stored this way, and it must be MAPIDX == 1.
12 MAPSA	Map a Static Address Sets a static address into the list if MAPSA = 1 on a write with MAPIDX ≠ 0; otherwise, a dynamic address is used.
11-8 —	Reserved
7-1 DADDR	Dynamic Address Specifies the dynamic address (DA). This is the assigned dynamic address when DAVALID is 1 and is a static address if the MAPSA field is 1.
0 DAVALID	Dynamic Address Valid Determines whether a dynamic address is assigned. This field is 1 for ACK and 0 for NACK when using the A731h KEY. 0b - DANOTASSIGNED: a dynamic address is not assigned 1b - DAASSIGNED: a dynamic address is assigned

45.7.23 Target Maximum Limits (SMAXLIMITS)

Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the controller (or the originally requested limits). The maximum limits are not enabled in the hardware design, including maximum read and write lengths. If the maximum read and write lengths are enabled, then the current setting (including the default request) shows up in this register (SMAXLIMITS).

Diagram

Fields

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum Write Length Indicates the maximum write length, which must be between 8 to 4095 (saturation). The application must not set the maximum write length to a higher value than the maximum write length set by the controller.
15-12 —	Reserved
11-0 MAXRD	Maximum Read Length Indicates the maximum read length, which must be between 16 to 4095 (saturation). The application must not set the maximum read length to a higher value than the maximum read length set by the controller.

45.7.24 Target ID Part Number (SIDPARTNO)

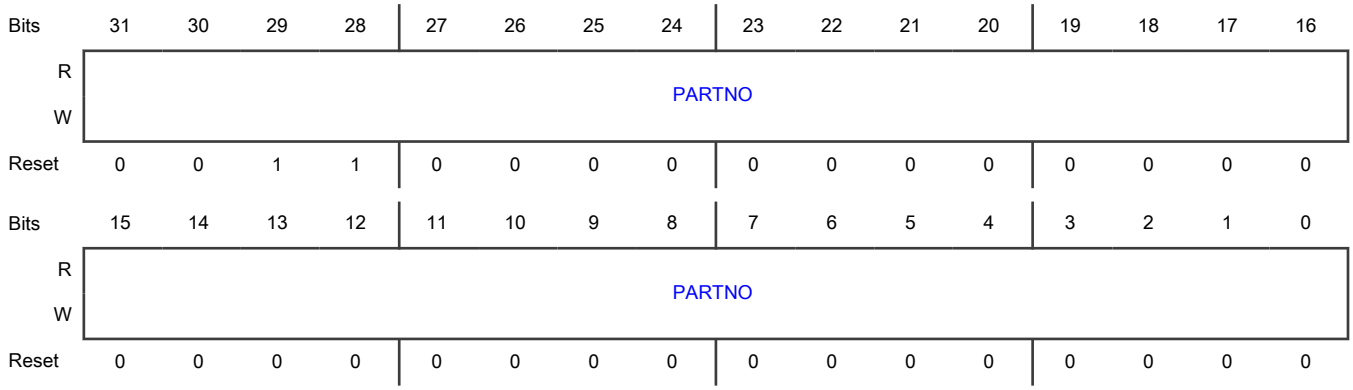
Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows you to write the ID part number. You must write a nonzero value into the PARTNO field because 0 is not valid.

Diagram



Fields

Field	Function
31-0 PARTNO	Part Number

45.7.25 Target ID Extension (SIDEXT)

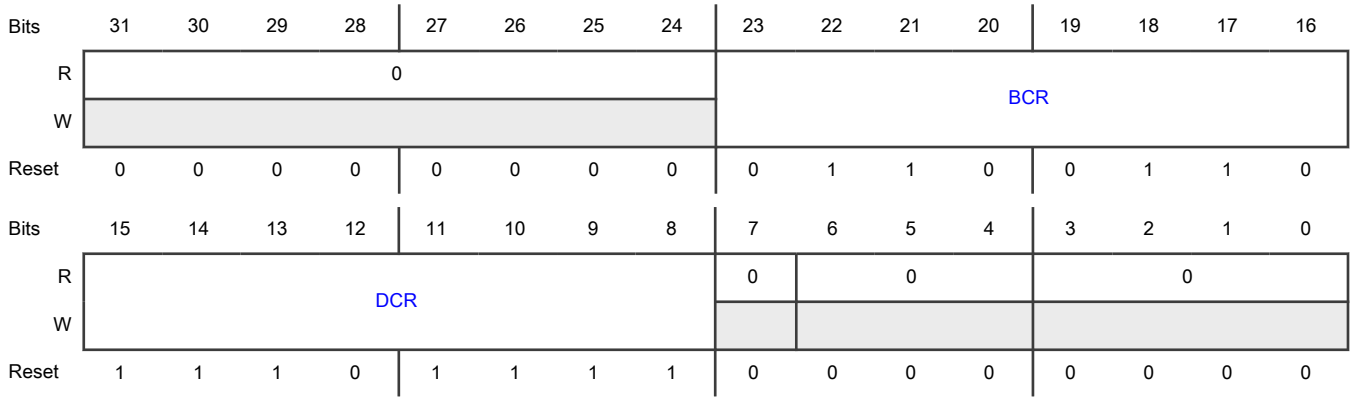
Offset

Register	Offset
SIDEXT	70h

Function

Allows you to write the ID extension of DCR and/or BCR.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Sets the value for BCR, if this field is configured. Otherwise, the default value is considered. This field controls features such as secondary controller and slow-speed requirements.
15-8 DCR	Device Characteristic Register Sets the value for DCR, if this field is configured. Otherwise, the default value is considered.
7 —	Reserved
6-4 —	Reserved
3-0 —	Reserved

45.7.26 Target Vendor ID (SVENDORID)

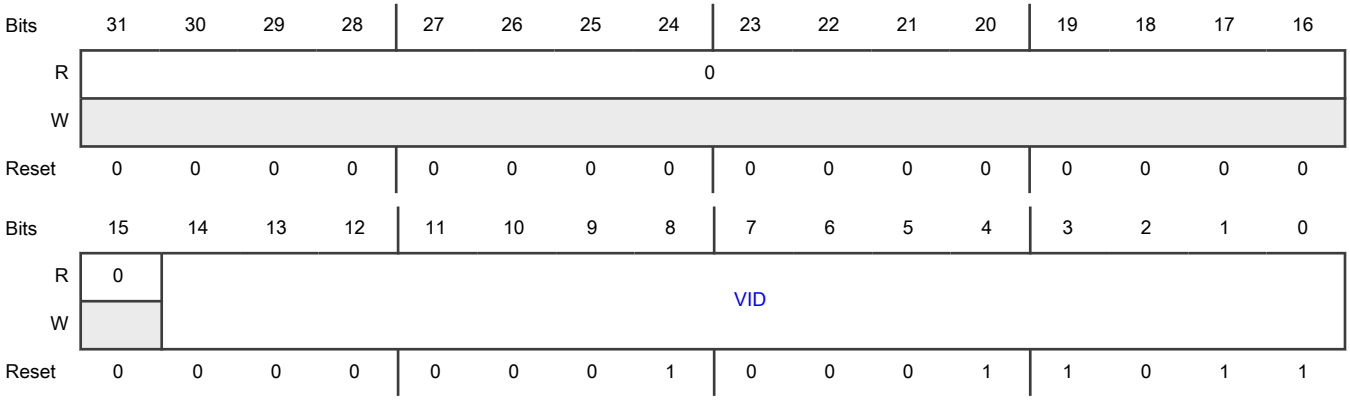
Offset

Register	Offset
SVENDORID	74h

Function

Allows you to write the vendor ID. The default value is the chip vendor ID, and is set from the constant field. When using the chip vendor ID, the part number (PARTNO) does not collide with other uses. The MIPI vendor ID is available to all companies (MIPI membership is not required). To get a vendor ID, make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID Configures the 15-bit MIPI vendor ID. If not configured, the default value is considered.

45.7.27 Target Time Control Clock (STCCLOCK)

Offset

Register	Offset
STCCLOCK	78h

Function

Allows you to dynamically set the time control clock and accuracy information. The clock frequency and accuracy are constants set by the hardware. If the clock can be adjusted (that is, divided) or if the accuracy could vary with knowable information, then the clock may be set via this register, which must be updated whenever the clock source is changed.

Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock Frequency Indicates the clock frequency in 0.5 MHz steps. For example, a value of 20 in this field indicates a frequency of 10 MHz. Default set by parameters if configured.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 ACCURACY	Clock Accuracy Indicates the clock accuracy in 1/10ths of %. For example, a value of 15 indicates an accuracy of 1.5%. Default set by parameters if configured.

45.7.28 Target Message Map Address (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

Allows you to determine which address is matched when STATUS[MATCHED] = 1. This register is used when the DYNADDR register builds a list of extra DAs or SAs to match. It holds the last three matches.

Diagram

5 —	Reserved
4 —	Reserved
3-0 —	Reserved

45.7.30 Controller Control (MCTRL)

Offset

Register	Offset
MCTRL	84h

Function

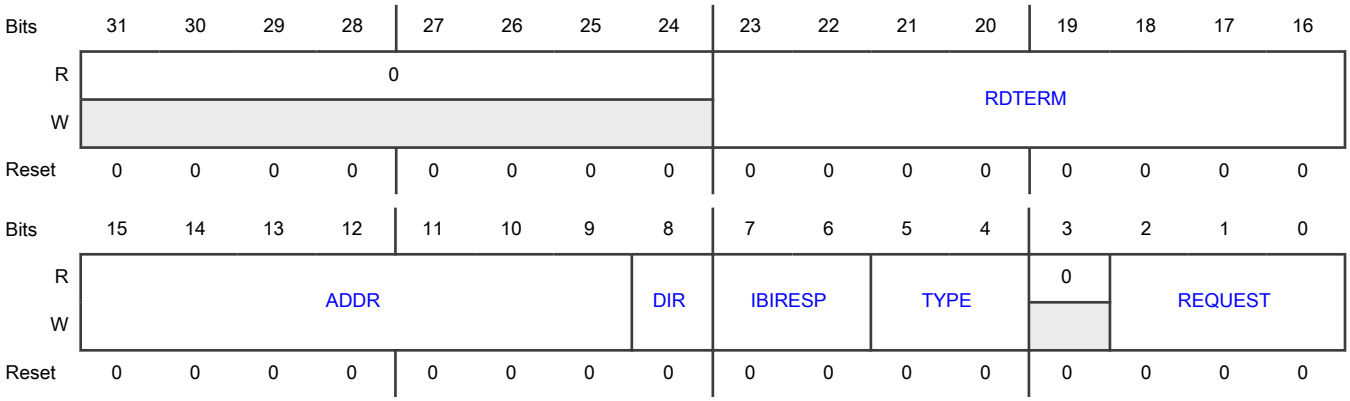
Starts activities on the I3C or I2C bus (see the MWMSG registers). A request cannot be changed when a message is in progress; the REQUEST field becomes 0 automatically.

You must write to MCTRL fields as per use case or as mentioned in Operating modes. Bit read and write checking may not work independently.

NOTE

If MCONFIG[MSTENA] is configured for I2C Controller mode (legacy I2C), only REQUEST = 1 and REQUEST = 2 are accepted. Also, fields are constrained to I2C-supported fields.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read Terminate Counter Determines when to terminate a read operation: • For I2C, this field controls when to NACK a read. • For I3C, this field can be used to terminate (end) a read: — If RDTERM is 0, it has no effect. — If RDTERM is 1, the read terminates after the next character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— If RDTERM is 2, the read terminates after the next two characters. The field supports up to 255 characters. In DDR mode, RDTERM terminates the read based on word counts (for DDR) instead of byte counts (for SDR). The field self-clears when MSTATUS[COMPLETE] becomes 1. **NOTE** You may write 1 to this field anytime, but a value greater than 1 must be written when starting EmitStartAddress.
15-9 ADDR	Address Indicates the type of address: I3C dynamic address or I2C static address. Some values are not allowed based on the bus that is used (I3C or I2C).
8 DIR	Direction Indicates the direction, write or read. 0b - Write 1b - Read
7-6 IBIRESP	In-Band Interrupt Response Indicates the response to use when you get an IBI from START, and when to force using an IBI ACK NACK request when completing a manual IBI. Completion of a manual IBI means that the target DA is known, and so the mandatory byte (or not) is specified by the application when acknowledging. This field is also used when a message is emitted in Message mode using the MWMSG_SDR or MWMSG_DDR registers. If an IBI with MDB (mandatory byte) is ACKed, the controller limits it to a maximum of eight more bytes after the MDB. RDTERM = 1 can be used with REQUEST = NONE to terminate data from a target sooner. If this field is 0b, it indicates ACK (acknowledge). When REQUEST = 1 (EmitStartAddr) or REQUEST = 7 (AutoIBI), Controller In-band Interrupt Registry and Rules (MIBIRULES) decides whether to ACK with mandatory byte. When REQUEST = 3 (IBIAckNack), ACK with no mandatory byte. If this field is 1b, it indicates NACK (reject) or no acknowledgement. If this field is 10b, it indicates acknowledge with mandatory byte. When REQUEST = 1 or REQUEST = 7, ignore Controller In-band Interrupt Registry and Rules (MIBIRULES). Do not use this setting unless only targets with a mandatory byte can cause an IBI. When REQUEST = 3, ACK with mandatory byte. If this field is 11b, it indicates manual. When REQUEST = 1 or REQUEST = 7, stop and wait for a decision using the IBI ACK NACK request. When REQUEST = 3, this field is reserved. **NOTE** A CR and HJ always cause IBIRESP to become 3 (manual) so the application must decide. 00b - ACK (acknowledge) 01b - NACK (reject) 10b - Acknowledge with mandatory byte

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Manual
5-4 TYPE	Bus Type with EmitStartAddr Works with REQUEST to determine the bus type. See Determining bus types and modes for more information. The following values are valid only if REQUEST is 1. 00b - I3C 01b - I2C 10b - DDR 11b - Reserved
3 —	Reserved
2-0 REQUEST	Request Emits the requested operation when performing in pieces, instead of performing by message. You must check Controller Status (MSTATUS) because some requests can only be made in some states. For example, the system cannot enter SDR mode from DDR mode, and it cannot use an incorrect request in DAA mode. If this field is 0b, it indicates that no request is present (NONE). The REQUEST field returns to NONE after finishing a request. Controller Status (MSTATUS) indicates the state of the controller. See AutoIBI mode. NONE is written as 0 only in these cases: when writing 1 to MCTRL[RDTERM] (to stop a read in progress) or when configuring MCTRL[IBIRESP] for MSG use. If this field is 1b, it emits START with address and direction (EMITSTARTADDR), either from Stopped state or in the middle of a single data rate (SDR) message. If from Stopped state (Idle), then EmitStart may be prevented by an event (such as IBI, CR, HJ). In this case, an appropriate interrupt is signaled. EmitStart can be resubmitted. If this field is 10b, it emits a STOP on bus (EMITSTOP). Must be in SDR mode. In DAA mode, emitting STOP exits DAA mode. If this field is 11b, it indicates manual IBI ACK or NACK (IBIACKNACK). When MCTRL[IBIRESP] indicates a hold on an IBI to allow a manual decision, this request completes it. The field uses MCTRL[IBIRESP] to provide the information. If this field is 100b, and if currently not in DAA mode, it emits START, 7E, ENTDAA sequence, and then emits 7E/R to process the first target (PROCESSDAA). Stops just before the new dynamic address (DA) is to be emitted. The DA is written using Controller Write Data Byte (MWDATAB), then process DAA is requested again to write the new address, and then it starts the next unless marked to STOP. An MSTATUS indicating NACK means DA was not accepted (for example, parity error). If PROCESSDAA is NACKed on the 7E/R request, meaning no more targets need a DA, then a COMPLETE is signaled (along with DONE) and a STOP issued. If TYPE = 2 or 3, the DA is assigned and then it emits a STOP (instead of starting a new 7E/R request). If TYPE = 1 or 3, then the DA is taken from the ADDR field (bits 6:0). If this field is 110b, it emits an exit pattern from any state (force exit and target reset). End DDR mode (including MSGDDR), including a STOP afterward. If MCTRL[TYPE] is 2, perform a target reset action

Table continues on the next page...

Table continued from the previous page...

Field	Function
	(RSTACT can prevent the reset in the target). Target reset may follow immediately after RSTACT CCC or STOP. If this field is 111b, the target is held in a Stopped state, but autoemits a START, 7E sequence when the target holds SDA low for an IBI (AUTOIBI). Actual IBI handling is defined by MCTRL[IBIRESP]. 000b - NONE 001b - EMITSTARTADDR 010b - EMITSTOP 011b - IBIACKNACK 100b - PROCESSDAA 101b - Reserved 110b - Force Exit and Target Reset 111b - AUTOIBI

45.7.31 Controller Status (MSTATUS)

Offset

Register	Offset
MSTATUS	88h

Function

Indicates the controller status, including which events cause interrupts. The peripherals share the IRQ (called parallel-to-target status).

Because a peripheral can either be in Controller or Target mode, but not both at the same time, only one (target or controller peripheral) can cause the IRQ. If there is an IRQ and the peripheral is a controller, then this register (MSTATUS) indicates the status.

If there is an IRQ and the peripheral is a target, then Target Status (SSTATUS) indicates the status.

This register self-clears if the COMPLETE field becomes 1.

If the MCONFIG register is configured only for I2C, some states and fields never remain active (for example, DAA or IBI).

Diagram

W			W1C			W1C	W1C	W1C								
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI Address Indicates the address of: • The IBI when MSTATUS[IBITYPE] = 1. • The CR, when MSTATUS[IBITYPE] = 2. • 7'h2 when HJ, when MSTATUS[IBITYPE] = 3.
23-20 —	Reserved
19 NOWMASTER	Module is now Controller Flag Indicates whether the module is now a controller. That is, it was previously a target, and controllership acceptance was requested from the previous controller and controllership was accepted. The reverse operation (controller becomes a target) does not need an interrupt because the application grants it through the GETACCMST CCC. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not a controller 1b - Controller When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 —	Reserved
15 ERRWARN	Error or Warning Indicates whether an error occurred, such as improper register use, overrun, or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. See Controller Errors and Warnings (MERRWARN) for more information. 0b - No error or warning 1b - Error or warning
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) Won Flag Indicates whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. Arbitration requires manual intervention for CR and HJ, and optionally requires it for IBI if MCTRL[IBIRESP] = 3 (manual). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No IBI arbitration won 1b - IBI arbitration won When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	TX Buffer or FIFO Not Full Indicates whether the buffer, FIFOm, or message register can accept another byte or halfword. FIFO uses trigger level. If DMA is enabled for transmitting, it transfers data as long as it is not full. 0b - Receive buffer or FIFO full 1b - Receive buffer or FIFO not full
11 RXPEND	RXPEND Indicates whether a message is being received from a target and bytes are in the input buffer or FIFO: • When using a FIFO, this message is at least one FIFO trigger's worth (a minimum of one byte in the FIFO). • When DMA is enabled for receiving, the DMA is signaled. RXPEND becomes 0 when the data is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No receive message pending 1b - Receive message pending
10 COMPLETE	Complete Flag Indicates whether a message is complete: • With MWMSG_SDR or MWMSG_DDR, the COMPLETE condition occurs when MWMSG_SDR_CONTROL[LEN] or MWMSG_DDR_CONTROL[LEN] reaches 0. • When MCTRL[REQUEST] = 1 (EmitStartAddr), this COMPLETE condition occurs after the end of a write operation, or after a read operation has terminated or ended. • With an IBI (AutoIBI or EmitStartAddr), the COMPLETE condition occurs at the end of IBI data (if any). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 MCTRLDONE	Controller Control Done Flag Indicates whether the module has completed an MCTRL request. MCTRLDONE automatically becomes 0 when writing a new control. If MCTRL[REQUEST] = 1 (EmitStartAddr), MCTRLDONE becomes 1 when the address goes out (and is ACKed, NACKed, or ended in an IBI). If ACKed, MSTATUS[COMPLETE] becomes 1 after the write or read data is complete. If MCTRL[REQUEST] = 4 (ProcessDAA), MCTRLDONE becomes 1 when the module is ready to emit the dynamic address (DA) for the target, or when no more targets are ACKing. This condition can be determined by using the MSTATUS[BETWEEN] and MSTATUS[STATE] fields. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not done 1b - Done When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 SLVSTART	Target Start Flag Indicates whether a target is or was requesting a START by holding SDA low. Handling starts automatically when MCTRL[REQUEST] = 7 (AutoIBI). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Target not requesting START 1b - Target requesting START When writing 0b - No effect 1b - Clear the flag
7-6 IBITYPE	In-Band Interrupt (IBI) Type Indicates the type of IBI of the last event that won the arbitration, whether the interrupt was ACKed, NACKed, or pending. 00b - NONE (no IBI: this status occurs when MSTATUS[IBIWON] becomes 0) 01b - IBI 10b - CR 11b - HJ
5 NACKED	Not Acknowledged Indicates whether the last start and address sequence was NACKed (was not ACKed by the addressed target). 0b - Not NACKed 1b - NACKed (not acknowledged)
4 BETWEEN	Between Indicates whether the controller is active between messages or dynamic address assignments (DAA). It is active when: • MSTATUS[STATE] is MSGSDR, DDR, or DAA, or NORMACT, and the state is between messages or DAAs. It is expecting a new message or DAA to start (or STOP or exit). • MSTATUS[STATE] is NORMACT. The module is waiting for the transmit FIFO to be not empty or the receive FIFO to be not full. 0b - Inactive (for other cases) 1b - Active
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-0 STATE	State of the Controller Indicates the current controller state. If this field is 0b, it indicates that the controller is idle (the bus has stopped.) If this field is 1b, it indicates target request. The bus has stopped but a target is holding SDA low. When using auto-emit IBI (MCTRL[REQUEST] = 7), the controller does not remain in this state. If this field is 10b, it indicates entry into Single Data Rate Message mode, using MWMSG_SDR. If this field is 11b, it indicates entry into normal active SDR mode, using MCTRL, MWDATA*n*, and MRDATA*n* registers. The controller remains in this state until a STOP is issued. If this field is 100b, it indicates entry into Double Data Rate Message mode, using MWMSG_DDR or the normal method with DDR. The controller remains in the DDR state until the controller exits using EXIT (emitting the Exit pattern). If this field is 101b, it indicates entry into Dynamic Address Assignment (ENTDAA) mode. If this field is 110b, it indicates wait for an IBI ACK/NACK decision. If this field is 111b, it indicates receiving an IBI. This state is used after IBI, CR, or HJ has won an arbitration. The IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow. 000b - IDLE (bus has stopped) 001b - SLVREQ (target request) 010b - MSGSDR 011b - NORMACT 100b - MSGDDR 101b - DAA 110b - IBIACK 111b - IBIRCV

45.7.32 Controller In-band Interrupt Registry and Rules (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using IBI, and keeps a registry of the targets that use the IBI byte.

This register defines the IBI mandatory byte rules for the targets and determines which targets do (or do not) have a mandatory byte.

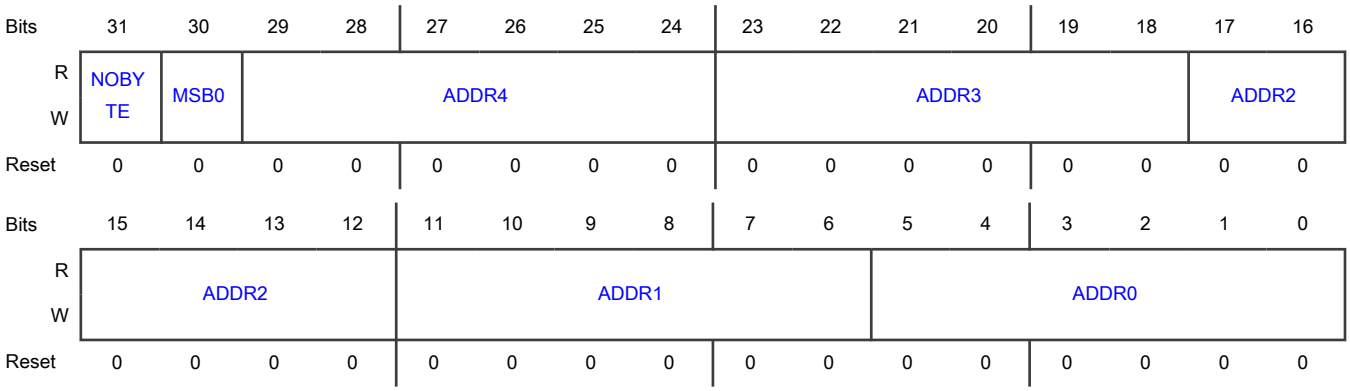
Concerning ADDR*n* fields: The address has 6 bits. Assuming that MIBIRULES[MSB0] = 1, the most significant bit of each address is 0. In this case, each address is 7 bits (usually written as A7 to A1) and A7 must be 0. If the application does not use that optimal convention, the "manual" method of IBI ACK handling must be used (see MCTRL[IBIRESP] for more information).

By default, the ADDR*n* values indicate the targets with a mandatory byte. If MIBIRULES[NOBYTE] = 1, the ADDR*n* values indicate targets that do not have a mandatory IBI byte.

NOTE

A7 = 0 is only needed for targets that use IBI. For legacy I2C devices, A7 can use any valid value because I2C devices cannot cause an IBI.

Diagram



Fields

Field	Function
31 NOBYTE	No IBI byte Specifies whether the ADDR*n* fields refer to targets with or without a mandatory IBI byte. 0b - With mandatory IBI byte 1b - Without mandatory IBI byte
30 MSB0	Most Significant Address Bit is 0 Specifies whether MSB is 0 for all I3C dynamic addresses. Assigning 1 to this field allows the START header to be optimized. 0b - MSB is not 0 1b - MSB is 0
29-24 ADDR4	ADDR4 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
23-18 ADDR3	ADDR3 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
17-12 ADDR2	ADDR2 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-6 ADDR1	ADDR1 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
5-0 ADDR0	ADDR0 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

45.7.33 Controller Interrupt Set (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Returns the status of the interrupt enables when read. This register sets interrupt enables for select fields in Controller Status (MSTATUS):

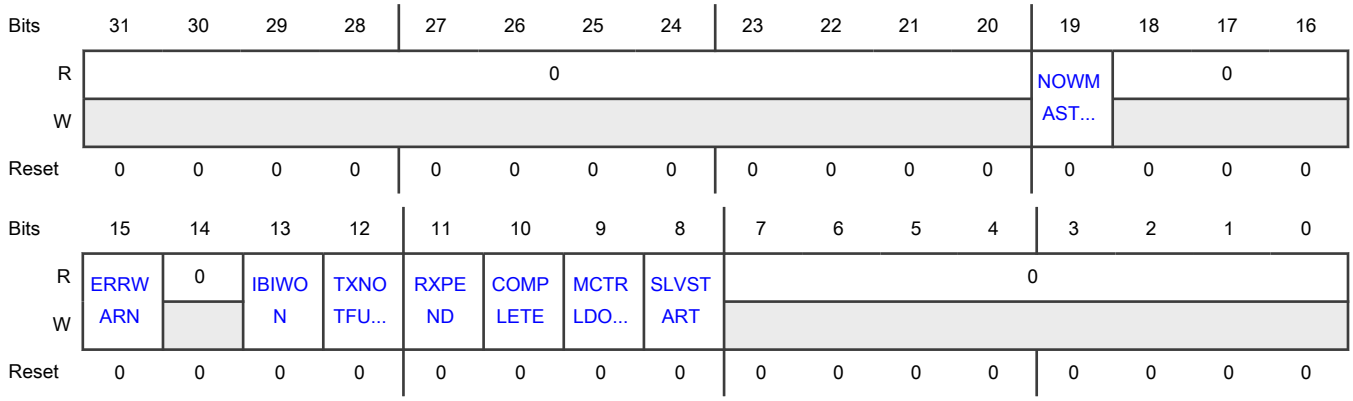
- To activate an interrupt enable, write 1 to its corresponding field.
- To disable an interrupt enable, write 1 to the appropriate field in Controller Interrupt Clear (MINTCLR). Writing 0 to the interrupt enable in MINTSET does not disable the interrupt.

The interrupt registers allow masking of interrupt sources as well as checking which interrupts are activated in Controller Status (MSTATUS). The normal method is to enable an interrupt and then after that interrupt fires, clear the interrupt either by writing to Controller Status (MSTATUS) or via an action on the corresponding data register. The interrupt is level-held, meaning that the interrupt remains 1 until the cause is cleared by some method. The module prevents races; if a new event comes in, that new event is not lost.

These interrupts are parallel to Target Interrupt Set (SINTSET) and Target Interrupt Clear (SINTCLR), and only one interrupt set is active depending on the state (controller or target operation):

- MINTSET: Sets interrupt enables for MSTATUS fields. Reading the MINTSET register returns the status of the interrupt enables.
- MINTCLR: Clears interrupt enables for MSTATUS fields.
- MINTMASKED: Returns the value of the MSTATUS fields ANDed with their interrupt enables.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 NOWMASTER	Now Controller Interrupt Enable Enables the corresponding interrupt to indicate whether the module is now a controller (now this I3C module is a controller). That is, it was previously a target; controllership acceptance was requested from the previous controller and it was accepted. 0b - Disable 1b - Enable
18-16 —	Reserved
15 ERRWARN	Error or Warning (ERRWARN) Interrupt Enable Enables the corresponding interrupt to indicate whether an error occurred, such as improper register use, overrun or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. 0b - Disable 1b - Enable
14 —	Reserved
13 IBIWON	IBI Won Interrupt Enable Enables the corresponding interrupt to indicate whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. 0b - Disable 1b - Enable
12	Transmit Buffer/FIFO Not Full Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXNOTFULL	Enables the corresponding interrupt to indicate whether the buffer, FIFOm, or message register can accept another byte or halfword. 0b - Disable 1b - Enable
11 RXPEND	Receive Pending Interrupt Enable Enables the corresponding interrupt to indicate whether a message is being received from a target and bytes are in the input buffer or FIFO.
10 COMPLETE	Completed Message Interrupt Enable Enables the corresponding interrupt to indicate whether a message is complete. 0b - Disable 1b - Enable
9 MCTRLDONE	Controller Control Done Interrupt Enable Enables the corresponding interrupt to indicate whether the module has completed an MCTRL request. 0b - Disable 1b - Enable
8 SLVSTART	Target Start Interrupt Enable Enables the corresponding interrupt to indicate whether a target is or was requesting a START by holding SDA low. 0b - Disable 1b - Enable
7-0 —	Reserved

45.7.34 Controller Interrupt Clear (MINTCLR)

Offset

Register	Offset
MINTCLR	94h

Function

Clears interrupt enables for select fields in Controller Status (MSTATUS). Writing 1 clears the corresponding interrupt enable. Writing 0 has no effect.

Diagram

45.7.36 Controller Errors and Warnings (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

Contains errors and warnings. When any errors or warnings are not 0, then MSTATUS[ERRWARN] is 1.

Parallel-to-target ERRWARN:

- In Controller mode, use this register (MERRWARN).
- In Target mode, use Target Errors and Warnings (SERRWARN).

The error fields in both registers (MERRWARN and SERRWARN) are similar in meaning.

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 —	Reserved
20 TIMEOUT	Timeout Error Flag Indicates an error caused by the module stalling for too long in a frame. This stalling occurs when: • The transmit FIFO or receive FIFO is not handled, and the bus is stuck in the middle of a message. • No STOP is issued after data transfer (there is a gap between messages). • IBI manual is used and no decision has been made. The maximum stall period is 10 kHz or 100 µs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
19 INVREQ	Invalid Request Error Flag Indicates an error caused by an invalid use of a request: • Not using IBI ACK NACK when stopped in manual hold for IBI acknowledgment. • Using a request other than ForceStop or ForceExit when in a message. Other requests are valid when the message is done. • Other mismatched uses (for example, IBI ACK NACK in normal states). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
18 MSGERR	Message Error Flag Indicates an error caused by:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Trying to write to or read from the MWMSG_SDR register when in a DDR message. • Trying to write to or read from the MWMSG_DDR register when in an SDR message. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
17 OWRITE	Overwrite Error Flag Indicates an error caused by trying to write to Controller Write Data Byte (MWDATAB) when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Overread Error Flag Indicates an error caused by: • Trying to read from Controller Read Data Byte (MRDATAB) when the FIFO is empty. • Trying to read from the MRMSG_SDR register or the MRMSG_DDR register when no message has yet started. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing

Field	Function
4 TERM	Terminate Error Flag Indicates an error when this controller terminates a target read because the read exceeded the count for the message. This error is valid only when using the MWMSG_SDR or MWMSG_DDR register. If you write to the MWMSG_SDR or MWMSG_DDR register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
3 WRABT	Write Abort Error Flag Indicates an error caused by the I2C target NACKing the write data, terminating the message. For example, the controller is writing in I2C and the target NACKed the write. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
2 NACK	Not Acknowledge Error Flag Indicates an error caused by the target or targets NACKing (not acknowledging) the last address. If 7Eh is the address, then it indicates all targets NACKed the last address. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** In HDR mode, this error occurs when an address is not accepted (as opposed to NACKed). **NOTE** This field behaves differently for register reads and writes. When reading

Field	Function
	0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Flag Indicates an underrun for HDR-BT. This error occurs when attempting to write from an empty transmit FIFO. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
0 —	Reserved

45.7.37 Controller DMA Control (MDMACTRL)

Offset

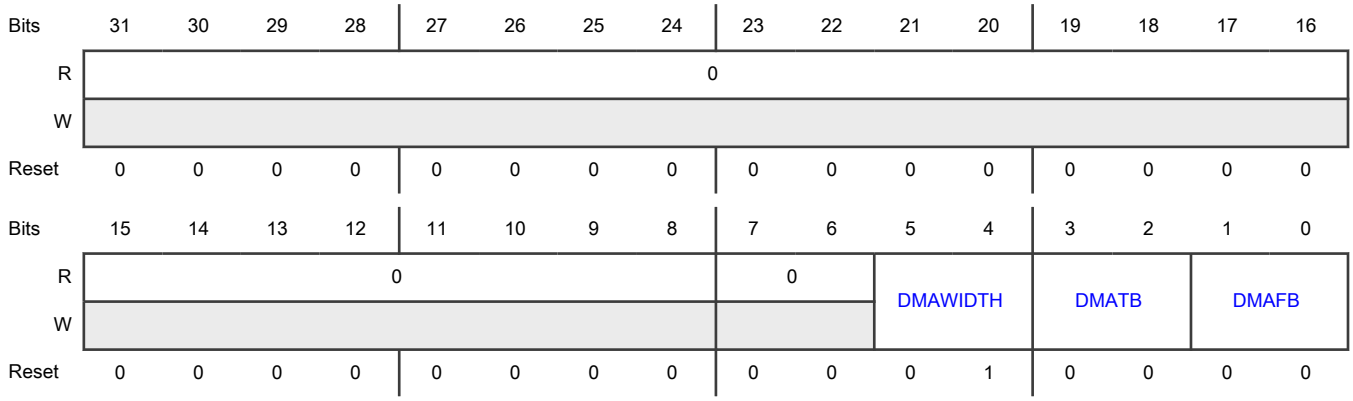
Register	Offset
MDMACTRL	A0h

Function

Allows DMA to be used for inbound and outbound messages. DMA is much more useful for a controller than for a target because the controller directs the bus traffic and actions. DMA can be used with a controller in these ways:

- Push or pull data for MCTRL[REQUEST] = 1 (EmitStartAddr) request written by the processor.
- Implementing message mode, completely controlled by DMA.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	DMA Width Specifies the data width of DMA operations. The halfword (16 bits) setting ensures that two bytes are free or available in FIFO. 00b,01b - Byte 10b - Halfword (16 bits) 11b - Reserved
3-2 DMATB	DMA to Bus Represents the DMA write (to-bus) trigger. When DMATB = 1 or DMATB = 2, I3C requests DMA when a transmit trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until full, unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or repeated START causes DMATB to become 0 (see SCONFIG[MATCHSS]). Normally, DMA enable must be used only in Controller Message mode. 00b - DMA not used 01b - Enable DMA for one frame (ended by DMA or terminated) 10b - Enable DMA until DMA is turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved
1-0	DMA from Bus

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMAFB	Represents the DMA read (from-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a receive trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until empty unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or Repeated START causes DMAFB to automatically become 0 (see SCONFIG[MATCHSS]). **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the controller and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - Enable DMA for one frame 10b - Enable DMA until DMA is turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved

45.7.38 Controller Data Control (MDATACTRL)

Offset

Register	Offset
MDATACTRL	ACh

Function

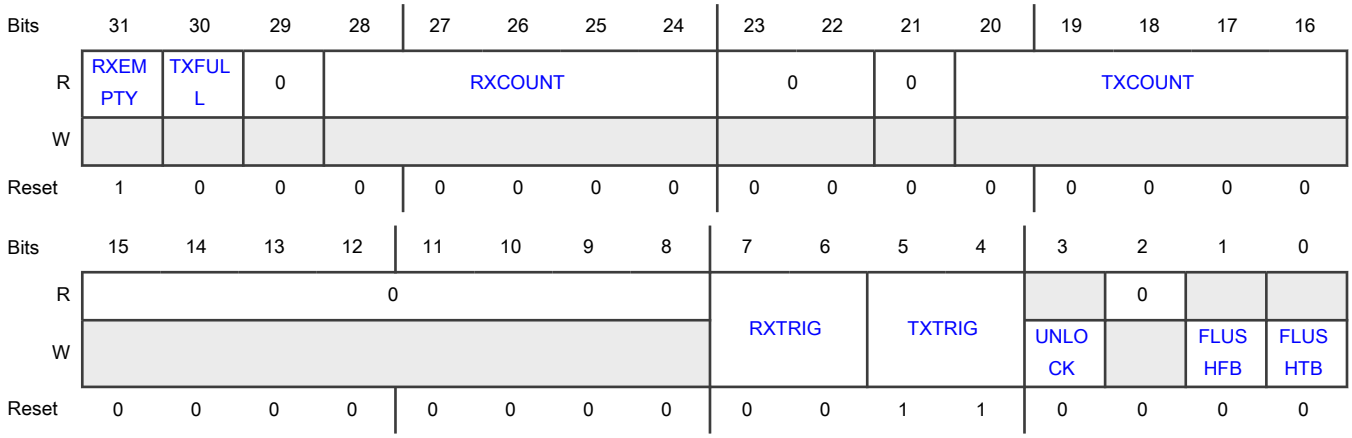
Assists in data control when there is no FIFO. This register also assists the FIFO when FIFO is available (regardless of size), and this assistance allows some control over the FIFO behavior. In particular, the register provides control over when to interrupt when a particular state of fullness or emptiness is reached. It also controls behavior related to width, when the width is not 1 byte wide.

This register acts as an alias of Target Data Control (SDATACTRL).

NOTE

When flushing a FIFO if DMA is in use, disable the DMA channel first. You must not use FIFO flush when a message (in that direction) is in flight.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Receive Entry Count Contains the count of entries in the receive FIFO or buffer. Entry size for SDR and HDR-DDR is in bytes.
23-22 —	Reserved
21 —	Reserved
20-16 TXCOUNT	Transmit Entry Count Contains the count of entries waiting in the TXFIFO. This count is the number of entries that the application has written to the transmit FIFO that have not yet gone onto the bus. Entry size for SDR and HDR-DDR is in bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. This field affects the RXPEND interrupt. 00b - Trigger when not empty (default) 01b - Trigger when 1/4 full or more 10b - Trigger when 1/2 full or more 11b - Trigger when 3/4 full or more
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. This field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Trigger when 1 less than full or less (default)
3 UNLOCK	Unlock Unlocks the functionality so that the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 (unlocked) in the same cycle when writing to TXTRIG or RXTRIG. If this field is 0 (locked), RXTRIG and TXTRIG fields cannot be changed on a write. 0b - Locked 1b - Unlocked
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Flushes from-bus buffer or FIFO. You normally do not use this field. **NOTE** Before using FLUSHFB, disable the DMA (MDMACTRL[DMAFB] = 0). Then use FLUSHFB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer
0	Flush To-Bus Buffer or FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Function
FLUSHTB	Flushes to-bus buffer or FIFO. This field is used when the controller terminates a to-bus message (read) prematurely. **NOTE** Before using FLUSHTB, disable the DMA (MDMACTRL[DMATB] = 0). Then use FLUSHTB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer

45.7.39 Controller Write Data Byte (MWDATAB)

Offset

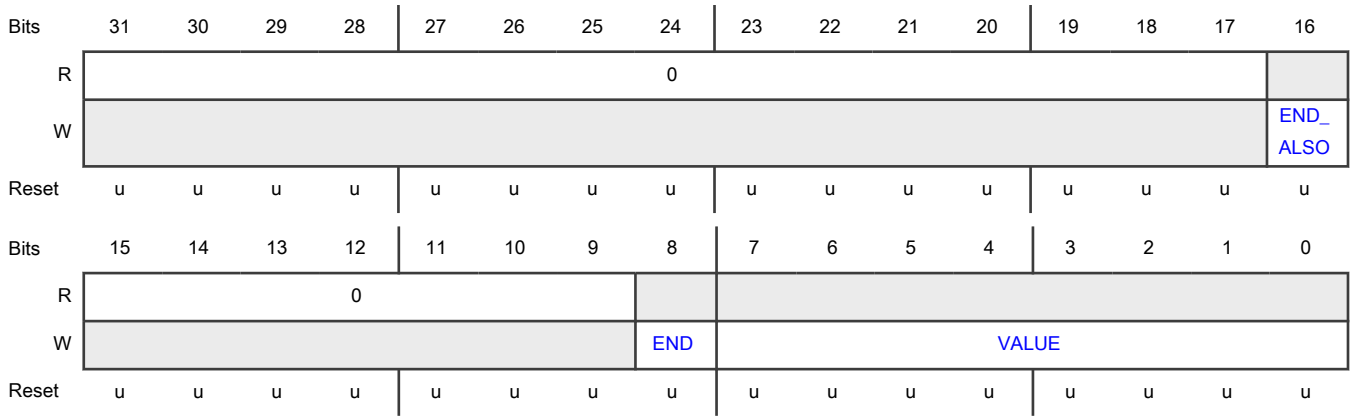
Register	Offset
MWDATAB	B0h

Function

Allows writing bytes to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte (SWDATAB).

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 END_ALSO	End of Message ALSO Indicates end of message, used to end an outbound message normally. Every message must indicate when it is the last message to be sent. This method can be used with the MDATABE register. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End of Message Indicates the end of a message. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
7-0 VALUE	Data Byte Represents the byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

45.7.40 Controller Write Data Byte End (MWDATABE)

Offset

Register	Offset
MWDATABE	B4h

Function

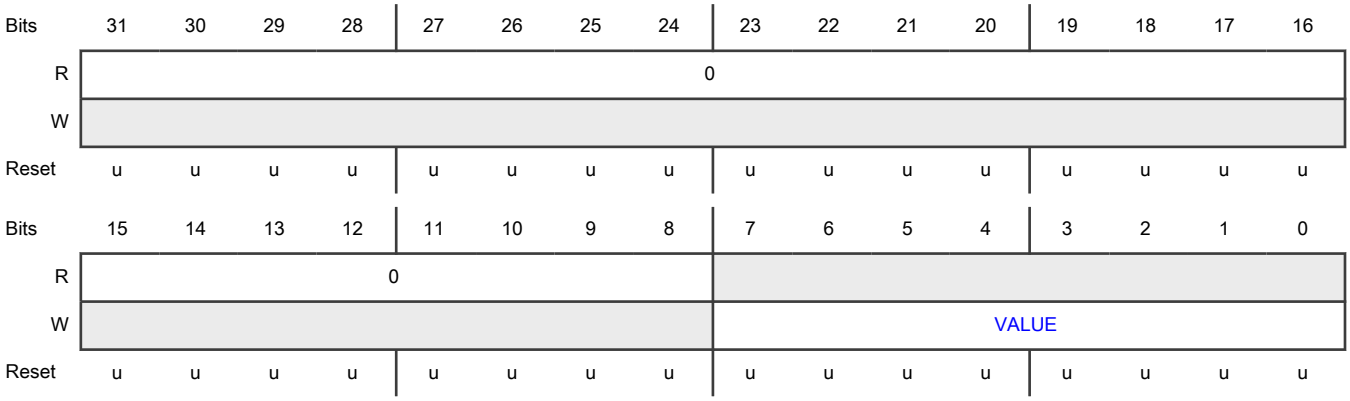
Allows writing the last byte to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte End (SWDATABE).

NOTE

MWDATABE can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data Represents the last byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

45.7.41 Controller Write Data Halfword (MWDATAH)

Offset

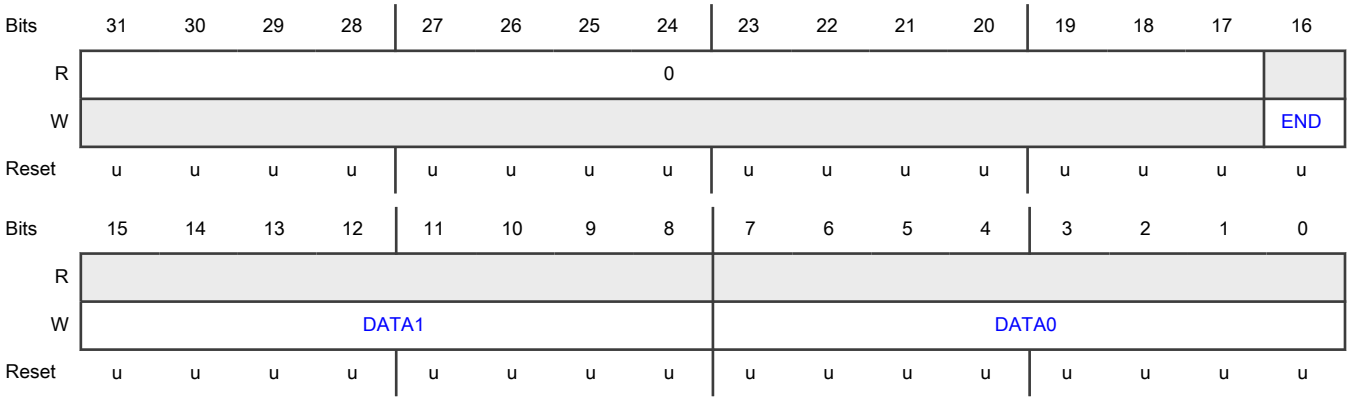
Register	Offset
MWDATAH	B8h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used, sending the low byte followed by the high byte. An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword (SWDATAH).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Indicates the end of a message. For this register, this field always marks DATA1 as the end. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

45.7.42 Controller Write Data Halfword End (MWDATAHE)

Offset

Register	Offset
MWDATAHE	BCh

Function

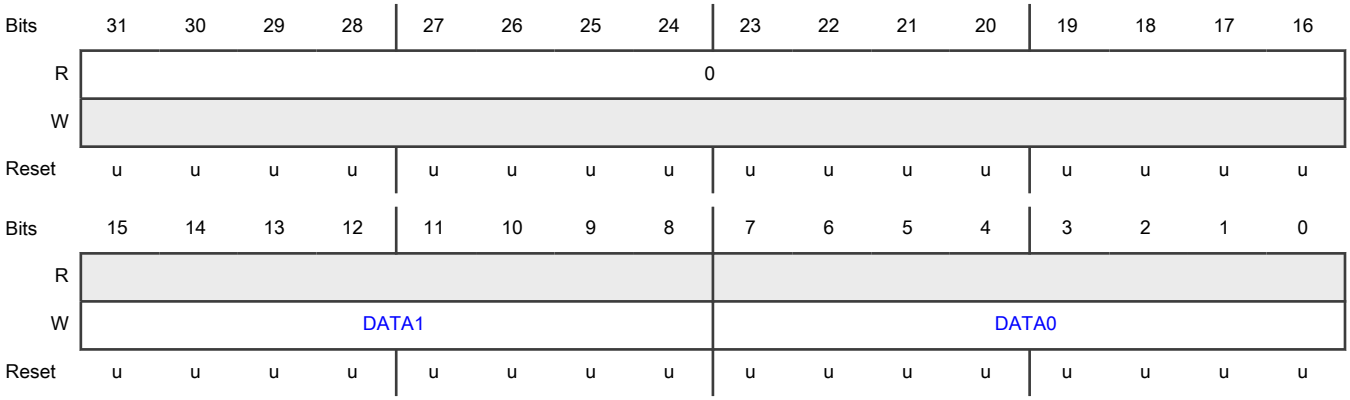
Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way as it does to Controller Write Data Halfword (MWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

You must not write a halfword unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword End (SWDATAHE).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

45.7.43 Controller Read Data Byte (MRDATAB)

Offset

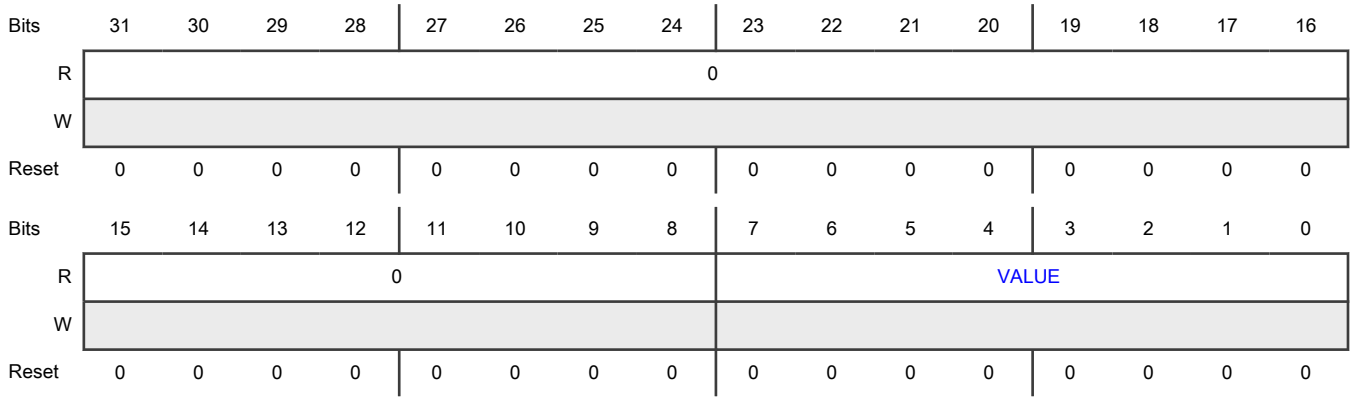
Register	Offset
MRDATAB	C0h

Function

Allows reading bytes written by the target after an SDR read, or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Read Data Byte (SRDATAB).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte read from the controller (and written by the target).

45.7.44 Controller Read Data Halfword (MRDATAH)

Offset

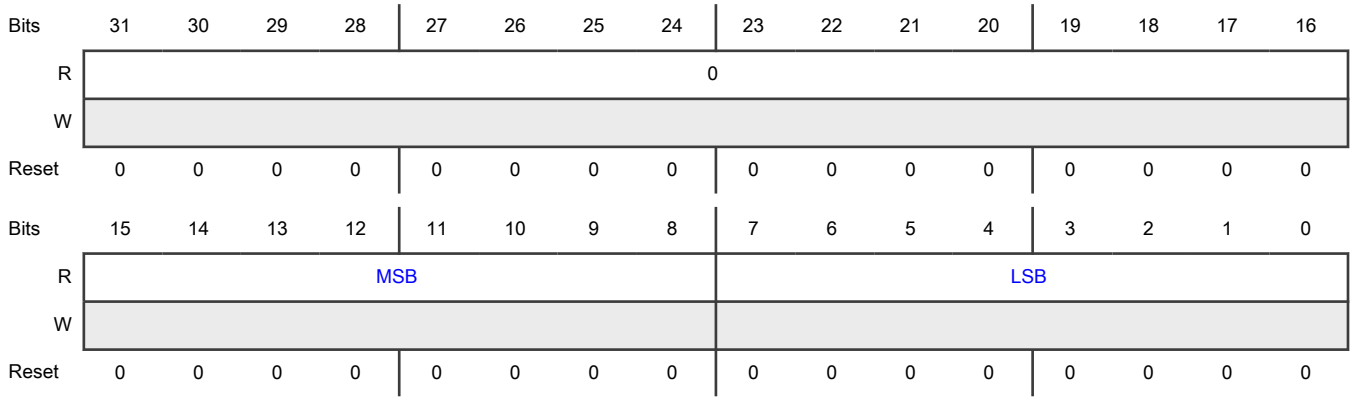
Register	Offset
MRDATAH	C8h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the receive FIFO level trigger or MDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Represents the second byte read from the controller (and written by the target).
7-0 LSB	Low Byte Represents the first byte read from the controller (and written by the target).

45.7.45 Controller Write Byte Data 1 (to Bus) (MWDATAB1)

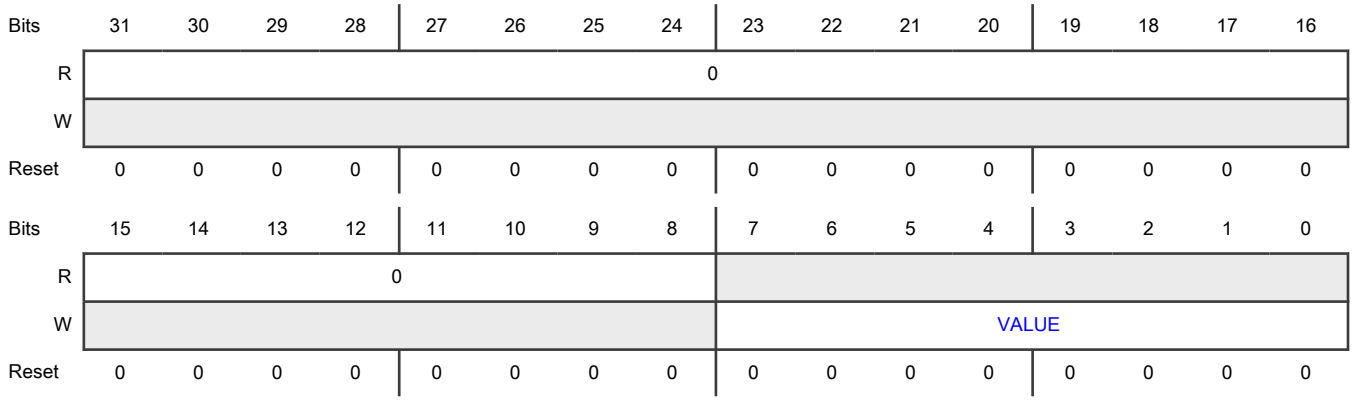
Offset

Register	Offset
MWDATAB1	CCh

Function

Allows writing bytes to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. This register does not have the END bits and is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

45.7.46 Controller Write Halfword Data (to Bus) (MWDATAH1)

Offset

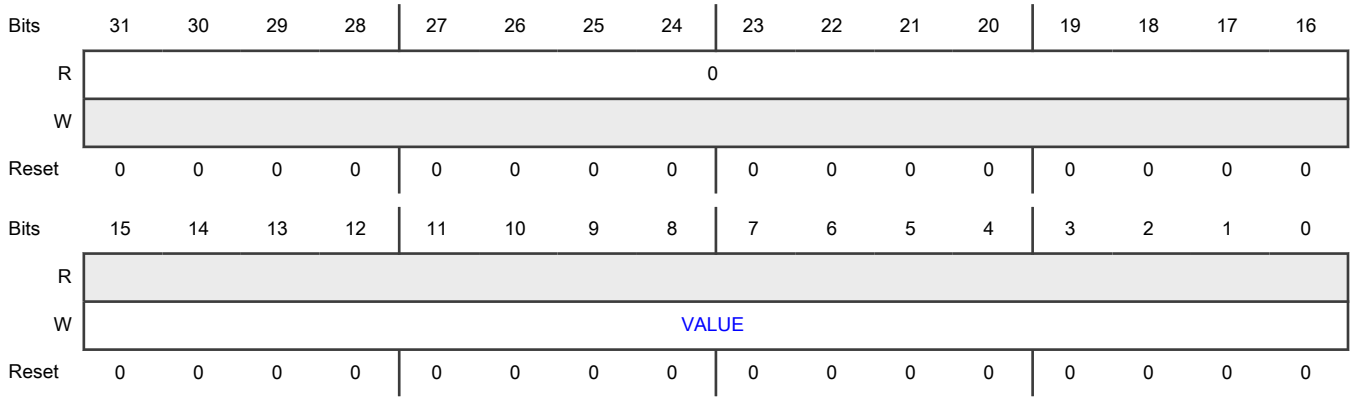
Register	Offset
MWDATAH1	CCh

Function

Allows writing a byte pair (halfword) to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. It does not have the END bits as present in Controller Write Data Halfword (MWDATAH). This register is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

MWDATAH1 shares the same address as MWDATAB1. MDMACTRL[DMAWIDTH] determines which one is set.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

45.7.47 Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Allows setting up and writing 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal and has two modes—control and data:

- For the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- For subsequent writes, this register functions as MWMSG_SDR_DATA.
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

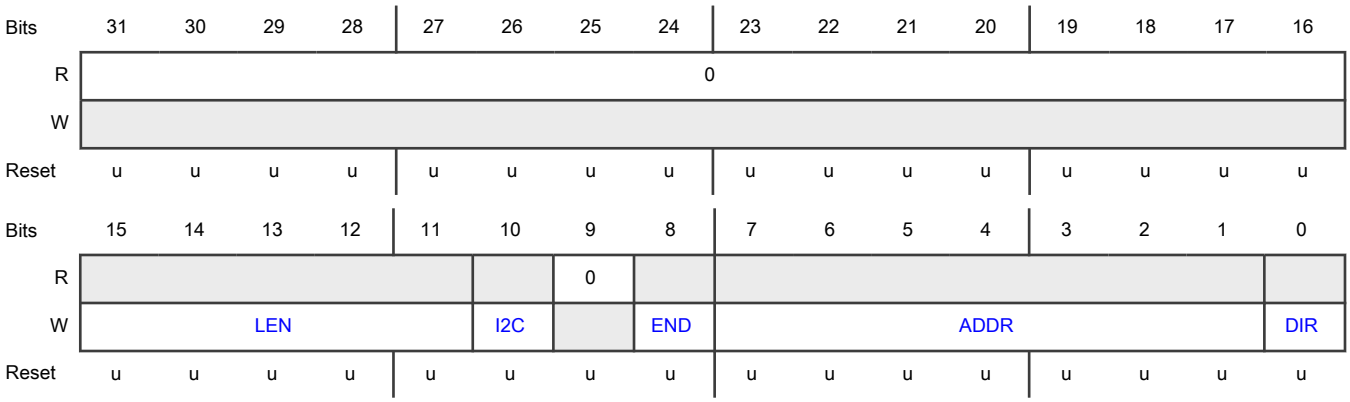
When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the length (see the LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 2 (MSGSDR) and MSTATUS[BETWEEN] = 0, the register (at this offset address) functions as the MWMSG_SDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_SDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode.

The control word contains the byte length (6-bit), address, direction, and how it ends (stop, ready for next, continuation with more length). If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_SDR_CONTROL register (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-11 LEN	Length Indicates the byte length of the message. If LEN = 0, then only END is used (and it does not use the address if stopped). LEN = 1 must not be used. The minimal LEN size is 2 bytes (LEN = 2).
10 I2C	I2C Specifies whether the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR Message Indicates the end of SDR message. MSTATUS[COMPLETE] = 1 when done. The end can happen: • Before LEN bytes are read in I3C mode, if a target ends sooner. • Before LEN bytes are written in I2C mode, if a target NACKs. If this field is 0, the SDR message ends waiting for a new SDR message (issues a Repeated START for a new message). If this field is 1, the SDR message ends at the STOP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not the end 1b - End
7-1 ADDR	Address Contains the address to be written.
0 DIR	Direction 0b - Write 1b - Read

45.7.48 Controller Write Message Data in SDR mode (MWMSG_SDR_DATA)

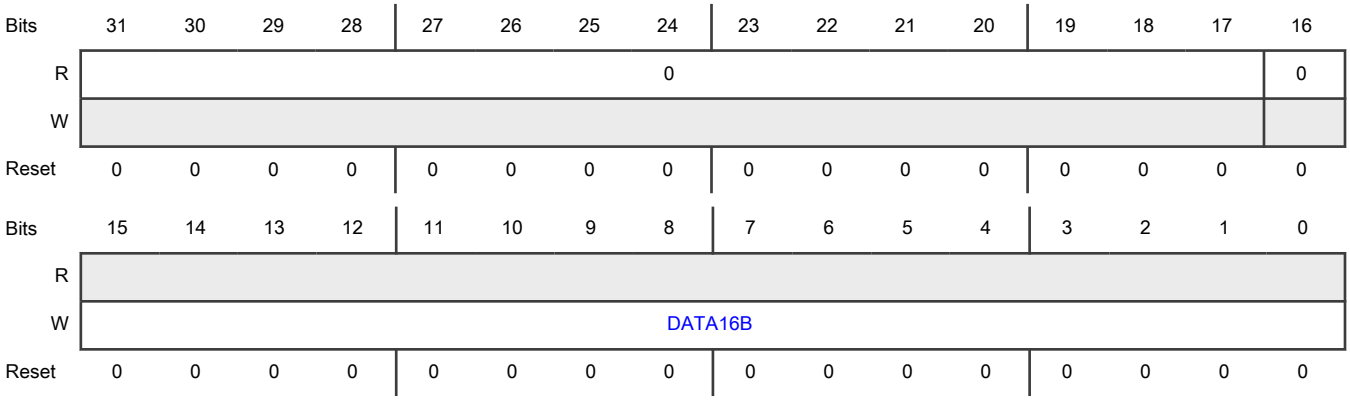
Offset

Register	Offset
MWMSG_SDR_DATA	D0h

Function

Contains the 16-bit word to be written in Single Data Rate (SDR) mode. This register functions in a way similar to MWMSG_SDR_CONTROL.

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 —	Reserved
15-0 DATA16B	Data

45.7.49 Controller Read Message in SDR mode (MRMSG_SDR)

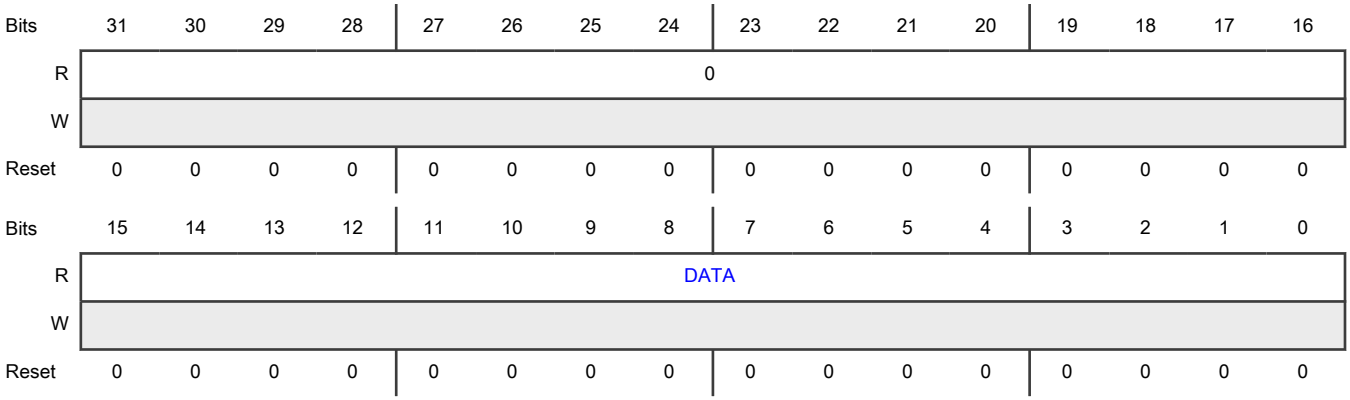
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Allows reading 16-bit words from a target in SDR Message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from the target: • If the length (LEN) is an odd number, the upper byte is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the target ends before LEN is finished, the module treats the read as completed. • If the target is not done before LEN is finished and END is not a continuation, the read is terminated.

45.7.50 Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Allows setting up and writing 16-bit words in DDR mode. The register has three modes:

- The first write to set up a new message functions as the MWSMSG_DDR_CONTROL register.
- The second write contains the functions as shown in the MWMSG_DDR_CONTROL2 register.
- For subsequent writes, this register functions in a way similar to Controller Write Message Data in DDR mode (MWMSG_DDR_DATA).
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the length (see LEN field) counts down or until data with END = 1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 4 (MSGDDR) and MSTATUS[BETWEEN] = 0, then the register (at this offset address) functions as the MWMSG_DDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_DDR_CONTROL register, as long as MSTATUS[STATE] is not in another mode.

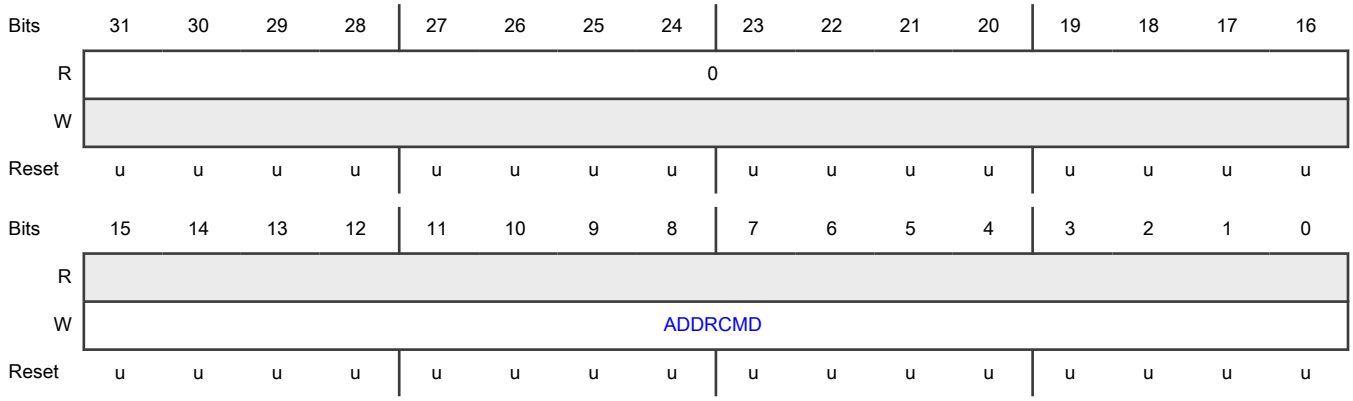
The main control word contains the 16-bit word length and how it ends (stop, ready for next, continuation with more length). Then the command word contains the command and address for read or write. If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_DDR_CONTROL, MWMSG_DDR_CONTROL2, and MWMSG_DDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_DDR_CONTROL register (instead of using MCTRL and MxDATAB).

NOTE

The module handles preamble, parity, and CRC.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ADDRCMD	Address Command Indicates the first data write after control write, with LEN ≠ 0. This is formatted as: • Bits 15:9: target address to read or write • Bit 8: reserved, must be 0 • Bit 7: 1 if read, 0 if write • Bits 6:0: CMD as 7-bit value, always for controller

45.7.51 Controller Write Message in DDR Mode Control 2 (MWMSG_DDR_CONTROL2)

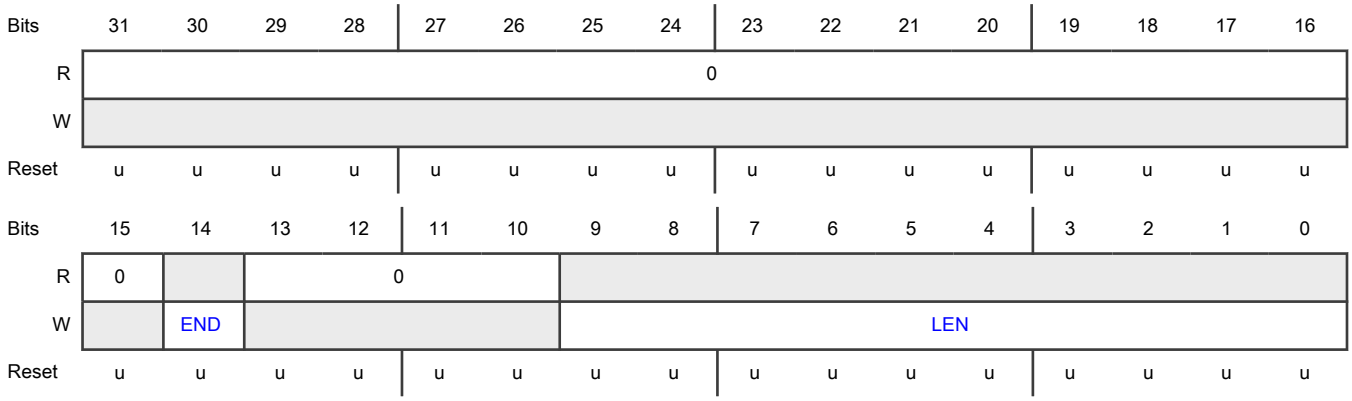
Offset

Register	Offset
MWMSG_DDR_CONTROL2	D8h

Function

Contains the second control word instructions with the length of message and end.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 END	End of Message Indicates the end of DDR message. MSTATUS[COMPLETE] becomes 1 when done. The end can happen before LEN bytes are read if the target ends sooner. If this field is 0, DDR message ends waiting for a new DDR message (issues an HDR restart for the new message). If this field is 1, DDR message ends on HDR exit. 0b - Not the end 1b - End
13-10 —	Reserved
9-0 LEN	Length of Message Contains the length of the message (including the command) in halfwords, up to 2046 bytes. If LEN = 0, then only END is applied: • For reads, + 1 for the CRC. For example, to read 4 bytes (2 halfwords), use 1 + 2 + 1 for CMD + 2 halfwords + CRC. • For writes, LEN is the number of halves of data bytes + 1 (for command).

45.7.52 Controller Write Message Data in DDR mode (MWMSG_DDR_DATA)

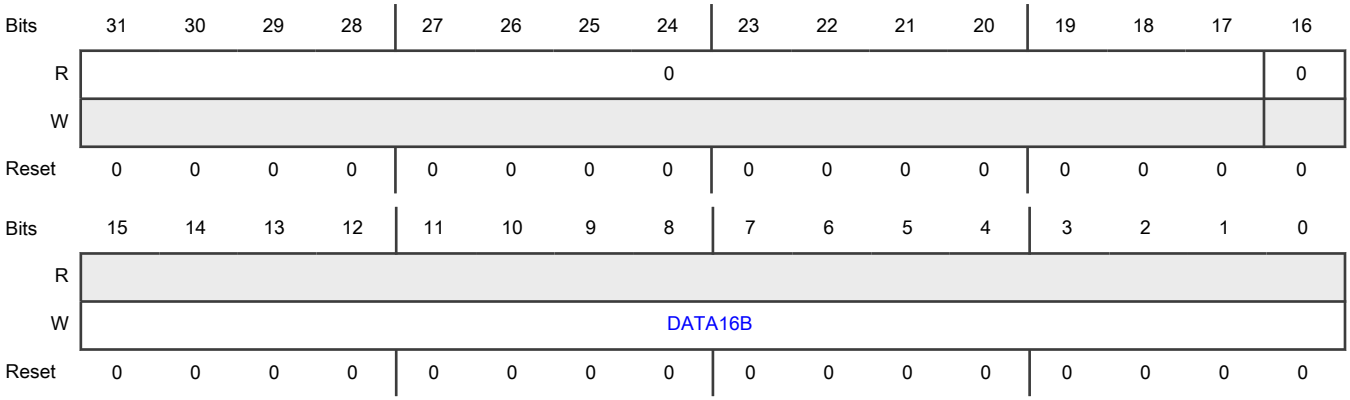
Offset

Register	Offset
MWMSG_DDR_DATA	D8h

Function

Contains the 16-bit word to be written in DDR mode. This register functions in a way similar to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 —	Reserved
15-0 DATA16B	Data

45.7.53 Controller Read Message in DDR mode (MRMSG_DDR)

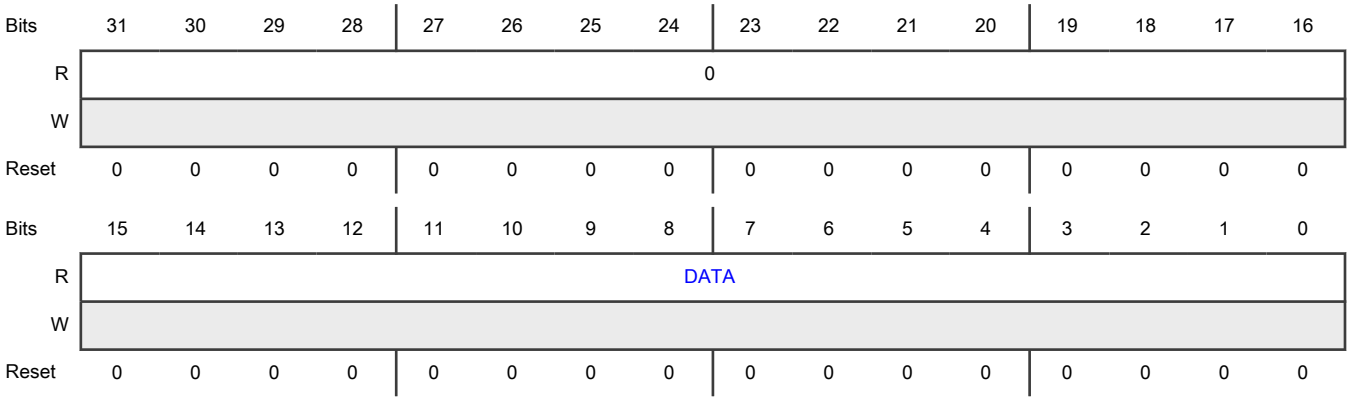
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Allows reading 16-bit words from a target in DDR Message mode from an active message started with MWMSG_DDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from a target. The first byte is the LSB, and is in DATA[7:0]. The second byte is the MSB, and is in DATA[15:8]: • If the target ends before the entire length of the message (MWMSG_DDR[LEN]) is read, the module considers the DATA read as completed. In I3C mode, the target can indicate the end of message (the last byte). Otherwise, the controller terminates the message if the message is more than the controller can accept. • If the target has not yet finished sending DATA before the entire length of the message (MWMSG_DDR[LEN]) is read and END is not a continuation, the DATA read is terminated.

45.7.54 Controller Dynamic Address (MDYNADDR)

Offset

Register	Offset
MDYNADDR	E4h

Function

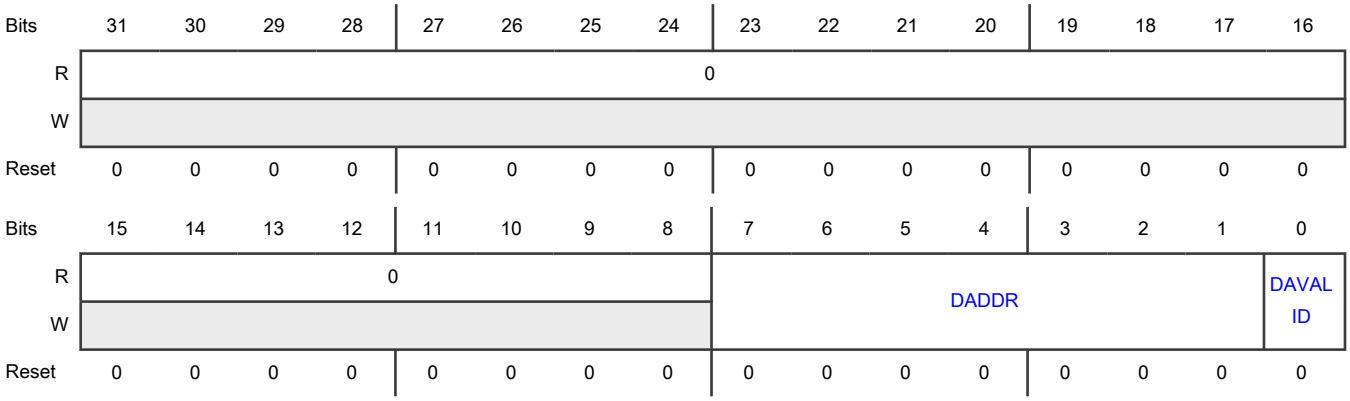
Allows the I3C module to write its own dynamic address (DA) when the module changes from Controller mode to Target mode.

If this device is the main controller (the controller during bus initialization), then the device may use this mechanism to assign itself its DA. When the device hands off control to a secondary controller, it becomes a target itself. This DA must be written before switching to Target mode and must not be changed once in Target mode (it is not clock-safe to do so). It must be written with a valid address value in DADDR if DAVALID = 1.

NOTE

The main controller also uses DEFSLVS CCC to define the target addresses, including itself. This mechanism is how secondary controllers know this address. If the controller is not the main controller, then this mechanism must not be used.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 DADDR	Dynamic Address Contains the assigned dynamic address when DAVALID = 1.
0 DAVALID	Dynamic Address Valid 0b - No valid DA assigned 1b - Valid DA assigned

45.7.55 Map Feature Control 0 (SMAPCTRL0)

Offset

Register	Offset
SMAPCTRL0	11Ch

Function

Provides map feature control.

The SMAPCTRL*n* registers are named SMAPCTRL0, SMAPCTRL1, and so on based on the number of mapped addresses. MAPCTRL0 represents the primary DA or SA with SMAPCTRL1 onwards being the mapped addresses.

The features of the SMAPCTRL*n* registers depend on configuration. SMAPCTRL0 acts differently, as described in this chapter.

In general, this mechanism is intended to replace the DYNADDR register for all MAP-related uses.

When using the Auto-MAP and DASA or AASA, the slot is changed from SA to DA. If the controller then issues RSTDAA, the application must rewrite the static addresses and enable them because they are marked disabled.

Diagram

46.1.1 Module instances

This device has two instances of the LPSPI module, LPSPI0, and LPSPI1.

46.1.2 Host request configuration

Both of the LPSPI0 and LPSPI1 support host request feature.

The input trigger that can be used as host request input is from TRGMUX, refer to Trigger multiplexer (TRGMUX) for more details.

46.2 Overview

LPSPI provides an efficient interface (either as a controller or peripheral) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 329. Updated terms

Updated term	Deprecated term
Controller	Master
Peripheral	Slave

46.2.1 Block diagram

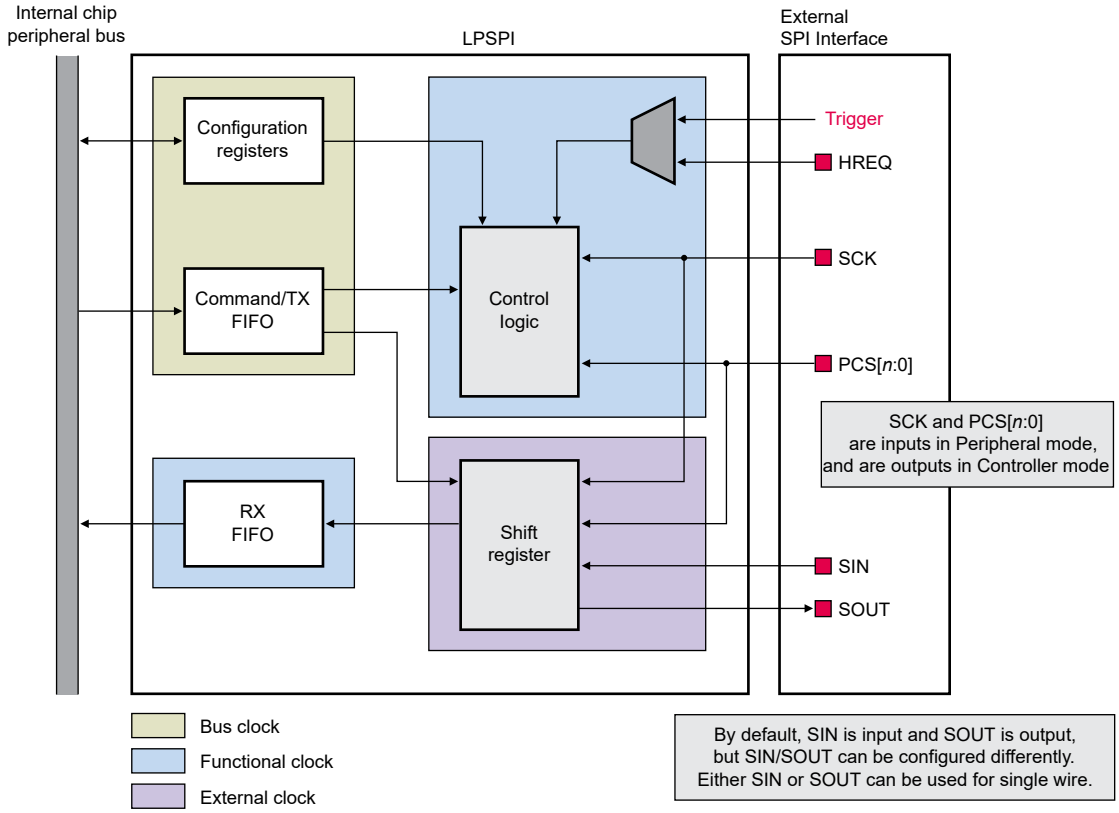

Figure 173. Block diagram

46.2.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses
- Operation continues in Sleep mode, if configured to do so and an appropriate clock is available
- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 4 peripheral chip selects in Controller mode
- Support available for Peripheral mode
- 8-word transmit and command FIFO
- 8-word receive FIFO
- Flexible timing parameters in Controller mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge

- Option to use host request to control the start of an SPI bus transfer
- Receive data match logic that discards nonmatching data and interrupt on data match

46.3 Functional description

46.3.1 Controller mode

46.3.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 330 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

Table 330. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle.	The command word is pulled from the FIFO, and this command word controls all subsequent transfers.
LPSPI is busy and TCR[CONTC] is 0.	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1.	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Controller mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 331 for TCR fields and associated functionality related to data transfer.

Table 331. Command word in Controller mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different peripheral devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1):	Y

Table continues on the next page...

Table 331. Command word in Controller mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.	

46.3.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

46.3.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI controller to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

46.3.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.

- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

46.3.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you can only change Clock Configuration (CCR) when LPSPI is disabled (CR[MEN] = 0), to support interfacing with different peripheral devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

NOTE

The minimum value shown in Table 332 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 332. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external peripheral requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 332. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

Figure 174 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

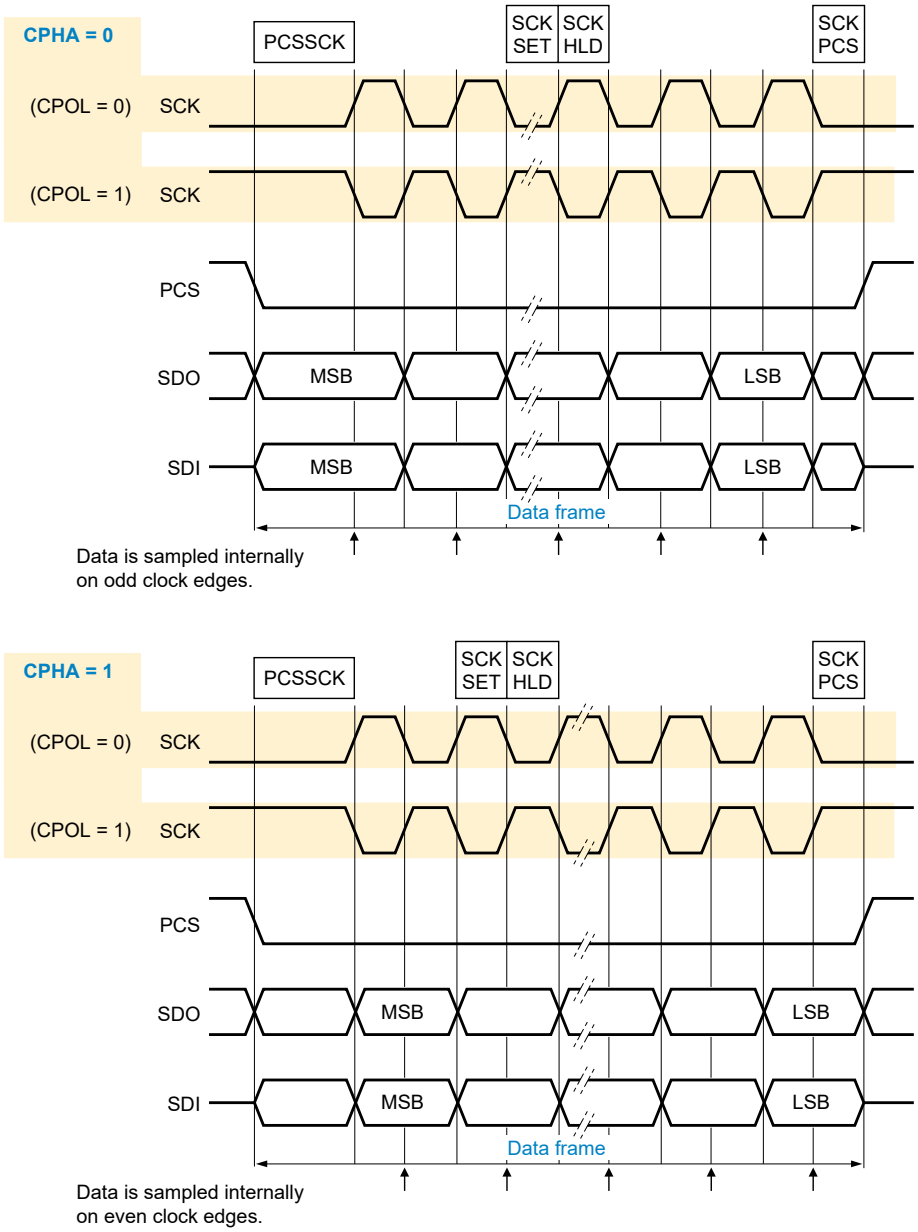

Figure 174. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

46.3.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

46.3.1.5 Clock loopback

Configure the LPSPI controller to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the peripheral.

See the chip data sheet for the specific input setup time in Controller Loopback mode.

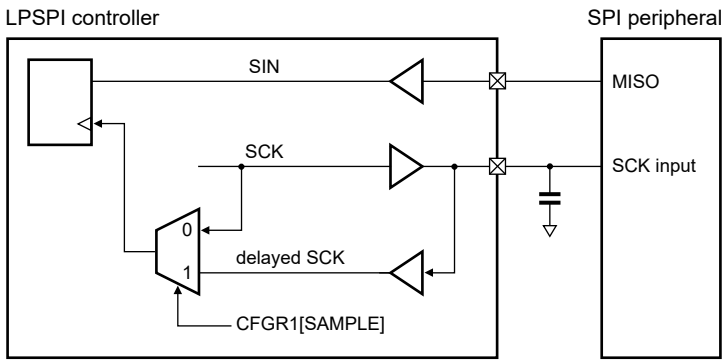

Figure 175. Clock loopback

46.3.2 Peripheral mode

LPSPI Peripheral mode:

- Uses the same shift register and logic that Controller mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

46.3.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Peripheral mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Peripheral mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 333. Command word in Peripheral mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register.
CONTC	Continuing command	When the continuing command is enabled in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

46.3.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

46.3.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

46.3.2.4 Clocked interface

LPSPI supports interfacing with external controllers that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

46.3.3 Low-power modes

LPSPI remains functional during low-power modes, if CR[DOZEN] = 0 and LPSPI uses an external or internal clock source that remains enabled. LPSPI can generate an interrupt or DMA request to cause a wake-up from low-power modes.

46.3.4 Debug mode

Table 334. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug or Halted mode)	Can continue operating in Debug mode, if CR[DBGEN] = 1

46.3.5 Clocking

Table 335. LPSPI clocks

Type of clock	Description
Functional	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Controller and Peripheral modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK).
External	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends on the mode (Controller or Peripheral): — In Controller mode, the SCK clock is generated internally. — In Peripheral mode, the SCK clock is supplied externally.
Bus	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information for more.

46.3.6 Reset

Table 336. LPSPI resets

Type of reset	Description
Chip	Resets the LPSPI logic and registers to their default states.
Software	• Resets the LPSPI logic and registers to their default states, except for the Control register. • The LPSPI software reset is controlled using CR[RST].
FIFO	• Resets the transmit and command FIFO and the receive FIFO. • CR[RTF] and CR[RRF] are write-only. • After being reset, FIFO is empty.

46.3.7 Interrupts and DMA requests

The following table lists sources (status flags) that can generate LPSPI interrupts and LPSPI transmit and receive DMA requests.

Table 337. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER].	Y	TX	Y

Table continues on the next page...

Table 337. Interrupts and DMA requests (continued)

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDF	Receive data flag	Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER].	Y	RX	Y
WCF	Word complete flag	Indicates that the word is complete and the last bit of the word has been sampled.	Y	N	Y
FCF	Frame complete flag	Indicates that the frame is complete and PCS is deasserted.	Y	RX	Y
TCF	Transfer complete flag	Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty.	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set.	Y	N	Y
DMF	Data match flag	Indicates that the received data matches the configured data match value.	Y	N	Y
MBF	Module busy flag	Indicates that LPSPI is busy performing an SPI bus transfer.	N	N	N

46.3.7.1 End-of-packet DMA transfer

The end-of-packet functionality is designed for serial interfaces where you may not be aware of the size of the transfer in advance and the data is pushed by an external device. Examples include UART receive, I2C Peripheral mode, and SPI Peripheral mode. The end-of-packet processing is intended to ensure that data is not stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet is different for each serial interface but the serial peripheral and DMA process it in the same way. For example, UART end of packet is signaled by an idle line condition, I2C end of packet by a stop and/or repeated start condition, and SPI end of packet by PCS negation.

If you configure the serial peripheral to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, then data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop is complete and no additional data is pulled from the receive FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes following end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of the packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop is complete, including final offsets and optional interrupts, channel linking and scatter/gather. The final destination address can optionally be saved in the system memory or is available in the destination address register.

After the DMA terminates the major loop, no servicing of the receive FIFO occurs until either software or hardware reconfigures the DMA (for example, channel linking or scatter/gather). This delay must be minimized to avoid receiver FIFO overrun. NXP does not recommend automatic DMA end-of-packet processing when there are only a few words transferred between end-of-packet conditions. That is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

46.3.7.2 DMA support registers

To support efficient DMA transfers to the transmit and control FIFO, an alias register supports 32-bit write access to the Transmit Command (TCR) and an alias region supports incrementing 32-bit write accesses to the Transmit Data (TDR).

- Transmit Command Burst (TCBR) is a 32-bit alias register for writing to TCR.
- Transmit Data Burst (TDBR0 - TDBR127) is a 512-byte alias region that supports writing to the TDR.

The burst alias locations are contiguous. A DMA transfer can start by writing to the TCBR register to initialize the transfer and then increment into the TDBR region without changing the DMA transfer size. The alias registers can also be used by the DMA to perform burst transfers when accessing the transmit FIFO.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform writes to the TDBR unless there is sufficient room in the transmit FIFO.

Receive Data Burst (RDBR0 - RDBR127) is a 512-byte alias region that supports reading the Receive Data. This can be used by the DMA to perform burst transfers when accessing the receive FIFO.

46.3.8 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 338. Peripheral triggers

Type of trigger	Description	Additional information
Frame output	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts). • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output	The word output trigger: • Asserts at the end of each received word. • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	
Input	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input:	

Table continues on the next page...

Table 338. Peripheral triggers (continued)

Type of trigger	Description	Additional information
	• The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected. • When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle.	

46.4 External signals

Table 339. External signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[0]	Peripheral chip select	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[1]/HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0: • Input in either Peripheral mode or when used as controller host request • Output in either Controller mode or when used as peripheral host request	I/O
PCS[2]/DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3]/DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers	I/O

Table continues on the next page...

Table 339. External signals (continued)

Signal	Name	Description	I/O
		• Output in half-duplex parallel data transmit transfers	
SOUT/DATA[0]	Serial data output	Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers)	I/O
SIN/DATA[1]	Serial data input	Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers)	I/O

46.5 Initialization

This module does not require initialization.

46.6 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

46.6.1 LPSPI register descriptions

46.6.1.1 LPSPI memory map

LPSPI0 base address: 4003_6000h

LPSPI1 base address: 4003_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0200_0004h

600h - 7FCh	Receive Data Burst (RDBR0 - RDBR127)	32	R	0000_0000h

46.6.1.2 Version ID (VERID)

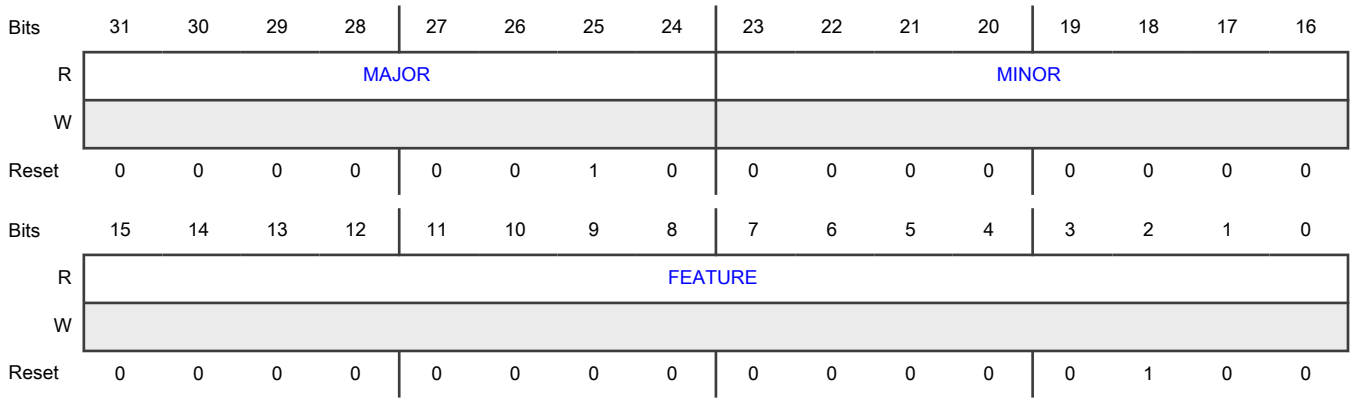
Offset

Register	Offset
VERID	0h

Function

Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number of the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

46.6.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Contains:

- Number of PCS pins.
- Receive FIFO size.
- Transmit FIFO size.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								PCSNUM							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RXFIFO								TXFIFO							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

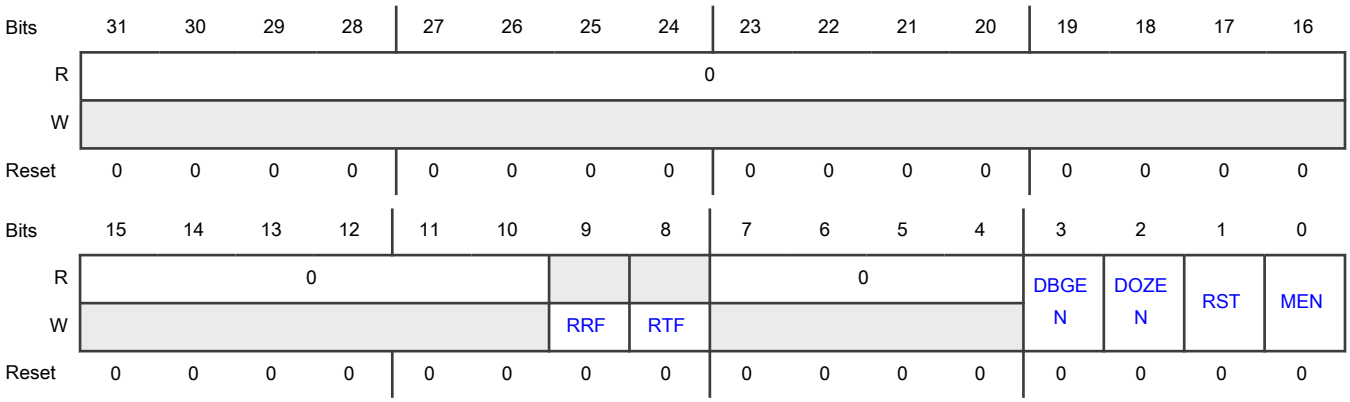
46.6.1.4 Control (CR)

Offset

Register	Offset
CR	10h

Function
Contains fields that control the module operation.

Diagram



Fields

Field	Function
31-10	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads 0. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI when the CPU is in Debug mode. If this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). You must update this field only when LPSPI is disabled (MEN = 0). 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables LPSPI when the chip is in Doze mode. You must update this field only when LPSPI is disabled (MEN = 0). 0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable Enables the module. After writing 0, MEN remains set until LPSPI has completed the current transfer and is idle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable

46.6.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains data flow status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0							MBF	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		DMF	REF	TEF	TCF	FCF	WCF	0						RDF	TDF
W			W1C	W1C	W1C	W1C	W1C	W1C								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag Indicates, in Controller mode, whether there is data to transmit and LPSPI is able to transmit (for example, the HREQ pin is asserted). The HREQ pin deasserts after the PCS pin deasserts and the LPSPI controller has waited for half the time specified in CCR[DBT] with no new data to transmit. Peripheral mode sets this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-14 —	Reserved
13 DMF	Data Match Flag Indicates whether the received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No match 1b - Match When writing 0b - No effect 1b - Clear the flag
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
11 TEF	Transmit Error Flag Indicates a transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No underrun 1b - Underrun When writing 0b - No effect 1b - Clear the flag
10 TCF	Transfer Complete Flag Indicates, in Controller mode, whether all transfers are complete and LPSPI has returned to the Idle state and the transmit FIFO is empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 FCF	Frame Complete Flag Indicates whether a frame transfer is complete after PCS deasserts. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
8 WCF	Word Complete Flag Indicates whether the last bit of a received word is sampled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

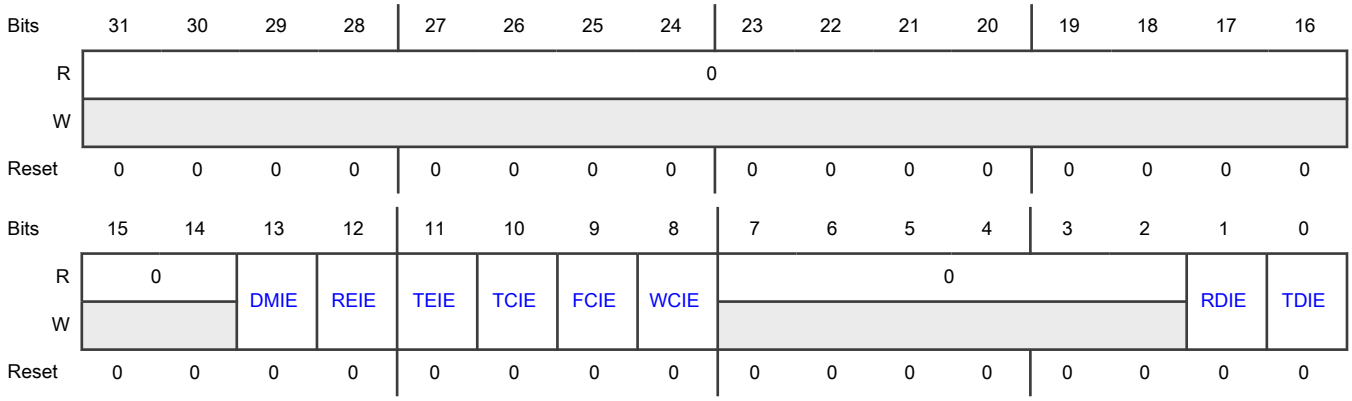
46.6.1.6 Interrupt Enable (IER)

Offset

Register	Offset
IER	18h

Function
Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 DMIE	Data Match Interrupt Enable Enables the data match interrupt. 0b - Disable 1b - Enable
12 REIE	Receive Error Interrupt Enable Enables the receive error interrupt. 0b - Disable 1b - Enable
11 TEIE	Transmit Error Interrupt Enable Enables the transmit error interrupt. 0b - Disable 1b - Enable
10 TCIE	Transfer Complete Interrupt Enable Enables the transfer complete interrupt. 0b - Disable 1b - Enable
9 FCIE	Frame Complete Interrupt Enable Enables the frame complete interrupt. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 WCIE	Word Complete Interrupt Enable Enables the word complete interrupt. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables the receive data interrupt. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables the transmit data interrupt. 0b - Disable 1b - Enable

46.6.1.7 DMA Enable (DER)

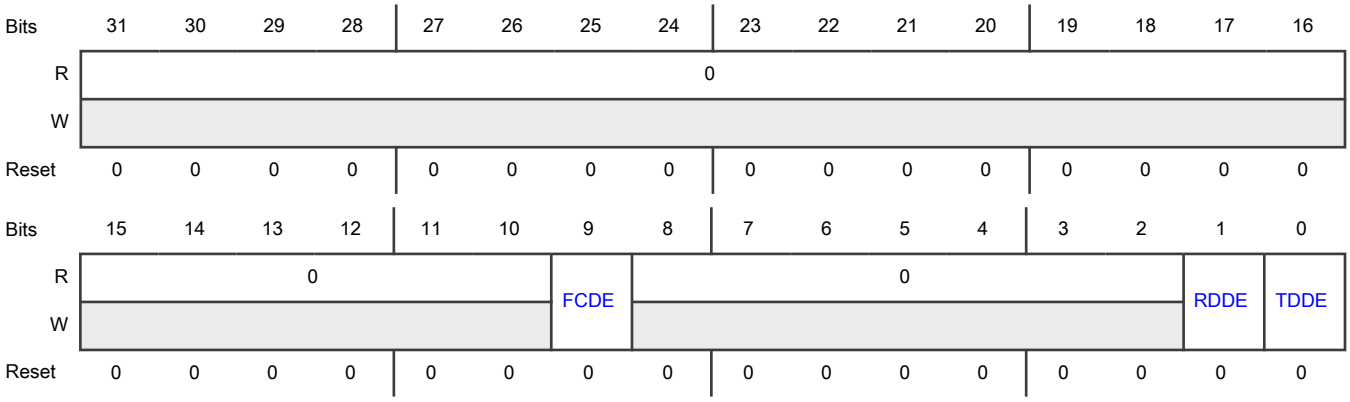
Offset

Register	Offset
DER	1Ch

Function

Enables the DMA data flow.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 FCDE	Frame Complete DMA Enable Enables DMA end-of-packet processing. After the last word of a frame is read from the receive data FIFO, reading the receive data FIFO returns an end-of-packet signal with the receive data forced to FFFF_FFFFh. This continues until the DMA minor loop completes, and then SR[FCF] deasserts if the receive FIFO is empty or if LPSPI is busy (SR[MBF] = 1). 0b - Disable 1b - Enable
8-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables the receive data DMA. 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables the transmit data DMA. 0b - Disable 1b - Enable

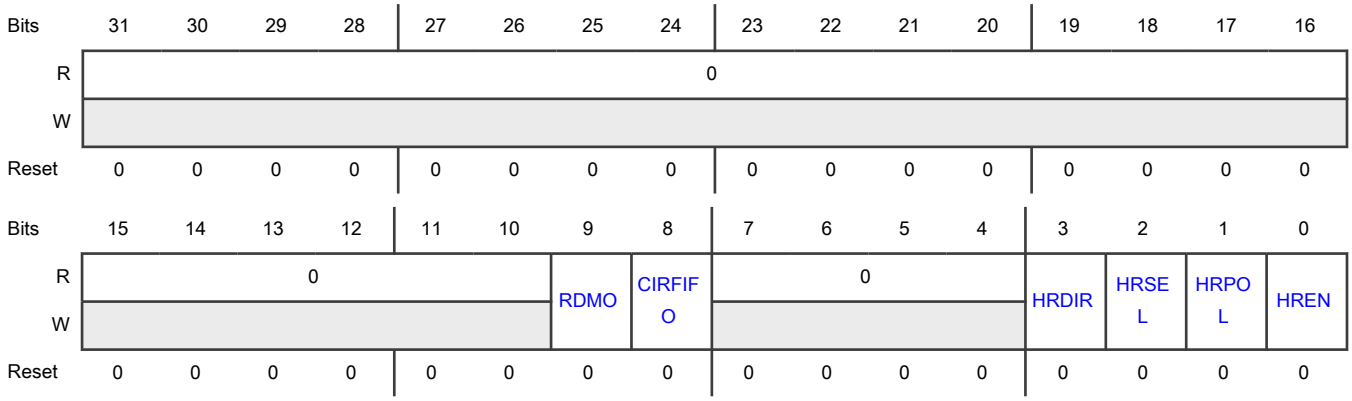
46.6.1.8 Configuration 0 (CFGR0)

Offset

Register	Offset
CFGR0	20h

Function
Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only Enables receive data match. When enabled, all received data that does not cause SR[DMF] to assert is discarded: • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable Enables circular FIFO. When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. You must configure the HREQ pin only as an output when LPSPI is in Peripheral mode. The HREQ pin direction must be an input for Controller mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable Enables LPSPI, in Controller mode, to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Peripheral mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

46.6.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function

Includes fields to configure LPSPI. You must write to this register only when LPSPI is disabled.

In addition to pin and output configurations, this register contains match configuration details; the following table shows match conditions specified in MATCFG.

Table 340. Match conditions for CFGR1[MATCFG]

Condition	Description
Match first data word with compare word	Match if first data word equals MATCH0 logically ORed with MATCH1 first_data_word == (MATCH0 || MATCH1)
Match any data word with compare word	Match if any data word equals MATCH0 logically ORed with MATCH1 any_data_word == (MATCH0 || MATCH1)
Sequential match, first data word	Match if first data word equals MATCH0, and second data word equals MATCH1 (first_data_word == MATCH0) && (second_data_word == MATCH1)
Sequential match, any data word	Match if any data word equals MATCH0, and the next data word equals MATCH1 (any_data_word == MATCH0) && (next_data_word == MATCH1)
Match first data word (masked) with compare word (masked)	Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (first_data_word && MATCH1) == (MATCH0 && MATCH1)
Match any data word (masked) with compare word (masked)	Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (any_data_word && MATCH1) == (MATCH0 && MATCH1)

Diagram

Fields

Field	Function
31-29 —	Reserved
28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 PCSCFG	Peripheral Chip Select Configuration Specifies PCS pin configuration. When performing parallel transfers, you must configure this field to enable the desired transfer. 0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1. 0b - Retain last value 1b - 3-stated
25-24 PINCFG	Pin Configuration Specifies the pins used for input and output data during serial transfers. **NOTE** When performing parallel transfers, this field must be 00b or 10b. 00b - SIN is used for input data; SOUT is used for output data 01b - SIN is used for both input and output data; only half-duplex serial transfers are supported 10b - SOUT is used for both input and output data; only half-duplex serial transfers are supported 11b - SOUT is used for input data; SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Specifies the condition that causes SR[DMF] to assert. See the match conditions listed in Table 1 for more information. **NOTE** When writing to this field, either the old value or new value must be in the disabled state (0). You cannot transition from a nonzero value to another nonzero value. 000b - Match is disabled 001b - Reserved 010b - Match first data word with compare word 011b - Match any data word with compare word 100b - Sequential match, first data word 101b - Sequential match, any data word 110b - Match first data word (masked) with compare word (masked)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	111b - Match any data word (masked) with compare word (masked)
15-12 —	Reserved
11-8 PCSPOL	Peripheral Chip Select Polarity Specifies the polarity of each PCS pin. Bit *n* in this field (the least-significant bit is bit 0) corresponds to PCS[*n*]. 0000b - Active low 0001b - Active high
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LPSPI, when in Peripheral mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. See Partial received word for more information. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LPSPI, when in Controller mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Peripheral mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least four LPSPI functional clock cycles, divided by the prescaler (see TCR[PRESCALE]) selected between each word to ensure correct operation. This field is ignored in Controller mode. **NOTE** Set TCR[CPHA] = 1 before enabling the module by setting CR[MEN] = 1. 0b - Disable 1b - Enable
1	Sample Point

Table continues on the next page...

Table continued from the previous page...

Field	Function
SAMPLE	Specifies the SCK clock edge on which LPSPI, when in Controller mode, samples input data. Writing 1 to this field causes LPSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration, the input data setup time in Controller mode is equal to the input data setup time in Peripheral mode. In Peripheral mode, this field is ignored. **NOTE** When SAMPLE = 1, both the input and output buffers must be enabled for the SCK pin. Buffers are configured at the chip level. 0b - SCK edge 1b - Delayed SCK edge
0 MASTER	Controller Mode Specifies the LPSPI operating mode, Controller or Peripheral. This field directly controls the direction of the SCK and PCS pins. 0b - Peripheral mode 1b - Controller mode

46.6.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

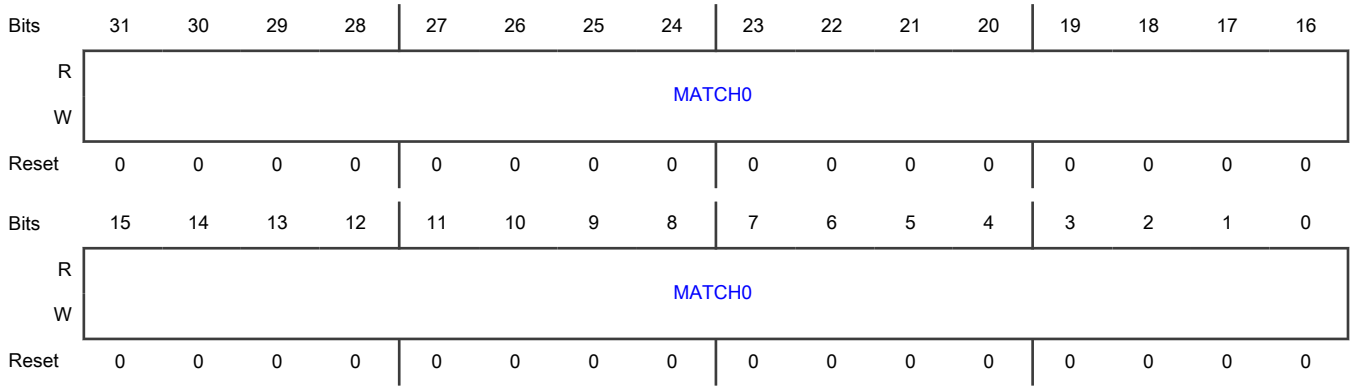
Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register when CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH0	Match 0 Value Specifies the MATCH0 value to be compared against received data.

46.6.1.11 Data Match 1 (DMR1)

Offset

Register	Offset
DMR1	34h

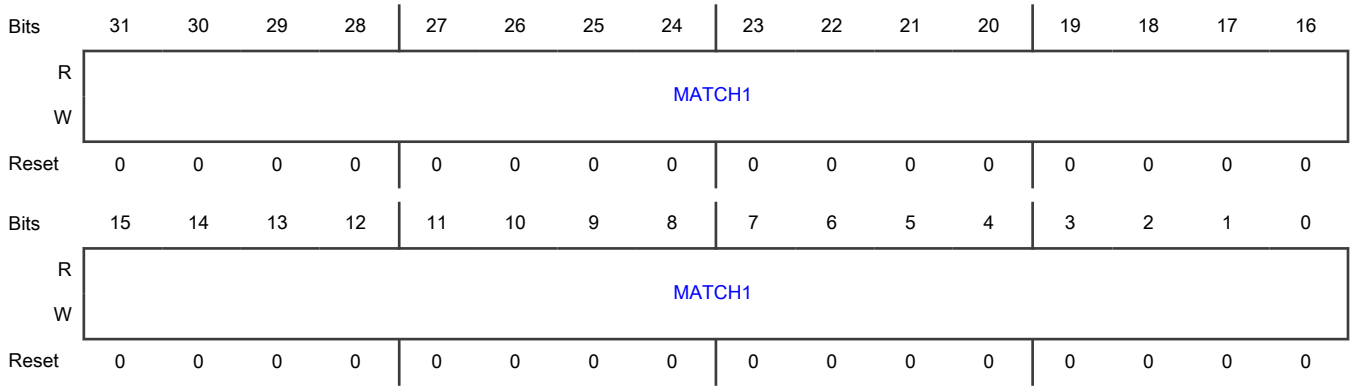
Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register while CFGR1[MATCFG] > 0.

Diagram



Fields

Field	Function
31-0 MATCH1	Match 1 Value Specifies the MATCH1 value to be compared against received data.

46.6.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields that are used only in Controller mode; you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1, do one of the following:

- Write to all four fields in Clock Configuration (CCR) simultaneously and only once in a 32-bit data.
- Modify the values of CCR[SCKPCS] and/or CCR[PCSSCK]; write only these two upper bytes in a 16-bit data or one of them in an 8-bit data.
- Modify CCR1[PCSPCS] and CCR1[SCKSCK] only or CCR1[SCKSET] and CCR1[SCKHLD] only, write respectively to CCR[DBT] or CCR[SCKDIV] in 8-bit data.

Diagram

Fields

Field	Function
31-24	SCK-to-PCS Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKPCS	Configures SCK-to-PCS delay. In Controller mode, this field helps you configure the delay from the last SCK edge to PCS negation: • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 174 for more information.
23-16 PCSSCK	PCS-to-SCK Delay Configures PCS-to-SCK delay. In Controller mode, this field helps you configure the delay from PCS assertion to the first SCK edge: • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 174 for more information.
15-8 DBT	Delay Between Transfers Configures the delay between transfers. Writing to this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0 SCKDIV	SCK Divider Updates the contents of CCR1[SCKSET] and CCR1[SCKHLD]. Baud rate = function clock ÷ (2^PRESCALE × (SCKSET + SCKHLD + 2))

46.6.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields, which are used only in Controller mode. You can change them only when LPSPI is disabled (CR[MEN] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKSCK								PCSPCS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	SCKHLD								SCKSET							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay Configures SCK inter-frame delay in Controller mode: • This field helps you configure the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with the value written.
23-16 PCSPCS	PCS to PCS Delay Configures PCS to PCS delay in Controller mode: • This field helps you configure the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is two cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between two transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the selected prescaler. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8	SCK Hold

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKHLD	Configures the hold phase of the SCK pin in Controller mode: • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • It is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 174 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup Configures the setup phase of the SCK pin in Controller mode: • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • It is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 174 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

46.6.1.14 FIFO Control (FCR)

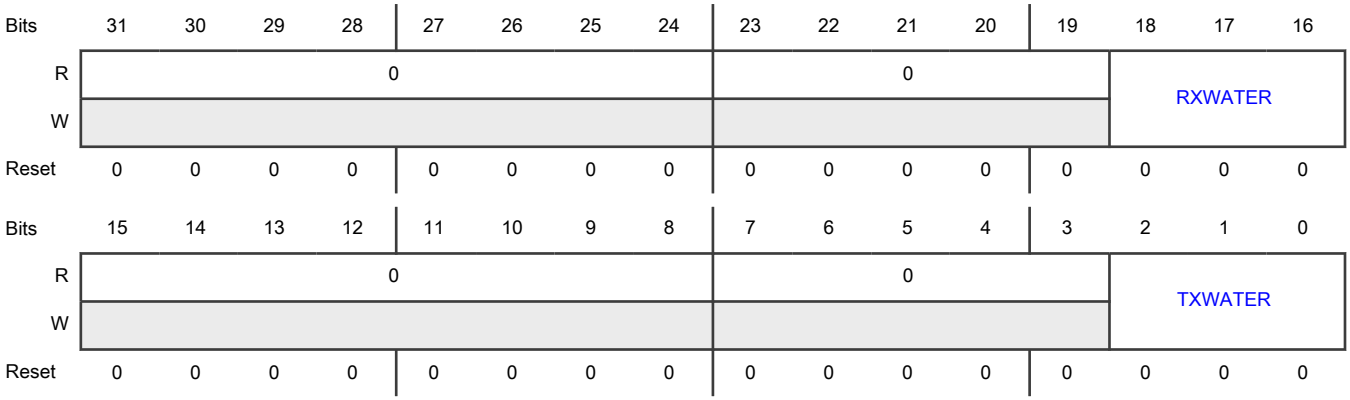
Offset

Register	Offset
FCR	58h

Function

Contains the receive FIFO and transmit FIFO watermark values.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-19 —	Reserved
18-16 RXWATER	Receive FIFO Watermark Causes LPSPI to set SR[RDF] when the number of words in the receive FIFO is greater than RXWATER. Writing a value equal to or greater than the FIFO size truncates the written value.
15-8 —	Reserved
7-3 —	Reserved
2-0 TXWATER	Transmit FIFO Watermark Causes LPSPI to set SR[TDF] when the number of words in the transmit FIFO is equal to or less than TXWATER. Writing a value equal to or greater than the FIFO size truncates the written value.

46.6.1.15 FIFO Status (FSR)

Offset

Register	Offset
FSR	5Ch

Function

Contains fields that indicate the number of words currently stored in the receive and transmit FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Function
31-24 —	Reserved
23-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Indicates the number of words currently stored in the receive FIFO.
15-8 —	Reserved
7-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Indicates the number of words currently stored in the transmit FIFO.

46.6.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Pushes the data into the transmit FIFO, in the same order as written.

When you write to either this register or to Transmit Data (TDR), each write pushes data into the transmit FIFO. You must write to this register only using 32-bit writes, which are tagged and cause the command register to update; after that the entry reaches the top of the FIFO and LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word:

- In Controller mode, writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when PCS deasserts.
- In Controller mode, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- In Peripheral mode, the command word must be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the transmit FIFO after writing to this register; wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading this register returns the current state of the register. Reading this register at the same time that it is loaded from the transmit FIFO can return an incorrect register value. It is recommended to:

- Read this register when the transmit FIFO is empty.
- Read this register more than once and then compare the returned values.

Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. You can update this field only when PCS is deasserted. See Figure 174 for more information. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase Indicates whether data is captured or changed on the leading edge of SCK and captured or changed on the following edge of SCK. You can update this field only when PCS is deasserted. See Figure 174 for more information. 0b - Captured 1b - Changed
29-27 PRESCALE	Prescaler Value Specifies the division of the LPSPI functional clock. For all SPI bus transfers, this value is applied to Clock Configuration (CCR). You can update this field only when PCS is deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. This field is updated only when PCS is deasserted. **NOTE** This entire field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Transfer using PCS[3]
23 LSBF	LSB First Indicates whether data is transferred with MSB first or LSB first. 0b - MSB first 1b - LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disable byte swap 1b - Enable byte swap
21 CONT	Continuous Transfer Enables continuous transfer: • In Controller mode, this field keeps PCS asserted at the end of the frame size until a command word is received that starts a new frame. • In Peripheral mode, when this field is enabled, LPSPI only transmits the first FRAMESZ bits, after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Disable 1b - Enable
20 CONTC	Continuing Command Enables the command word to be changed within a continuous transfer in Controller mode: • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64 bits, then a continuing command word must be loaded on a 64-bit boundary. In Peripheral mode, this field modifies the internal RXMSK and TXMSK configuration after the first FRAMESZ bits and until PCS negation: • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1, this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits. This allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19	Receive Data Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXMSK	Masks receive data (receive data is not stored in the receive FIFO). 0b - Normal transfer 1b - Mask receive data
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from the transmit FIFO and the output pin is 3-stated). In Controller mode, TXMSK initiates a new transfer that cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either RXMSK or TXMSK must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

46.6.1.17 Transmit Data (TDR)

Offset

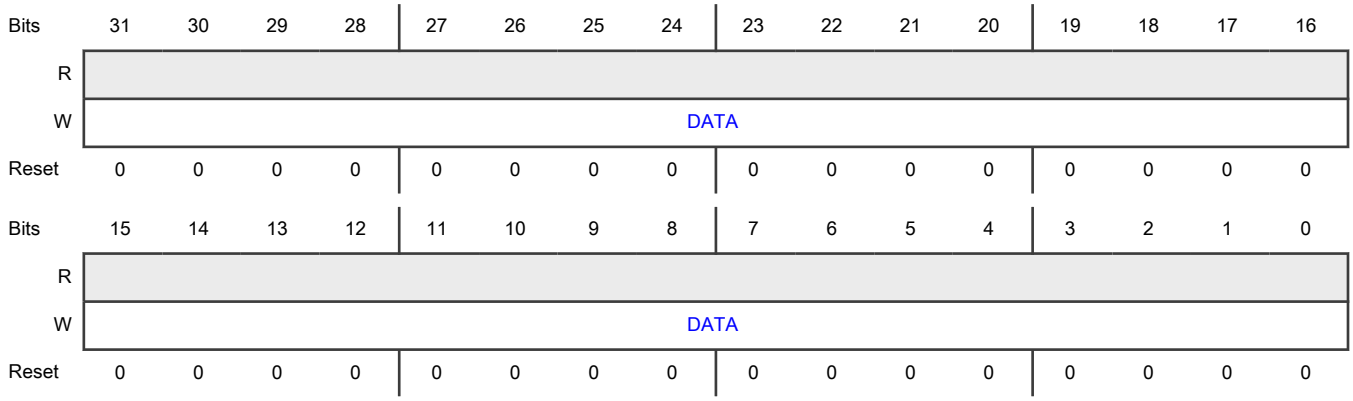
Register	Offset
TDR	64h

Function

Pushes the data into the transmit FIFO, in the same order that the data is written. You can write to this register using 32-, 16-, or 8-bit writes.

When you write to this register or to Transmit Command (TCR), each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Indicates transmit data. Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits) means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

46.6.1.18 Receive Status (RSR)

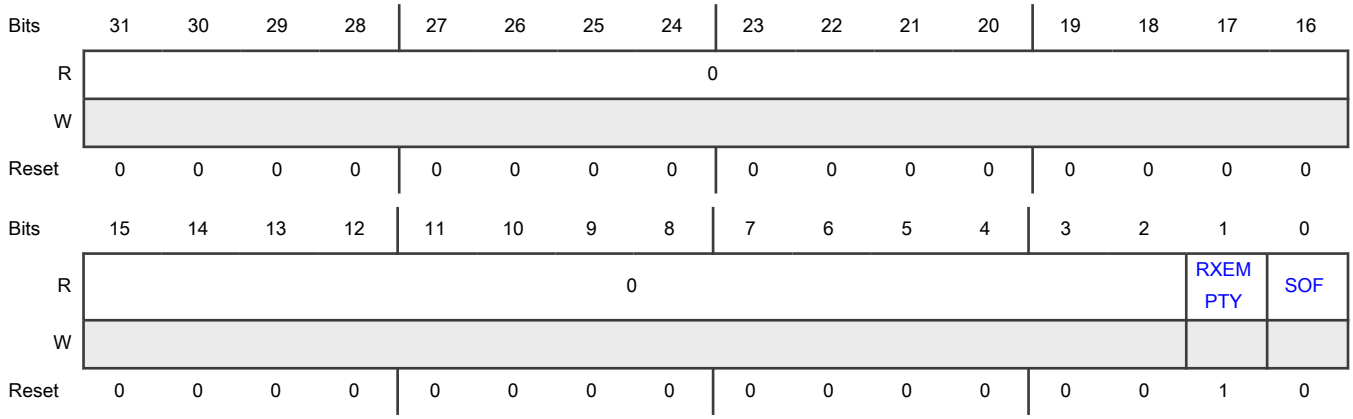
Offset

Register	Offset
RSR	70h

Function

Contains data flow status fields for receive FIFO.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RXEMPTY	RX FIFO Empty Indicates whether the receive FIFO is empty. 0b - Not empty 1b - Empty
0 SOF	Start of Frame Indicates whether this is the first data word received after PCS assertion. 0b - Subsequent data word or RX FIFO is empty (RXEMPTY=1). 1b - First data word

46.6.1.19 Receive Data (RDR)

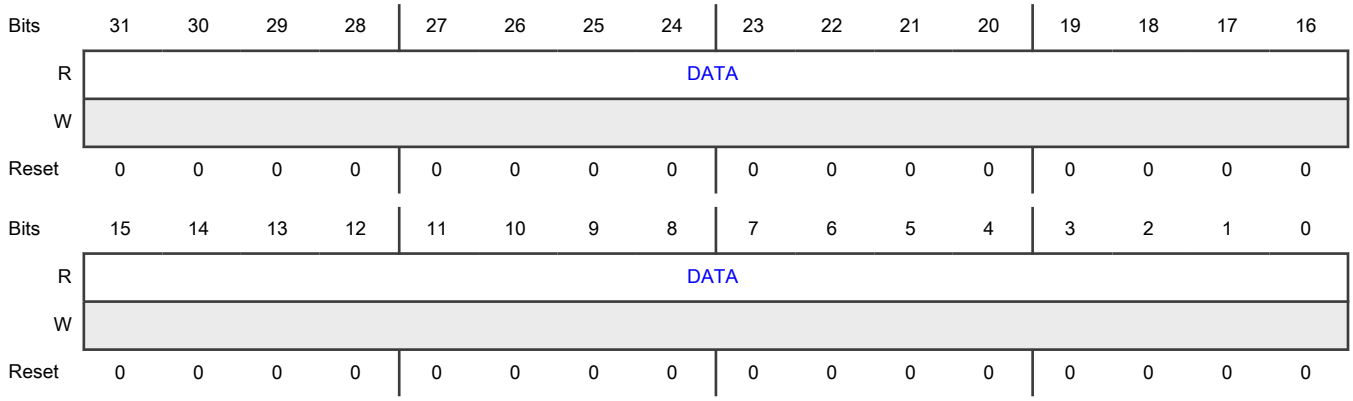
Offset

Register	Offset
RDR	74h

Function

Pulls the first entry from the receive FIFO.

Diagram



Fields

Field	Function
31-0 DATA	Receive Data

46.6.1.20 Receive Data Read Only (RDROR)

Offset

Register	Offset
RDROR	78h

Function

Returns the first entry in the receive FIFO but does not remove the data from the FIFO.

Chapter 47
Low Power Universal Asynchronous Receiver/ Transmitter (LPUART)

47.1 Chip-specific LPUART information

Table 341. Reference links to related information

Topic	Related module	Reference
Full description	LPUART	LPUART
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

47.1.1 Module instances

This device has two instances of the LPUART module, LPUART0, and LPUART1.

47.2 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and infrared data association (IrDA)-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

47.2.1 Block diagram

Figure 176 shows the transmitter portion of LPUART.

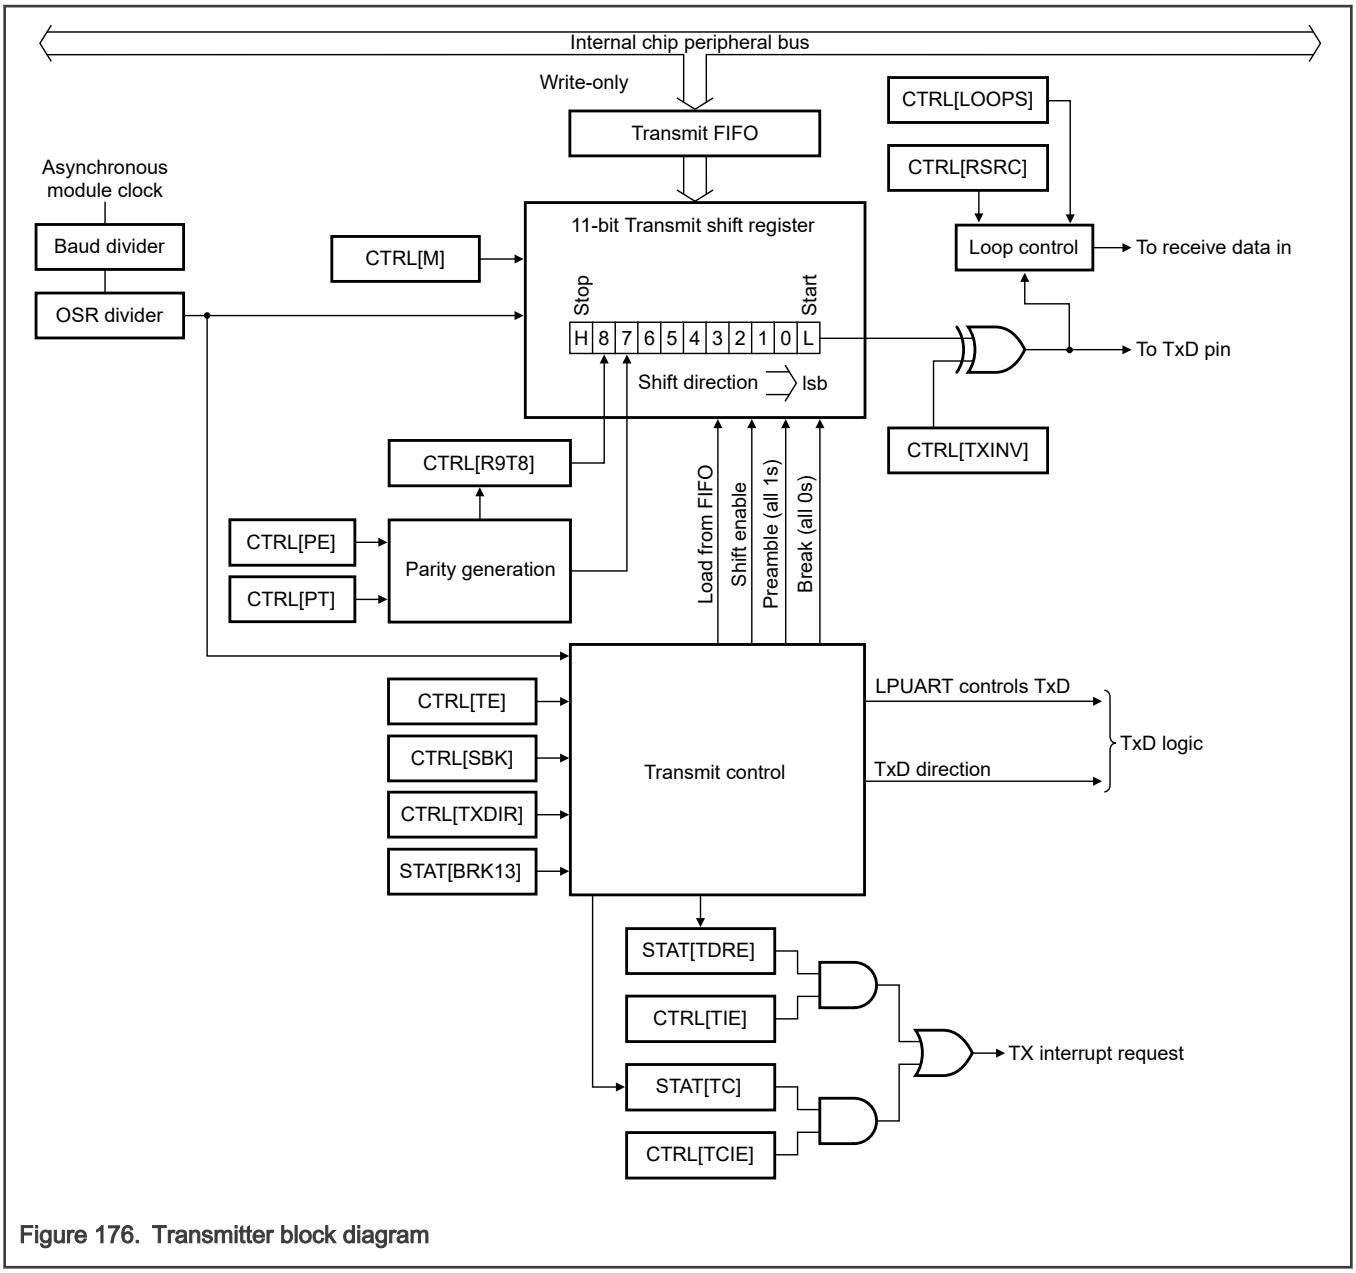

Figure 176. Transmitter block diagram

Figure 177 shows the receiver portion of LPUART.

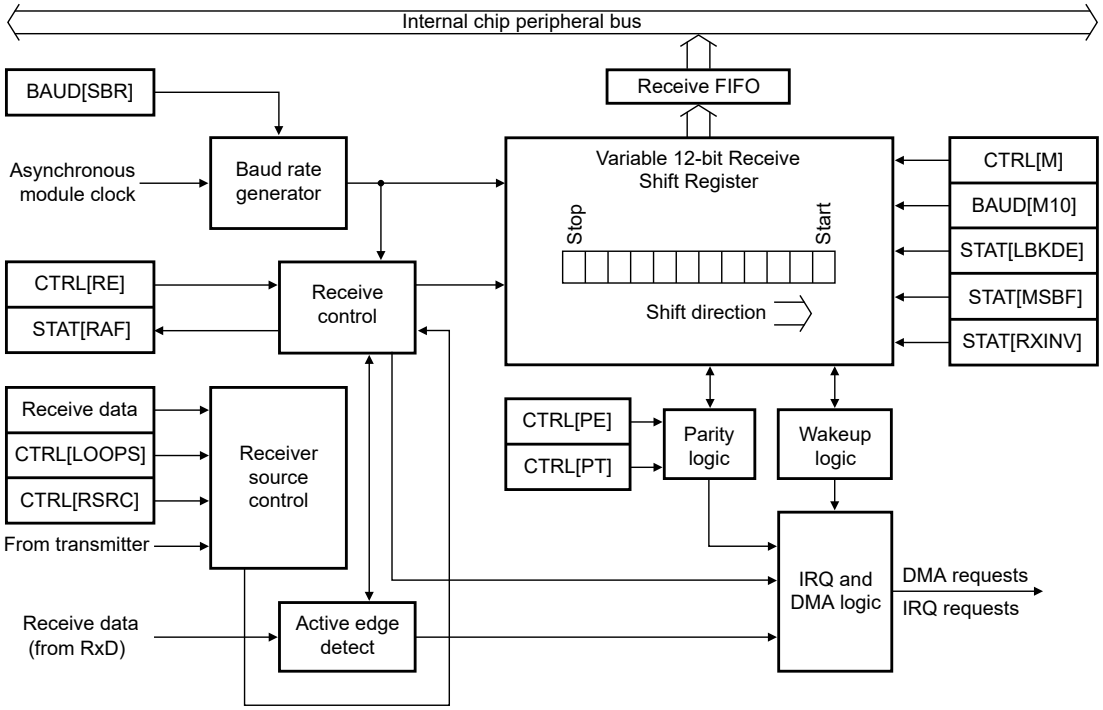

Figure 177. Receiver block diagram

47.2.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) from 4× to 32×
- Asynchronous operation of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wake-up methods:
  - Idle line wake-up

  - Address mark wake-up
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

47.3 LPUART register descriptions

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. LPUART does not verify whether programmed values in the registers are correct; you must write valid values to them.

47.3.1 LPUART memory map

LPUART0 base address: 4003_8000h

LPUART1 base address: 4003_9000h

47.3.2 Version ID (VERID)

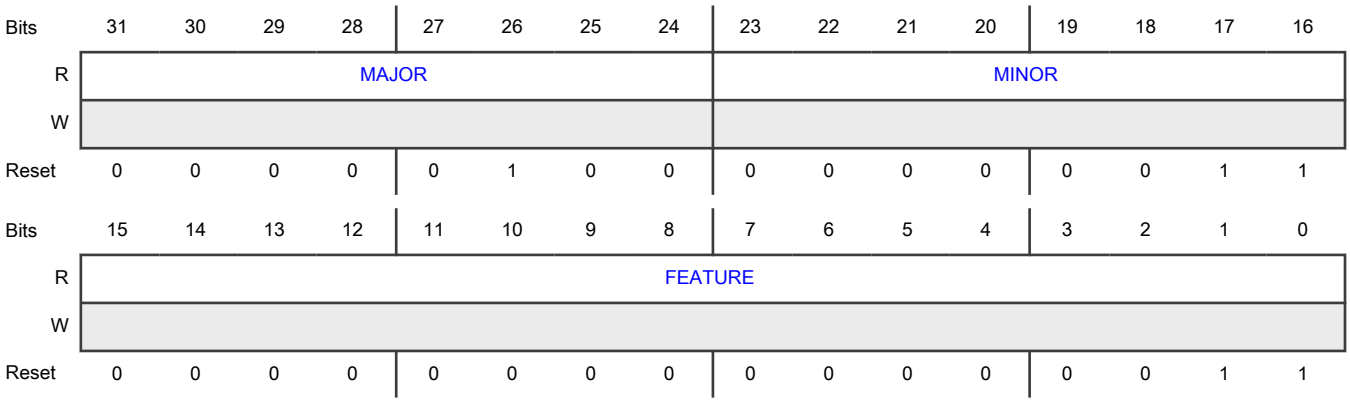
Offset

Register	Offset
VERID	0h

Function

Indicates the version integrated for this instance on the chip and also specifies the inclusion and exclusion of several optional features.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number for the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number for the module specification.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 FEATURE	Feature Identification Number Indicates the feature set number. 0000_0000_0000_0001b - Standard feature set 0000_0000_0000_0011b - Standard feature set with MODEM and IrDA support

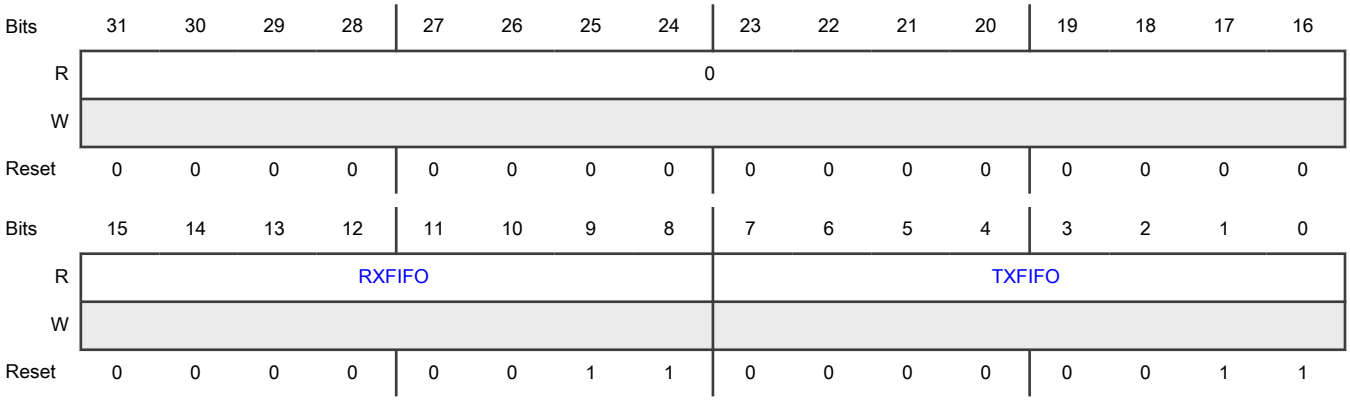
47.3.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function
Indicates the parameter configuration for this instance on the chip.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 RXFIFO	Receive FIFO Size Indicates the number of characters in the receive FIFO, which is 2^RXFIFO.
7-0 TXFIFO	Transmit FIFO Size Indicates the number of characters in the transmit FIFO, which is 2^TXFIFO.

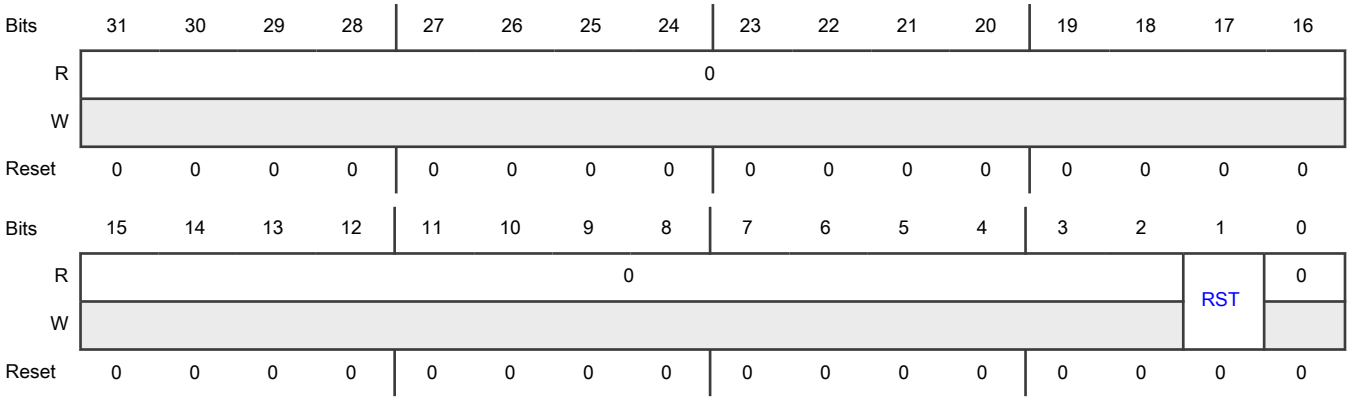
47.3.4 Global (GLOBAL)

Offset

Register	Offset
GLOBAL	8h

Function
Performs global functions.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RST	Software Reset Specifies whether the module is reset. This field resets all internal logic and registers, except Global (GLOBAL). The reset takes effect immediately and remains asserted until you negate it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 —	Reserved

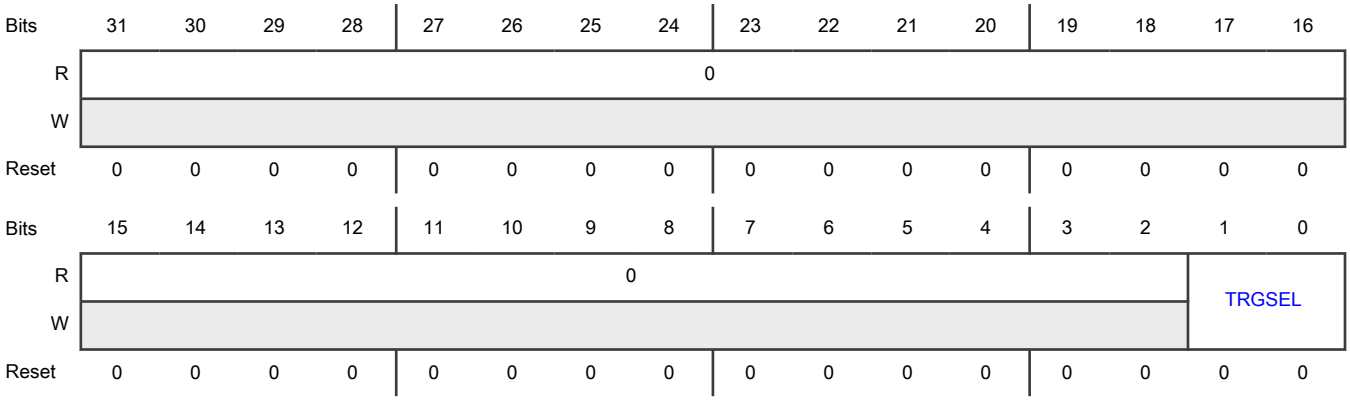
47.3.5 Pin Configuration (PINCFG)

Offset

Register	Offset
PINCFG	Ch

Function
Enables the selection of input pins.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 TRGSEL	Trigger Select Configures the input trigger usage. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Input trigger disabled 01b - Input trigger used instead of the RXD pin input 10b - Input trigger used instead of the CTS_B pin input 11b - Input trigger used to modulate the TXD pin output, which (after TXINV configuration) is internally ANDed with the input trigger

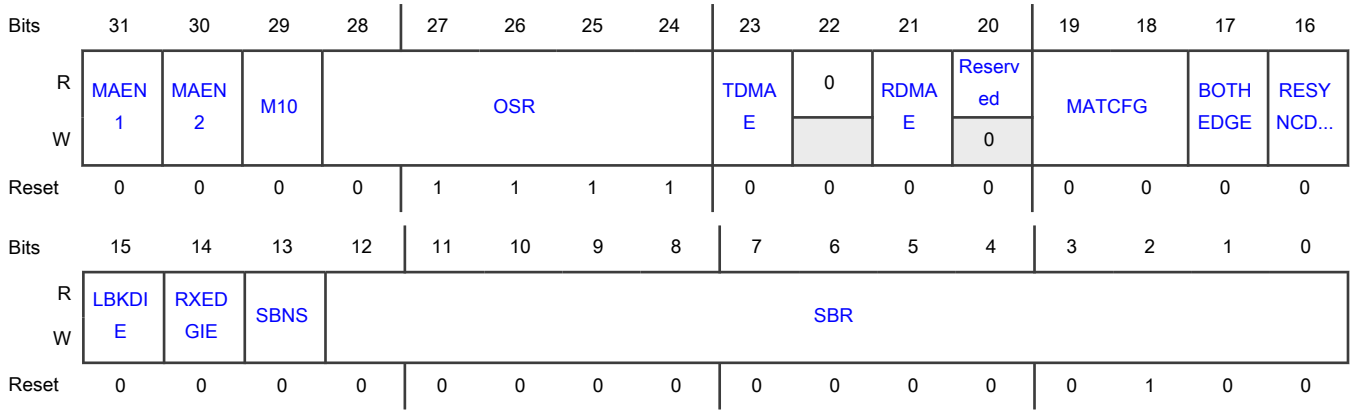
47.3.6 Baud Rate (BAUD)

Offset

Register	Offset
BAUD	10h

Function
Configures the baud rate.

Diagram



Fields

Field	Function
31 MAEN1	Match Address Mode Enable 1 Enables automatic address matching or data matching mode for MATCH[MA1]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
30 MAEN2	Match Address Mode Enable 2 Enables automatic address matching or data matching mode for MATCH[MA2]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
29 M10	10-Bit Mode Select Causes the tenth bit to be a part of the serial transmission. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Receiver and transmitter use 10-bit data characters
28-24 OSR	Oversampling Ratio Configures the OSR of the receiver. You must change the value of this field only when both the transmitter and receiver are disabled. **NOTE** BAUD[OSR] results in an OSR of BAUD[OSR] + 1, for example, BAUD[OSR] = 0_0101b results in a final division by 6. 0_0000b - Results in an OSR of 16 0_0001b - Reserved 0_0010b - Reserved 0_0011b - Results in an OSR of 4 (requires BAUD[BOTHEDGE] to be 1) 0_0100b - Results in an OSR of 5 (requires BAUD[BOTHEDGE] to be 1) 0_0101b - Results in an OSR of 6 (requires BAUD[BOTHEDGE] to be 1) 0_0110b - Results in an OSR of 7 (requires BAUD[BOTHEDGE] to be 1) 0_0111b - Results in an OSR of 8 0_1000b - Results in an OSR of 9 0_1001b - Results in an OSR of 10 0_1010b - Results in an OSR of 11 0_1011b - Results in an OSR of 12 0_1100b - Results in an OSR of 13 0_1101b - Results in an OSR of 14 0_1110b - Results in an OSR of 15 0_1111b - Results in an OSR of 16 1_0000b - Results in an OSR of 17 1_0001b - Results in an OSR of 18 1_0010b - Results in an OSR of 19 1_0011b - Results in an OSR of 20 1_0100b - Results in an OSR of 21 1_0101b - Results in an OSR of 22 1_0110b - Results in an OSR of 23 1_0111b - Results in an OSR of 24 1_1000b - Results in an OSR of 25 1_1001b - Results in an OSR of 26

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1_1010b - Results in an OSR of 27 1_1011b - Results in an OSR of 28 1_1100b - Results in an OSR of 29 1_1101b - Results in an OSR of 30 1_1110b - Results in an OSR of 31 1_1111b - Results in an OSR of 32
23 TDMAE	Transmitter DMA Enable Enables STAT[TDRE] to generate a DMA request. 0b - Disable 1b - Enable
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable Enables STAT[RDRF] to generate a DMA request. 0b - Disable 1b - Enable
20 —	Reserved
19-18 MATCFG	Match Configuration Configures the match addressing mode used. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Address match wake-up 01b - Idle match wake-up 10b - Match on and match off 11b - Enables RWU on data match and match on or off for the transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given OSR. This field must be 1 for OSRs between x4 and x7 and is optional for higher OSRs. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver samples input data using the rising edge of the baud rate clock. If this field is 1, the receiver samples input data using the rising and falling edges of the baud rate clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Rising edge 1b - Both rising and falling edges
16 RESYNCDIS	Resynchronization Disable Disables resynchronization of the received data word when a data one followed by data zero transition is detected. You must change the value of this field only when the receiver is disabled. 0b - Enable 1b - Disable
15 LBKDIE	LIN Break Detect Interrupt Enable Enables STAT[LBKDIF] to generate hardware interrupt requests. If this field is 0, hardware interrupts from STAT[LBKDIF] (uses polling) are disabled. If this field is 1, hardware interrupts are requested when STAT[LBKDIF] is 1. 0b - Disable 1b - Enable
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables STAT[RXEDGIF] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[RXEDGIF] are disabled. If this field is 1, hardware interrupts are requested when STAT[RXEDGIF] is 1. Changing the value of CTRL[LOOPS] or CTRL[RSRC] when this field (RXEDGIE) is 1 can cause STAT[RXEDGIF] to become 1. 0b - Disable 1b - Enable
13 SBNS	Stop Bit Number Select Determines whether data characters include one or two stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - One stop bit 1b - Two stop bits
12-0 SBR	Baud Rate Modulo Divisor Sets the modulo divide rate for the baud rate generator. • If SBR is 0, baud rate generator is disabled. • If SBR is 1–8191, baud rate = baud clock ÷ ((OSR + 1) × SBR). You must update the 13-bit baud rate setting [SBR12:SBR0] only when both the transmitter and receiver are disabled (both CTRL[RE] and CTRL[TE] are 0).

47.3.7 Status (STAT)

Offset

Register	Offset
STAT	14h

Function

Provides the module status.

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag Indicates whether a LIN break character is detected. This field becomes 1 when the LIN break detect circuitry is enabled and a LIN break character is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag Indicates whether an active edge on the receive pin has occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 whenever the receiver is enabled and an active edge (falling if STAT[RXINV] is 0; rising if STAT[RXINV] is 1) on the RXD pin occurs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not occurred 1b - Occurred When writing 0b - No effect 1b - Clear the flag
29 MSBF	MSB First Specifies the first bit that is transmitted after the start bit. If this field is 0, LSB (bit 0) is the first bit transmitted after the start bit (which means, the first bit received after the start bit is identified as bit 0). If this field is 1, MSB (identified as bit 9, bit 8, bit 7, or bit 6) is the first bit that is transmitted, after the start bit, depending on the settings of CTRL[M], CTRL[PE], and BAUD[M10]. Writing 1 to this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - LSB 1b - MSB
28 RXINV	Receive Data Inversion Specifies whether receive data is inverted. Writing 1 to this field reverses the polarity of the received data input. You must change the value of this field only when the receiver is disabled. **NOTE** Writing 1 to this field inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Inverted 1b - Not inverted
27 RWUID	Receive Wake Up Idle Detect Controls, for CTRL[RWU] on idle character detection, whether the idle character that wakes up the receiver writes 1 to STAT[IDLE]. For address match wake-up, this field controls whether STAT[IDLE] = 1 when the address does not match. You must change the value of this field only when the receiver is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] does not become 1 when an address does not match. If this field is 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] becomes 1 when an address does not match. 0b - STAT[IDLE] does not become 1 1b - STAT[IDLE] becomes 1
26 BRK13	Break Character Generation Length Selects the longer transmitted break character length. The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - 9 to 13 bit times 1b - 12 to 15 bit times
25 LBKDE	LIN Break Detection Enable Enables LIN break detection. If this field is 0, LIN break detect is disabled, and only a normal break character can be detected. If this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] is 0), 12 bit times (if CTRL[M] is 1), or 13 bit times (if BAUD[M10] is 1). This field selects a longer break character detection length. When the field is 1, receive data is not stored in the receive FIFO. **NOTE** This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it ignores all characters except a LIN break. 0b - Disable 1b - Enable
24 RAF	Receiver Active Flag Indicates whether the LPUART receiver is idle or active. This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line. 0b - Idle, waiting for a start bit 1b - Receiver active (RXD pin input not idle)
23 TDRE	Transmit Data Register Empty Flag Indicates whether the transmit FIFO level is greater than, equal to, or less than the watermark.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0 again, write to Data (DATA). This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Greater than watermark 1b - Equal to or less than watermark
22 TC	Transmission Complete Flag Indicates whether the transmitter is active. This field becomes 0 when a transmission is in progress or a preamble or break character is loaded; in other words, when the transmitter is active (sending data, a preamble, or a break). The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted; in other words, when the transmission activity is complete. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active 1b - Transmitter idle
21 RDRF	Receive Data Register Full Flag Indicates whether the receive FIFO level is less than, equal to, or greater than the watermark. This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA). A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received. 0b - Equal to or less than watermark 1b - Greater than watermark
20 IDLE	Idle Line Flag Indicates whether an idle line is detected. This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end

Table continues on the next page...

Table continued from the previous page...

Field	Function
	of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line. For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Idle line detected 1b - Idle line not detected When writing 0b - No effect 1b - Clear the flag
19 OR	Receiver Overrun Flag Indicates whether there is receive overrun. This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received. When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun 1b - Receive overrun (new LPUART data is lost) When writing 0b - No effect 1b - Clear the flag
18 NF	Noise Flag Indicates whether noise is detected in the received character of Data (DATA). The advanced sampling technique used in the receiver takes three samples in each of the received bits. If some of these samples disagree with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No noise detected 1b - Noise detected When writing 0b - No effect 1b - Clear the flag
17 FE	Framing Error Flag Indicates whether a framing error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No framing error detected (this does not guarantee that the framing is correct) 1b - Framing error detected When writing 0b - No effect 1b - Clear the flag
16 PF	Parity Error Flag Indicates whether a parity error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received when parity is enabled (CTRL[PE] is 1) and the parity bit in the received character does not agree with the expected parity value. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No parity error detected 1b - Parity error detected When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 MA1F	Match 1 Flag Indicates whether the received data is equal to MATCH[MA1]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA1 1b - Equal to MA1 When writing 0b - No effect 1b - Clear the flag
14 MA2F	Match 2 Flag Indicates whether the received data is equal to MATCH[MA2]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA2]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA2 1b - Equal to MA2 When writing 0b - No effect 1b - Clear the flag
13-10 —	Reserved
9-8 —	Reserved
7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field has no effect when configured for LSB first and you must change the value of this field only when both the transmitter and receiver are disabled. If this field is 0, address mark in character is MSB. If this field is 1, the address mark is stored in Data (DATA) at MSB (or MSB-1 when the parity bit is enabled). In other words, the address mark in character is the last bit before the stop bit (or parity bit when enabled). 0b - Disable 1b - Enable
0 LBKFE	LIN Break Flag Enable Enables the LIN break flag to assert whenever a LIN break character is detected. Unlike STAT[LBKDE], this does not impact data being stored in the receive data buffer, but does cause STAT[LBKDIF] to become 1 whenever a LIN break is detected. Because a LIN break is longer than a normal character, the LIN break triggers a write to STAT[RDRF] with the data fields as 0 and STAT[FE] as 1. The character following the LIN break has DATA[LINBRK] as 1 to indicate that the previous character was a LIN break. You must change the value of this field only when both the transmitter and receiver are disabled. If this field is 1, the LIN break character is detected at a length of 11-bit times (if CTRL[M] is 0), 12 (if CTRL[M] is 1), or 13 (if BAUD[M10] is 1). 0b - Disable 1b - Enable

47.3.8 Control (CTRL)

Offset

Register	Offset
CTRL	18h

Function

Controls various optional features of the LPUART system.

You must write to the fields of this register only when both the transmitter and receiver are disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 R8T9	Receive Bit 8 Transmit Bit 9 Contains R8 and T9 that correspond to different functions. R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA). T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written.
30 R9T8	Receive Bit 9 Transmit Bit 8 Contains R9 and T8 that correspond to different functions. R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA). T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R9 is a read-only field and T8 is a write-only field; the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode Determines the direction of data at the TXD pin, in Single-Wire mode, when LPUART is configured for a single-wire half-duplex operation (CTRL[LOOPS] and CTRL[RSRC] are 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Input 1b - Output
28 TXINV	Transmit Data Inversion Specifies whether transmit data is inverted. Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Not inverted 1b - Inverted
27 ORIE	Overrun Interrupt Enable Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. 0b - Disable 1b - Enable
26 NEIE	Noise Error Interrupt Enable Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled. 0b - Disable 1b - Enable
25 FEIE	Framing Error Interrupt Enable Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled. 0b - Disable 1b - Enable
24 PEIE	Parity Error Interrupt Enable Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled. 0b - Disable 1b - Enable
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] is 1. 0b - Disable 1b - Enable
22	Transmission Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCIE	Enables STAT[TC] to generate interrupt requests if STAT[TC] is 1. 0b - Disable 1b - Enable
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] is 1. 0b - Disable 1b - Enable
20 ILIE	Idle Line Interrupt Enable Enables hardware interrupts. This field enables STAT[IDLE] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[IDLE] are disabled and polling is used, and if this field is 1, hardware interrupts are enabled when STAT[IDLE] is 1. 0b - Disable 1b - Enable
19 TE	Transmitter Enable Enables the LPUART transmitter. Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated. You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] and DATA[R9T9] = 1. 0b - Disable 1b - Enable
18 RE	Receiver Enable Enables the LPUART receiver. After you write 0 to this field, this field remains 1 until the receiver finishes receiving the current character (if any). 0b - Disable 1b - Enable
17 RWU	Receiver Wake-Up Control Specifies whether the LPUART receiver in standby is waiting for a wake-up condition. You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] is 0 or an address match when CTRL[WAKE] is 1 and STAT[RWUID] is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write 1 to this field only when CTRL[WAKE] is 0 (wake-up on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an Idle condition is detected before the IDLE flag is allowed to be reasserted. 0b - Normal receiver operation 1b - LPUART receiver in standby, waiting for a wake-up condition
16 SBK	Send Break Specifies whether queue break character(s) are to be sent. Writing 1 and then 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is 1, and bit times of logic 0 are queued as long as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent. You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - Normal transmitter operation 1b - Queue break character(s) to be sent
15 MA1IE	Match 1 (MA1F) Interrupt Enable Enables the MA1F interrupt. 0b - Disable 1b - Enable
14 MA2IE	Match 2 (MA2F) Interrupt Enable Enables the MA2F interrupt. 0b - Disable 1b - Enable
13 —	Reserved
12 —	Reserved
11 M7	7-Bit Mode Select Specifies the data characters that the receiver and transmitter use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must change the value of this field only after both the transmitter and receiver are disabled. 0b - 8-bit to 10-bit 1b - 7-bit
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before you write 1 to STAT[IDLE]. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
7 LOOPS	Loop Mode Select Selects Loop mode. After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]). 0b - Normal operation: RXD and TXD use separate pins 1b - Loop mode or Single-Wire mode
6 DOZEEN	Doze Mode Enables LPUART in Doze mode. If this field is 1, LPUART remains active when not in Doze mode. 0b - Enable 1b - Disable
5 RSRC	Receiver Source Select Determines the source of the receiver shift register input if CTRL[LOOPS] is 1. This field has no effect unless CTRL[LOOPS] is 1. If this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin. If this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input. 0b - Internal Loopback mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Single-wire mode
4 M	9-Bit Or 8-Bit Mode Select Specifies the data characters that the receiver and transmitter use. 0b - 8-bit 1b - 9-bit
3 WAKE	Receiver Wake-Up Method Select Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character • An idle condition on the receive pin input signal If this field is 0, CTRL[RWU] is configured for idle line wake-up, and if this field is 1, CTRL[RWU] is configured with address mark wake-up. 0b - Idle 1b - Mark
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - After the start bit 1b - After the stop bit
1 PE	Parity Enable Enables hardware parity generation and checking. If parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - Disable 1b - Enable
0 PT	Parity Type Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1): • Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Even parity means that the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity 1b - Odd parity

47.3.9 Data (DATA)

Offset

Register	Offset
DATA	1Ch

Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

NOTE

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

Diagram

Fields

Field	Function
31-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 NOISY	Noisy Data Received Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise. 0b - Received without noise 1b - Received with noise
14 PARITYE	Parity Error Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - Received without a parity error 1b - Received with a parity error
13 FRETSC	Frame Error Transmit Special Character Specifies the way the dataword is received. For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0. 0b - Received without a frame error on reads or transmits a normal character on writes 1b - Received with a frame error on reads or transmits an idle or break character on writes
12 RXEMPT	Receive Buffer Empty Indicates whether the receive buffer contains valid data. This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register. 0b - Valid data 1b - Invalid data and empty
11 IDLINE	Idle Line Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. It can be read as “1” on the first character when the receiver is first enabled. The difference between this field and STAT[IDLE] is that, STAT[IDLE] flag does not set on an idle line after the receiver is first enabled, it needs to receive a character before it can become set, whereas this field does not have this limitation and can be set on the first character received if an idle line is detected beforehand. 0b - Not idle 1b - Idle
10 LINBRK	LIN Break Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. If this field is 0, the LIN break detect circuitry is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not detected 1b - Detected
9 R9T9	Read receive FIFO bit 9 or write transmit FIFO bit 9
8 R8T8	Read receive FIFO bit 8 or write transmit FIFO bit 8
7 R7T7	Read receive FIFO bit 7 or write transmit FIFO bit 7
6 R6T6	Read receive FIFO bit 6 or write transmit FIFO bit 6
5 R5T5	Read receive FIFO bit 5 or write transmit FIFO bit 5
4 R4T4	Read receive FIFO bit 4 or write transmit FIFO bit 4
3 R3T3	Read receive FIFO bit 3 or write transmit FIFO bit 3
2 R2T2	Read receive FIFO bit 2 or write transmit FIFO bit 2
1 R1T1	Read receive FIFO bit 1 or write transmit FIFO bit 1
0 R0T0	Read receive FIFO bit 0 or write transmit FIFO bit 0

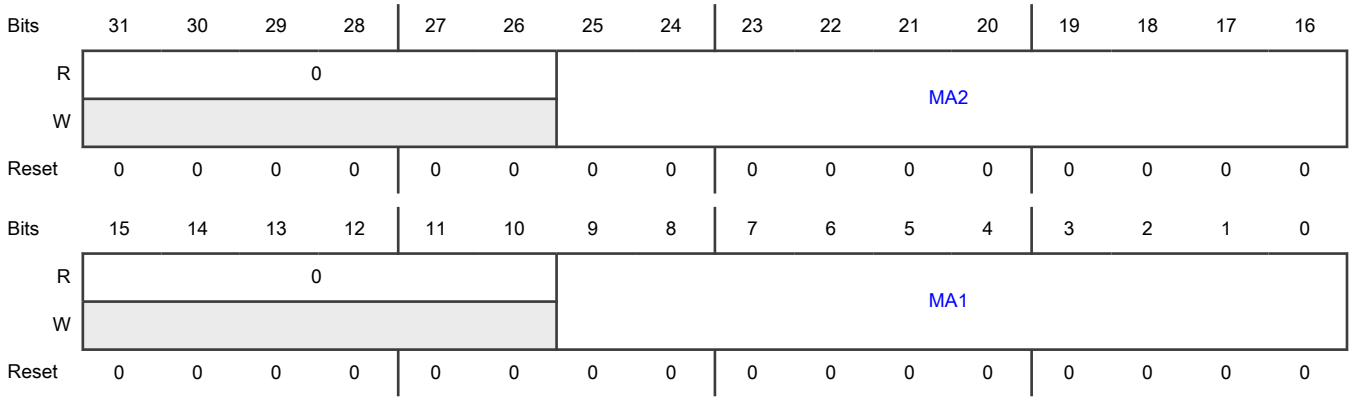
47.3.10 Match Address (MATCH)

Offset

Register	Offset
MATCH	20h

Function
Provides addresses for address matching during the receiver operation.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] only when the associated Baud Rate (BAUD) field is 0.
15-10 —	Reserved
9-0 MA1	Match Address 1 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] fields only when the associated field in Baud Rate (BAUD) is 0.

47.3.11 MODEM IrDA (MODIR)

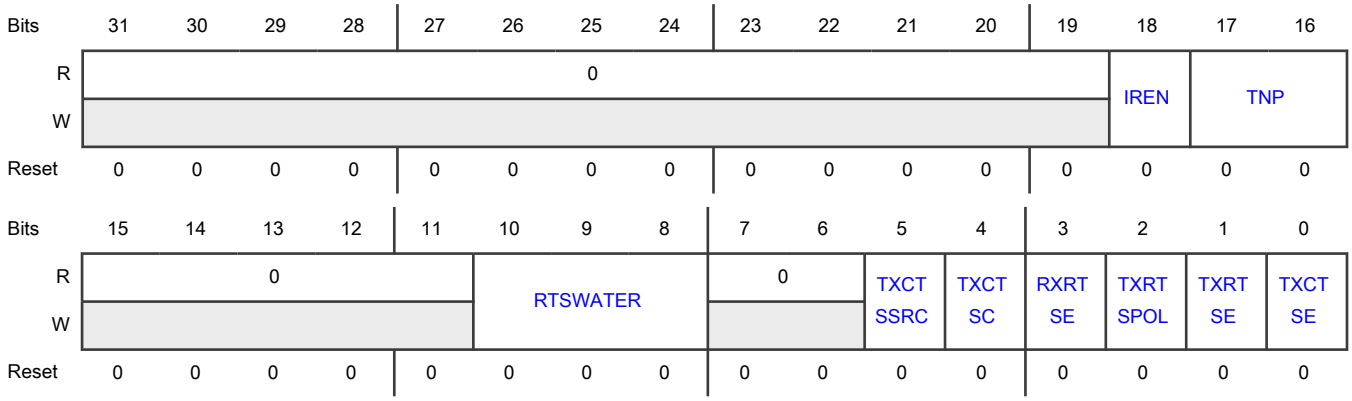
Offset

Register	Offset
MODIR	24h

Function

Controls options for setting the MODEM configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	IR Enable Enables IR modulation and demodulation. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Disable 1b - Enable
17-16 TNP	Transmitter Narrow Pulse Specifies whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled. You must change the value of this field only when both the transmitter and receiver are disabled. The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width. 00b - 1 ÷ OSR 01b - 2 ÷ OSR 10b - 3 ÷ OSR 11b - 4 ÷ OSR
15-11 —	Reserved
10-8 RTSWATER	Receive RTS Configuration Configures the assertion and negation of the receiver's RTS_B output. The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the

Table continues on the next page...

Table continued from the previous page...

Field	Function
	purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match. You must change the value of this field only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - The CTS_B pin 1b - An internal connection to the receiver address match result
4 TXCTSC	Transmit CTS Configuration Configures whether the CTS state or input is checked or sampled at the start of each character or only when the transmitter is idle. 0b - Sampled at the start of each character 1b - Sampled when the transmitter is idle
3 RXRTSE	Receiver RTS Enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver has no effect on RTS. If this field is 1, RTS is deasserted if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1. RTS is asserted if STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. **NOTE** Do not write 1 to both MODIR[RXRTSE] and MODIR[TXRTSE]. 0b - Disable 1b - Enable
2 TXRTSPOL	Transmitter RTS Polarity Controls the polarity of the transmitter RTS. This field does not affect the polarity of the receiver RTS that remains negated in the active-low state unless MODIR[TXRTSE] is 1. You must change the value of this field only when the transmitter is disabled. 0b - Active low 1b - Active high
1	Transmitter RTS Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXRTSE	Controls the operation of RTS before and after a transmission. You must change the value of this field only when the transmitter is disabled. If this field is 0, the transmitter has no effect on RTS, and if this field is 1, a character is placed into an empty transmit shift register. RTS asserts 1-bit time before the start bit is transmitted and deasserts 1-bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit. 0b - Disable 1b - Enable
0 TXCTSE	Transmitter CTS Enable Enables the operation of the transmitter. You can write 1 to this field irrespective of the states of MODIR[TXRTSE] and MODIR[RXRTSE]. If this field is 1, the transmitter checks the state of the CTS signal each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the TXD signal remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS, when a character is being sent, do not affect its transmission. 0b - Disable 1b - Enable

47.3.12 FIFO (FIFO)

Offset

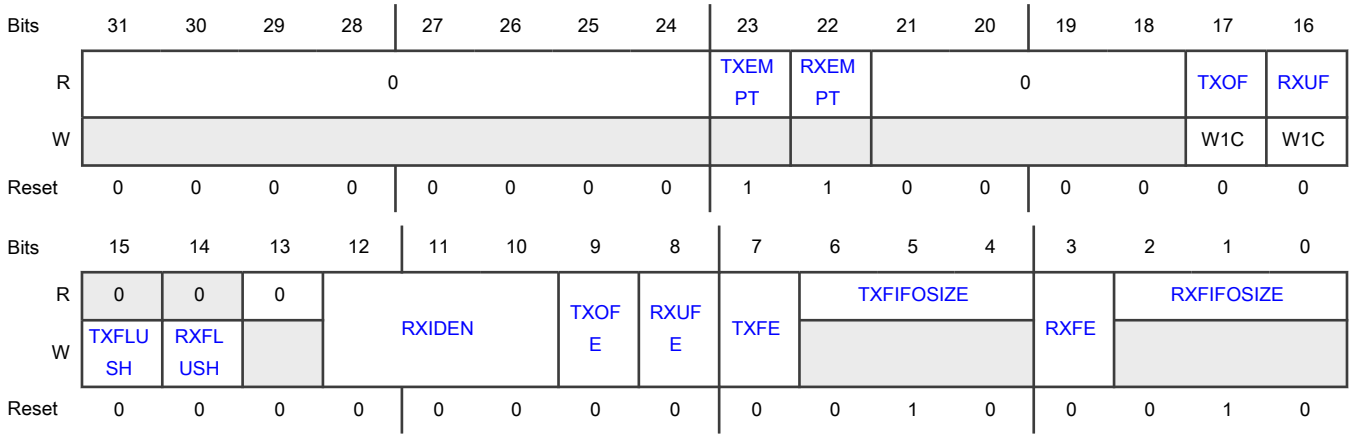
Register	Offset
FIFO	28h

Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO Or Buffer Empty Indicates whether the transmit buffer is empty. This field becomes 1 when there is no data in the transmit FIFO or buffer. The field does not consider data in the transmit shift register. 0b - Not empty 1b - Empty
22 RXEMPT	Receive FIFO Or Buffer Empty Indicates whether the receive buffer is empty. This field becomes 1 when there is no data in the receive FIFO or buffer. The field does not consider data in the receive shift register. 0b - Not empty 1b - Empty
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates whether more data has been written to the transmit FIFO than it can hold. If this field is 0, no transmit FIFO overflow has occurred since the last time the field was cleared, and if this field is 1, at least one transmit FIFO overflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[TXOFE]. However, an interrupt is issued to the host only if FIFO[TXOFE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
16 RXUF	Receiver FIFO Underflow Flag Indicates whether more data has been read from the receive FIFO than was present. If this field is 0, no receive FIFO underflow has occurred since the last time the field was cleared, and if this field is 1, at least one receive FIFO underflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[RXUFE]. However, an interrupt is issued to the host only if FIFO[RXUFE] is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underflow 1b - Underflow When writing 0b - No effect 1b - Clear the flag
15 TXFLUSH	Transmit FIFO Flush Causes all data that is stored in the transmit FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the transmit FIFO or buffer clears out. This does not affect data in the transmit shift register. 0b - No effect 1b - All data flushed out
14 RXFLUSH	Receive FIFO Flush Causes all data that is stored in the receive FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the receive FIFO or buffer clears out.

Table continues on the next page...

47.4 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

47.4.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time. LPUART requires BAUD[SBR] and BAUD[OSR] to accurately match the baud rate requirement. There is a relationship between the required baud rate and the input clock frequency, SBR, and OSR. See the below figure for details.

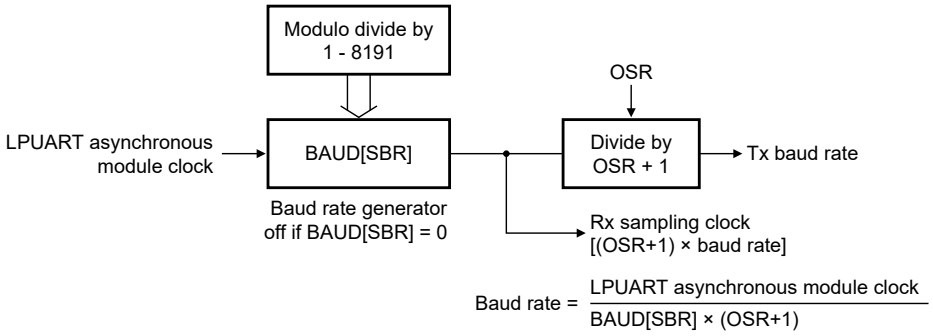

Figure 178. Baud rate generation

Baud rate generation is subject to these sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit (see Data sampling technique) are also closer together, which may impact noise sensitivity.

47.4.2 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. A noise error will occur if the three samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the three stop bit samples are a logic zero.

As the receiver samples an incoming frame, it may resynchronize the oversampling clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

In general, increasing the number of samples per bit will increase the baud rate tolerance and decreasing the number of samples per bit will reduce the baud rate tolerance. Note that since LPUART implements triple voting on consecutive receive data samples, increasing the number of samples per bit will move those samples closer together which would reduce the width of noise that can be filtered by the triple voting logic.

47.4.3 Calculating baud rate tolerance

Using the following definitions:

- SAM is the number of sample points per bit (valid range from 8 to 32; equal to (OSR + 1) × (BOTHEDGE + 1)).
- BIT is the number of bits in a character including start, data and stop bits (valid range from 9 to 13).

The ideal baud rate tolerance can be calculated as follows:

- Slow data rate tolerance = ((SAM ÷ 2) - 1) ÷ ((SAM × BIT) - (SAM ÷ 2) + 2)
- Fast data rate tolerance = ((SAM ÷ 2) - 2) ÷ (SAM × BIT)

As an example, if configured for 8-bit data, 1 stop bit (BIT = 10) and with OSR=0x7 and BOTHEDGE = 1 (SAM = 16):

- Slow data rate tolerance = (8 - 1) ÷ (160 - 8 + 2) = 7 ÷ 154 = 4.54%
- Fast data rate tolerance = (8 - 2) ÷ 160 = 6 ÷ 160 = 3.75%

If configured for 9-bit data with 1 stop bit (BIT = 11) with same oversampling configuration, then:

- Slow data rate tolerance = (8 - 1) ÷ (176 - 8 + 2) = 7 ÷ 170 = 4.12%
- Fast data rate tolerance = (8 - 2) ÷ 176 = 6 ÷ 176 = 3.41%

NOTE

Additional factors can contribute to a lower baud rate tolerance than the ideal. These include clock uncertainty or jitter on the LPUART functional clock source, differences in rise and fall times on the transmitter output and synchronization of the external receive pin to the local LPUART functional clock.

47.4.4 Transmitter functional description

This section describes the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the Idle state. The transmitter then remains idle until data is available in the transmit FIFO and programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in transmit FIFO is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

47.4.4.1 Break character length

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, write 0 and then write 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

Table 342. Break character length

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
0	0	0	0	0	10
0	0	0	0	1	11
0	0	0	1	0	9
0	0	0	1	1	10

1	1	0	—	1	14
1	—	1	—	0	15
1	—	1	—	1	15

47.4.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with CTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

47.4.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

47.4.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

The following figure shows the receiver enable signal asserted. This connection can also connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled when driving. A pullup can pull RXD to a nonfloating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

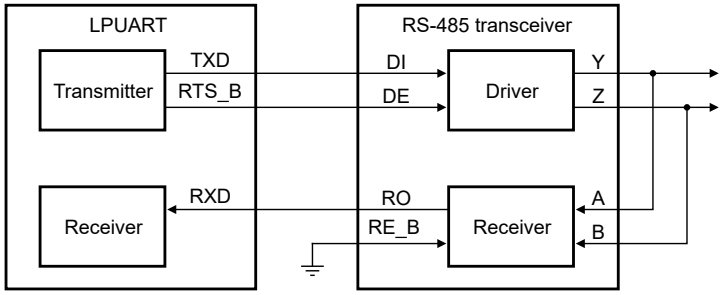

Figure 179. Transceiver driver enable using RTS_B

47.4.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data.
- Different variations of the receiver wake-up function.

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, along with N (7, 8, 9, 10) bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full (STAT[RDRF] = 0), the data character is transferred to the receive FIFO, resulting in STAT[RDRF] becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the FIFO by reading Data (DATA). See Interrupts for details about flag clearing.

47.4.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes they are synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, noise flag (STAT[NF]) becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the "1->0" (one to zero) transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This synchronization to the start bit is termed as resynchronization.

When BAUD[RESYNCDIS] is 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] is 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

Table 343. LPUART resynchronization settings

Resynchronization	BAUD[RESYNCDIS] = 0	BAUD[RESYNCDIS] = 1
For the starting bit falling edge	Yes	Yes
For all falling edges after the start bit	Yes	No

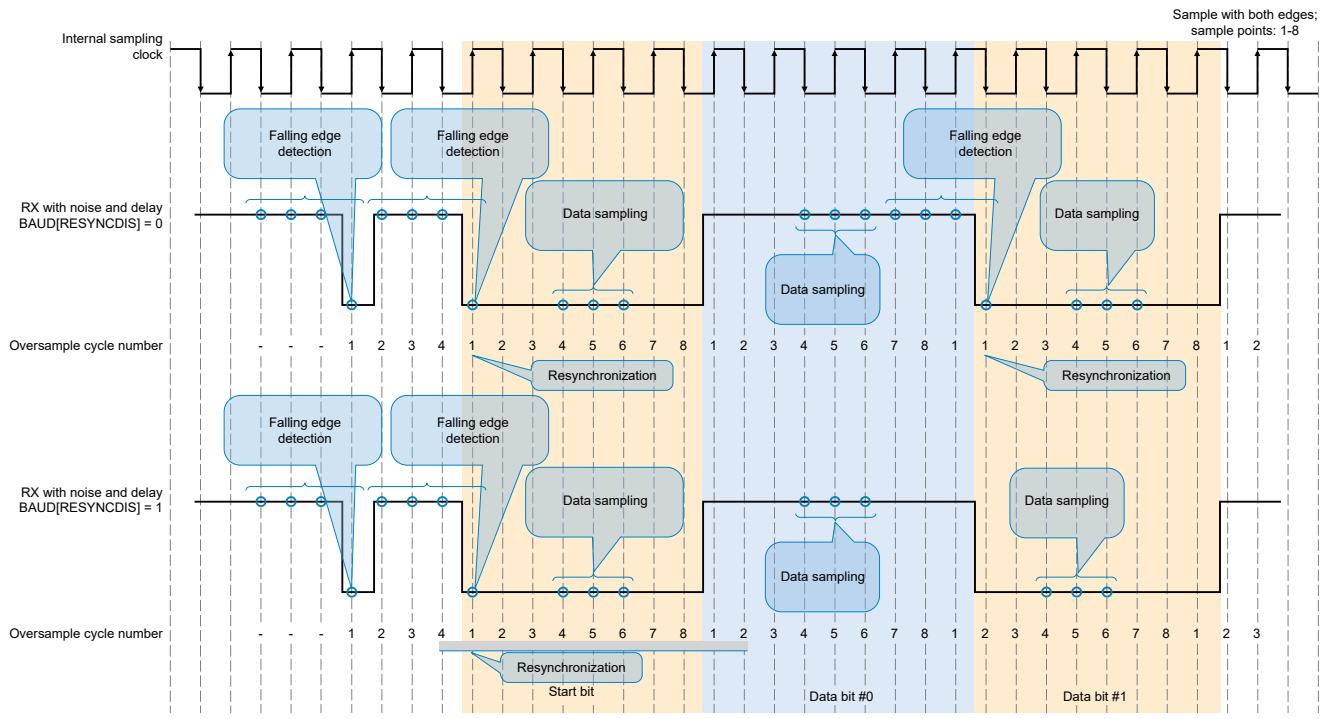

Figure 180. LPUART resynchronization diagram

47.4.5.2 Receiver wake-up operation

Receiver wake-up and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wake-up, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 344. Receiver wake-up options

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wake-up
0	0	X	X	Normal operation
1	0	00	00	Receiver wake-up on idle line; STAT[IDLE] = 0
1	0	00	01	Receiver wake-up on idle line; STAT[IDLE] = 1
1	0	00	10	Receiver wake-up on address mark
1	1	11	10	Receiver wake-up on data match
0	1	00	X0	Address mark address match; STAT[IDLE] = 0 for discarded characters
0	1	00	X1	Address mark address match; STAT[IDLE] = 1 for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match on and match off; STAT[IDLE] = 0 for discarded characters
0	1	10	X1	Match on and match off; STAT[IDLE] = 1 for discarded characters

47.4.5.2.1 Idle line wake-up

When CTRL[WAKE] is 0, you can configure the receiver for an idle line wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

When CTRL[RWU] is set the receiver ignores everything until an idle condition is detected. After the idle condition is detected the CTRL[RWU] is cleared by hardware and the receiver starts receiving data.

The STAT[RWUID] indicates that whether the STAT[IDLE] flag is set or not as a result of the idle condition detection which clears CTRL[RWU].

The STAT[RWUID] says that if the STAT[IDLE] flag is to be set as a result of the idle condition which clears CTRL[RWU].

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

These are the ways to detect an idle line:

- When CTRL[ILT] is 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] is 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

47.4.5.2.2 Address mark wake-up

When CTRL[WAKE] is 1, you can configure the receiver for an address mark wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address mark wake-up.

Address mark wake-up allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address mark bit is received even if the receiver is sleeping during most of this character time.

47.4.5.2.3 Data match wake-up

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data match wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] is 1, or that matches MATCH[MA2] when BAUD[MAEN2] is 1.

47.4.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or the second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1 if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or the second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

47.4.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred

to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

47.4.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

NOTE

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

47.4.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] is 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.
- When RTS is driven by receiver, it will be negated when the receiver is disabled irrespective of the FIFO level.

47.4.6 Additional LPUART functions

47.4.6.1 Data modes

You can configure the LPUART transmitter and receiver to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but you must read them before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address mark wake-up so that the ninth data bit can serve as the wake-up bit. The 10-bit Data mode is typically used with parity and address mark wake-up so that the ninth data bit can serve as the wake-up bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

47.4.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle line wake-up and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

47.4.6.3 Loop mode

Enable Loop mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 0. You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

47.4.6.4 Single-Wire mode

Enable Single-Wire mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 1. Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

47.4.7 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

47.4.7.1 Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, for one oversampling clock period.

47.4.7.2 Input trigger

LPUART supports a peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger (active high) instead of the CTS_B (active low) pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.

- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free-running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

47.4.8 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

47.4.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is 1.

47.4.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

47.4.8.3 Start-bit detection

When STAT[RXINV] is 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

47.4.8.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

47.4.8.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

47.4.8.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

47.4.9 Modes of operation

47.4.9.1 Low-Power modes

LPUART remains functional during low-power modes, provided CTRL[DOZEEN] is 0 and the LPUART functional clock is enabled. LPUART can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPUART to be disabled in low-power modes, when CTRL[DOZEEN] is 1. In this case, the transmitter and receiver finish transmitting and receiving the current word.

If LPUART is disabled in low-power modes, it can generate a wake-up via STAT[RXEDGIF] if the receiver detects an active edge.

NOTE

See the chip-specific information for specific low-power modes available on your chip.

47.4.9.2 Debug mode

LPUART remains functional in Debug mode.

47.4.10 Clocking

Table 345. Types of clocks

Clock	Description
Functional	Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wake-up.
Bus	Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

47.4.11 Reset

Table 346. Types of resets

Reset	Description
Chip	Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states.
Software	Resets the LPUART logic and registers to their default states, except for Global (GLOBAL). GLOBAL[RST] controls the LPUART software reset.
FIFO	Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty.

47.4.12 Interrupts

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. If STAT[TDRE] is 1, it indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] is 1, a hardware interrupt is requested when STAT[TDRE] is 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] is 1, a hardware interrupt is requested when STAT[TC] is 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] field is 0.

When a program detects that STAT[RDRF] is 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has 1 as the value of STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition getting lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (the value of CTRL[RE] being 1).

47.5 External signals

Table 347. External signals

Signal	Description	I/O
TXD	Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or the transmit direction is configured for receive data.	I/O
RXD	Receive data	I
CTS_B	Clear-to-send	I
RTS_B	Request-to-send	O

47.6 Initialization

This module does not require initialization.

Chapter 48
CAN (FlexCAN)

48.1 Chip-specific FlexCAN information

Table 348. Reference links to related information

Topic	Related module	Reference
Full description	CAN	CAN
System memory map		System memory map
Clocking		Clock distribution
Signal multiplexing	Port control	Signal multiplexing

48.1.1 Module instances

The parts with CAN module have two instance: CAN0 and CAN1. Refer to Ordering information for parts have CAN module.

48.1.2 Enhanced Rx FIFO under DMA operation

In order to use the DMA feature, the ERFCR[ERFWM] must be configured as 0b.

ERFSR[ERFDA] is set by the hardware when there is at least one frame available to be read from the Enhanced Rx FIFO, and ERFSR[ERFWMI] is set by the hardware when the number of frames stored in the FIFO is greater than 0 (the watermark defined by ERFCR[ERFWM]). A DMA request is generated when ERFSR[ERFWMI] is set. Upon receiving the request, the DMA controller can read the message in the Enhanced Rx FIFO output. The DMA controller performs one read loops in the FIFO output defined by ERFCR[ERFWM]. Also, each message reading process must end by the address defined in ERFCR[DMALW].

48.1.3 Maximum data rate

The maximum data rate for CAN in this device is 8 Mbps. Refer to device's Data sheet for more information.

48.1.4 Can timestamp

The CAN module includes two clock inputs.

- Interface clock- the interface clock provides the timing reference for the bus transactions between the module and the bus fabric of the chip.
- Functional clock- the functional clock provides the timing reference for the operation of the module.

The system clock generator (SCG) and peripheral clock controller (PCC) control both these clocks. No additional clocking options are available for this module.

This chip implements two FlexCAN modules with the same configuration. The chip adds the 32-bit timestamp feature as follows:

- Input tmr_tick_ext on CANn is driven by a synchronized version (to CANn bus clock) of the LPIT0 Channel n trigger output (where n is the CAN instance number).

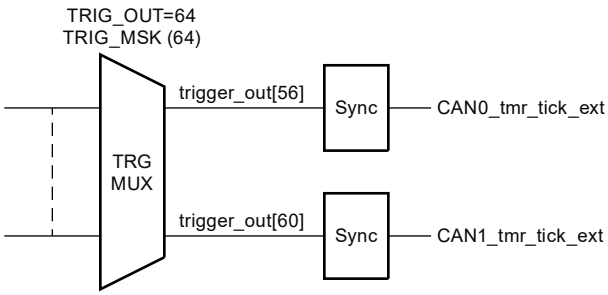

Figure 181. FlexCAN 0/1 Timer Tick Connections

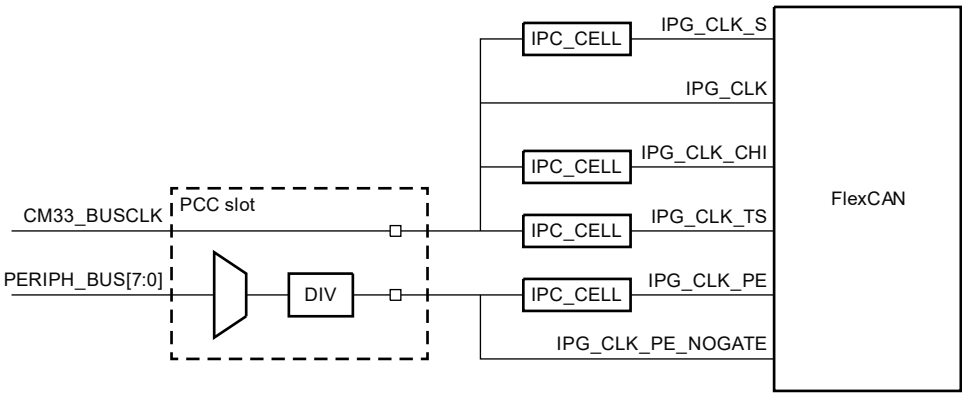

Figure 182. FlexCAN 0/1 Clocking

- Input timestamp_base[31:0] to both instances shall be driven by a free running 32-bit counter ,which increments on every clock cycle that is clocked by the CAN0 bus clock and reset by CAN0 peripheral reset.

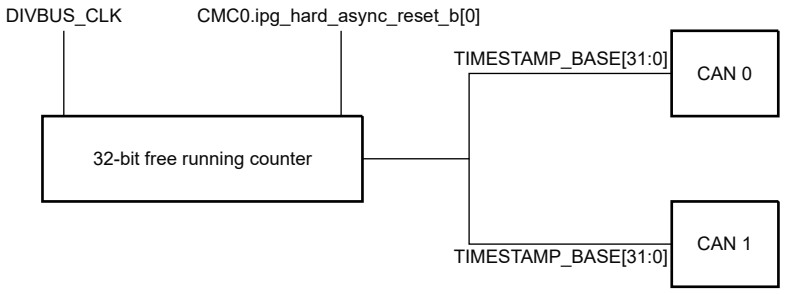

Figure 183. FlexCAN 0/1 Timestamp

NOTE

To enable CAN1 high-resolution timestamp counter, software must bring the CAN0 module out of reset, which means, MRCC_CAN0[RSTB] = 1 and MRCC_CAN0[CC] != 0.

48.1.5 FlexCAN reset

The chip level hard reset input of FlexCAN is controlled by MRCC_CANn[RSTB], therefore a FlexCAN hard reset leads to reset all the module which result in all registers being affected by this reset. The chip level soft reset input is not supported on this device, use MCR[SOFTRST] to initiate a soft reset of the FlexCAN.

48.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in CAN Flexible Data (FD) mode. In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

48.2.1 Block diagram

Figure 184 shows the main submodules implemented in FlexCAN.

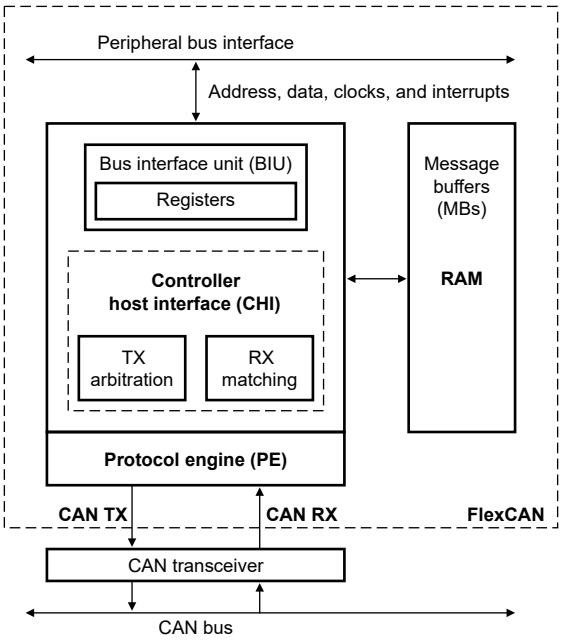

Figure 184. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling
- CAN FD message detection

Controller Host Interface (CHI) manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

Bus Interface Unit (BIU) controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks

- Address and data buses
- Interrupt outputs
- DMA
- Test signals

48.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*:
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Programmable bit rate (see chip-specific FlexCAN information for specific maximum rate configuration)
  - Content-related addressing
- Compliance with the ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 12 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity or matching with received frames (Pretended Networking mode)
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames

- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 16 extended or 32 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask
- Complete backward compatibility with previous FlexCAN version
- Pretended networking functionality in low power: Doze mode, Stop mode

48.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 384). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 385).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

48.3.1 Modes of operation

FlexCAN has these functional modes:

Table 349. Functional modes

Mode	Description
Normal	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own

Table continues on the next page...

Table 349. Functional modes (continued)

Mode	Description
	message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 350. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes
Pretended network support	Yes	No

FlexCAN can operate in these low-power modes:

Table 351. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Doze	FlexCAN enters this mode when MCR[DOZE] is 1, Doze mode is requested at chip level, and FlexCAN writes 1 to MCR[LPMACK]. When in Doze mode, FlexCAN issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. This mode is exited when: • MCR[DOZE] becomes 0 • The chip is removed from Doze mode • Or activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Doze mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.

Table continues on the next page...

Table 351. Low-power modes (continued)

Mode	Description
Pretended Network (PN)	FlexCAN can operate in this mode with Doze mode or Stop mode. Before entering one of these low-power modes, you must write 1 to MCR[PNET_EN]. When in a low-power mode, CHI subblock clocks are shut down and CAN_PE subblock remains clocked. The receive process remains active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, a wake-up interrupt is issued to the system. When MCR[PNET_EN] becomes 1, the CPU must disable Self-Wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR).

48.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

48.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

48.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

It is not recommended to use Module Disable mode under Pretended Networking mode. Write 0 to MCR[MDIS] and wait for MCR[LPMACK] to become 0 before writing 1 to MCR[PNET_EN].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items are accessible:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

48.3.1.1.3 Doze mode

This is a system low-power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion of MCR[LPMACK] by FlexCAN. The CPU must only consider FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register.

Also, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request

- CPU negating MCR [DOZE]
- Self-Wake mechanism

In the Self-Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then after detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it does not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK after wakeup from Doze mode.

Table 352. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

48.3.1.1.4 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it

up. Table 353 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 353. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

48.3.1.1.5 Pretended Networking (PN) mode

This special low-power mode receives wake-up messages with low power consumption. This mode can be selected to operate together with Doze mode or Stop mode. Before entering a low-power mode, MCR[PNET_EN] must be 1. After entering a low-power mode, the CHI subblock is shut down and the CAN_PE subblock is kept active. The receive process is still active to filter incoming messages (see Receive process in Pretended Networking mode) as defined by the configuration registers (see Pretended Networking Control 1 (CTRL1_PN)). Upon detecting a wake-up event, FlexCAN issues a wake-up interrupt to the system.

To enter Pretended Networking mode, FlexCAN must be in Normal mode, not in Freeze or Module Disable mode. In Pretended Networking mode, FlexCAN keeps itself synchronized with the CAN bus in Doze or Stop mode. Then, when either Doze or Stop mode is requested, FlexCAN:

1. Waits to be in the Idle state, or waits for the third bit of Intermission, then verifies that it is recessive.
2. Writes 1 to MCR[LPMACK].
3. Requests the shutdown of the CHI submodule clock, while keeping the PE submodule clock active.

FlexCAN can exit Pretended Networking mode in one of these ways:

- The CPU removes the Doze mode request.
- The CPU writes 0 to MCR[DOZE].
- The CPU removes the Stop mode request.
- FlexCAN waits until Bus Idle, or until the third bit of Intermission state, to write 0 to MCR[LPMACK].

The above exit events can be triggered:

- By FlexCAN, after detecting a wake-up event and issuing the respective interrupt.
- By the CPU itself, when another method wakes it up.

Consequently, FlexCAN waits until the Bus Idle state, or until the third bit of the Intermission state, to write 0 to MCR[LPMACK] and resume Normal mode. This procedure ensures that FlexCAN is synchronized to the CAN bus after exiting Pretended Networking mode. The CPU must wait for MCR[LPM_ACK] to become 0 before performing any access to FlexCAN.

When MCR[PNET_EN] becomes 1, the CPU must disable the self-wake-up by writing 0 to MCR[SLFWAK] (see Module Configuration (MCR)).

NOTE

For more information about the difference between FD and non-FD regarding this feature, see Table 350.

48.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 364.[3]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 388 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.

[3] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 384 and Table 385 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

48.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

48.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

48.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

48.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 354. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

48.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 355. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

48.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.

- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait for Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.
- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait for Bus Idle state). If a resynchronization occurs during the Wait for Bus Idle state, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

48.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.

3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 384 and Table 385 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 384. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

48.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.
- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 356.

Table 356. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

48.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

48.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR31)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

48.3.6 Receive process in Pretended Networking mode

Pretended Networking mode adds specific wake-up functionality in low-power modes (Doze and Stop mode). When Pretended Networking (PN) mode is enabled by writing 1 to MCR[PNET_EN], FlexCAN continues processing received CAN messages in low-power mode. FlexCAN is able to detect specific wake-up messages by filtering them against identifier (ID) and payload target values using preselected matching criteria.

NOTE

Wake-up functionality is not available for messages in CAN FD format. When in PN mode, CAN FD format messages are ignored.

PN registers are located in the 0B00h–0B7Ch address range and can be written only in Freeze mode. These registers are used for writing PN configuration (both control and target values) prior to entering PN mode. They are also used for reading wake-up flags and the received message ID and data when returning to Normal mode after wake-up. The CPU must wait for MCR[LPMACK] to become 0 before performing any access to FlexCAN PN registers.

PN control registers are described in Pretended Networking Control 1 (CTRL1_PN) and Pretended Networking Control 2 (CTRL2_PN). The control fields that configure the filtering criteria are:

- Payload filtering selection: CTRL*n*_PN[PLFS]
- ID filtering selection: CTRL*n*_PN[IDFS]
- Filtering combination selection: CTRL*n*_PN[FCS]

Table 357. PN target values

Value	Description
FLT_IDE	IDE target value used to filter the incoming message by its format (standard or extended)
FLT_RTR	RTR target value used to filter the incoming message by its type (data or remote frame)
FLT_DLC_HI and FLT_DLC_LO	Target DLC range used to filter the size of the payload of an incoming message
FLT_ID1	ID target value used to filter the incoming message ID (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in an ID range)
FLT_ID2	ID target value used as the upper limit in an ID range
PL1	Payload target value used to filter the incoming message payload (equal to, smaller than or equal to, greater than or equal to, or the lower limit value in a payload range)
PL2	Payload target value used as the upper limit in a payload range

IDE, RTR, ID, and payload filters have their respective masks. The ones in these masks determine which bits are considered in equality comparisons. The zeroes in these masks determine which bits are don't care. ID and payload masks are used only for exact ID and exact payload comparisons.

48.3.6.1 ID filtering

The IDs of incoming messages can be filtered based on the following criteria:

- Match the exact ID value, found by comparing the ID field of the incoming message to the content of target Pretended Networking ID Filter 1 (FLT_ID1). The ID mask is used.
- Less than or equal to the maximum range of ID. That is, any message with ID value smaller than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.
- Greater than or equal to the minimum range of ID. That is, any message with ID value greater than or equal to the content of target FLT_ID1 is accepted. The ID mask is not used.
- Inside a range of IDs. Any message with an ID value greater than or equal to the content of target FLT_ID1 and smaller than or equal to the content of target Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK) is accepted. The ID mask is not used.

See CTRL1_PN[IDFS].

The above criteria for ID filtering must be coherent with FLT_IDE and FLT_RTR target values in Pretended Networking ID Filter 1 (FLT_ID1). Only RX frames that match the respective IDE and RTR bits to the contents of FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] are compared. When a range of IDs is selected (CTRL1_PN[IDFS] = 11), both FLT_ID1 and FLT_ID2 are referred to the same FLT_IDE and FLT_RTR fields in FLT_ID1.

The ID mask is applied only to the exact ID comparison filtering option (CTRL1_PN[IDFS] = 00) to determine which bits are considered in the comparison. For the exact match option, the mask can select any bit within the ID field. For maximum range, minimum range, and inside range comparisons, the ID mask is not considered.

The IDE and RTR masks are applied in both exact and range ID comparison filtering options to determine which bits are considered in comparison.

48.3.6.2 Payload filtering

Similar to the ID criteria, 64-bit data or payloads (PL) of incoming messages can be filtered based on the following criteria:

- A match with the exact payload value, found by comparing the payload field of the incoming message to the content of PL1. The payload mask is used.
- Less than or equal to the maximum range of payload. That is, any message with payload value smaller than or equal to the content of PL1 is accepted. The payload mask is not used.
- Greater than or equal to the minimum range of payload. That is, any message with payload value greater than or equal to the content of PL1 is accepted. The payload mask is not used.
- Inside a range of payloads. Any message with a payload value greater than or equal to the content of PL1 and smaller than or equal to the content of PL2 is accepted. The payload mask is not used.

See CTRL1_PN[PLFS].

The above criteria for payload filtering must be coherent with upper and lower limit values in Pretended Networking Data Length Code (DLC) Filter (FLT_DLC). The payload of an incoming message is filtered using the selected criteria only if the DLC value of the incoming message is inside a DLC range:

- Greater than or equal to FLT_DLC[FLT_DLC_LO] (lower limit)
- Lower than or equal to FLT_DLC[FLT_DLC_HI] (upper limit)

A DLC value outside the specified range results in a mismatch. If you configure FLT_DLC_LO = FLT_DLC_HI, only payloads of the specified quantity of bytes are filtered. DLC is not maskable.

When the inside range of payloads option is selected (CTRL1_PN[PLFS] = 11), both PL1 and PL2 are considered with the 8-byte data length. All data bytes excluded by the DLC of the received message are considered to have value zero.

The payload mask is only used in the exact match option (CTRL1_PN[PLFS] = 00). This mask determines which bits or bytes in the 8-byte data field of both incoming message and the contents of PL1 register are used for matching. Mask length must meet the expected range of DLC values. For maximum range, minimum range, and inside range comparisons, the payload mask is not considered.

When FlexCAN receives a remote frame and CTRL1_PN[FCS] is configured to select payload comparison, payload filtering is not considered and the comparison results in a mismatch.

48.3.6.3 Other filtering

Incoming messages can also be filtered based on the quantity and rate of message reception, specifically:

- Several messages that match the filtering criteria for ID or payload for a predefined number of times. This number can be from 1 to 255. See Pretended Networking Control 1 (CTRL1_PN).
- No message matching the filtering criteria for ID or payload up to a timeout trigger. That is, non-reception of a matching message for a defined quantity of time. See Pretended Networking Control 2 (CTRL2_PN).

When the counter reaches the predefined timeout value, FlexCAN can generate a wake-up timeout event from an internal timer with associated comparator circuitry capable of generating a timeout flag. This behavior is specified in CTRL2_PN[MATCHTO].

The above filtering criteria can be used together as follows:

- Message ID filtering only
- Message ID filtering and Payload filtering
- Message ID filtering only occurring *n* times
- Message ID filtering and Payload filtering occurring *n* times

The timeout counter runs concurrently with the reception filtering process. Both engines (timeout counter and message filtering) are independent. If an incoming message matches the selected filter criteria, the timeout counter continues counting until the CPU wakes up. If the timeout counter reaches the target value, the message filtering process continues to filter incoming messages until the CPU wakes up. WU_MTC[MCOUNTER] reports the number of matched messages that occurred in Pretended Networking mode up to the moment the CPU wakes up.

In Pretended Networking mode, the wake-up event that may occur sets the respective wake-up flag (see Pretended Networking Wake-Up Match (WU_MTC)):

- WU_MTC[WUMF] indicates a successful match meeting the selected filtering criteria.
- WU_MTC[WTOF] indicates a timeout trigger.

Any of these flags generates interrupts to the CPU, provided the respective mask bits are enabled (CTRL1_PN[WUMF_MSK] = 1 or CTRL1_PN[WTOF_MSK] = 1).

There are four Wake-up Message Buffers (WMBs) used to store incoming messages in Pretended Networking mode. Up to four messages can be stored (see Wake-Up Message Buffer (WMB0_CS - WMB3_CS)).

When CTRL1_PN[NMATCH] = 1, only one message is received if the filtering criteria are matched. This message is stored in WMB0.

If CTRL1_PN[NMATCH] is between two and four, WMB1, WMB2, and WMB3 store the second, third, and fourth matching messages, respectively.

If CTRL1_PN[NMATCH] is greater than four, the last four matching messages are stored in the WMBs. The WMB index indicates the arrival order. The last message is stored in WMB3.

Only the valid data bytes of the incoming match message are stored in the data field of WMBs. The non-valid data bytes are read as zero. If DLC = 0 and RTR = 1, the data field is filled with zeroes. In any of the above cases, the wake-up interrupt is generated only when the filtering criteria are completed and CTRL1_PN[WUMF_MSK] = 1.

When a non-match wake-up event occurs (timeout or external) and WU_MTC[MCOUNTER] ≥ 4, the message stored in WMB0 does not have valid content. WMB0 is used as a buffer for the current message in the CAN bus. Messages received during Pretended Networking mode do not have time stamps, and the respective field in the WMB structure must be ignored.

In low-power mode (Doze or Stop), all processes are shut down except for the PN functionality inside the CAN_PE subblock, which remains clocked by the oscillator clock (see Clock domains and restrictions). FlexCAN continues to receive incoming messages, but only compares them to the predefined target values according to the selected filtering criteria. The matching, arbitration, move-in, and move-out processes, normally available in Normal mode, are not performed in Pretended Networking mode.

FlexCAN in Pretended Networking reacts to messages on the CAN bus in the same manner as in Normal mode. It generates acknowledge bits, detect and count errors, and so on.

48.3.7 Move process

There are two types of move process: move-in and move-out.

48.3.7.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

48.3.7.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of the Intermission field
- During the Bus Off state, when the TX error counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait for Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

48.3.8 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

48.3.8.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.

- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

48.3.8.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

48.3.8.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN,

FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

48.3.9 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 12 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 185 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

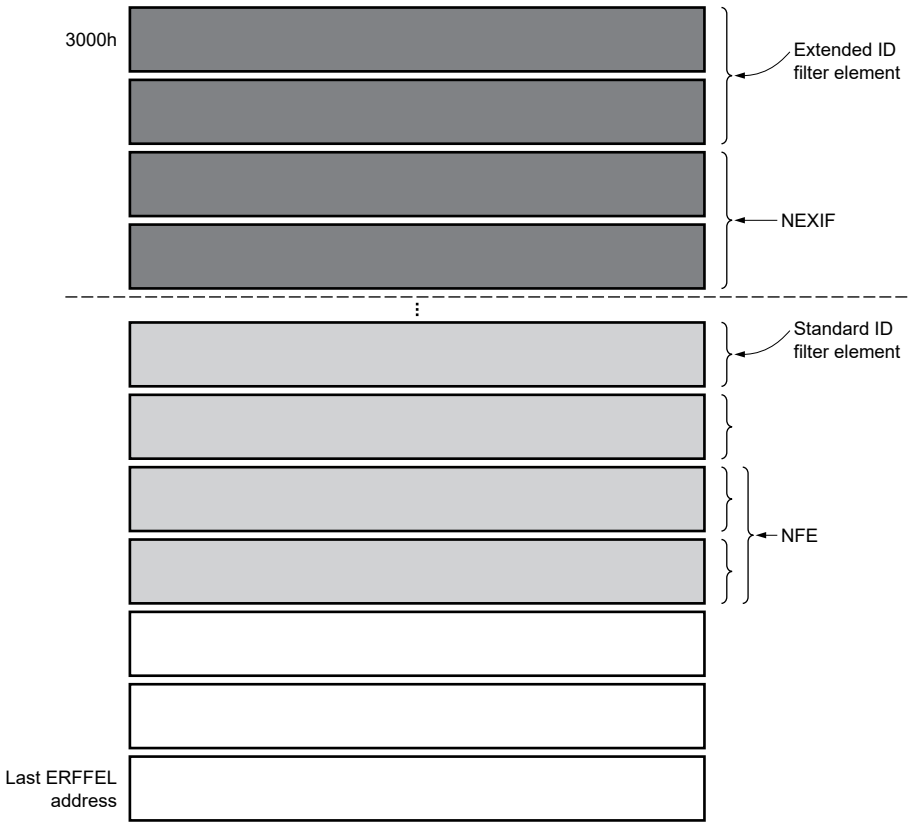

Figure 185. Number of enhanced RX FIFO filter elements

48.3.9.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 358.

Table 358. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR Filter	STD ID Filter		Reserved		RTR MASK	STD ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 359.

Table 359. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTR Filter	STD ID Filter2		Reserved		RTR MASK	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 360.

Table 360. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 361.

Table 361. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter	
Reserved		RTR MASK	EXT ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 362.

Table 362. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter2	
Reserved		RTR MASK	EXT ID Filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 363.

Table 363. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID Filter 1	

48.3.9.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 388.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 398 and Table 399. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

48.3.9.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

48.3.10 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 350 for information about the difference between FD and non-FD regarding this feature.

48.3.10.1 Legacy RX FIFO in DMA operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 350 for information about the difference between FD and non-FD regarding this feature.

48.3.10.2 Clear legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

48.3.11 ACK suppression

FlexCAN does not send acknowledgment when connected through CAN HUB and ACK suppression is enabled by CTRL2[ASD]. When any of the on-chip CAN controllers (connected through CAN HUB) are transmitting, all the on-chip receivers do not send the acknowledgment of received frames. All the on-chip receivers accept the frames only when there is acknowledgment by external receivers. If there is no acknowledgment by external receivers, the frame is dropped and the BIT error is notified.

48.3.12 CAN protocol-related features

48.3.12.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

48.3.12.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

48.3.12.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in the classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 186 illustrates the message formats for classical and FD frames with either standard or extended ID.

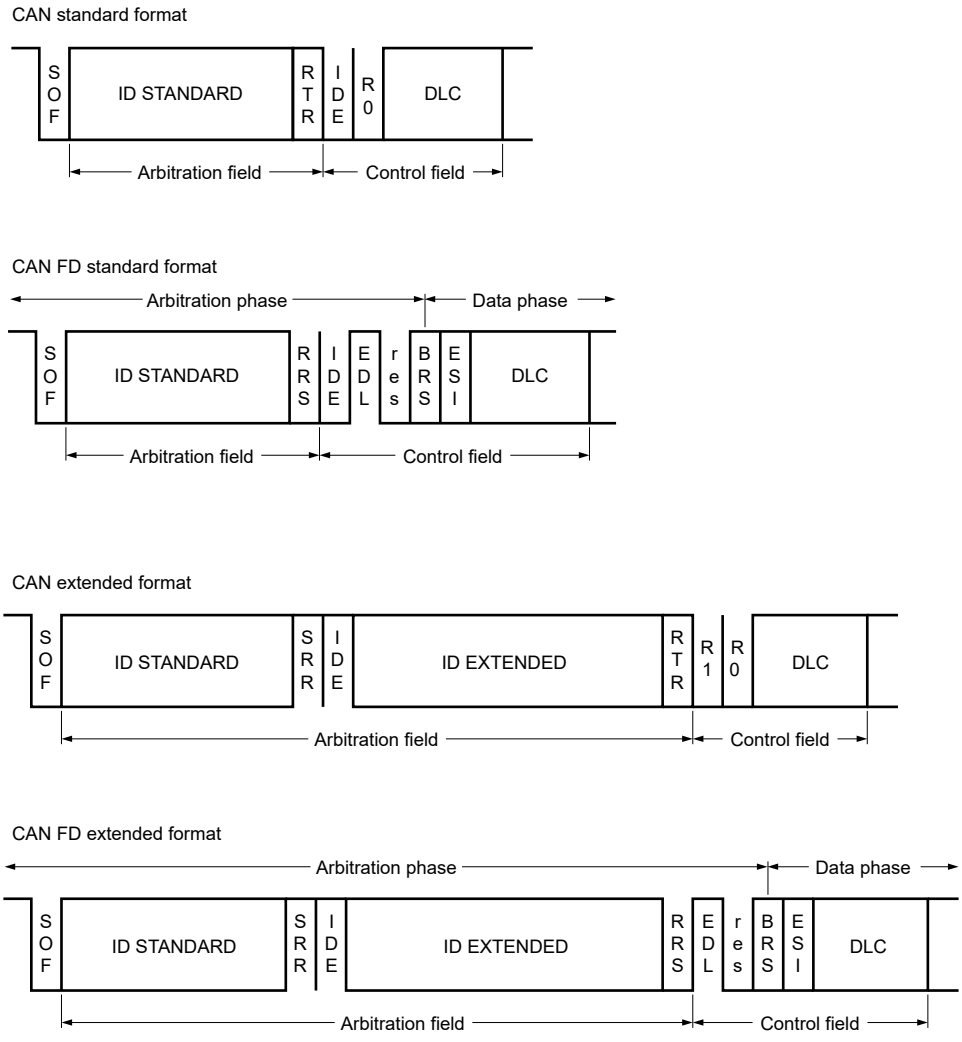

Figure 186. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a

set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

48.3.12.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 187 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

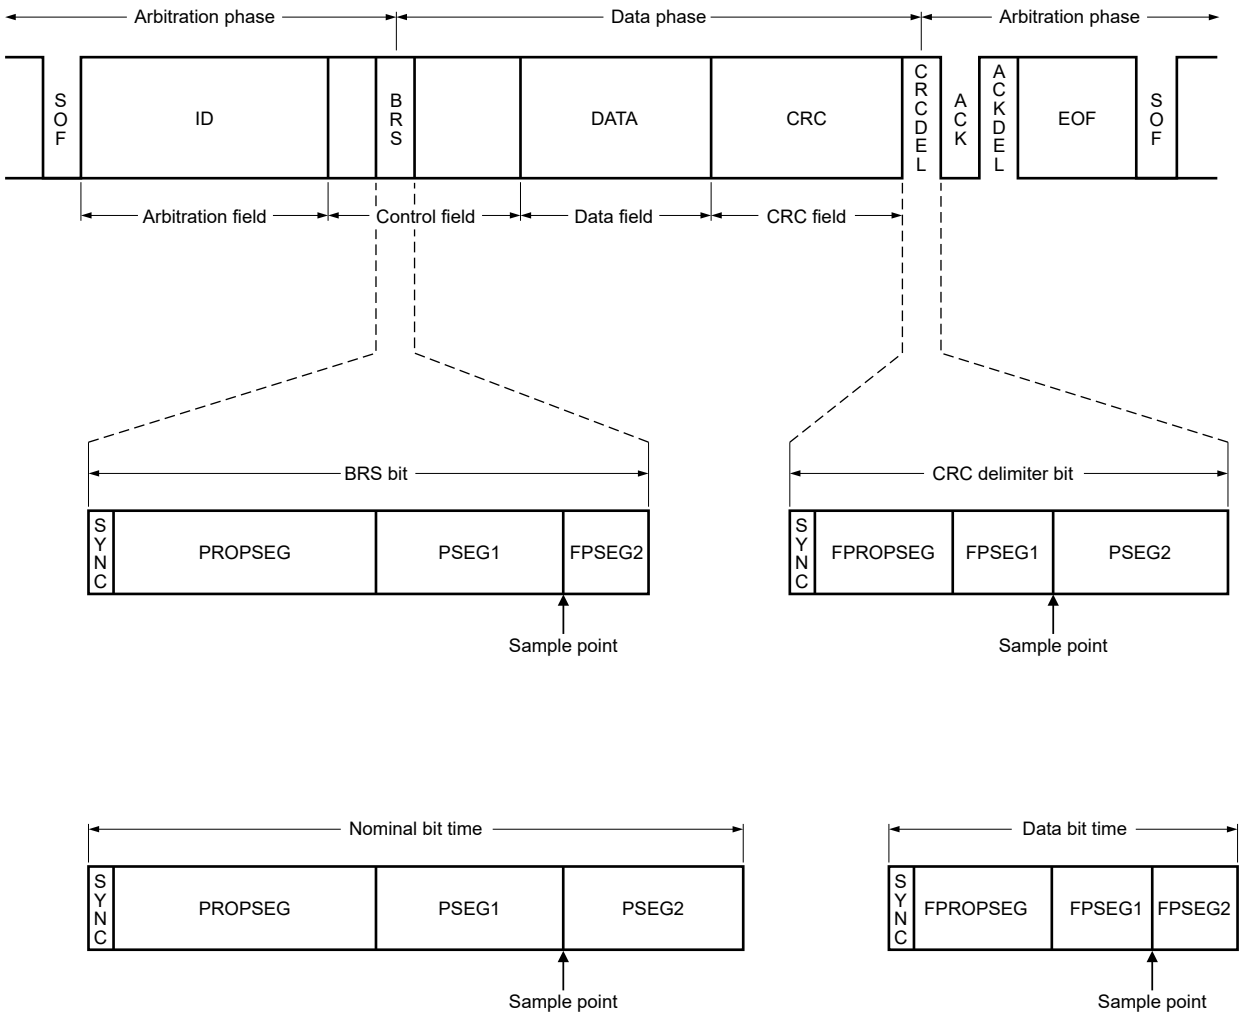

Figure 187. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

48.3.12.2.3 ESI in CAN FD

The value of the ESI field is determined by either of the following:

- The error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node
- The original transmitting node when FlexCAN is acting as a gateway for the message

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 364.

Table 364. Written versus transmitted values of the ESI field

FlexCAN fault confinement status at start of frame	ESI field of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

48.3.12.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

48.3.12.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]

- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

48.3.12.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

48.3.12.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 188). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

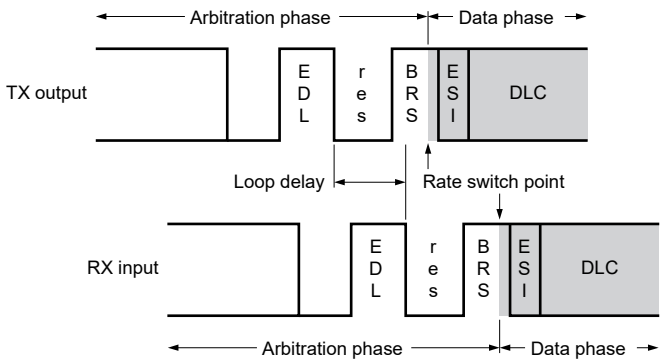

Figure 188. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
$$or$$
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \ if \ ETDCEN$$

Equation 5. TDC offset calculation

Figure 189 shows the SSP position when these settings are used.

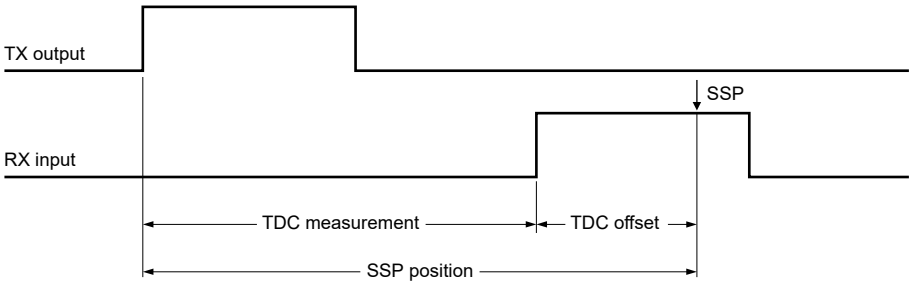

Figure 189. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 190 shows the secondary sample point position when the transceiver delay measurement is disabled.

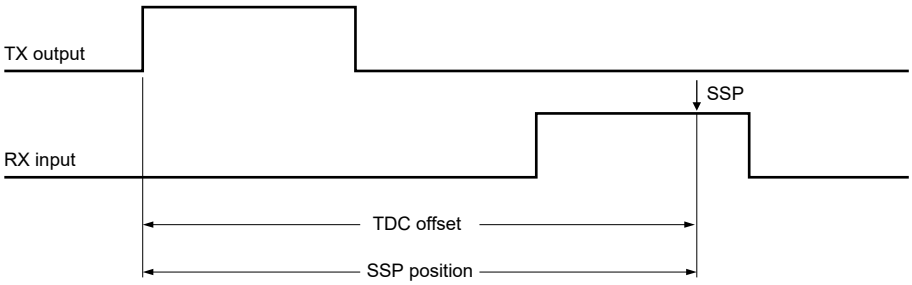

Figure 190. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

48.3.12.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.

- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

48.3.12.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

48.3.12.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter. See the chip-specific FlexCAN timestamp implementation.

48.3.12.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame
- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE]. See the chip-specific FlexCAN timestamp implementation.

48.3.12.8 Protocol timing

Figure 191 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule.

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

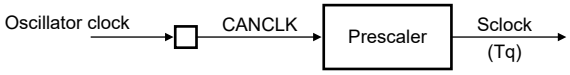

Figure 191. CAN engine clocking scheme

48.3.12.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial clock (Sclock). (See Equation 6.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 6. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 7. CAN bit time and baud rate

48.3.12.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 192. See also Figure 193 , Figure 194, and Table 365.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

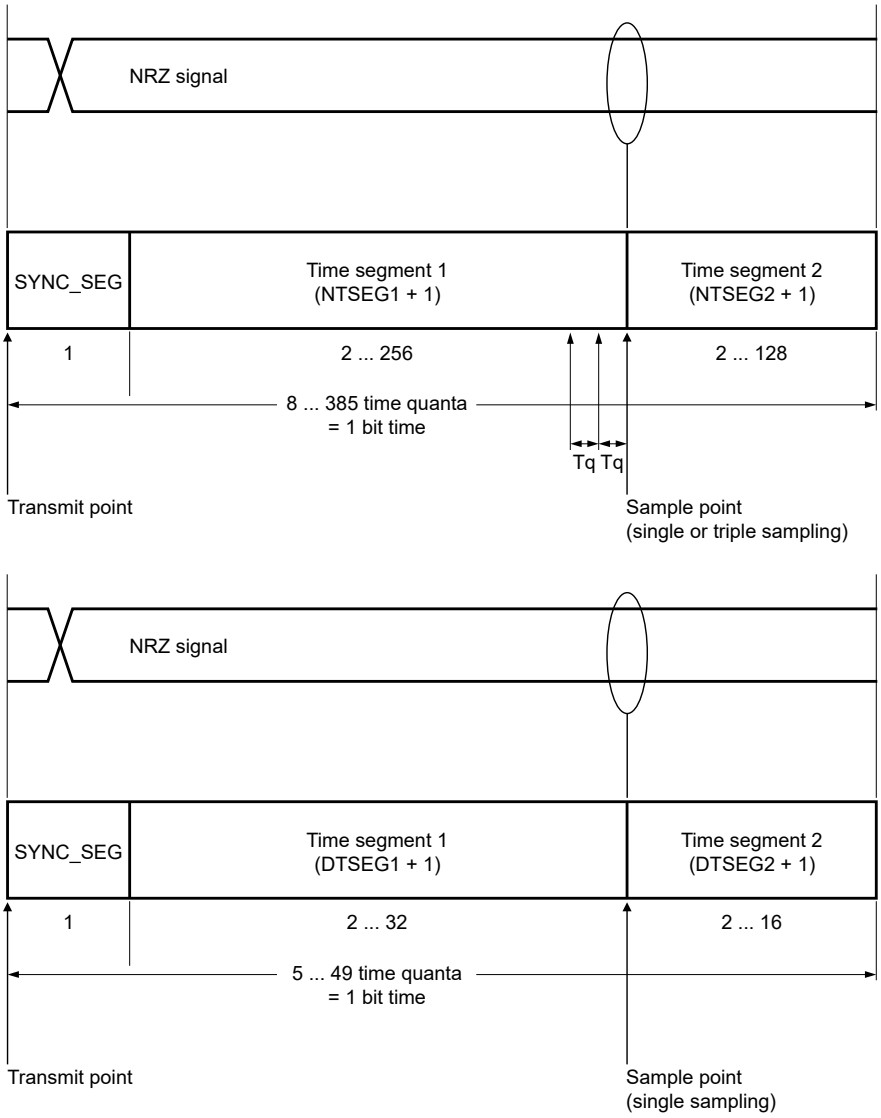

Figure 192. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.

- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

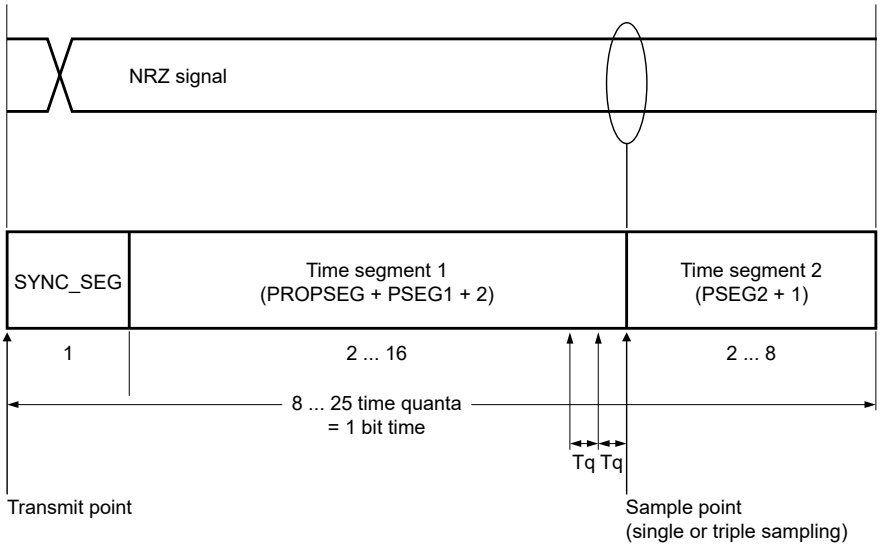

Figure 193. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

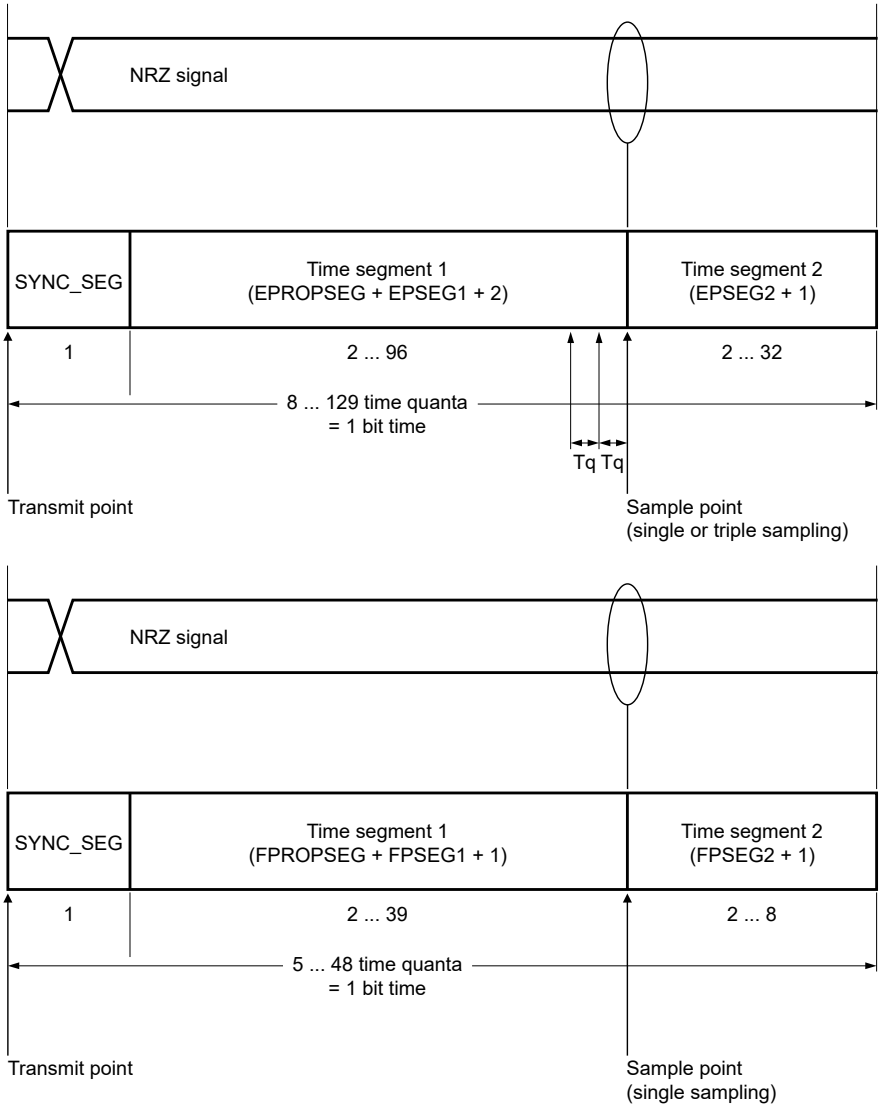

Figure 194. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 365. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 366 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 366. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard ISO 11898-1:2015.

48.3.12.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 8. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 9. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 191), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

48.3.12.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

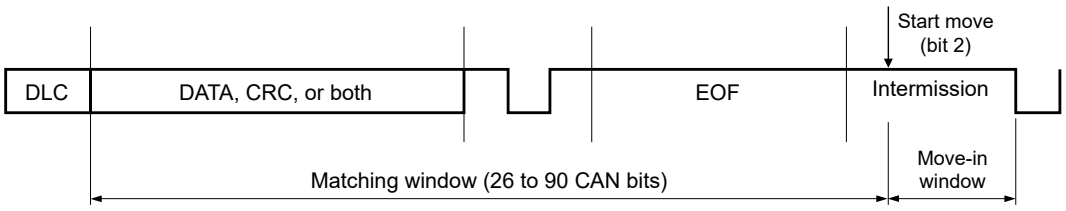

Figure 195. Matching and move-in time windows

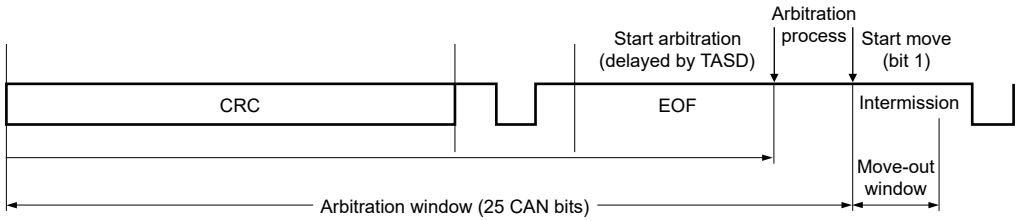

Figure 196. Arbitration and move-out time windows

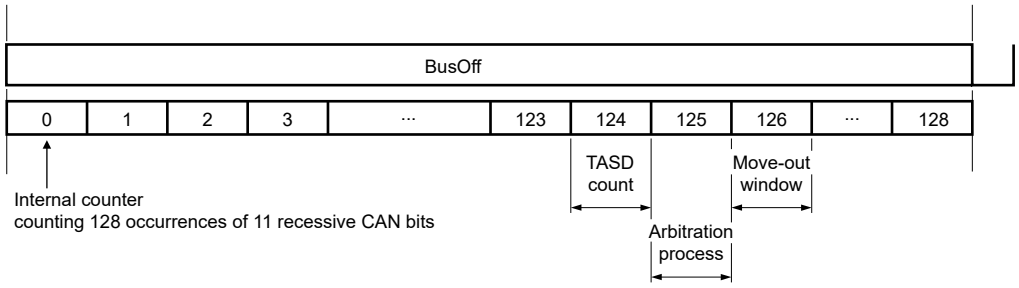

Figure 197. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

48.3.12.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 198, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

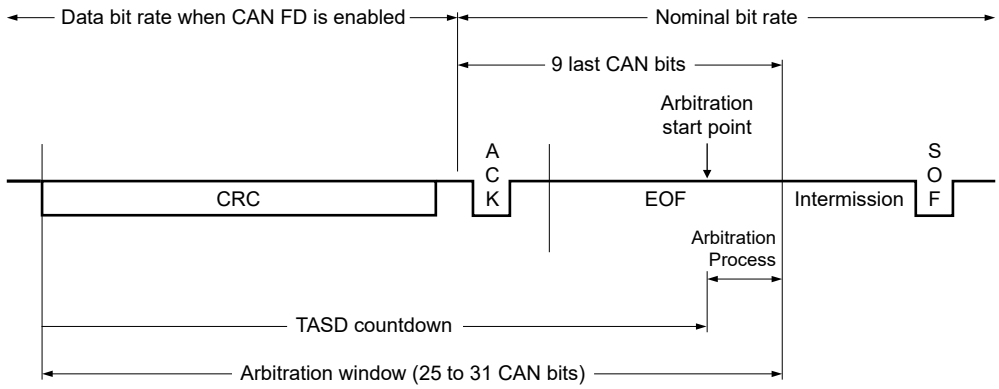

Figure 198. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 10. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 11. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 11.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 12. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 13. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

48.3.12.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 367. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 368. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	6.67

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)

- Bit rate in arbitration phase = 1 Mbaud

Table 369. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0

48.3.13 Clocks

The following table describes the clock sources for FlexCAN. See the chip clocking chapter for clock setting, configuration, and gating information.

Table 370. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

48.3.13.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 371.

Table 371. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16

Table continues on the next page...

Table 371. Minimum number of peripheral clocks per CAN bit for Classical CAN format (continued)

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	1	0	16
32	1	0	17
16	0	1	16
32	0	1	19

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 371 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

48.3.13.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 14. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 372. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 372. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53

Table continues on the next page...

Table 372. Number of fast CAN bits in a CAN FD frame (continued)

Minimum number of data bytes	DLC field	NumOfFastBits
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 15. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 16. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 17. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 18. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

Equation 19. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 372. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 20. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 21. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 22. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 23. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 373 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 373. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Minimum payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

48.3.14 Reset

You can reset FlexCAN in the following ways:

- Soft reset:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 376.
  - The chip level soft reset input is not supported, use the MCR[SOFTRST] to trigger a soft reset.

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

When the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

48.3.15 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers

- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - Wake Up Match
  - Wake Up Timeout
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag
- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up

- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

The interrupt sources for Pretended Networking (Wake-up by Match Flag and Wake-up by Timeout Flag) can be read in Pretended Networking Wake-Up Match (WU_MTC). The respective interrupt mask bits are located in Pretended Networking Control 1 (CTRL1_PN).

48.3.16 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used.
    For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.
    - The memory space 0090h–017Fh is available.
    - The space 0180h–087Fh is reserved.
    - The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
    - In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

    As a rule, free memory space for general purpose depends only on MCR[MAXMB].
  - If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules below.
3. Write operation has no effect.

4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

48.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 375 and described in the following subsections.

Table 375. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

48.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

48.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

48.5 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

48.5.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Enhanced RX FIFO Interrupt Enable (ERFIER)	Yes
Enhanced RX FIFO Status (ERFSR)	Yes
High-Resolution Timestamp (HR_TIME_STAMP)	No
Enhanced RX FIFO	No
Enhanced RX FIFO Filter Element (ERFFEL)	No

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

48.5.2 FlexCAN register descriptions

The following table shows the FlexCAN memory map.

The address range from offset 80h–27Fh allocates the thirty-two 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–23BCh allocates the rest of Enhanced RX FIFO 11 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

48.5.2.1 FlexCAN memory map

CAN0 base address: 4003_B000h

48.5.2.2 Module Configuration (MCR)

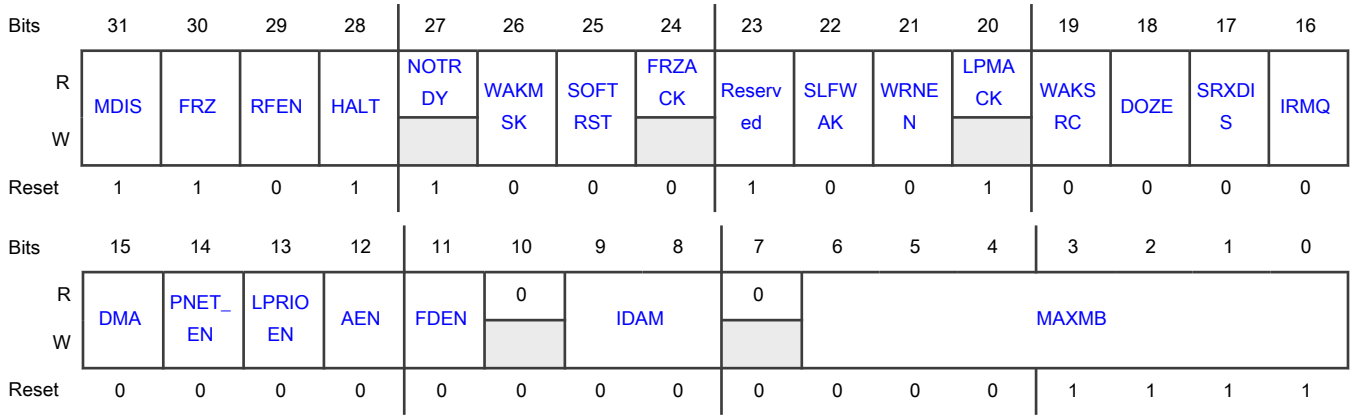
Offset

Register	Offset
MCR	0h

Function

Defines global system configurations, including the module operation modes and the maximum message buffer configuration.

Diagram



Fields

Field	Function
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0b - Enable 1b - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. 0b - Disable 1b - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 371. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0b - Disable 1b - Enable
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. 0b - No request 1b - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Doze mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0b - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1b - FlexCAN is in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0b - Disabled 1b - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No reset 1b - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore, you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0b - Not in Freeze mode, prescaler running. 1b - In Freeze mode, prescaler stopped.
23 —	Reserved
22 SLFWAK	Self-Wake-Up Feature Enables the self-wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Doze mode, FlexCAN requests to resume its clocks. If enabled to do so, it also generates a wake-up interrupt to the CPU. If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. When MCR[PNET_EN] = 1, this feature must be disabled. 0b - Disable 1b - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
20 LPMACK	Low-Power Mode Acknowledge Indicates whether FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). When FlexCAN is in Pretended Networking mode, this field becomes 0 within 180 CAN bits after the low-power mode request removal. 0b - Not in a low-power mode 1b - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0b - No filter applied 1b - Filter applied
18 DOZE	Doze Mode Enable Determines whether FlexCAN can enter low-power mode when Doze mode is requested at chip level. This field is automatically reset when FlexCAN wakes from Doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0b - Disable 1b - Enable
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Enable 1b - Disable
16 IRMQ	Individual RX Masking and Queue Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0b - Disable 1b - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
14 PNET_EN	Pretended Networking Enable Enables Pretended Networking functionality. When in Doze mode or Stop mode, the PE subblock is kept operational. It can process RX message filtering as defined by the Pretended Networking configuration registers. See Receive process in Pretended Networking mode. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Disable 1b - Enable
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0b - Disable 1b - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0b - Disabled 1b - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015. **NOTE** If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0b - Disable 1b - Enable
10 —	Reserved
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00b - Format A: One full ID (standard and extended) per ID filter table element. 01b - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10b - Format C: Four partial 8-bit standard IDs per ID filter table element. 11b - Format D: All frames rejected.
7 —	Reserved
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 371.

48.5.2.3 Control 1 (CTRL1)

Offset

Register	Offset
CTRL1	4h

Function

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

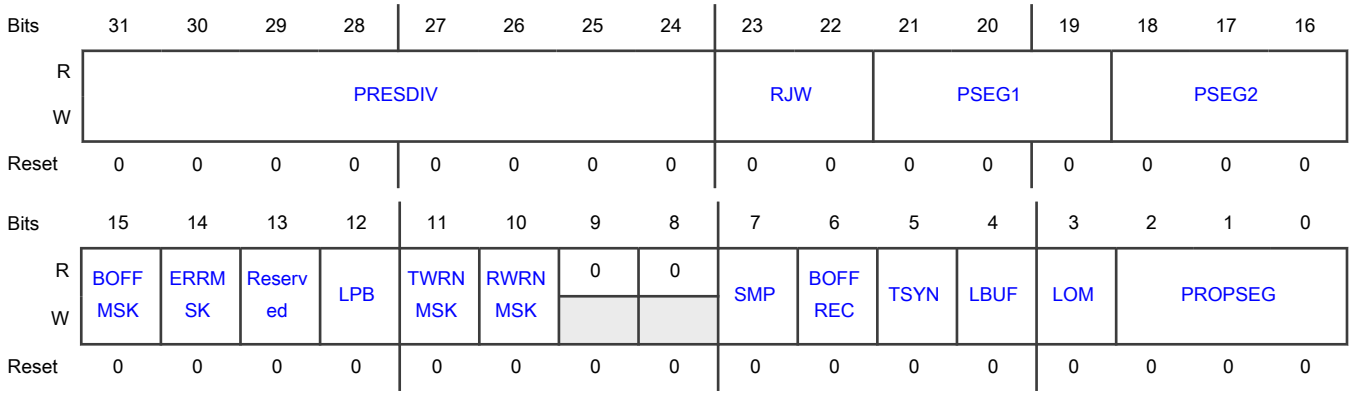
NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Interrupt disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Interrupt disabled 1b - Interrupt enabled
13 —	Reserved **NOTE** Writeable only if the module is disabled. Otherwise the access type is read-only.
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0b - Disabled 1b - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled 1b - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0b - Disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enabled
9 —	Reserved
8 —	Reserved
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0b - One sample is used to determine the bit value. 1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN protocol standard ISO 11898-1:2015 for details. 0b - Enabled 1b - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Buffer with highest priority is transmitted first. 1b - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0b - Listen-Only mode is deactivated. 1b - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

48.5.2.4 Free-Running Timer (TIMER)

Offset

Register	Offset
TIMER	8h

Function

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop, Pretended Networking, and Freeze modes.

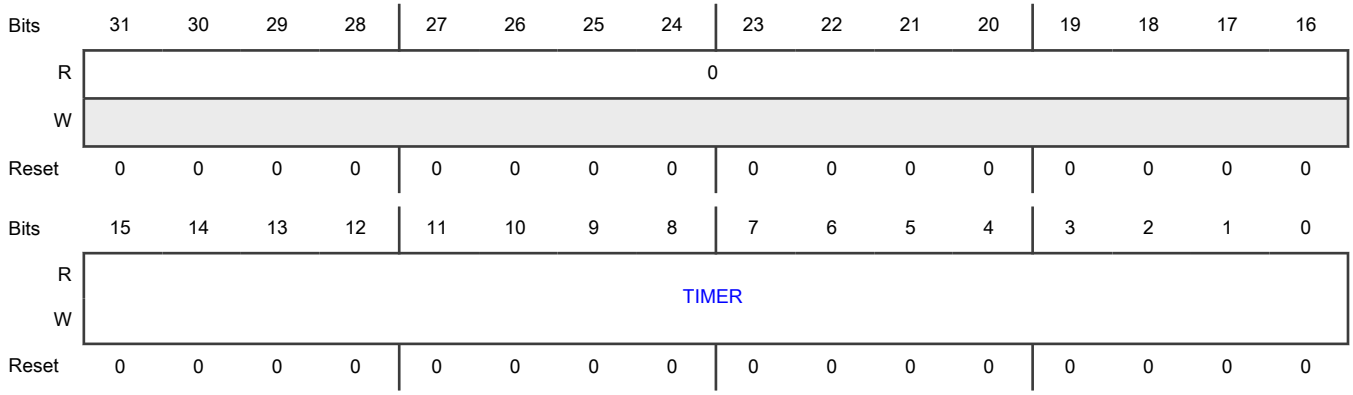
The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 TIMER	Timer Value Contains the free-running counter value.

48.5.2.5 RX Message Buffers Global Mask (RXMGMASK)

Offset

Register	Offset
RXMGMASK	10h

Function

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

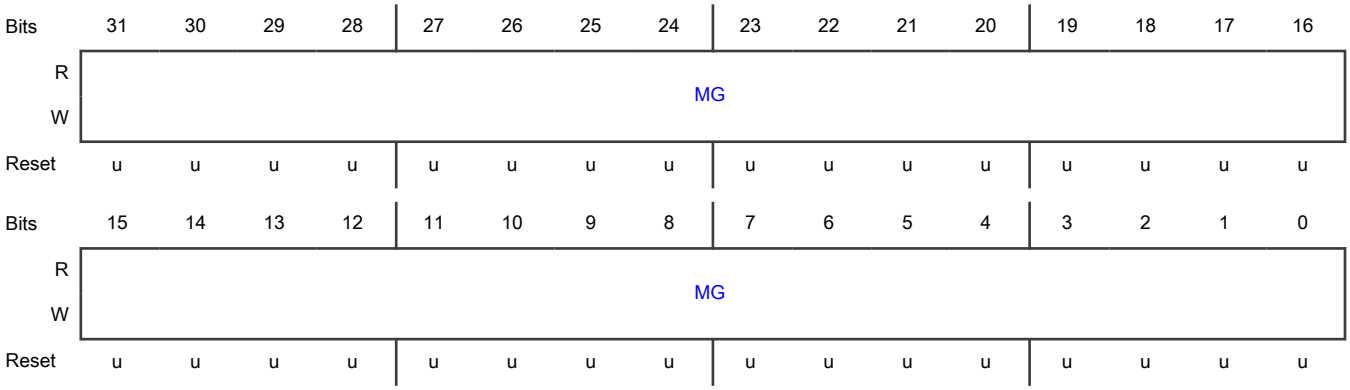
This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

48.5.2.6 Receive 14 Mask (RX14MASK)

Offset

Register	Offset
RX14MASK	14h

Function

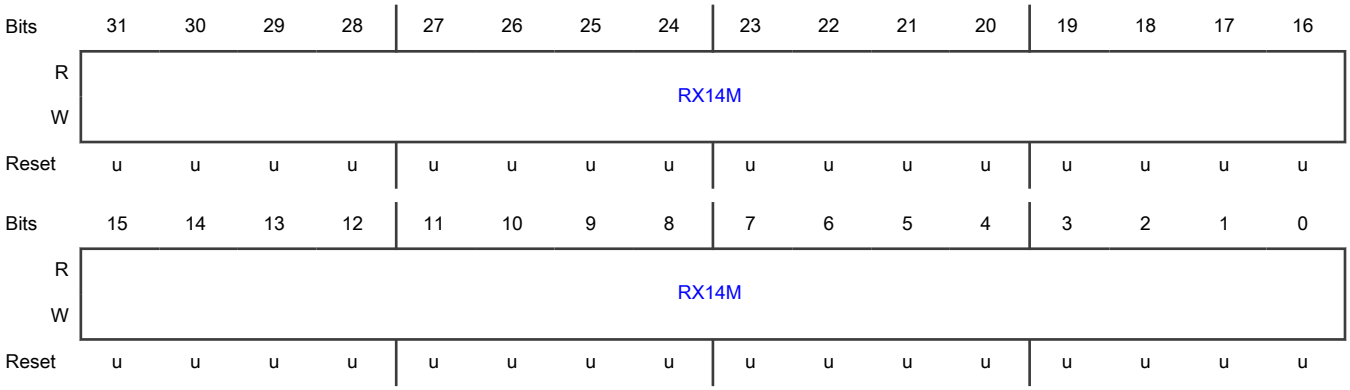
Masks the filter fields of MB14.

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

48.5.2.7 Receive 15 Mask (RX15MASK)

Offset

Register	Offset
RX15MASK	18h

Function

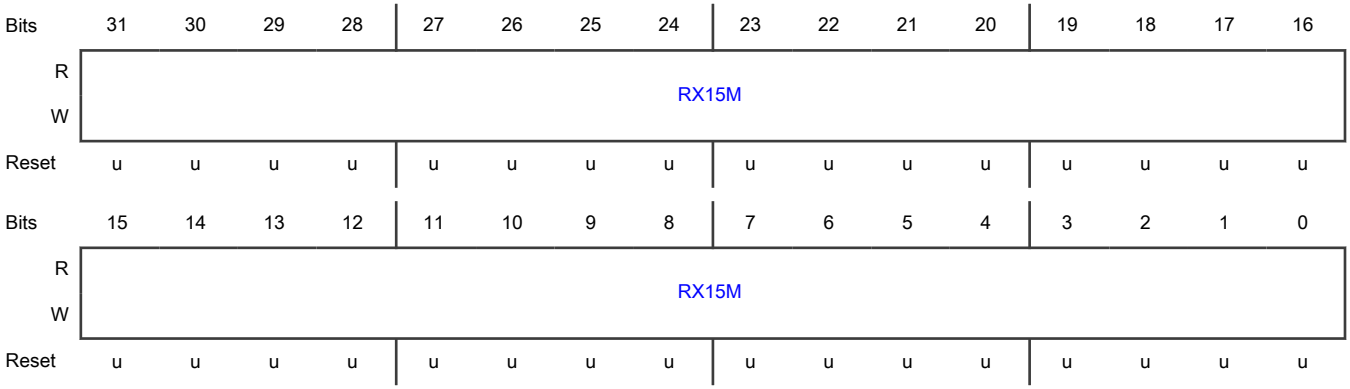
Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

48.5.2.8 Error Counter (ECR)

Offset

Register	Offset
ECR	1Ch

Function

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

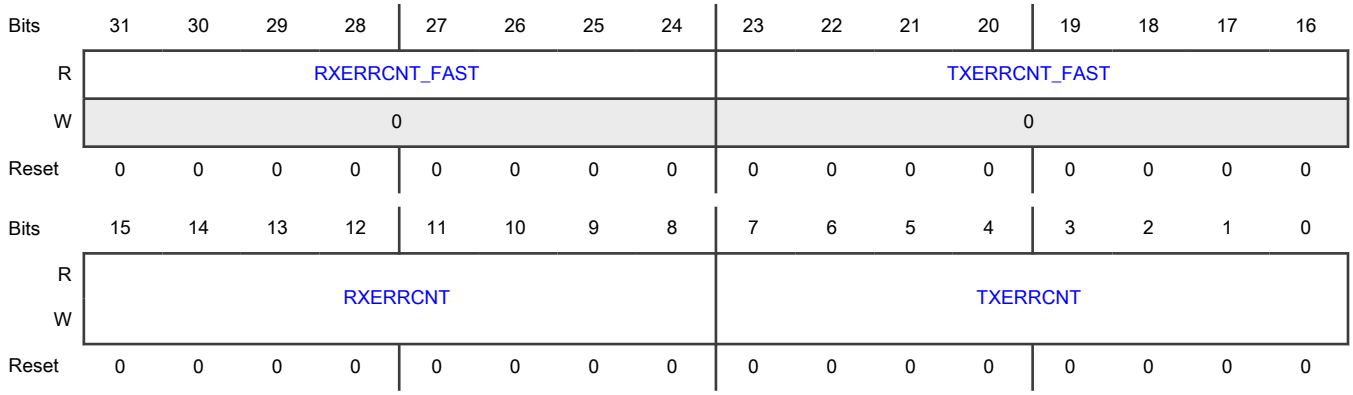
The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.
- When FlexCAN is in Pretended Networking mode, RXERRCNT and RXERRCNT_FAST keep counting errors, and error flags are stored. TXERRCNT and TXERRCNT_FAST preserve their values and do not change, because no transmission occurs in Pretended Networking mode. Error counters and error flags that changed values in Pretended Networking mode are updated in this register and in Error and Status 1 (ESR1) when FlexCAN returns to Normal mode. If FlexCAN is in Pretended Networking mode, the FAST error flags in ESR1 are not set.

NOTE

See Fault confinement in the CAN Protocol standard ISO 11898-1:2015 for details.

Diagram



Fields

Field	Function
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.
7-0 TXERRCNT	Transmit Error Counter Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

48.5.2.9 Error and Status 1 (ESR1)

Offset

Register	Offset
ESR1	20h

Function

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST

— FRMERR_FAST

— STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST
- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 377. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard ISO 11898-1:2015 for details.

Fields

Field	Function
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A CRC error occurred since last read of this register.
27	Fast Form Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRMERR_FAST	Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - A stuffing error occurred since last read of this register.
25-24 —	Reserved
23 —	Reserved
22 —	Reserved
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0b - No overrun 1b - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0b - No such occurrence. 1b - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0b - No such occurrence 1b - FlexCAN module has completed Bus Off process.
18	CAN Synchronization Status Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
SYNCH	Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0b - Not synchronized 1b - Synchronized
17 TWRNINT	TX Warning Interrupt Flag Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is not updated. 0b - No such occurrence 1b - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. When FlexCAN returns to Normal mode from Pretended Network mode (see Receive process in Pretended Networking mode), this bit is updated to reflect the RX error counter state. 0b - No such occurrence 1b - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending an error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as recessive is received as dominant.

Table continues on the next page...

Table continued from the previous page...

Field	Function
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. This field is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0. 0b - No error 1b - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This flag is updated when FlexCAN returns to Normal mode from Pretended Network mode. After a read operation, the field's value clears to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. Additionally, this flag is updated when FlexCAN returns to Normal mode from Pretended Networking mode. After a read operation, the field's value clears to 0. 0b - No such occurrence. 1b - RXERRCNT is greater than or equal to 96.
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 377. 0b - Not IDLE 1b - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 377. 0b - Not transmitting 1b - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00b - Error Active 01b - Error Passive 1xb - Bus Off

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0b - Not receiving 1b - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0b - No such occurrence. 1b - Indicates setting of any error flag in the Error and Status register.
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up: • Doze mode • Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0b - No such occurrence. 1b - Indicates that a recessive-to-dominant transition was received on the CAN bus.

48.5.2.10 Interrupt Masks 1 (IMASK1)

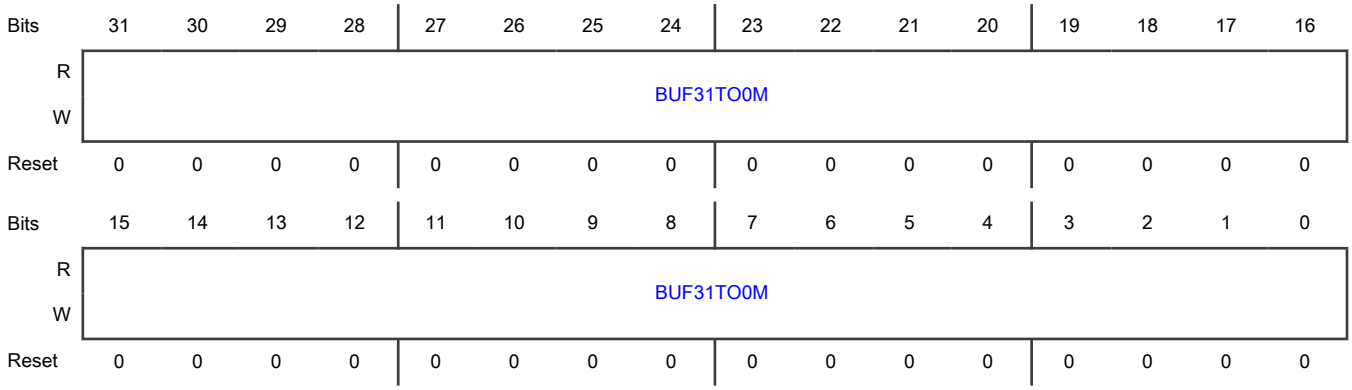
Offset

Register	Offset
IMASK1	28h

Function

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Diagram



Fields

Field	Function
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

48.5.2.11 Interrupt Flags 1 (IFLAG1)

Offset

Register	Offset
IFLAG1	30h

Function

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN]

value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

W	W1C								W1C	W1C	W1C	W1C				W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0b - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1b - MB7 completed transmission or reception, or FIFO overflow.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0b - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1b - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0b - No occurrence of completed transmission or reception, or no frames available 1b - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions. 0b - MB0 has no occurrence of successfully completed transmission or reception. 1b - MB0 has successfully completed transmission or reception.

48.5.2.12 Control 2 (CTRL2)

Offset

Register	Offset
CTRL2	34h

Function

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 378 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 378. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask
0h	8	MB 0–7	MB 8–31	Elements 0–7	None

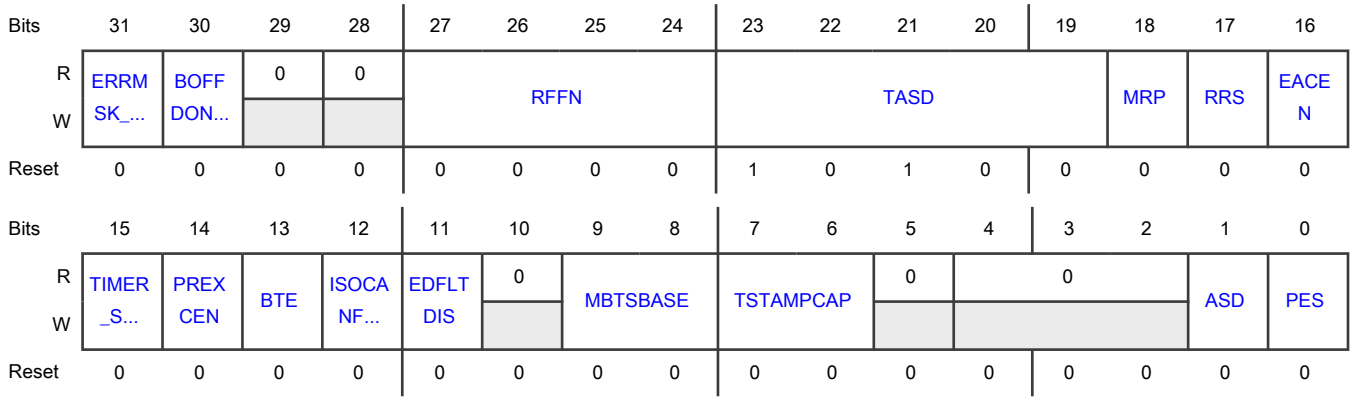
Diagram



Fields

Field	Function
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0b - Disable 1b - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0b - Disable 1b - Enable
29 —	Reserved
28 —	Reserved
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 378. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19 TASD	Transmission Arbitration Start Delay Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes. 0b - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1b - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0b - Generated 1b - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0b - Disable 1b - Enable
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free-running timer counter. If CAN bit clock is selected, it defines the baud rate on the CAN bus. If External time tick is selected, the period can be adjusted to match the baud rate on the CAN bus. It can also be adjusted to a different value as required. See the chip-specific section for details about the external time tick. You can only write to this field in Freeze mode. 0b - CAN bit clock 1b - External time tick
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard ISO 11898-1:2015 for details. 0b - Disabled 1b - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification ISO 11898-1:2015 (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard ISO 11898-1:2015. 0b - Disable 1b - Enable
11 EDFLTDIS	Edge Filter Disable Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard ISO 11898-1:2015 for details. 0b - Enabled 1b - Disabled
10 —	Reserved
9-8 MBTSBASE	Message Buffer Timestamp Base Selects the timebase used for capturing the 16-bit TIME_STAMP field of the message buffer register. This field can be written in Freeze Mode only. 00b - TIMER 01b - Lower 16 bits of high-resolution timer 10b - Upper 16 bits of high-resolution timer 11b - Reserved
7-6	Timestamp Capture Point

Table continues on the next page...

Table continued from the previous page...

Field	Function
TSTAMPCAP	Configures the point in time when a 32-bit timebase is captured during a CAN frame. This base is stored in the high-resolution timestamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start-of-frame bit or the point when CAN frame is considered valid. This point is the seventh bit of the end-of-frame for transmission and the sixth bit of the end-of-frame for reception. For CAN FD frames, the high-resolution timestamp can be captured at the start of frame, when a CAN FD frame is considered valid, or the res bit. You can only write to this field in Freeze mode. 00b - Disabled 01b - End of the CAN frame 10b - Start of the CAN frame 11b - Start of frame for classical CAN frames; res bit for CAN FD frames
5 —	Reserved
4-2 —	Reserved
1 ASD	ACK Suppression Disable Disables the ACK suppression logic. You can only write to this field in Freeze mode. 0b - Enabled 1b - Disabled
0 PES	Payload Byte and Bit Order Selection Selects the byte order for the payload of transmit and receive frames. **NOTE** You can only write to this field in Freeze mode. 0b - Big-endian 1b - Little-endian

48.5.2.13 Error and Status 2 (ESR2)

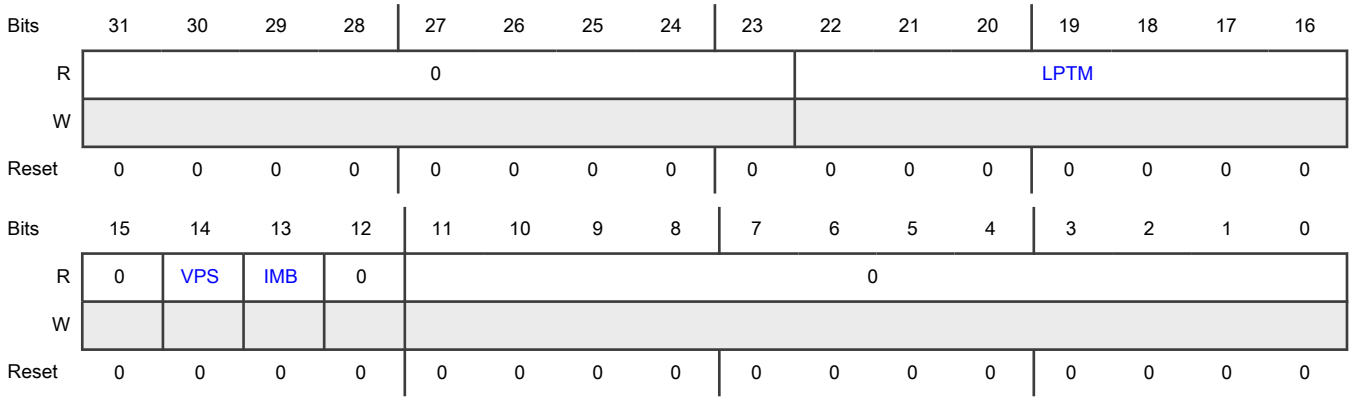
Offset

Register	Offset
ESR2	38h

Function

Reports general status information.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0b - Invalid 1b - Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0b - Message buffer indicated by ESR2[LPTM] is not inactive. 1b - At least one message buffer is inactive.
12 —	Reserved
11-0 —	Reserved

48.5.2.14 Cyclic Redundancy Check (CRCR)

Offset

Register	Offset
CRCR	44h

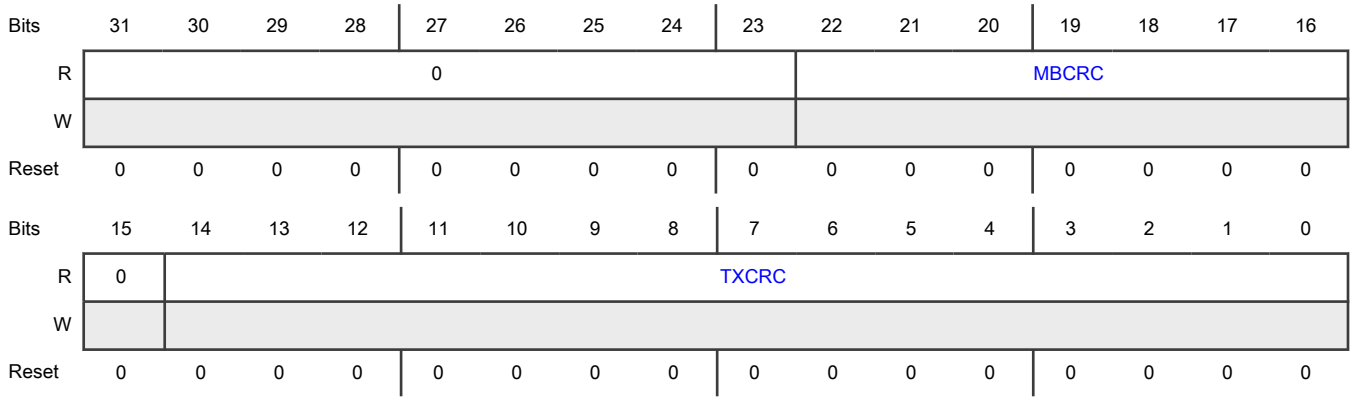
Function

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard ISO 11898-1:2015 for details.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

48.5.2.15 Legacy RX FIFO Global Mask (RXFGMASK)

Offset

Register	Offset
RXFGMASK	48h

Function

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

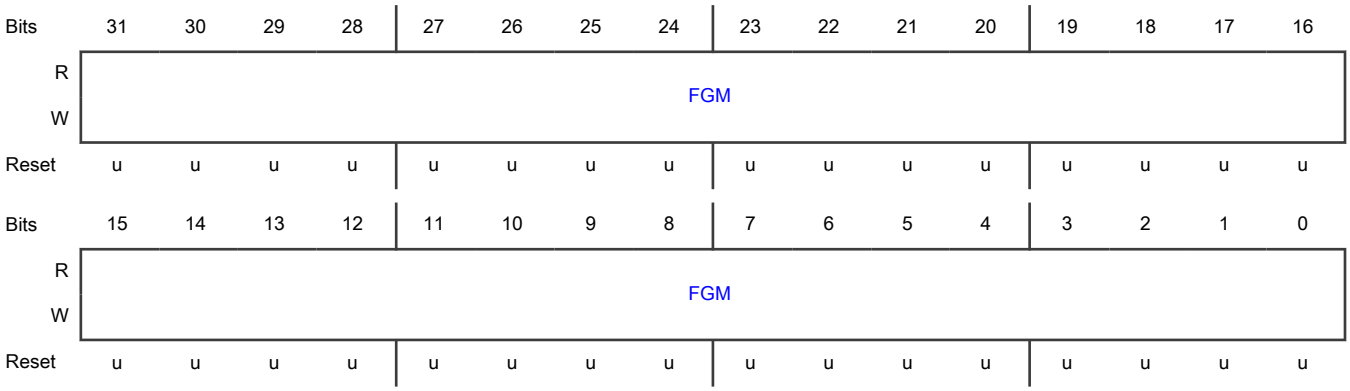
The following table shows how the FGM bits correspond to each IDAF field.

Table 379. Correspondence of Legacy RX FIFO global mask bits to IDF fields

Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Diagram



Fields

Field	Function
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

48.5.2.16 Legacy RX FIFO Information (RXFIR)

Offset

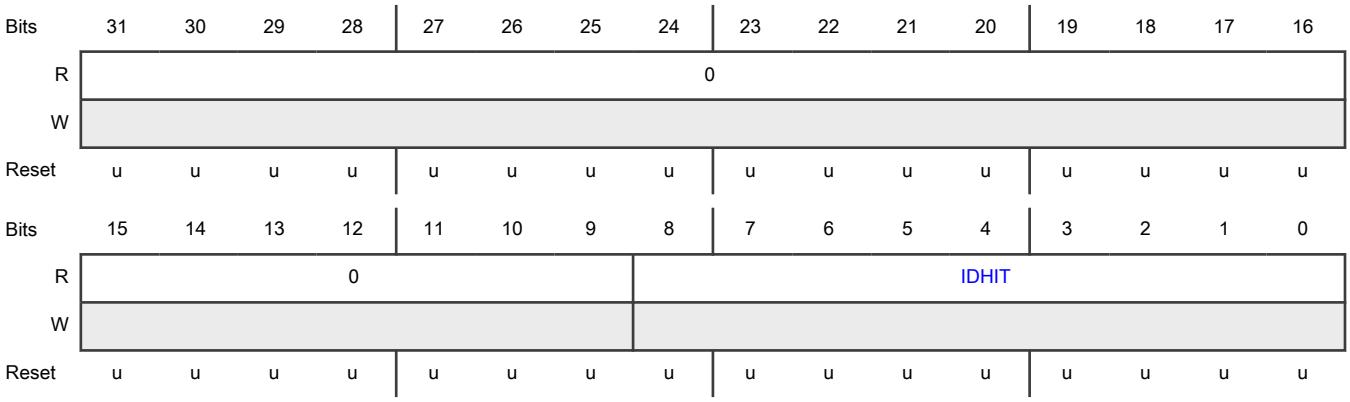
Register	Offset
RXFIR	4Ch

Function

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

48.5.2.17 CAN Bit Timing (CBT)

Offset

Register	Offset
CBT	50h

Function

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

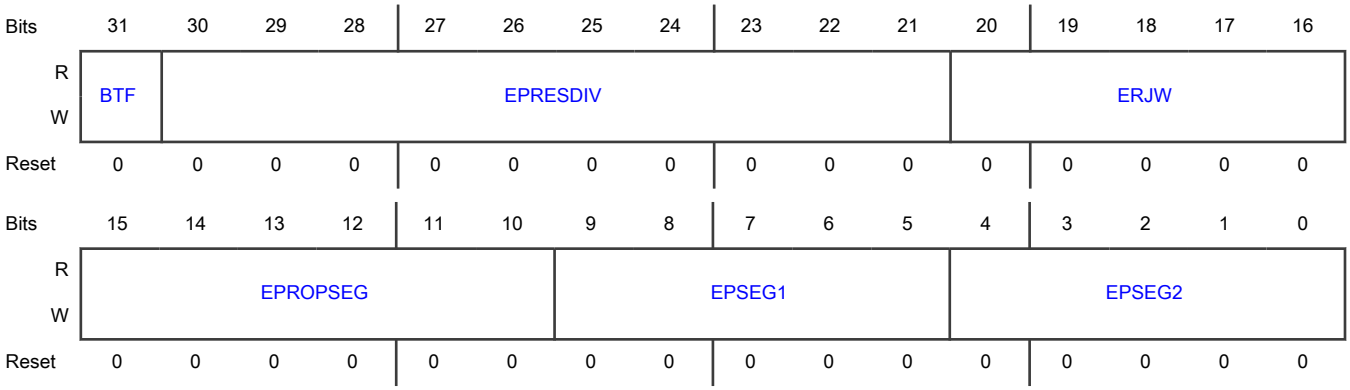
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1:2015.

NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Diagram



Fields

Field	Function
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0b - Disable 1b - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10 EPROPSEG	Extended Propagation Segment Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

48.5.2.18 Receive Individual Mask (RXIMR0 - RXIMR31)

Offset

For n = 0 to 31:

Register	Offset
RXIMRn	880h + (n × 4h)

Function

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

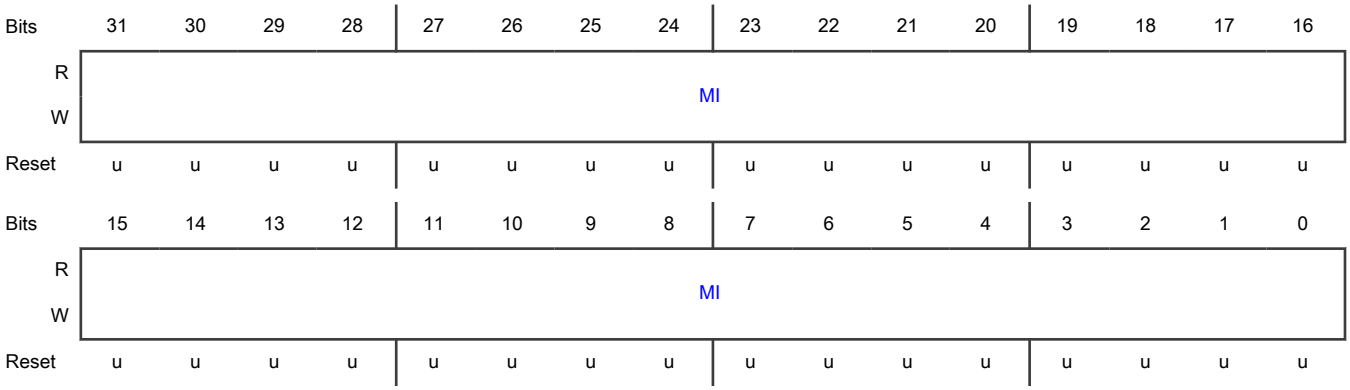
When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Diagram



Fields

Field	Function
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

48.5.2.19 Pretended Networking Control 1 (CTRL1_PN)

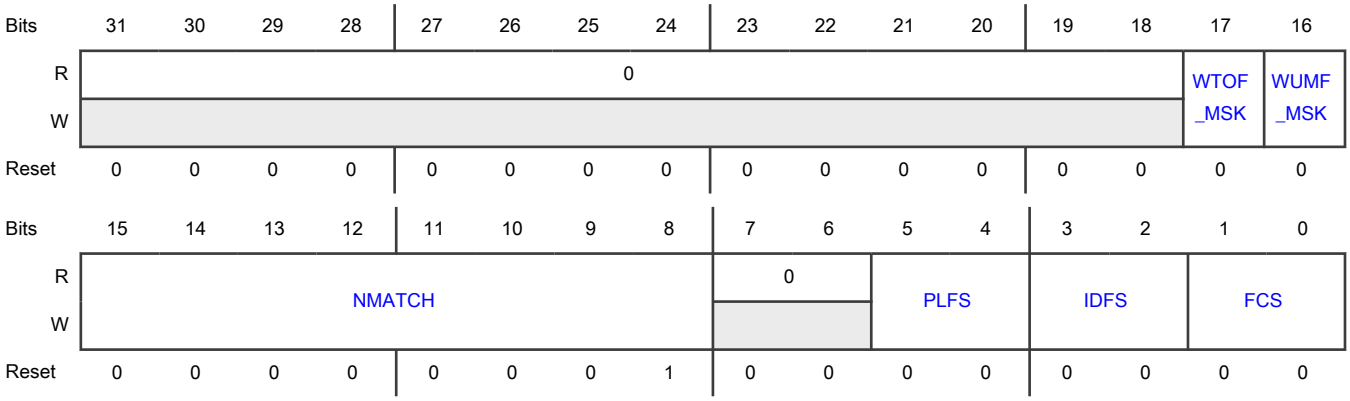
Offset

Register	Offset
CTRL1_PN	B00h

Function

Contains control bits for Pretended Networking mode filtering selection. Configure this register with the filter criteria to be used to receive wake-up messages. Fields in this register can be written in Freeze mode only, except for CTRL1_PN[WTOF_MSK] and CTRL1_PN[WUMF_MSK].

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF_MSK	Wake-up by Timeout Flag Mask Enables the generation of a wake-up event originated by a timeout. 0b - Disable 1b - Enable
16 WUMF_MSK	Wake-up by Matching Flag Mask Enables the generation of a wake-up event originated by a successful filtered RX message. 0b - Disable 1b - Enable
15-8 NMATCH	Number of Messages Matching the Same Filtering Criteria Defines the number of times a given message must match the predefined filtering criteria for ID or payload before generating a wake-up event. You can configure this quantity in the 1–255 range by using values 01h–FFh, respectively. 0000_0001b - Once 0000_0010b - Twice 1111_1111b - 255 times
7-6 —	Reserved
5-4 PLFS	Payload Filtering Selection Selects the level of payload filtering to be applied when FlexCAN is in Pretended Networking mode. When payload filtering is active, filtering does not accept remote messages (RTR = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Match payload contents to an exact target value 01b - Match a payload value greater than or equal to a specified target value 10b - Match a payload value smaller than or equal to a specified target value 11b - Match upon a payload value within a range of values, inclusive
3-2 IDFS	ID Filtering Selection Selects the level of ID filtering to be applied when FlexCAN is in Pretended Networking mode. In ID filtering, if FLT_ID2_IDMASK[IDE_MSK] = 1 and FLT_ID2_IDMASK[RTR_MSK] = 1, the IDE and RTR bits are considered part of the reception filter. 00b - Match ID contents to an exact target value 01b - Match an ID value greater than or equal to a specified target value 10b - Match an ID value smaller than or equal to a specified target value 11b - Match an ID value within a range of values, inclusive
1-0 FCS	Filtering Combination Selection Selects the filtering criteria to be applied when FlexCAN is in Pretended Networking mode. See Receive process in Pretended Networking mode for more details. 00b - Message ID filtering only 01b - Message ID filtering and payload filtering 10b - Message ID filtering occurring a specified number of times 11b - Message ID filtering and payload filtering a specified number of times

48.5.2.20 Pretended Networking Control 2 (CTRL2_PN)

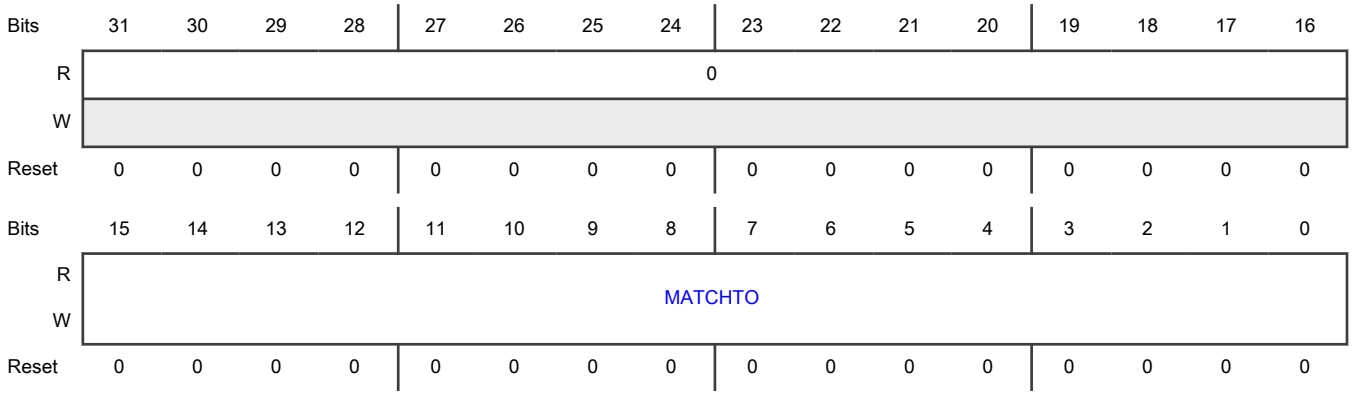
Offset

Register	Offset
CTRL2_PN	B04h

Function

Contains the configuration for the timeout value in Pretended Networking mode. You can only write to this register in Freeze mode.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 MATCHTO	Timeout for No Message Matching the Filtering Criteria Defines a timeout value that generates a wake-up event if MCR[PNET_EN] = 1. If the timeout counter reaches the target value when FlexCAN is in Pretended Networking mode, a wake-up event is generated. The timeout limit can be configured from 1 to 65535 to control an internal 16-bit incrementing timer to produce a trigger upon reaching this configured value. The internal timer is incremented based on periodic time ticks, where the period is 64 times the CAN Bit Time unit. Writing 0000h to this field disables the timeout.

48.5.2.21 Pretended Networking Wake-Up Match (WU_MTC)

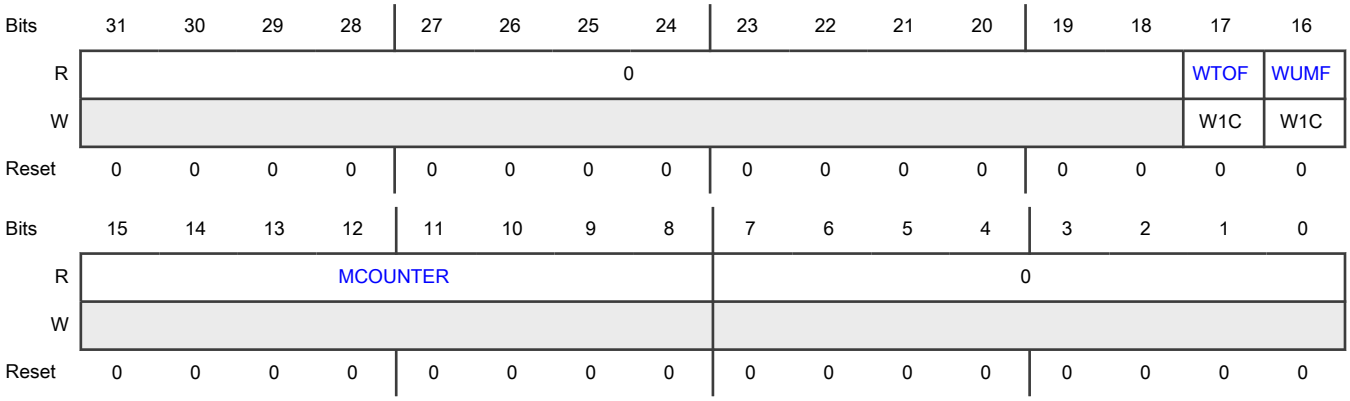
Offset

Register	Offset
WU_MTC	B08h

Function

Contains wake-up information related to the matching processes performed when FlexCAN receives frames in Pretended Networking mode.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 WTOF	Wake-up by Timeout Flag Bit Identifies whether FlexCAN has detected a timeout event during a time interval defined by CTRL2_PN[MATCHTO]. If CTRL1_PN[WTOF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
16 WUMF	Wake-up by Match Flag Identifies whether FlexCAN has detected a matching RX incoming message that meets the filtering criteria specified in Pretended Networking Control 1 (CTRL1_PN). If CTRL1_PN[WUMF_MSK] = 1, this flag generates a wake-up event. 0b - No event detected 1b - Event detected
15-8 MCOUNTER	Number of Matches in Pretended Networking Contains the number of times a given message has matched the predefined filtering criteria for ID or payload before a wake-up event. When FlexCAN enters Pretended Networking mode, this register is reset; soft reset does not affect it.
7-0 —	Reserved

48.5.2.22 Pretended Networking ID Filter 1 (FLT_ID1)

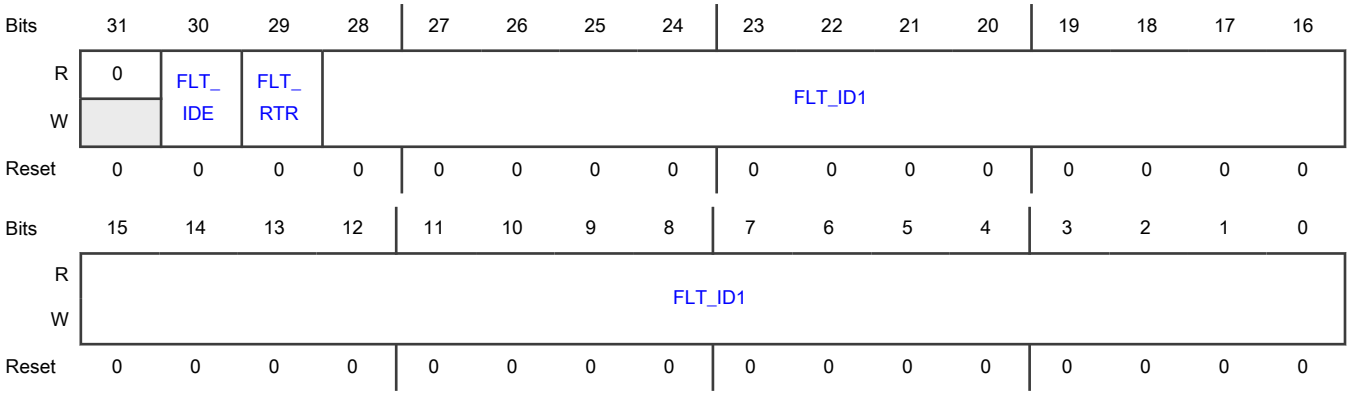
Offset

Register	Offset
FLT_ID1	B0Ch

Function

Contains FLT_ID1 target value, as well as IDE and RTR target values used to filter an incoming message ID. The FLT_ID1 is used for comparisons or as the lower limit value in an ID range detection. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31 —	Reserved
30 FLT_IDE	ID Extended Filter Identifies whether the frame format is standard or extended. It is used as part of the ID reception filter. 0b - Standard 1b - Extended
29 FLT_RTR	Remote Transmission Request Filter Identifies whether the frame is remote. It is used as part of the ID reception filter. 0b - Reject remote frame (accept data frame) 1b - Accept remote frame
28-0 FLT_ID1	ID Filter 1 for Pretended Networking filtering Defines either the 29 bits of an extended frame format, considering all bits, or the 11 bits of a standard frame format, considering only the leftmost 11 bits.

48.5.2.23 Pretended Networking Data Length Code (DLC) Filter (FLT_DLC)

Offset

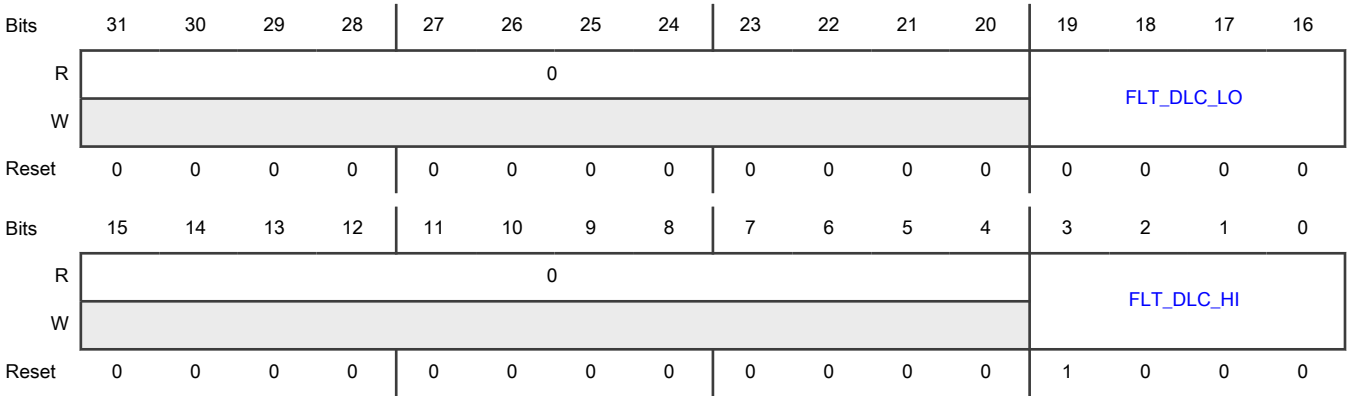
Register	Offset
FLT_DLC	B10h

Function

Contains the DLC inside a range of target values (FLT_DLC_LO and FLT_DLC_HI) used to filter an incoming message. The DLC range is used only for payload filtering. It can be written in Freeze mode only.

When a fixed quantity of data bytes is required, write the same value to FLT_DLC[FLT_DLC_LO] and FLT_DLC[FLT_DLC_HI]. See Receive process in Pretended Networking mode.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 FLT_DLC_LO	Lower Limit for Length of Data Bytes Filter Specifies the lower limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.
15-4 —	Reserved
3-0 FLT_DLC_HI	Upper Limit for Length of Data Bytes Filter Specifies the upper limit for the number of data bytes considered valid for payload comparison. It is used as part of payload reception filter.

48.5.2.24 Pretended Networking Payload Low Filter 1 (PL1_LO)

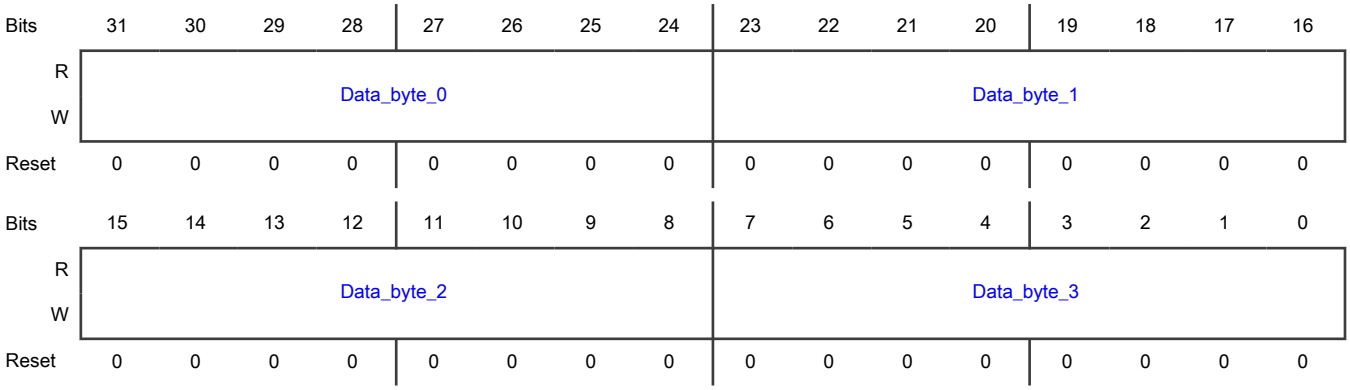
Offset

Register	Offset
PL1_LO	B14h

Function

Contains the low-order bits of the target value used to filter incoming message payload for payload filter 1. It is used for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_0	Data byte 0 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 0.
23-16 Data_byte_1	Data byte 1 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 1.
15-8 Data_byte_2	Data byte 2 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 2.
7-0 Data_byte_3	Data byte 3 Contains payload filter 1 low-order bits for PN payload filtering corresponding to data byte 3.

48.5.2.25 Pretended Networking Payload High Filter 1 (PL1_HI)

Offset

Register	Offset
PL1_HI	B18h

Function

Contains the high-order bits of the target value used to filter incoming message payload for payload filter 1. It is used either for comparisons or as the lower limit value in a payload range detection. It can be written in Freeze mode only.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Data_byte_4								Data_byte_5							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Data_byte_6								Data_byte_7							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_4	Data byte 4 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 4.
23-16 Data_byte_5	Data byte 5 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 5.
15-8 Data_byte_6	Data byte 6 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 6.
7-0 Data_byte_7	Data byte 7 Contains payload filter 1 high-order bits for PN payload filtering corresponding to data byte 7.

48.5.2.26 Pretended Networking ID Filter 2 or ID Mask (FLT_ID2_IDMASK)

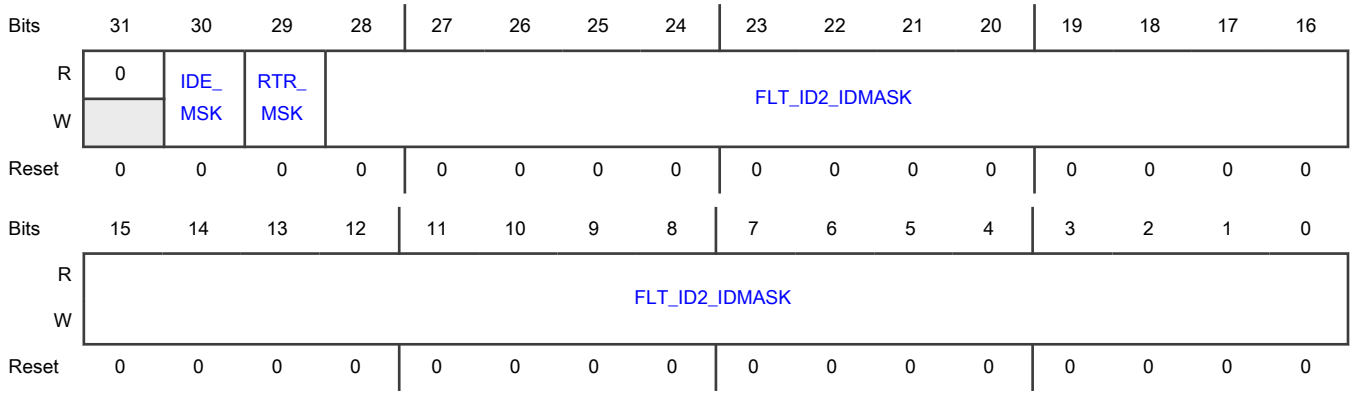
Offset

Register	Offset
FLT_ID2_IDMASK	B1Ch

Function

Contains FLT_ID2 target value used only as the upper limit value in ID range detection. When an exact ID filtering criterion is selected, this register stores the ID mask. IDE_MSK and RTR_MSK are used in both types of ID filtering (exact and range). These fields enable FLT_ID1[FLT_IDE] and FLT_ID1[FLT_RTR] to be used as part of the ID reception filter. This register can be written in Freeze mode only.

Diagram



Fields

Field	Function
31 —	Reserved
30 IDE_MSK	ID Extended Mask Indicates whether the frame format (standard or extended) is used as part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
29 RTR_MSK	Remote Transmission Request Mask Indicates whether the frame type (data or remote) is part of the ID reception filter. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.
28-0 FLT_ID2_IDMASK	ID Filter 2 for Pretended Networking Filtering or ID Mask Bits for Pretended Networking ID Filtering Defines filter values in range ID filtering: • Value in extended frame format (29 bits), considering FLT_ID2[28:0] • Value in standard frame format (11 bits), considering the FLT_ID2[28:18]. In this case, bits [17:0] are meaningless. Or, defines the mask values in exact ID filtering: • Values for extended frame format (29 bits), considering IDMASK[28:0] • Values for standard frame format (11 bits), considering IDMASK[28:18]. In this case, bits [17:0] are meaningless.

48.5.2.27 Pretended Networking Payload Low Filter 2 and Payload Low Mask (PL2_PLMASK_LO)

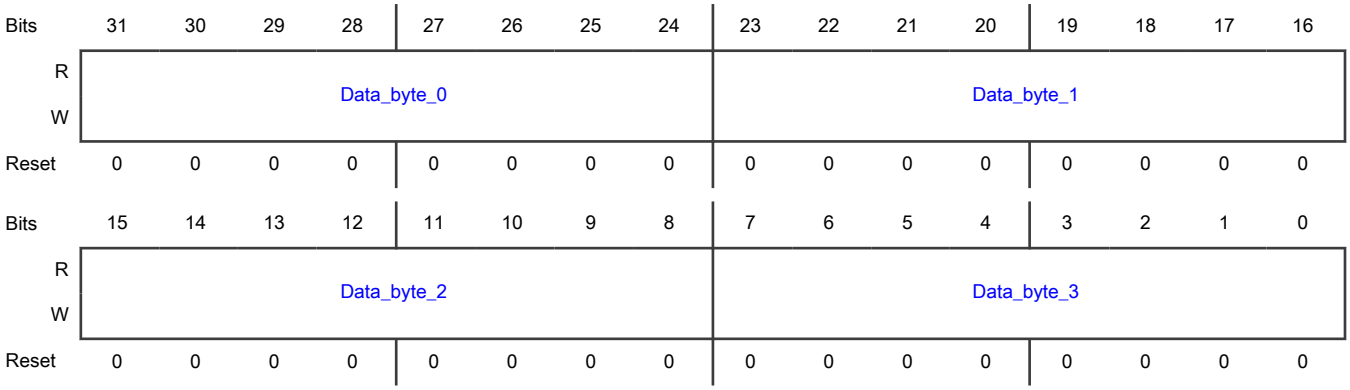
Offset

Register	Offset
PL2_PLMASK_LO	B20h

Function

Contains the low-order bits for Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the low-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 0
23-16 Data_byte_1	Data Byte 1 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 1
15-8 Data_byte_2	Data Byte 2 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 2
7-0 Data_byte_3	Data Byte 3 Contains payload filter 2 low-order bits, or Payload Mask low-order bits for PN payload filtering, corresponding to data byte 3

48.5.2.28 Pretended Networking Payload High Filter 2 and Payload High Mask (PL2_PLMASK_HI)

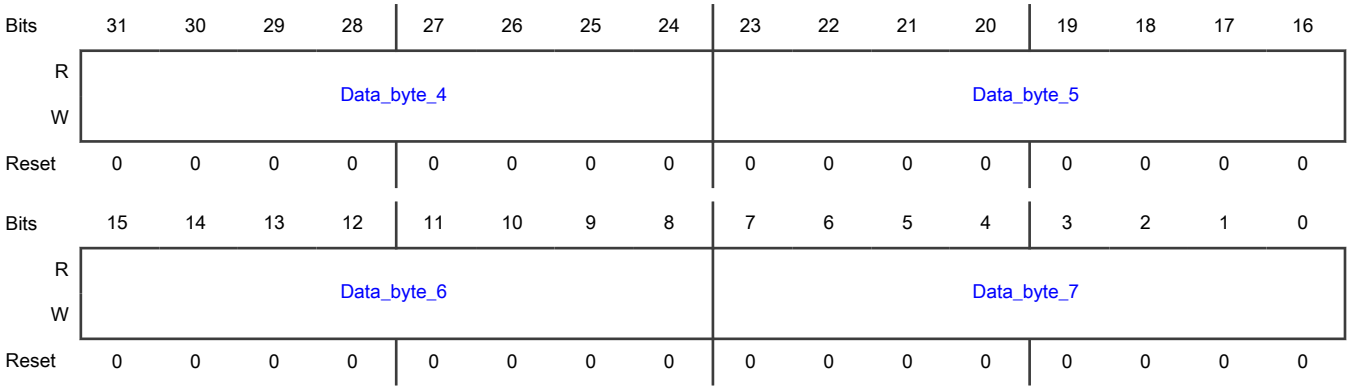
Offset

Register	Offset
PL2_PLMASK_HI	B24h

Function

Contains the high-order bits for the Payload Filter 2, used only as the upper limit value in a payload range detection. Also, when an exact payload filtering criterion is selected, this register is used as payload mask for the high-order bits. Otherwise, this register is unused. It can be written in Freeze mode only.

Diagram



Fields

Field	Function
31-24 Data_byte_4	Data Byte 4 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 4.
23-16 Data_byte_5	Data Byte 5 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 5.
15-8 Data_byte_6	Data Byte 6 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 6.
7-0 Data_byte_7	Data Byte 7 Contains payload filter 2 high-order bits, or Payload Mask high-order bits for PN payload filtering, corresponding to data byte 7.

48.5.2.29 Wake-Up Message Buffer (WMB0_CS - WMB3_CS)

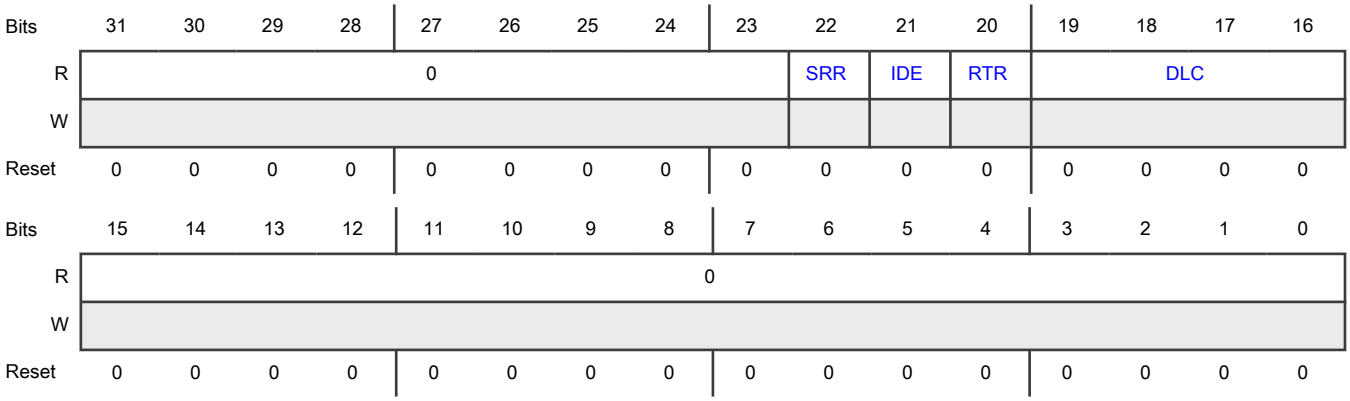
Offset

Register	Offset
WMB0_CS	B40h
WMB1_CS	B50h
WMB2_CS	B60h
WMB3_CS	B70h

Function

Stores the Control and Status information (IDE, RTR, and DLC fields) of an incoming RX message.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 SRR	Substitute Remote Request Identifies whether the request is dominant or recessive. This field is used only in extended format. You must write 1 to this field for transmission buffers. The value of this field is stored with the value received on the CAN bus for receiving buffers. If FlexCAN receives this field as dominant, it is interpreted as an arbitration loss. 0b - Dominant 1b - Recessive
21 IDE	ID Extended Bit Identifies whether the frame format is standard or extended.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Standard 1b - Extended
20 RTR	Remote Transmission Request Identifies whether the frame is remote or data 0b - Data 1b - Remote
19-16 DLC	Length of Data in Bytes Contains the length (in bytes) of the RX data received when FlexCAN is in Pretended Networking mode. FlexCAN writes this field, copied from the DLC (Data Length Code) field of the received frame. The DLC field indicates which data bytes are valid.
15-0 —	Reserved

48.5.2.30 Wake-Up Message Buffer for ID (WMB0_ID - WMB3_ID)

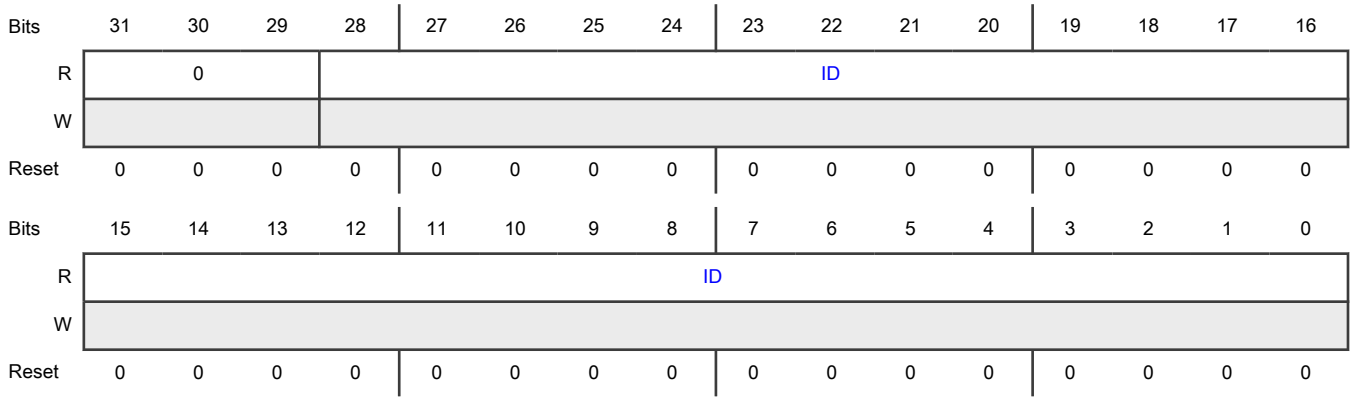
Offset

Register	Offset
WMB0_ID	B44h
WMB1_ID	B54h
WMB2_ID	B64h
WMB3_ID	B74h

Function

Stores the ID information of an incoming RX message.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-0 ID	Received ID in Pretended Networking Mode Stores the received ID, which is: • The 29 bits of the extended frame format (considering ID[28:0]) • The 11 bits of the standard frame format (considering ID[28:18] only; the remaining bits in the ID[17:0] range are meaningless).

48.5.2.31 Wake-Up Message Buffer for Data 0–3 (WMB0_D03 - WMB3_D03)

Offset

Register	Offset
WMB0_D03	B48h
WMB1_D03	B58h
WMB2_D03	B68h
WMB3_D03	B78h

Function

Stores data bytes 0–3 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Data_byte_0								Data_byte_1							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	Data_byte_2								Data_byte_3							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 Data_byte_0	Data Byte 0 Contains received payload corresponding to data byte 0 in Pretended Networking mode
23-16 Data_byte_1	Data Byte 1 Contains received payload corresponding to data byte 1 in Pretended Networking mode
15-8 Data_byte_2	Data Byte 2 Contains received payload corresponding to data byte 2 in Pretended Networking mode
7-0 Data_byte_3	Data Byte 3 Contains received payload corresponding to data byte 3 in Pretended Networking mode

48.5.2.32 Wake-Up Message Buffer Register Data 4–7 (WMB0_D47 - WMB3_D47)

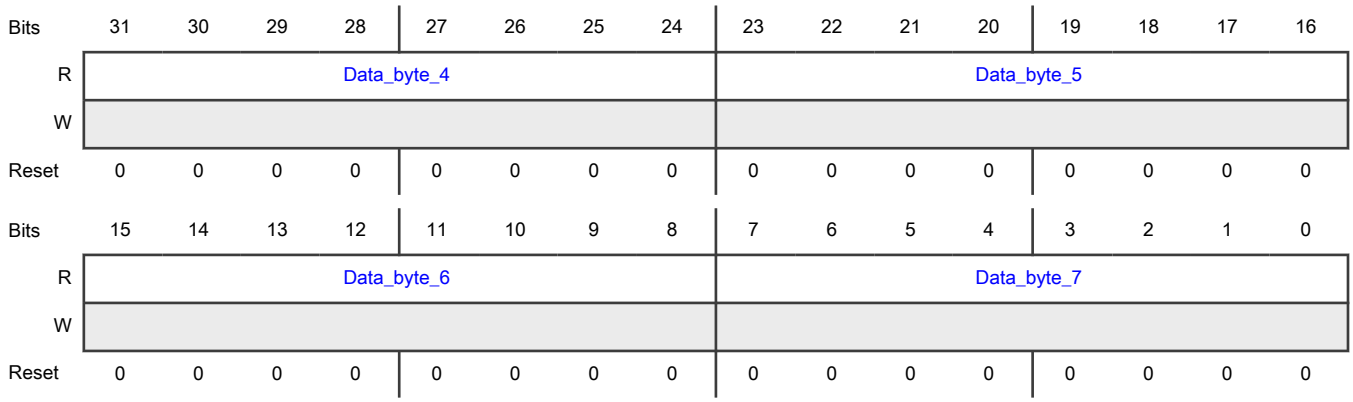
Offset

Register	Offset
WMB0_D47	B4Ch
WMB1_D47	B5Ch
WMB2_D47	B6Ch
WMB3_D47	B7Ch

Function

Stores the data bytes 4–7 of the payload information of an incoming RX message. The content of each register is cleared when the incoming matched message is either a remote frame (RTR = 1) or a data frame with DLC = 0.

Diagram



Fields

Field	Function
31-24 Data_byte_4	Data Byte 4 Contains received payload corresponding to data byte 4 in Pretended Networking mode
23-16 Data_byte_5	Data Byte 5 Contains received payload corresponding to data byte 5 in Pretended Networking mode
15-8 Data_byte_6	Data Byte 6 Contains received payload corresponding to data byte 6 in Pretended Networking mode
7-0 Data_byte_7	Data Byte 7 Contains received payload corresponding to data byte 7 in Pretended Networking mode

48.5.2.33 Enhanced CAN Bit Timing Prescalers (EPRS)

Offset

Register	Offset
EPRS	BF0h

Function

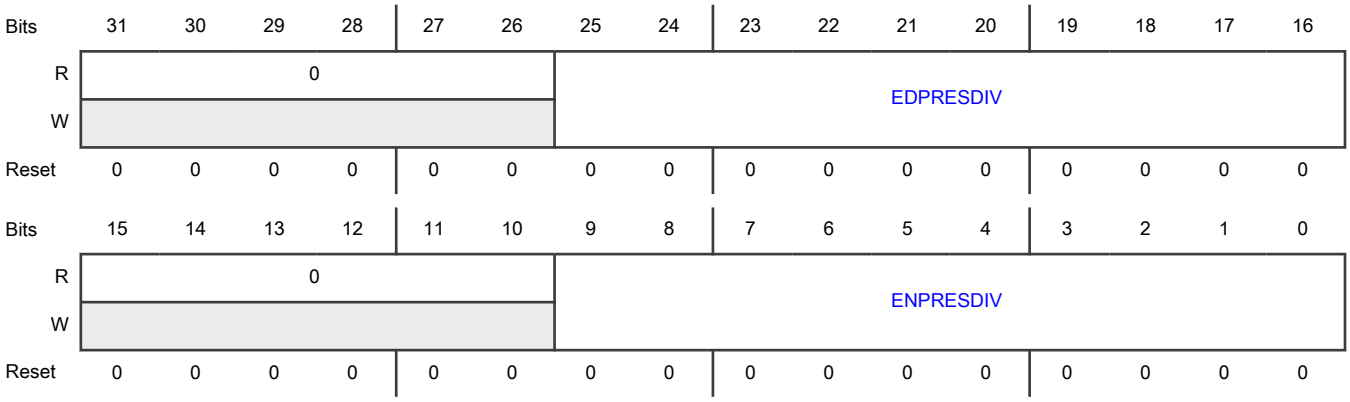
Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

48.5.2.34 Enhanced Nominal CAN Bit Timing (ENCBT)

Offset

Register	Offset
ENCBT	BF4h

Function

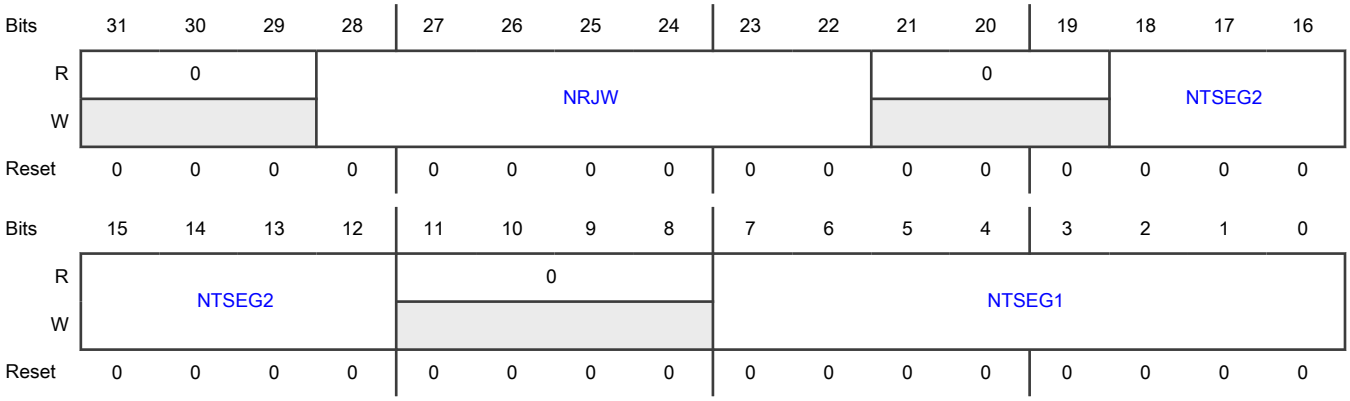
Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

48.5.2.35 Enhanced Data Phase CAN Bit Timing (EDCBT)

Offset

Register	Offset
EDCBT	BF8h

Function

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

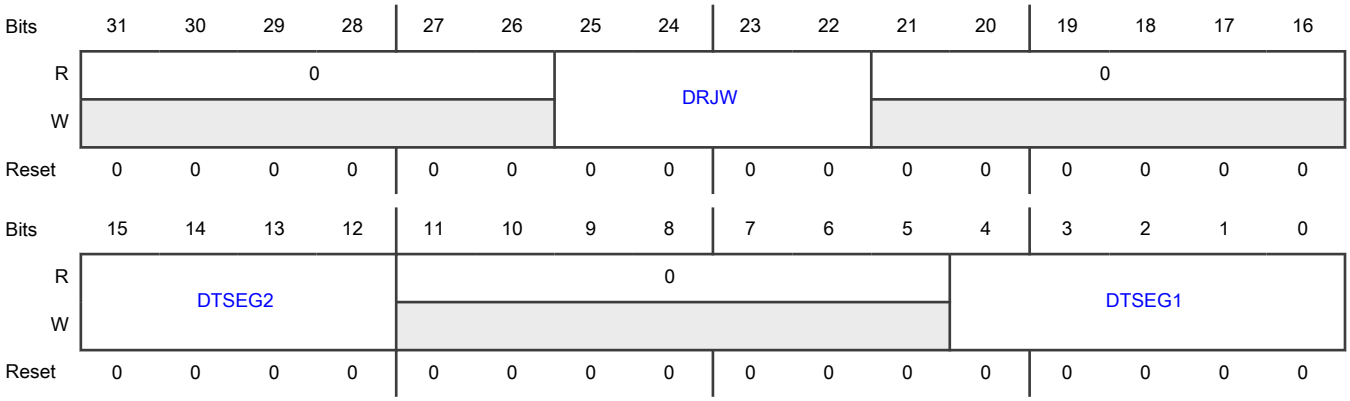
NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1:2015.

NOTE

DTSEG1 must be at least two time quanta.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

48.5.2.36 Enhanced Transceiver Delay Compensation (ETDC)

Offset

Register	Offset
ETDC	BFCh

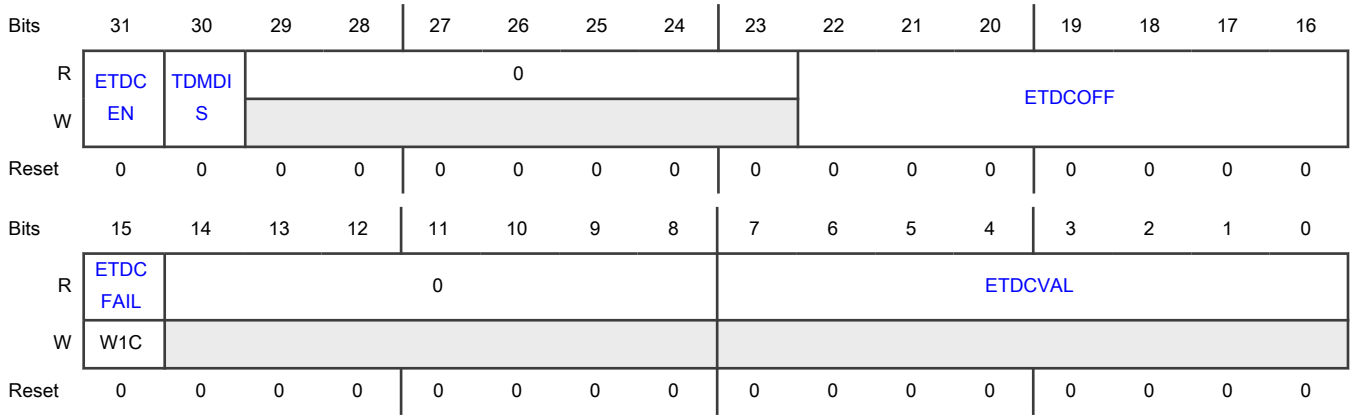
Function

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

NOTE

See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1:2015 for details.

Diagram



Fields

Field	Function
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1:2015 for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0b - Disable 1b - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0b - Enable 1b - Disable
29-23 —	Reserved
22-16	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Function
ETDCOFF	Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0b - In range 1b - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

48.5.2.37 CAN FD Control (FDCTRL)

Offset

Register	Offset
FDCTRL	C00h

Function

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 380.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

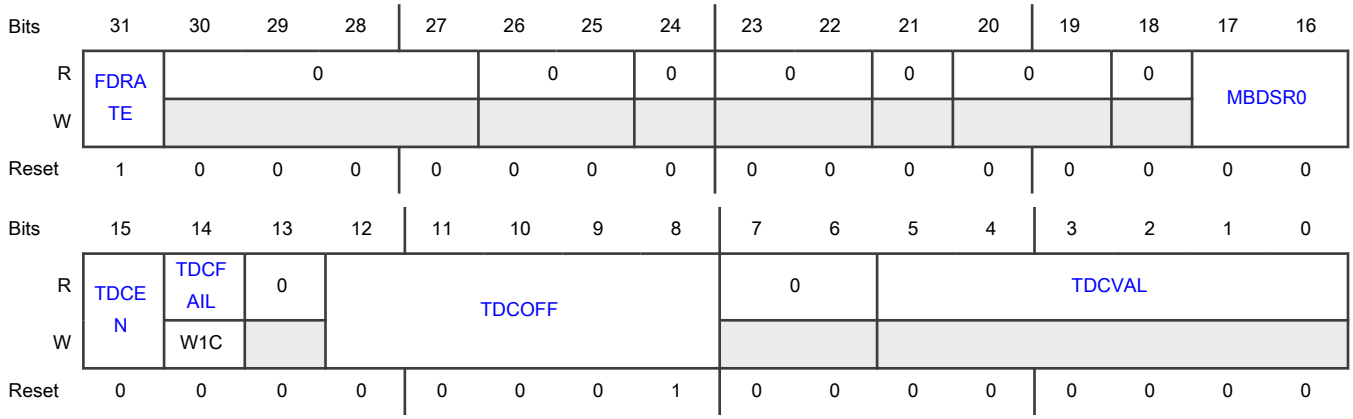
Table 380. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Diagram



Fields

Field	Function
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state. • The CAN bus is in the Bus Off state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0b - Disable 1b - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 —	Reserved
21 —	Reserved
20-19 —	Reserved
18 —	Reserved
17-16 MBDSR0	Message Buffer Data Size for Region 0 Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00b - 8 bytes 01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard ISO 11898-1:2015 for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - Disable 1b - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0b - In range 1b - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect. Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

48.5.2.38 CAN FD Bit Timing (FDCBT)

Offset

Register	Offset
FDCBT	C04h

Function

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

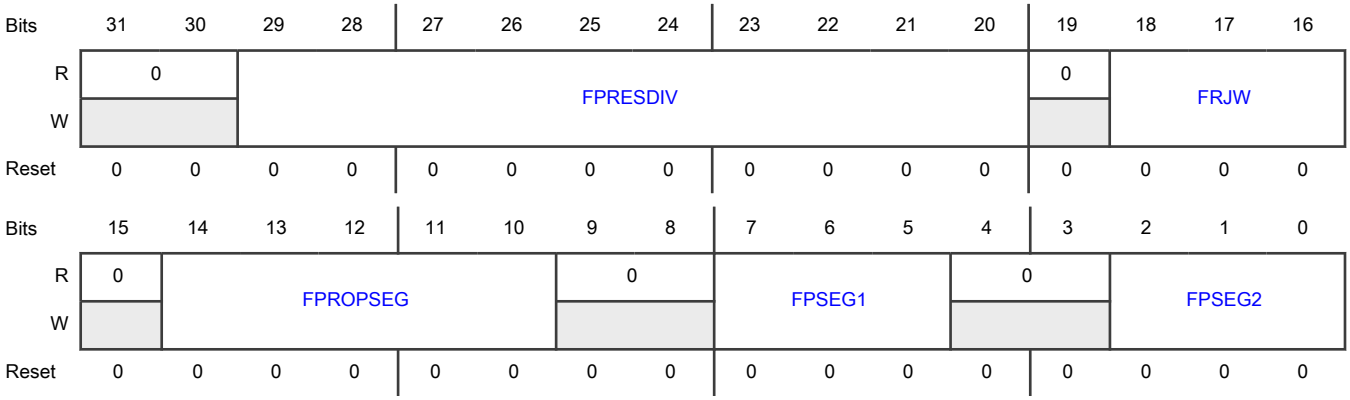
The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard ISO 11898-1:2015.

NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

48.5.2.39 CAN FD CRC (FDCRC)

Offset

Register	Offset
FDCRC	C08h

Function

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$\text{CRC_15} = \text{C599h}: \ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$\text{CRC_17} = \text{3685Bh}: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

$$\text{CRC_21} = \text{302899h}: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 24. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard ISO 11898-1:2015 for details.

R	FD_TXCRC															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

48.5.2.40 Enhanced RX FIFO Control (ERFCR)

Offset

Register	Offset
ERFCR	C0Ch

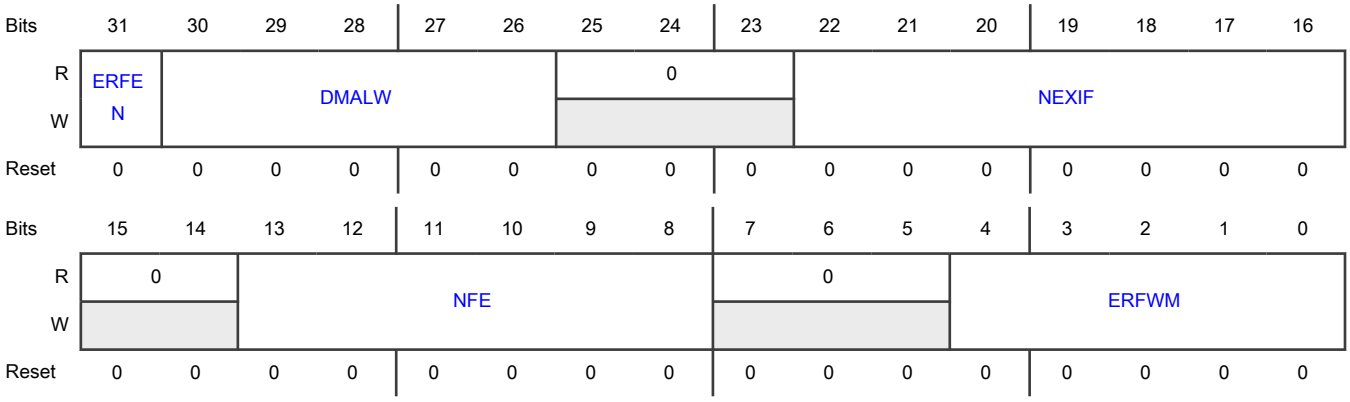
Function

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Diagram



Fields

Field	Function
31 ERFEN	Enhanced RX FIFO enable Enables the Enhanced RX FIFO. **NOTE** If MCR[RFEN] = 1, do not write 1 to this field. 0b - Disable 1b - Enable
30-26 DMALW	DMA Last Word Defines the last DMA address for each Enhanced RX FIFO element. This table shows the number of elements and the last address for each Enhanced RX FIFO element according to the value of DMALW.

DMALW	Number of 32-bit words transferred	Last FIFO address
0	1	2000h

Fields

Field	Function
31 ERFUFW	Enhanced RX FIFO Underflow Flag Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Overflow
29	Enhanced RX FIFO Watermark Indication Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERFWMI	Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0b - No such occurrence 1b - At least one message stored in Enhanced RX FIFO
27 ERFCLR	Enhanced RX FIFO Clear Writing 1 to this field during Freeze mode resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0b - No effect 1b - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0b - Not empty 1b - Empty
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0b - Not full 1b - Full
15 —	Reserved
14-6 —	Reserved
5-0	Enhanced RX FIFO Elements

Table continues on the next page...

Table continued from the previous page...

Field	Function
ERFEL	Indicates the number of CAN messages stored in the Enhanced RX FIFO.

48.5.2.43 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP31)

Offset

For n = 0 to 31:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

Function

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

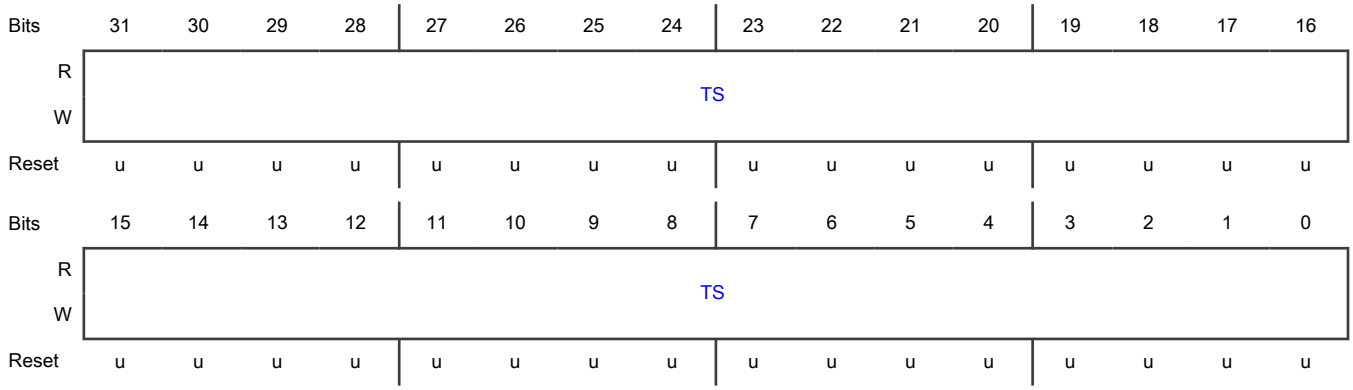
NOTE

Do not write to these registers outside Freeze mode.

Table 381. High-Resolution Timestamp register operation

TSTAMPCAP	Captured timebase	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

Diagram



Fields

Field	Function
31-0 TS	High-Resolution Timestamp Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value.

48.5.2.44 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31)

Offset

For n = 0 to 31:

Register	Offset
ERFFELn	3000h + (n × 4h)

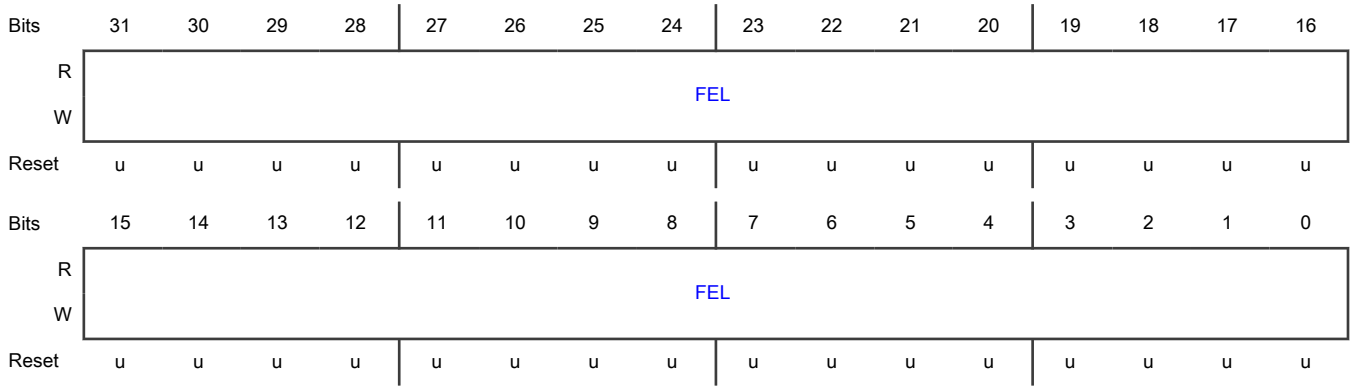
Function

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Diagram



Fields

Field	Function
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

48.5.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–27Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 382. Message buffer structure example with 64-byte payload

	31	30	29	28	27	24	23	22	21	20	19	18	17	16	15	8	7	0

Table 383. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 384).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 384 and Table 385. See Functional description.

Table 384. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer

Table continues on the next page...

Table 384. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
					is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
					request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or another message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.
3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 385. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.

Table continues on the next page...

Table 385. Message buffer code for TX buffers (continued)

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 386. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 384, Table 385, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

Table continues on the next page...

Table 386. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
		1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 382). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 388).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus. See Table 387 for Timestamp operation.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 388.

Table 387. Timestamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field

Table continues on the next page...

Table 387. Timestamp operation (continued)

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

48.5.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 389.

Table 389. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload

In this case, Table 390 indicates how the message buffers are arranged in RAM.

Table 390. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31

48.5.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

48.5.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 395. Legacy RX FIFO structure

	31 28 24	23	22	21	20	19 18 17 16	15 8	7 0
80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP	
84h		ID standard				ID extended		

Table continues on the next page...

Table 395. Legacy RX FIFO structure (continued)

88h	Data byte 0	Data byte 1	Data byte 2	Data byte 3
8Ch	Data byte 4	Data byte 5	Data byte 6	Data byte 7
90h–DCh	Reserved			
E0h	ID filter table element 0			
E4h	ID filter table element 1			
E8h–2D4h	ID filter table elements 2 to 125			
2D8h	ID filter table element 126			
2DCh	ID filter table element 127			
		= Unimplemented or reserved		

NOTE

Due to the limitation of the maximum number of MBs, the additional memory area starting at E0h and depending on the value of CTRL2[RFFN] can only extend up to 270h (usually occupied by MB 6-31), which contains the ID filter table (configurable from 8 to 104 table elements).

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAFs) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 396 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 396. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		
C	RXIDC_0 (std and ext = 31–24)		RXIDC_1 (std and ext = 23–16)		RXIDC_2 (std and ext = 15–8)		RXIDC_3 (std and ext = 7–0)		
			= Unimplemented or Reserved						

Table 397. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected.

Table continues on the next page...

Table 397. Field descriptions (continued)

Mnemonic	Field	Description
		0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

48.5.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 398. Enhanced RX FIFO structure

	31	30	29	28 … 24	23	22	21	20	19	18	17	16	15 … 8	7	6 … 0
2000h	EDL	BRS	ESI	Reserved		SRR	IDE	RTR	DLC				TIMESTAMP LEGACY		
2004h	Reserved			ID (standard/extended)									ID (extended)

14	2038h	203Ch
15	2048h	204Ch

Table 400. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format

Table continues on the next page...

Table 400. Field descriptions (continued)

Mnemonic	Field	Description
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 388 for more details.
LEGACY TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 387 for details about legacy timestamp operation.
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL31) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 401 shows how FlexCAN writes IDHIT according to each filter element.
HR TIMESTAMP	High-resolution Timestamp	32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp.

Table 401. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

48.6 Initialization and application information

48.6.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. If Pretended Networking mode is required, write 1 to MCR[PNET_EN].
    g. Enable the abort mechanism by writing 1 to MCR[AEN].
    h. Enable the local priority feature by writing 1 to MCR[LPRIOEN].
2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
    a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].

b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].

c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].

d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].

e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].

f. Determine the internal arbitration mode by programming CTRL1[LBUF].

3. Initialize the message buffers. (See Message buffer structure for message buffer details.)

   a. The control and status word of all message buffers must be initialized.

   b. If RX FIFO is enabled, the ID filter table must be initialized.

   c. Other entries in each message buffer should be initialized as required.

4. Initialize Receive Individual Mask (RXIMR0 - RXIMR31).

5. Write 1 to required interrupt mask bits in:

   - IMASK registers (for all message buffer interrupts)
   - Module Configuration (MCR) (for wake-up interrupt)
   - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)

6. If Pretended Networking mode is enabled, configure the necessary registers for selective wake-up.

7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

48.7 Glossary

Active message buffer	A message buffer is active if it can participate in the current matching or arbitration process.
Bus interface unit	FlexCAN submodule responsible for the interface to the CPU.
Bus off	See CAN Specification.[4]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[4] and ISO International Standard.[5]
CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[4]
Error frame	See CAN Specification.[4]
Error passive	See CAN Specification.[4]
Form error	See CAN Specification.[4]

[4] Controller Area Network - CAN Specification Version 2.0 Part A, Part B, Robert Bosch GmbH, 1991.
[5] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[4]
Information processing time	See CAN Specification.[4]
Intermission	See CAN Specification.[4]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[4]
Phase buffer segment	See CAN Specification.[4]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[4]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

49.1.1 Module instances

This device has one FlexIO module, FLEXIO0.

49.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.
- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

49.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

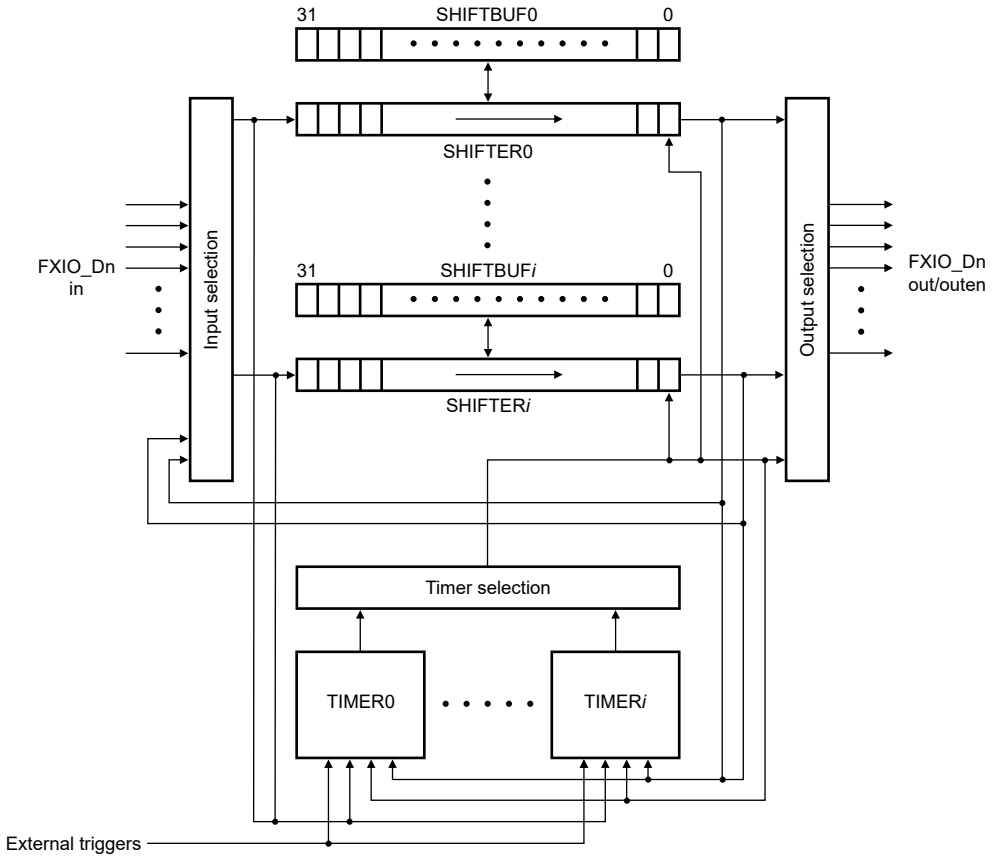

Figure 199. Block diagram

49.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:
  - Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during Stop mode
  - Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs
  - Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state
- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  - UART

— I2C

— SPI

— I2S

— Camera IF

— Motorola 68K or Intel 8080 bus

— PWM or waveform generation

— Input-capture (pulse-edge interval measurement), such as SENT

49.3 Functional description

49.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

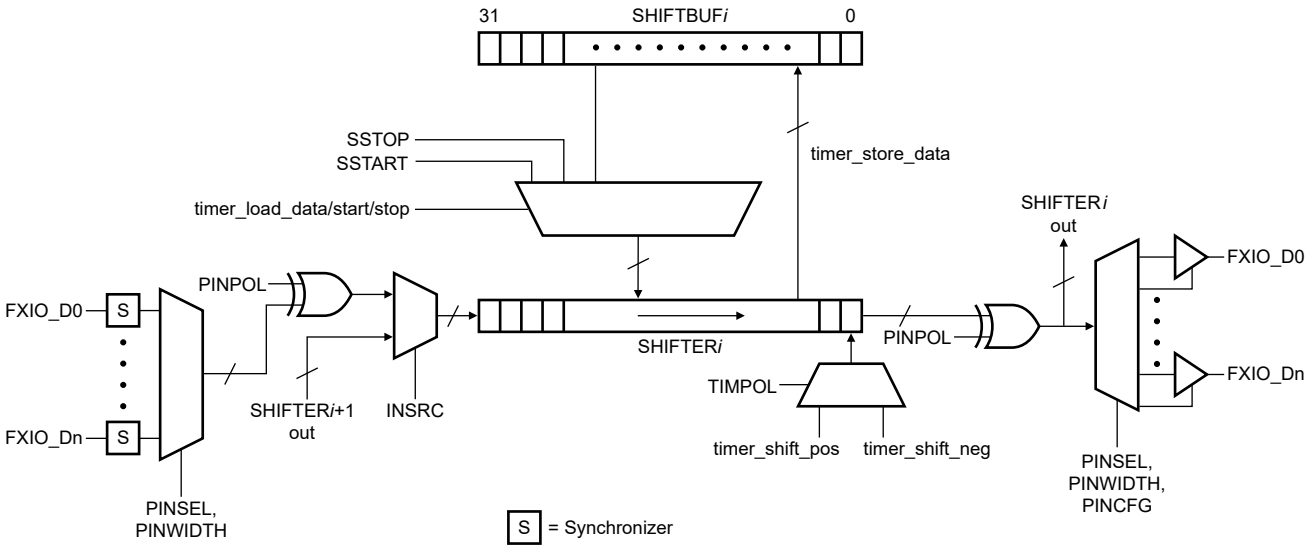

Figure 200. Shifter microarchitecture

49.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

49.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

49.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

49.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

49.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which can remain in a low-power mode.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

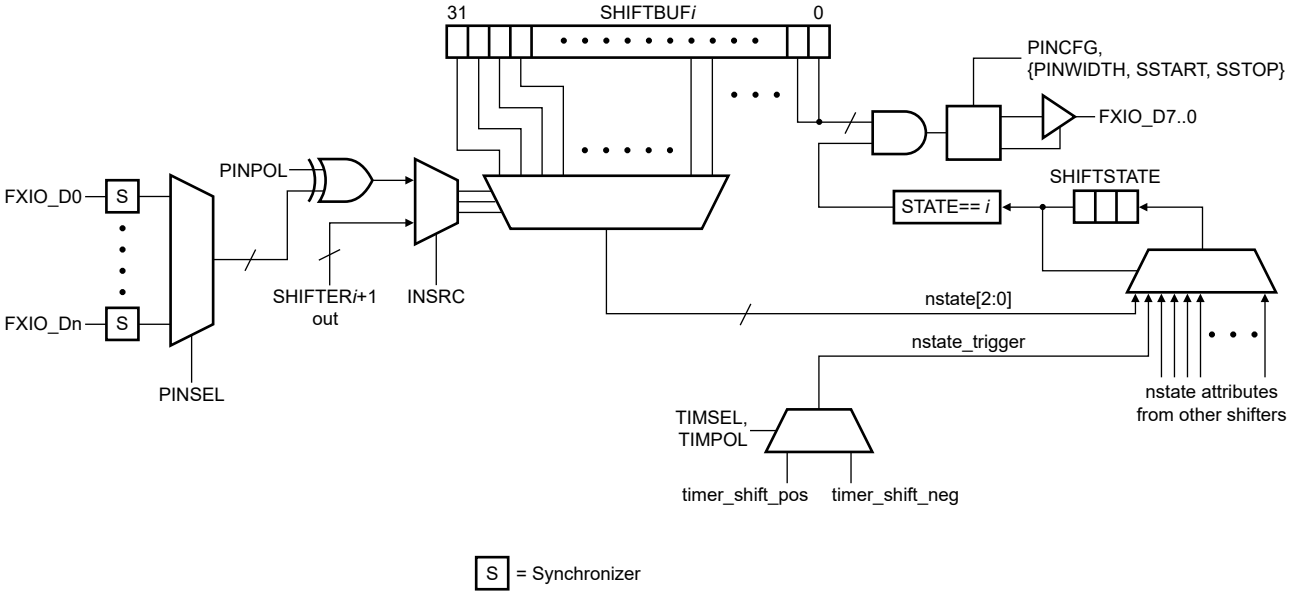

Figure 201. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 403. Next state computation for SHIFTSTATE[STATE] = *n*

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
0	0	0	SHIFTBUF*n*[2:0]
0	0	1	SHIFTBUF*n*[5:3]
0	1	0	SHIFTBUF*n*[8:6]
0	1	1	SHIFTBUF*n*[11:9]
...	...	...	...
1	1	1	SHIFTBUF*n*[23:21]

NOTE

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

49.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

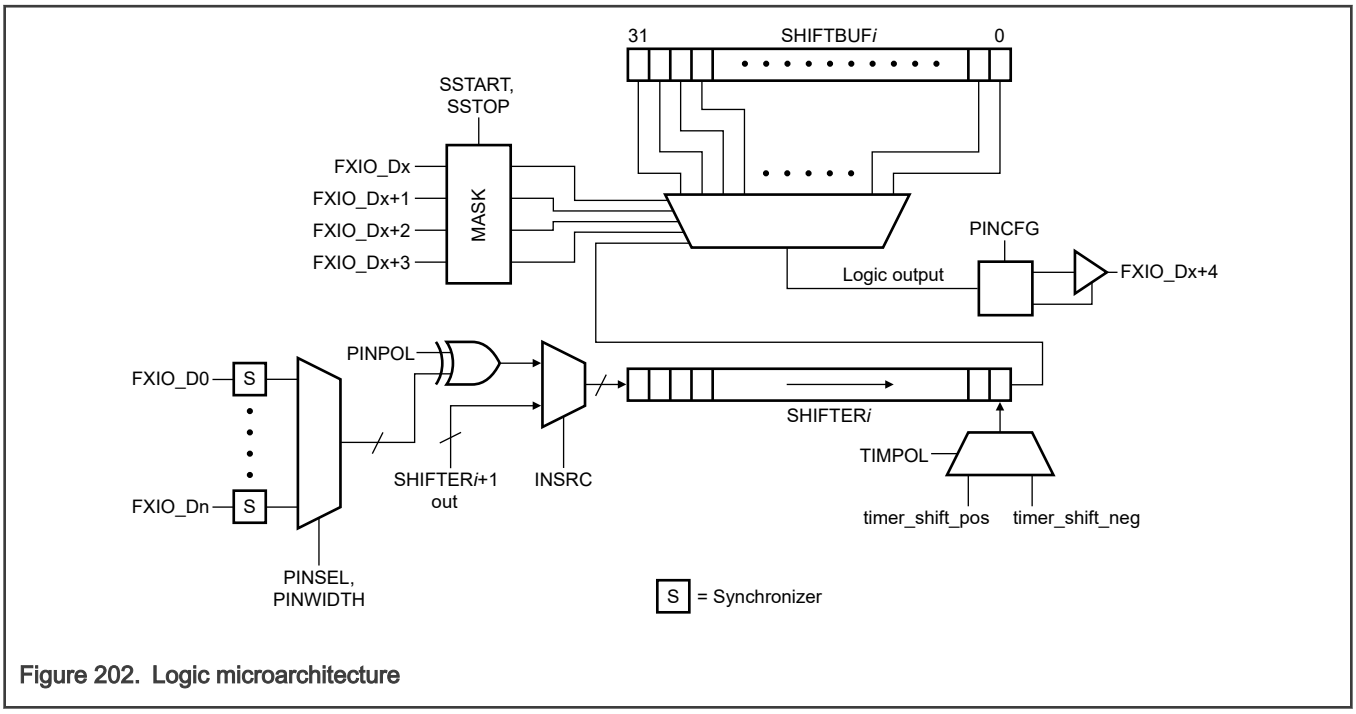

Figure 202. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 404. Logic lookup table for shifter *n*

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]

Table continues on the next page...

Table 404. Logic lookup table for shifter *n* (continued)

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

49.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

49.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

49.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

49.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

49.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

49.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

49.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare

register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

49.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

49.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

49.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

49.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

When more than one shifter or timer is configured to use the same pin for output data, then the output data to the pin is combined using an OR function. This also applies if more than one timer or shifter is configured to use the same pin for output enable.

49.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

49.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

49.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

49.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

49.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if CTRL[DOZEN] is 0 and the FLEXIO functional clock remains enabled.

The exception to this is in Deep Sleep mode. In this case, CTRL[DOZEN] is ignored and FLEXIO waits for all timers to complete any pending operation before acknowledging Deep Sleep mode entry.

49.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

49.3.6 Clocking

Table 405. FLEXIO clocks

Clock	Description
Functional clock	Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses.
Bus clock	Is used only for bus accesses to the control and configuration registers.

49.3.7 Reset

Table 406. FLEXIO reset types

Reset	Description
Chip reset	Resets the FLEXIO logic and registers to their default states on chip reset.
Software reset	Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register.

49.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 407. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low-power wake-up
SHIFTSTAT[SSF]	Shifter status flag	Y	Y	Y
SHIFTERR[SEF]	Shifter error flag	Y	N	Y
TIMSTAT[TSF]	Timer status flag	Y	Y	Y
PINSTAT[PSF]	Pin status flag	Y	N	Y
TRGSTAT[ETSF]	External trigger status flag	Y	N	Y

49.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

49.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

49.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

49.4 External signals

Table 408. External signals

Signal	Description	Direction
FXIO_D*n* (*n* = 0...31)	Bidirectional FLEXIO shifter and timer pin	Input or output

49.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).
3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

49.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

49.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 409. UART transmit configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.

Table continues on the next page...

Table 409. UART transmit configuration (continued)

Register	Value	Configuration
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h.
TIMCTL*n*	01C0_0001h	Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 410. UART transmit configuration for slow baud rate

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.

Table continues on the next page...

Table 410. UART transmit configuration for slow baud rate (continued)

Register	Value	Configuration
TIMCTL*n*	0740_0003h	Configure the 16-bit counter using the timer 1 output as an internal trigger source.
TIMCMP(*n* + 1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock, and configure TIMCMP[15:0] as (baud rate divider ÷ 2) - 1.
TIMCFG(*n* + 1)	0000_1200h	Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS.
TIMCTL(*n* + 1)	01C0_0003h	Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

49.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 411. UART receiver configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set

Table continues on the next page...

Table 411. UART receiver configuration (continued)

Register	Value	Configuration
		TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin positive edge and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	0000_0081h	Configure the dual 8-bit counter using the inverted pin 0 input.
SHIFTBUF*n*	Data to receive	You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 412. UART receiver with RTS configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.

Table continues on the next page...

Table 412. UART receiver with RTS configuration (continued)

Register	Value	Configuration
TIMCFG(*n* + 1)	0030_6100h	Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n* + 1)	0143_0003h	Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag.
SHIFTBUF*n*	Data to receive	You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

49.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

NOTE

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 413. SPI controller (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the negative edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the positive edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.

Table continues on the next page...

Table 413. SPI controller (CPHA = 0) configuration (continued)

Register	Value	Configuration
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using the inverted pin 3 output as target select.
SHIFTBUF*n*	Data to transmit	You can write transmit data to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

Table 414. SPI controller (CPHA = 1) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0021h	Start bit loads data on first shift.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the negative edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits x 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.

Table continues on the next page...

Table 414. SPI controller (CPHA = 1) configuration (continued)

Register	Value	Configuration
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using pin 2 output (shift clock), with the shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using inverted pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

49.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 415. SPI target (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the falling edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the rising edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0120_0600h	Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

TIMCFG*n*	0120_6602h	Configure start bit, enable on trigger rising edge, disable on trigger falling edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

49.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

NOTE

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

Table 417. I2C controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0.
SHIFTCFG(*n* + 1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n* + 1)	0180_0001h	Configure receive using timer 1 on the falling edge of clock with input data on pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger.
TIMCMP(*n* + 1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1.
TIMCFG(*n* + 1)	0020_1112h	Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input.
TIMCTL(*n* + 1)	01C0_0183h	Configure 16-bit counter using inverted pin 1 input (SCL).

49.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 418. I2S controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.

SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the falling edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted pin 2 output (bit clock), with

Table continues on the next page...

Table 418. I2S controller configuration (continued)

Register	Value	Configuration
		shifter 0 flag as the inverted trigger. Write 0 to the PINPOL field to invert the polarity of the output shift clock.
TIMCMP(*n* + 1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1.
TIMCFG(*n* + 1)	0000_0100h	Enable when timer 0 is enabled and never disable.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.

49.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 419. I2S target configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0180_0101h	Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger.
TIMCMP(*n* + 1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG(*n* + 1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(*n* + 1)	0340_0283h	Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger.
TIMCMP(*n* + 2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n* + 2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).
TIMCTL(*n* + 2)	04C0_0383h	Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written

Table continues on the next page...

Table 419. I2S target configuration (continued)

Register	Value	Configuration
		using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer.

49.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 420. SENT receiver configuration

Register	Value	Configuration
TIMCMP*n*	—	Stores counter value at the falling edge of the pin.
TIMCFG*n*	0000_6000h	Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTL*n*	0040_0007h	Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger.

49.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 421. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Configuration
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using timer 0 on the negative edge of clock.
TIMCMP*n*	0000_001Fh	Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

1. *n* = 0 or 4

49.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

Example configurations are provided for 1-beat and 16-beat transfers. Other lengths are also supported.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 422. Motorola 68K and Intel 8080 write configuration

Register	Value	Configuration
SHIFTCFG0...7	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with data output to FXIO_D[15:0].
SHIFTCTL1...7	0000_0002h	Configure transmit using timer 0 on the positive edge of clock.

Table continues on the next page...

Table 422. Motorola 68K and Intel 8080 write configuration (continued)

Register	Value	Configuration
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of beats × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2200h	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	01C3_1001h (Motorola 68K, 1 beat) 1DC3_1001h (Motorola 68K, 16 beats) 01C3_1081h (Intel 8080, 1 beat) 1DC3_1081h (Intel 8080, 16 beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with shifter 0 (1-beat) or shifter 7 (16 beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer; use the shifter status flag to indicate when data can be written using interrupt or DMA request.

Table 423. Motorola 68K and Intel 8080 read configuration

Register	Value	Configuration
SHIFTCFG0...6	000F_0100h	Configure 16-bit parallel shift in from the adjacent shifter.
SHIFTCFG7	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0080_0001h	Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats) 1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080), with shifter 7 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger.

Table continues on the next page...

Table 423. Motorola 68K and Intel 8080 read configuration (continued)

Register	Value	Configuration
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

49.6.11 Low-power state machine

Table 424 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Throughout this operation, the CPU can be kept in a stop or VLPS mode by writing 0 to CTRL[DOZEN] and ensuring that FLEXIO_CLK is enabled. Figure 203 shows the states and transitions implemented by this example.

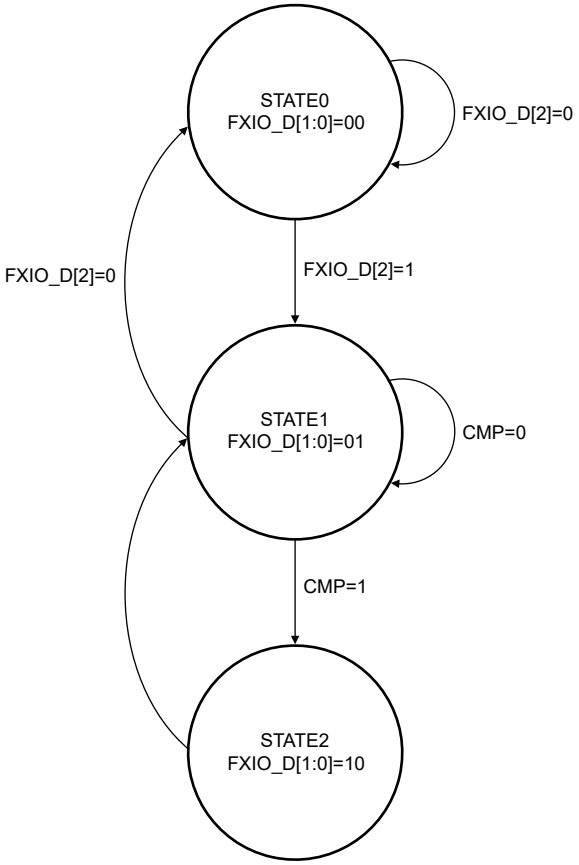

Figure 203. State diagram

Table 424. State machine configuration

Register	Value	Configuration
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1).

Table continues on the next page...

Table 424. State machine configuration (continued)

Register	Value	Configuration
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low.
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

49.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 425. Keypad interface configuration

Register	Value	Configuration
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern; each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In Logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure Logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care).
TIMCMP0	0000_00ffh	Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using the shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure four shifts at half the frequency of the timer 1 trigger.

Table continues on the next page...

Table 425. Keypad interface configuration (continued)

Register	Value	Configuration
TIMCFG2	0110_2100h	Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset.
TIMCTL2	0740_0001h	Configure dual 8-bit counter using timer 1 output as the trigger.
SHIFTBUF3	Keypad scan result	Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request.

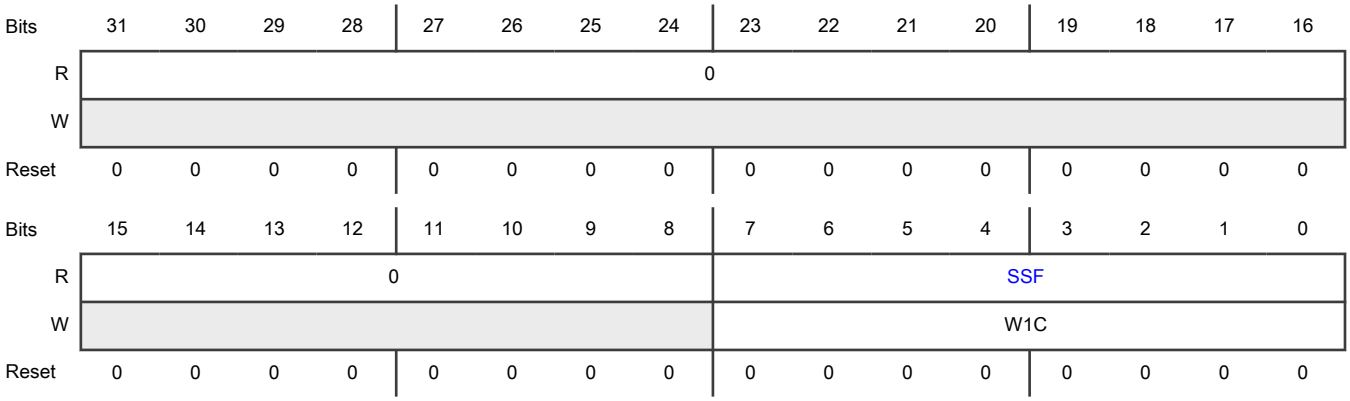
SHIFTSTAT	10h

Function
Contains shifter status flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag Indicates the shifter status. This flag is updated in one of the following cases: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), the status flag is set when SHIFTBUF is loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), the status flag is set when SHIFTBUF data is transferred to the shifter (SHIFTBUF is empty) or when SHIFTCTL*n*[SMOD] is initially configured as 010b (Transmit mode). The status flag is cleared when you write to the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), the status flag is set when a match occurs between SHIFTBUF and the shifter. The status flag is cleared when you read the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the status flag returns the current match result between SHIFTBUF and the shifter. You cannot clear the status flag by reading the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 110b (State mode), the status flag for a shifter sets when it is selected by the current state pointer. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the status flag returns the current value of the programmable logic block output. You can clear this status flag by writing a logic one to the flag for all modes except Match Continuous mode, State mode, and Logic mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

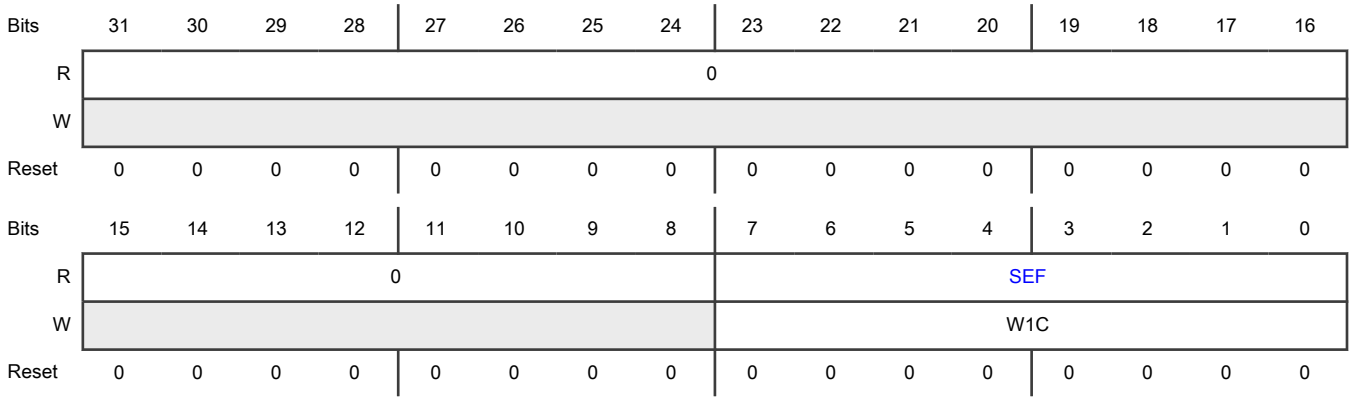
49.7.1.7 Shifter Error (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
Reports shifter errors.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flag Indicates shifter error flag status. This flag is set when one of the following events occurs: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), it indicates that either the shifter is ready to store new data into SHIFTBUF before the previous data is read from SHIFTBUF (SHIFTBUF overrun), or the received start or stop bit does not match the expected value. • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), it indicates that the shifter is ready to load new data from SHIFTBUF before new data is written into SHIFTBUF (SHIFTBUF underrun). • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), it indicates the occurrence of a match event before the previous match data is read from SHIFTBUF (SHIFTBUF overrun). • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the error flag is set when a match occurs between SHIFTBUF and the shifter. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the error flag is set when the output of the programmable logic block is asserted. For SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the flag can also be cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

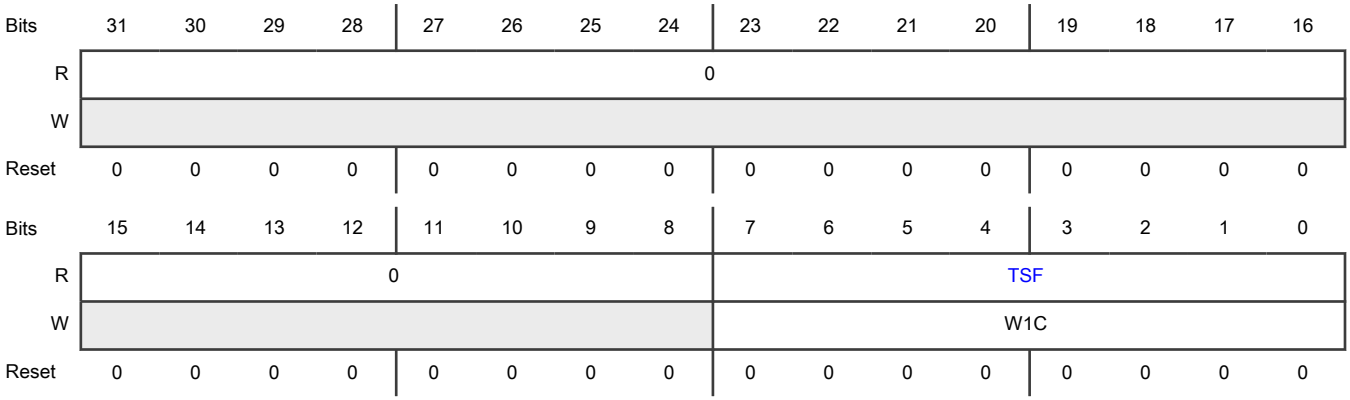
49.7.1.8 Timer Status Flag (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function
Reports timer status.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flag Indicates timer status. This flag is set depending on Timer mode: • In 8-bit baud counter mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 8-bit high PWM mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 16-bit counter mode, this flag is set when the 16-bit counter equals zero and decrements. • In 16-bit counter disable mode, TSF is set when a timer disable event is detected. • In 8-bit word counter mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 8-bit low PWM mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 16-bit input capture mode, TSF is set when a timer disable event is detected and the flag is clear. In this mode, you must read Timer Control (TIMCTL0 - TIMCTL7) only when TSF is set. **NOTE** This field behaves differently for register reads and writes.

Field	Function
	0b - Disable 1b - Enable

49.7.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

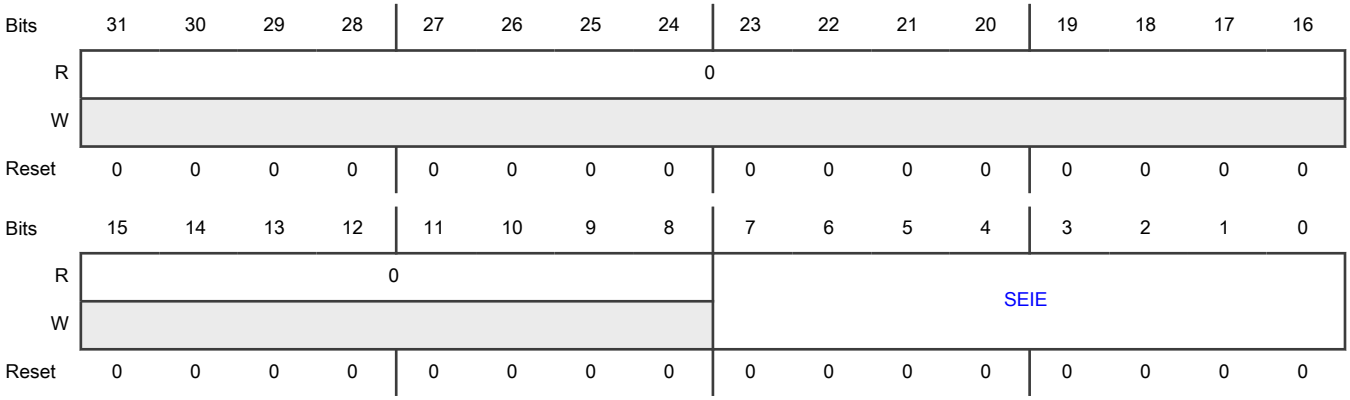
Offset

Register	Offset
SHIFTEIEN	24h

Function

Enables shifter error interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when the corresponding SHIFTERR[SEF] flag is set. If you write 0 to this field, SHIFTERR[SEF] is disabled; and if you write 1 to this field, SHIFTERR[SEF] is enabled. 0b - Disable 1b - Enable

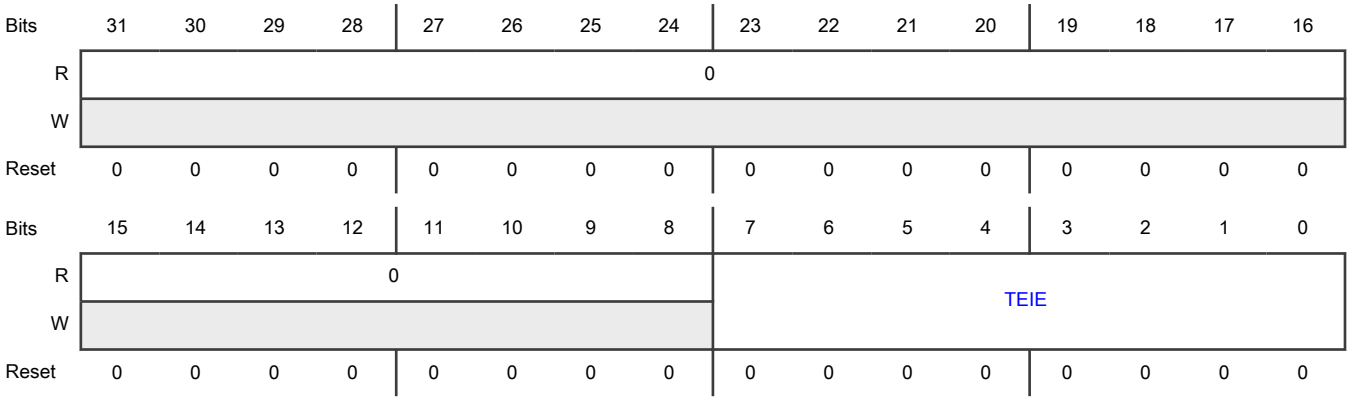
49.7.1.11 Timer Interrupt Enable (TIMIEN)

Offset

Register	Offset
TIMIEN	28h

Function
Enables timer status interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when the corresponding TIMSTAT[TSF] flag is set. If you write 0 to this field, TIMSTAT[TSF] is disabled; and if you write 1 to this field, TIMSTAT[TSF] is enabled. 0b - Disable 1b - Enable

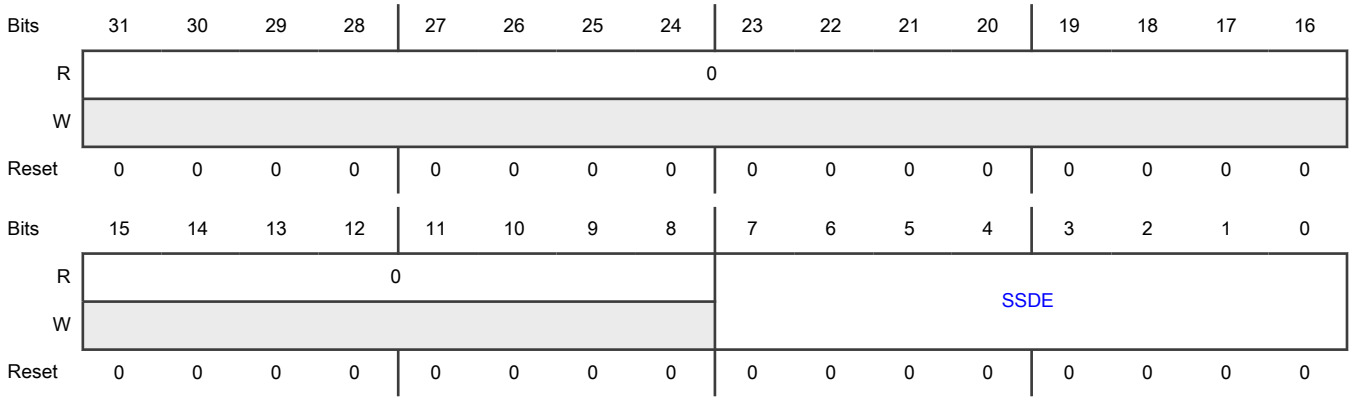
49.7.1.12 Shifter Status DMA Enable (SHIFTSDEN)

Offset

Register	Offset
SHIFTSDEN	30h

Function
Enables shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled. 0b - Disable 1b - Enable

49.7.1.13 Timer Status DMA Enable (TIMERSDEN)

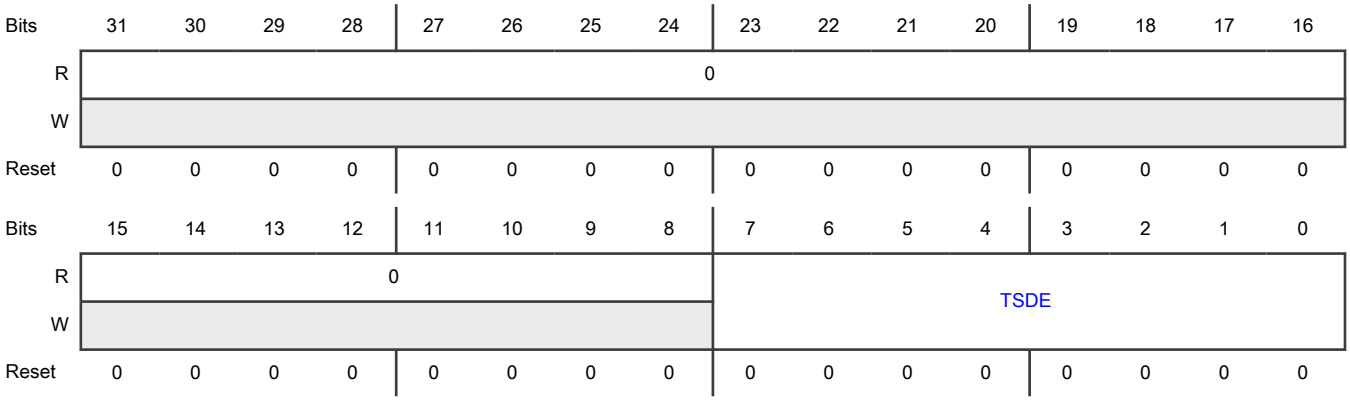
Offset

Register	Offset
TIMERSDEN	38h

Function

Enables DMA requests when the timer status flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when the corresponding TIMSTAT[TSF] flag is set. When the timer status DMA request is enabled, reading or writing to a timer compare register clears the corresponding timer status register. The DMA must therefore read or write to the timer compare register as part of the DMA transfer; otherwise, the DMA request remains asserted. 0b - Disable 1b - Enable

49.7.1.14 Shifter State (SHIFTSTATE)

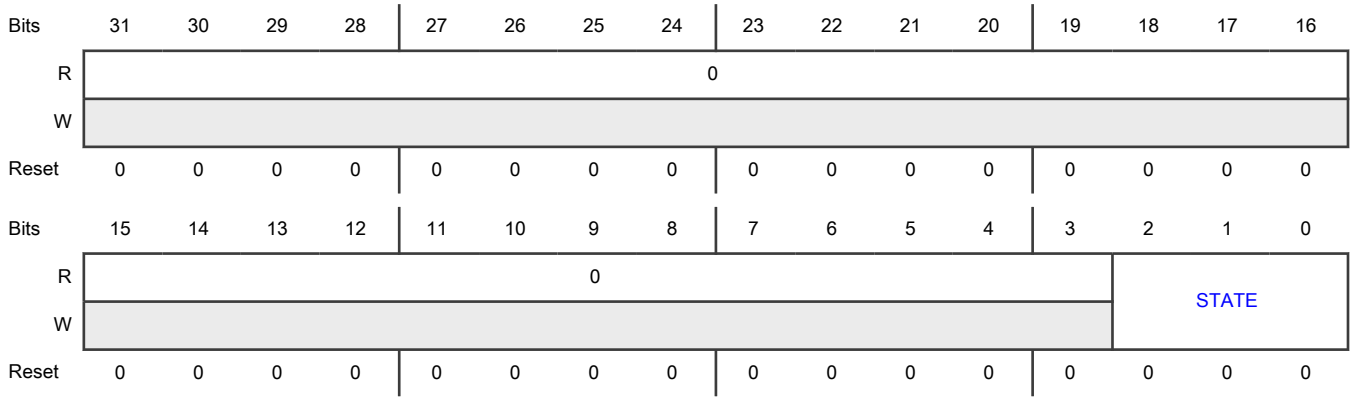
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains a pointer to track the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer Maintains a pointer to track the current shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the return of an incorrect state. The value that you write to this field overrides the current state.

49.7.1.15 Trigger Status (TRGSTAT)

Offset

Register	Offset
TRGSTAT	48h

Function

Contains external trigger status flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 ETSF	External Trigger Status Flag Specifies whether the external trigger status flag is set when a rising edge is detected on the corresponding external trigger input. **NOTE** This field behaves differently for register reads and writes. When reading 0000b - Clear 0001b - Set When writing 0000b - No effect 0001b - Clear the flag

49.7.1.16 External Trigger Interrupt Enable (TRIGIEN)

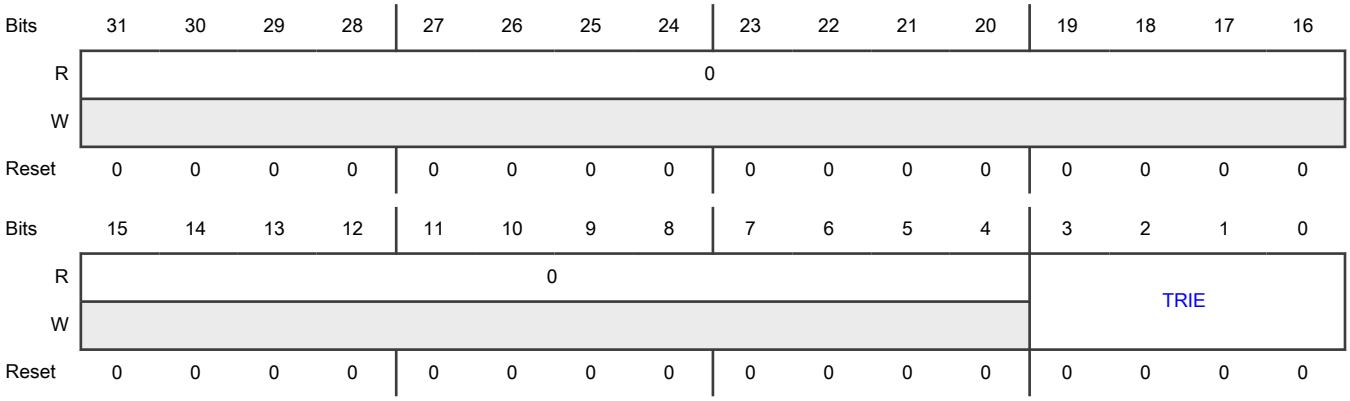
Offset

Register	Offset
TRIGIEN	4Ch

Function

Enables external trigger interrupts.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TRIE	External Trigger Interrupt Enable Enables interrupt generation when the corresponding TRGSTAT[ETSF] flag is set. If you write 0 to this field, TRGSTAT[ETSF] is disabled, and if you write 1 to this field, TRGSTAT[ETSF] is enabled. 0b - Disable 1b - Enable

49.7.1.17 Pin Status (PINSTAT)

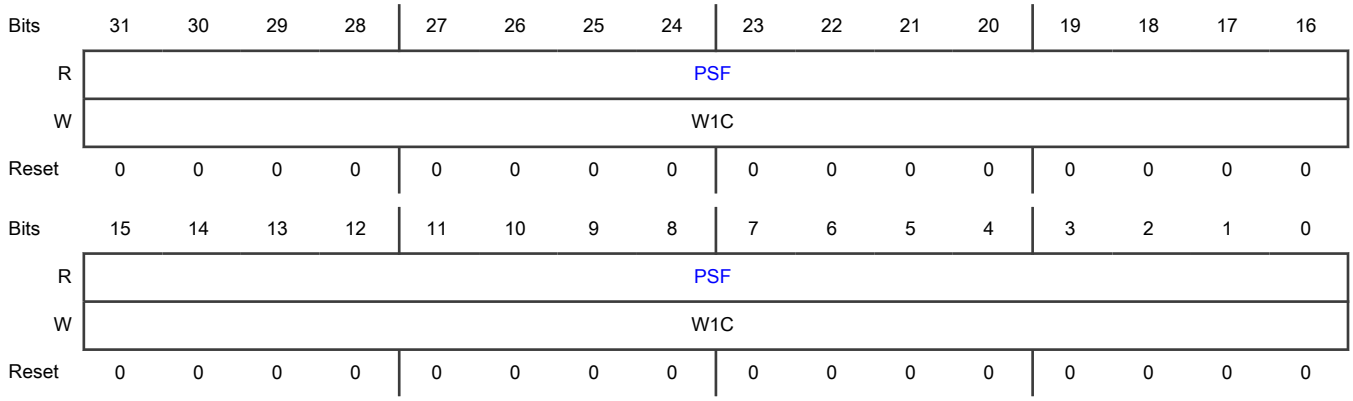
Offset

Register	Offset
PINSTAT	50h

Function

Contains pin status flags.

Diagram



Fields

Field	Function
31-0 PSF	Pin Status Flag Indicates whether the pin status flag is set when a rising edge or falling edge (if configured) is detected on the corresponding pin, as configured by the pin. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000_0000_0000_0000_0000b - Clear 0000_0000_0000_0000_0000_0000_0000_0001b - Set When writing 0000_0000_0000_0000_0000_0000_0000_0000b - No effect 0000_0000_0000_0000_0000_0000_0000_0001b - Clear the flag

49.7.1.18 Pin Interrupt Enable (PINIEN)

Offset

Register	Offset
PINIEN	54h

Function

Enables pin status interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 PRE	Pin Rising Edge Specifies whether the pin status flag is set whenever a rising edge is detected on the pin. 0b - Not set 1b - Set

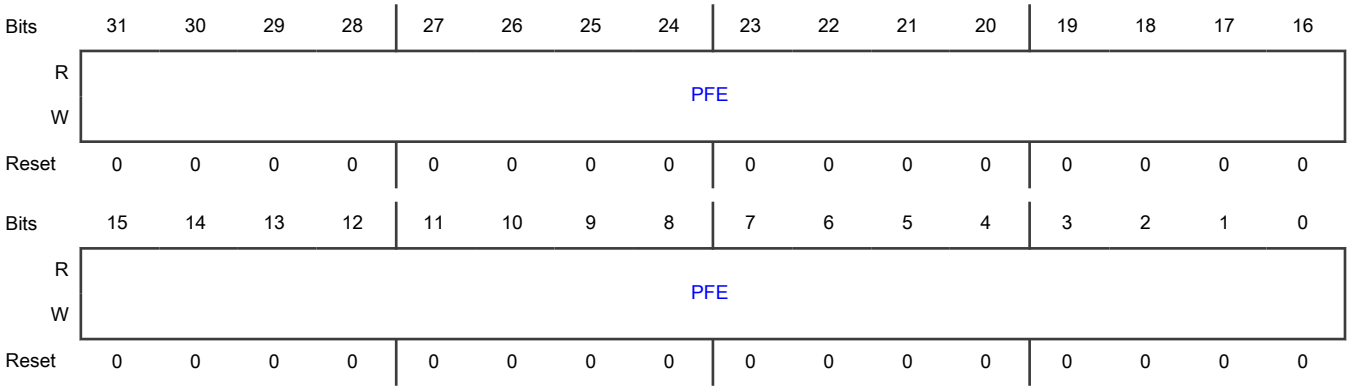
49.7.1.20 Pin Falling Edge Enable (PINFEN)

Offset

Register	Offset
PINFEN	5Ch

Function
Enables the pin status flag on a falling edge.

Diagram



Fields

Field	Function
31-0 PFE	Pin Falling Edge Specifies whether the pin status flag is set whenever a falling edge is detected on the pin. 0b - Not set 1b - Set

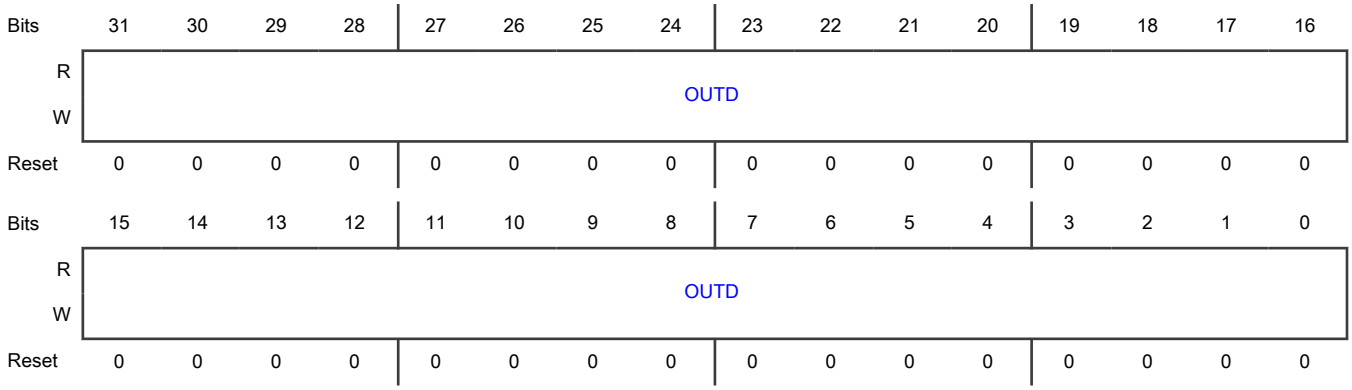
49.7.1.21 Pin Output Data (PINOUTD)

Offset

Register	Offset
PINOUTD	60h

Function
Contains data output when direct pin output is enabled.

Diagram



Fields

Field	Function
31-0 OUTD	Output Data Configures the value driven on the corresponding pin when direct pin output is enabled. 0b - Logic zero 1b - Logic one

49.7.1.22 Pin Output Enable (PINOUTE)

Offset

Register	Offset
PINOUTE	64h

Function
Enables pin output.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 OUTTOG	Output Toggle Configures the corresponding pins to toggle. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) is inverted and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD is inverted; corresponding field in PINOUTE becomes 1

49.7.1.27 Shifter Control (SHIFTCTL0 - SHIFTCTL7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Function

Provides shifter controls.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				TIMSEL				TIMPOL	0			PINCFG			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0				PINSEL				PINPOL	0			SMOD			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL = i selects TIMERi.
23 TIMPOL	Timer Polarity Determines whether the shift occurs on the positive edge or negative edge of the shift clock. 0b - Positive edge 1b - Negative edge
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration Specifies shifter pin configuration. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When initially configuring PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b and then perform a subsequent write to update the rest of the Control register with the value of PINCFG as 00b. 00b - Shifter pin output disabled 01b - Shifter pin open-drain or bidirectional output enable 10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-13 —	Reserved
12-8 PINSEL	Shifter Pin Select Selects the pin that is used by the shifter input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Shifter Pin Polarity Specifies the shifter pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to this register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active high 1b - Active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter. 000b - Disable 001b - Receive mode; capture the current shifter content into SHIFTBUF on expiration of the timer 010b - Transmit mode; load SHIFTBUF contents into the shifter on expiration of the timer 011b - Reserved 100b - Match Store mode; shifter data is compared to SHIFTBUF content on expiration of the timer 101b - Match Continuous mode; shifter data is continuously compared to SHIFTBUF contents 110b - State mode; SHIFTBUF contents store programmable state attributes 111b - Logic mode; SHIFTBUF contents implement programmable logic lookup table

49.7.1.28 Shifter Configuration (SHIFTCFG0 - SHIFTCFG7)

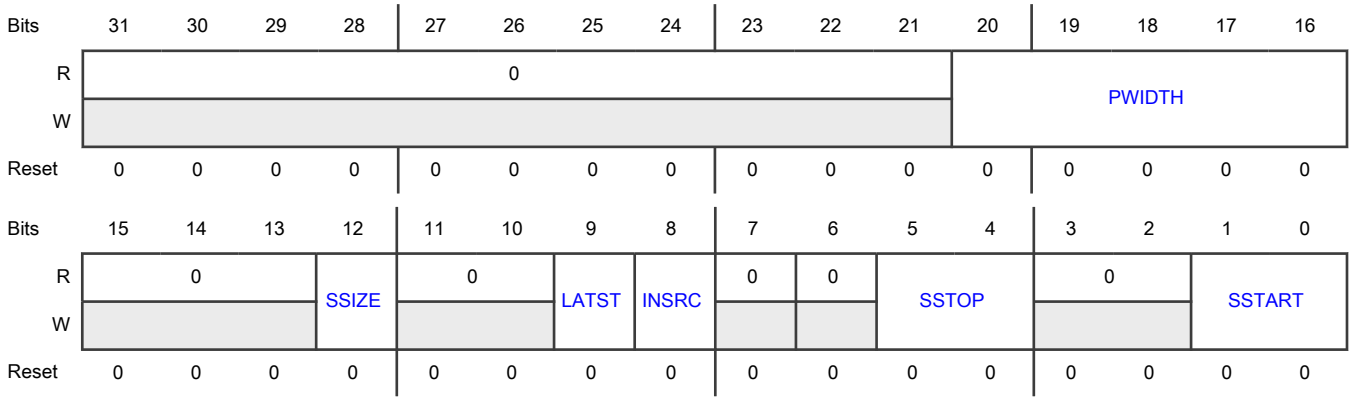
Offset

For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Function
Provides fields for shifter configuration.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 PWIDTH	Parallel Width Configures the number of bits to be shifted on each shift clock for all shifters: • 1-bit shift for PWIDTH = 0 • 2-bit shift for PWIDTH = 1 • 4-bit shift for PWIDTH = 2...3 • 8-bit shift for PWIDTH = 4...7 • 16-bit shift for PWIDTH = 8...15 • 32-bit shift for PWIDTH = 16...31 For shifters that support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with PINSEL, also selects the pins to be driven or sampled on each shift clock: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Shifters that do not support parallel transmit or parallel receive only support parallel shift when SHIFTCFG*n*[INSRC] = 1. If SHIFTCTL*n*[SMOD] = 110b (State mode), use this field to disable state outputs (see State mode).
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift registers. A 24-bit Shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations. When the Shift register is configured for a 24-bit shift, configuring PWIDTH as 8..15 performs a 12-bit shift and PWIDTH as 16..31 performs a 24-bit shift.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - 32-bit 1b - 24-bit
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match Shift register is configured to both shift and store on the same cycle. 0b - Store the pre-shift register state 1b - Store the post-shift register state
8 INSRC	Input Source Selects the input source for the shifter. Configuring this field as 1 is not supported for the last shifter. 0b - Pin 1b - Shifter n+1 output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop Allows automatic stop bit insertion, if the selected timer has also enabled a stop bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] is 1b or 100b (Receive mode or Match Store mode), this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] is 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Stop bit disabled for Transmitter, Receiver, and Match Store modes 01b - Stop bit disabled for Transmitter, Receiver, and Match Store modes; when timer is in stop condition, Receiver and Match Store modes store receive data on the configured shift edge 10b - Transmitter mode outputs stop bit value 0 in Match Store mode; if stop bit is not 0, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge) 11b - Transmitter mode outputs stop bit value 1 in Match Store mode; if stop bit is not 1, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)
3-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 SSTART	Shifter Start Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable 01b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift 10b - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag 11b - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag

49.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

Offset

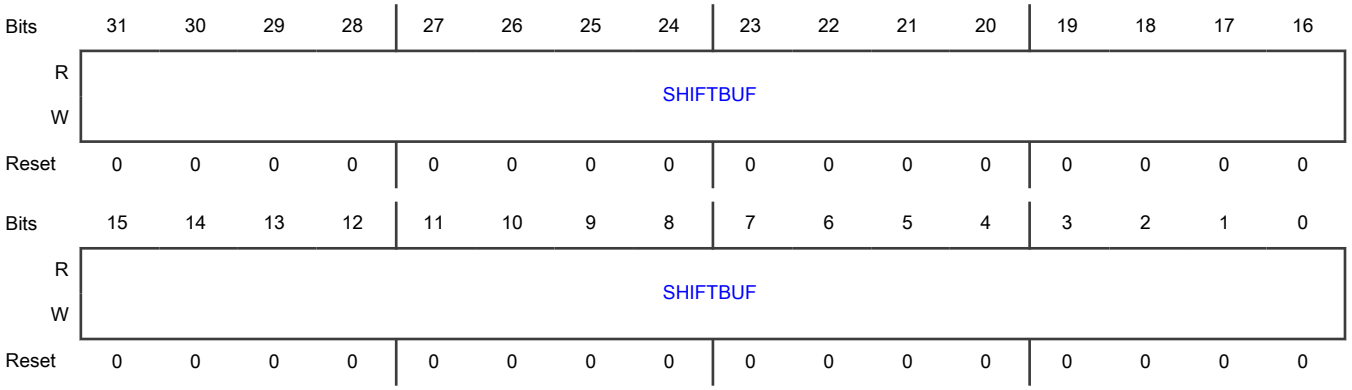
For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Function

Contains shift buffer data.

Diagram



Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]: • If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins. • If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). • If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode). • If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode).

49.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 SHIFTBUFBIS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31].

49.7.1.31 Shifter Buffer Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBYSn	300h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is byte-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

49.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Function

Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	SHIFTBUFBBS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), except that reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

49.7.1.33 Timer Control (TIMCTL0 - TIMCTL7)

Offset

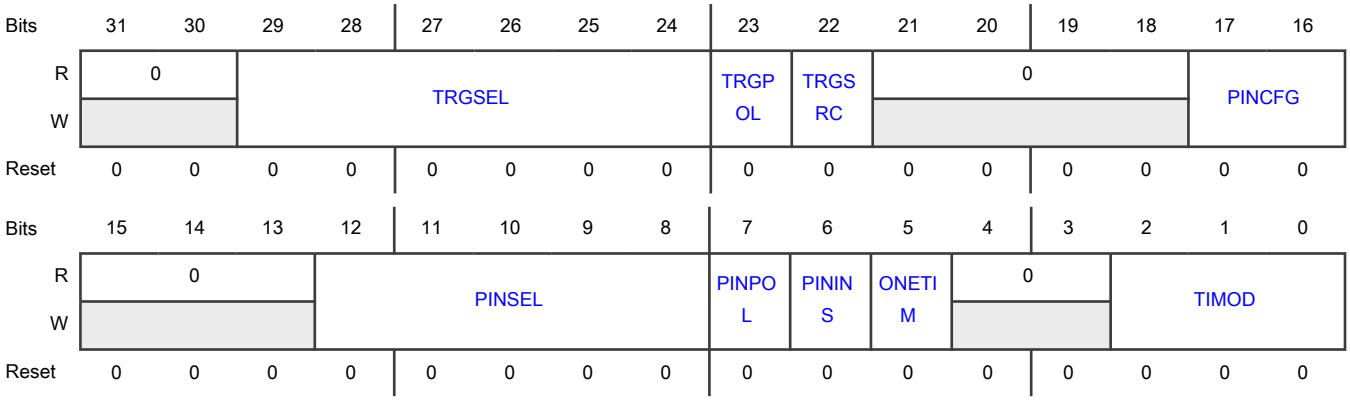
For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Function

Controls various settings for timer *n*.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 TRGSEL	Trigger Select Selects the trigger. The valid values for TRGSEL depend on the configuration of Parameter (PARAM): • If TRGSRC = 1, the valid values for *n* depend on the settings of PARAM[PIN], PARAM[TIMER], and PARAM[SHIFTER]. • If TRGSRC = 0, the valid values for *n* depend on PARAM[TRIGGER]. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, *n* = 0 to 31, for a shifter, *n* = 0 to 7, and for a timer, *n* = 0 to 7. If TRGSRC = 0, configure the trigger selection as *n* = external trigger *n* input. If TRGSRC = 1, you can configure the internal trigger to select an input pin as 2×*n* = pin *n* input. If TRGSRC = 1, you can configure the internal trigger to select a shifter or timer signal as: • 4×*n* + 1 = shifter *n* status flag • 4×*n* + 3 = timer *n* trigger output Following are the values for expanded internal trigger selection (TRGSRC = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000 = Pin 0 • 0001 = Shifter 0 flag • 0010 = Pin 1 • 0011 = Timer 0 trigger • 0100 = Pin 2 • 0101 = Shifter 1 flag • 0110 = Pin 3 • 0111 = Timer 1 trigger • ... • This continues up to pin 31, shifter 7, and timer 7.
23 TRGPOL	Trigger Polarity Specifies whether the trigger is active high or active low. 0b - Active high 1b - Active low
22 TRGSRC	Trigger Source Specifies whether the selected trigger source is external or internal. 0b - External 1b - Internal
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When you initially configure PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set the value of PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b, and then perform a subsequent write to update the rest of the Control register with PINCFG as 00b. 00b - Timer pin output disabled 01b - Timer pin open-drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12-8 PINSEL	Timer Pin Select Selects the pin that is used by the timer input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Timer Pin Polarity Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. 0b - Active high 1b - Active low
6 PININS	Timer Pin Input Select Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered. 0b - PINSEL selects timer pin input and output 1b - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL
5 ONETIM	Timer One Time Operation Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again. 0b - Generate the timer enable event as normal 1b - Block the timer enable event unless the timer status flag is clear
4-3 —	Reserved
2-0 TIMOD	Timer Mode Specifies the timer mode: • In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. • In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. • In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. • In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. • In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh. 000b - Timer disabled 001b - Dual 8-bit counters baud mode 010b - Dual 8-bit counters PWM high mode 011b - Single 16-bit counter mode 100b - Single 16-bit counter disable mode 101b - Dual 8-bit counters word mode 110b - Dual 8-bit counters PWM low mode 111b - Single 16-bit input capture mode

49.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Function

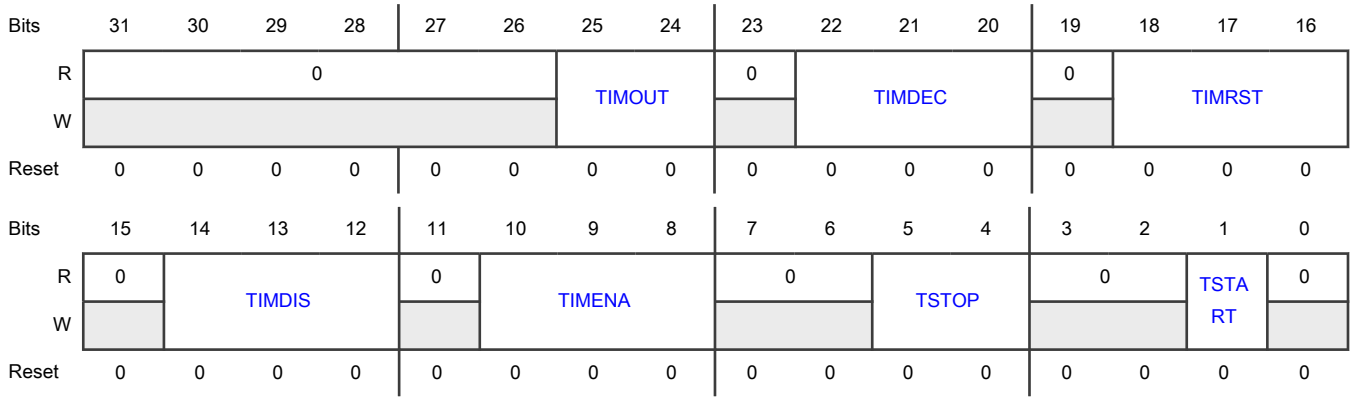
Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

NOTE

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00b - Logic one when enabled; not affected by timer reset 01b - Logic zero when enabled; not affected by timer reset 10b - Logic one when enabled and on timer reset 11b - Logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the timer decrement and that of the shift clock. 000b - Decrement counter on FLEXIO clock; shift clock equals timer output 001b - Decrement counter on trigger input (both edges); shift clock equals timer output 010b - Decrement counter on pin input (both edges); shift clock equals pin input 011b - Decrement counter on trigger input (both edges); shift clock equals trigger input 100b - Decrement counter on FLEXIO clock divided by 16; shift clock equals timer output 101b - Decrement counter on FLEXIO clock divided by 256; shift clock equals timer output 110b - Decrement counter on pin input (rising edge); shift clock equals pin input 111b - Decrement counter on trigger input (rising edge); shift clock equals trigger input
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8 bits that configure the baud rate. In all other modes, the timer reset resets full 16 bits of the counter. 000b - Never reset timer 001b - Timer reset on timer output high. 010b - Timer reset on timer pin equal to timer output 011b - Timer reset on timer trigger equal to timer output 100b - Timer reset on timer pin rising edge 101b - Reserved 110b - Timer reset on trigger rising edge 111b - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on timer n-1 disable 010b - Timer disabled on timer compare (upper 8 bits match and decrement) 011b - Timer disabled on timer compare (upper 8 bits match and decrement) and trigger low 100b - Timer disabled on pin rising or falling edge 101b - Timer disabled on pin rising or falling edge provided trigger is high 110b - Timer disabled on trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on timer n-1 enable 010b - Timer enabled on trigger high 011b - Timer enabled on trigger high and pin high

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Timer enabled on pin rising edge 101b - Timer enabled on pin rising edge and trigger high 110b - Timer enabled on trigger rising edge 111b - Timer enabled on trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Specifies whether the stop bit is enabled. The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Disabled 01b - Enabled on timer compare 10b - Enabled on timer disable 11b - Enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Specifies whether the start bit is enabled. If it is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Disabled 1b - Enabled
0 —	Reserved

49.7.1.35 Timer Compare (TIMCMP0 - TIMCMP7)

Offset

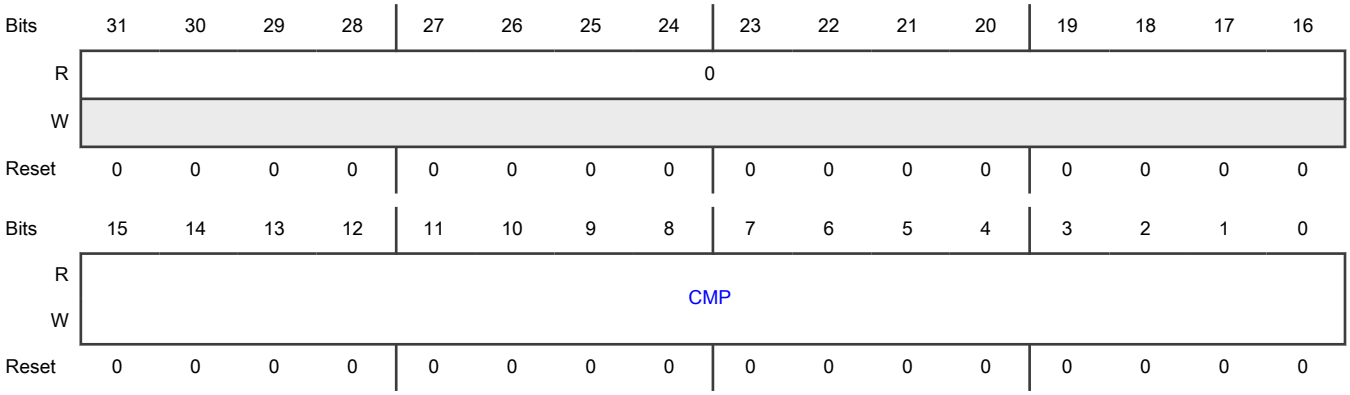
For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value Loads into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider as (CMP[7:0] + 1) × 2. The upper 8 bits configure the number of bits in each word as (CMP[15:8] + 1) ÷ 2. In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word as (CMP[7:0] + 1) ÷ 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) ÷ 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. You must read this register only when the timer status flag is set.

49.7.1.36 Shifter Buffer Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

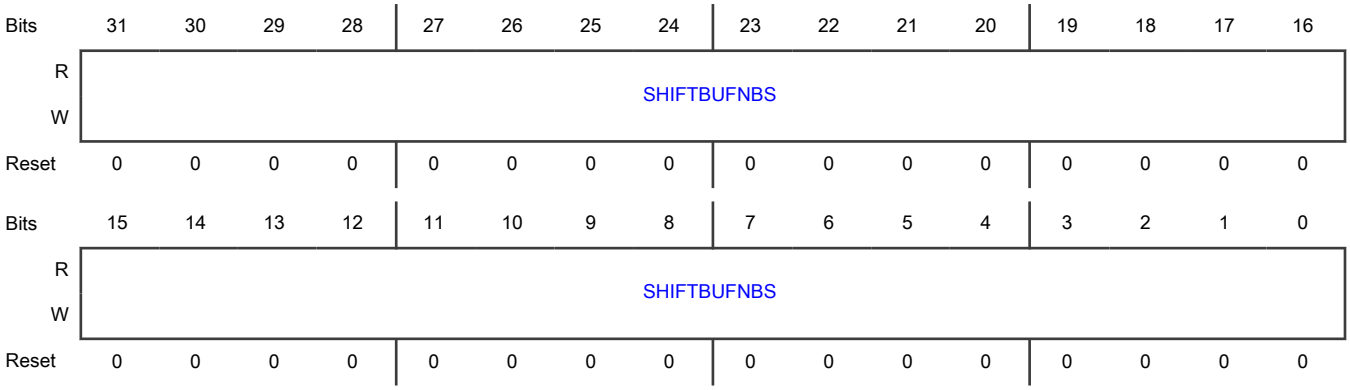
For n = 0 to 7:

Register	Offset
SHIFTBUFNBSn	680h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is nibble-swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFNBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are nibble-swapped within each byte. Reads return {SHIFTBUF[27:24], SHIFTBUF[31:28], SHIFTBUF[19:16], SHIFTBUF[23:20], SHIFTBUF[11:8], SHIFTBUF[15:12], SHIFTBUF[3:0], SHIFTBUF[7:4]}.

49.7.1.37 Shifter Buffer Halfword Swapped (SHIFTBUFHWS0 - SHIFTBUFHWS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFHWSn	700h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is halfword-swapped.

Signal multiplexing	Port control	Signal multiplexing

50.1.1 Module instances

This device has one instance of the SEMA42 module.

50.1.2 Domain ID

The following table lists modules assigned to each domain.

Table 427. SEMA42 domain ID assignment

Domain ID	Modules
M0	CM33 Code and Data in normal function mode
M1	CM33 Code and Data in debug mode
M2	eDMA
M3	EdgeLock Secure Enclave
M4	Data Stream
M5	Radio NBU
M6	DSP

50.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

NOTE

Terminology in this chapter has been updated as follows:

Table 428. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave
Stop	Abort

50.2.1 Block diagram

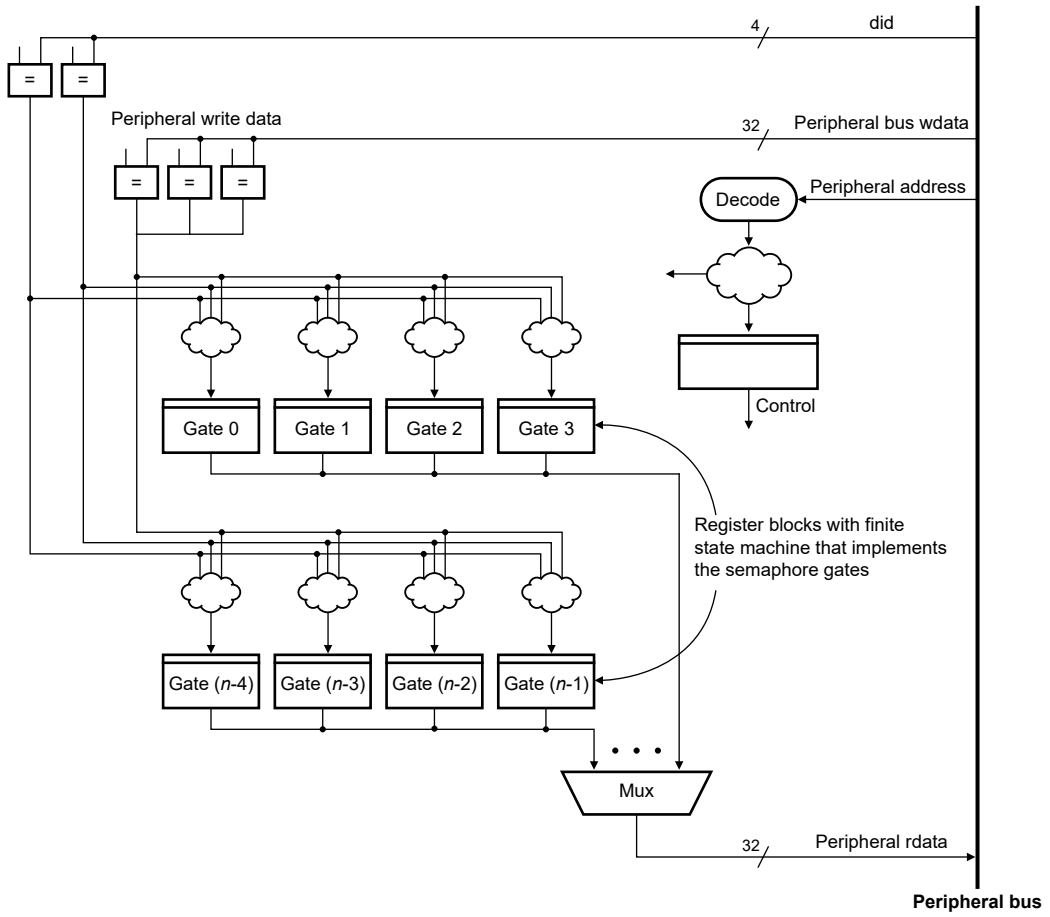

Figure 204. SEMA42 block diagram

50.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped target peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped target peripheral that offers programming-model accesses.

50.3 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

50.3.1 SEMA42 register descriptions

50.3.1.1 SEMA42 memory map

SEMA42 base address: 4003_F000h

Offset	Register	Width (In bits)	Access	Reset value
0h - Fh	Gate (GATE0 - GATE15) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	R	0000h
42h	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

50.3.1.2 Gate (GATE0 - GATE15)

Offset

For n = 0 to 15:

Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain initiators can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Table continued from the previous page...

Field	Function
	The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

50.3.1.3 Reset Gate Read (RSTGT_R)

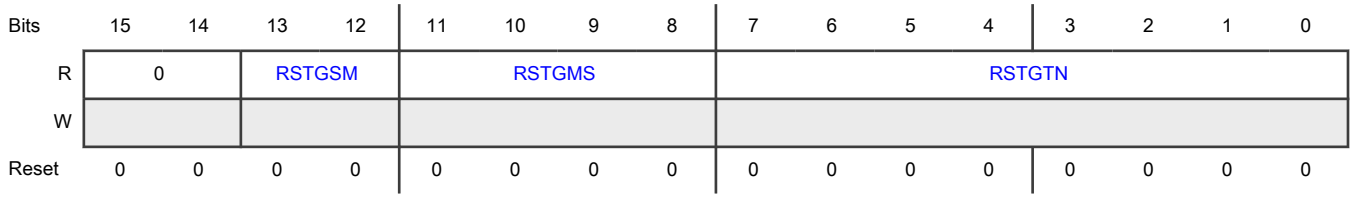
Offset

Register	Offset
RSTGT_R	42h

Function

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Diagram



Fields

Field	Function
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

50.3.1.4 Reset Gate Write (RSTGT_W)

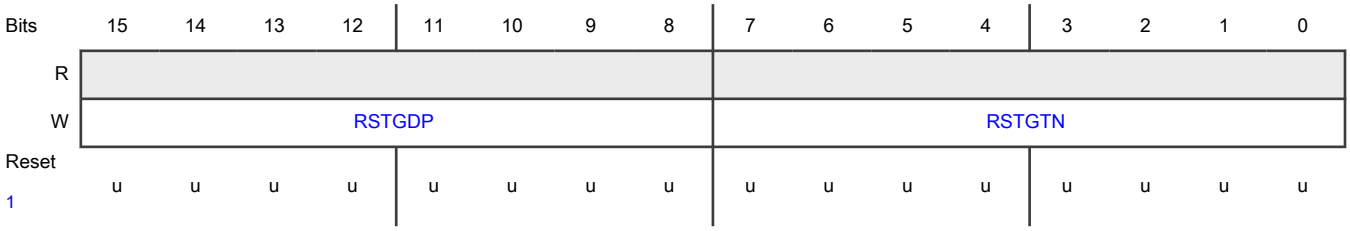
Offset

Register	Offset
RSTGT_W	42h

Function

Specifies the hardware gate to reset when data patterns are specified.

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

50.4 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 stops the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

50.4.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: domain*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

50.4.2 16 Hardware-enforced gates

Gates appear as a 16-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (initiator) 0

  if gate = 2h, then state = locked by domain (initiator) 1

  …

  if gate = Fh, then state = locked by domain (initiator) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

50.4.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

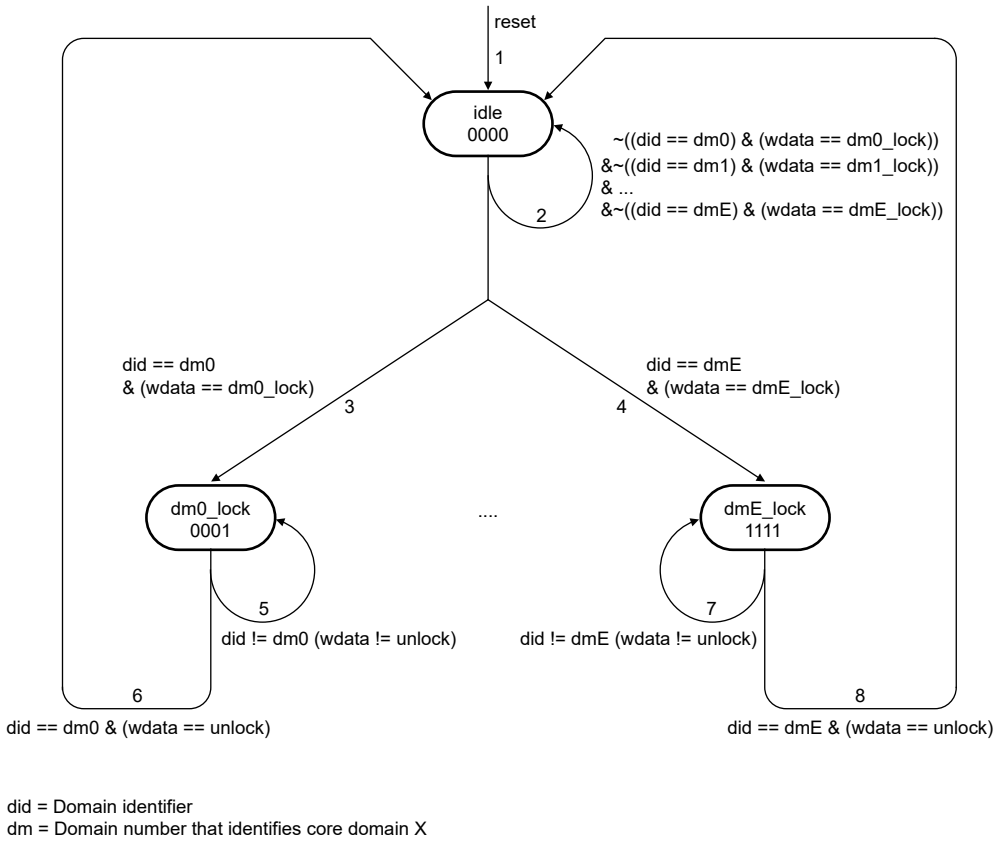


Figure 205. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 429. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.

Table continues on the next page...

Table 429. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

50.4.4 Clocking

Type of clock	Description
Module clock (clk)	Functions the module and controls the access to the registers.

50.4.5 Interrupts

This module has no interrupts.

50.5 External signals

This module has no external signals.

50.6 Initialization

This module does not require initialization.

51.2 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

51.2.1 Block diagram

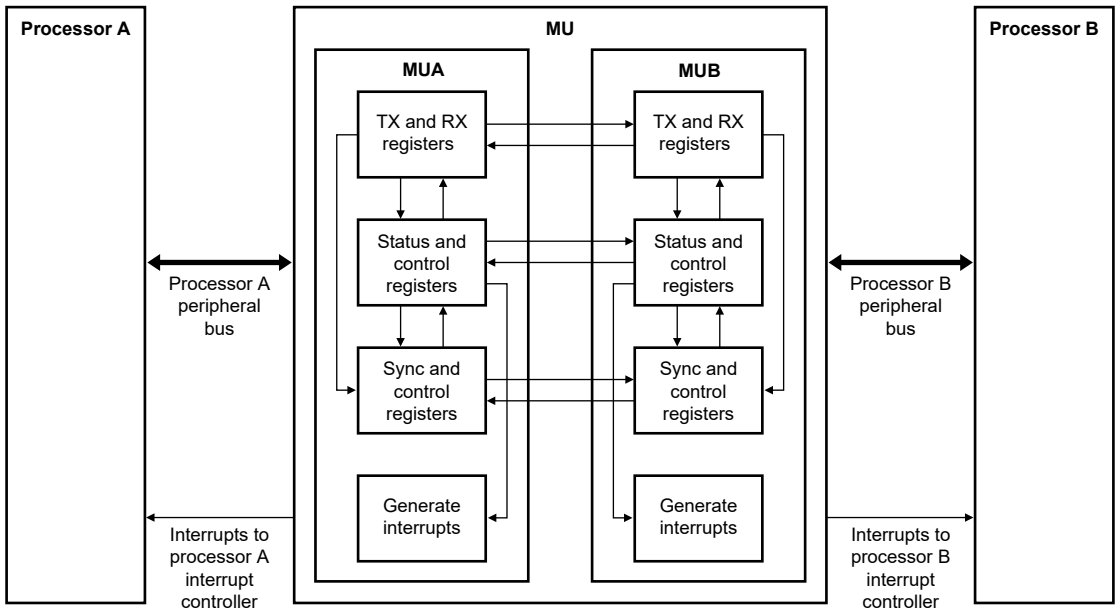

Figure 206. Block diagram

51.2.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores
  - To send data or messages from one side to the other, messaging unit A (MUA) provides 4 transmit registers and 4 receive registers. Messaging unit B (MUB) provides 4 transmit registers and 4 receive registers.
  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and the receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts
  - MU has 12 asynchronous interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 4 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
  - Processor A can initiate a non-maskable interrupt (NMI) to processor B.
  - Processor B can initiate a non-maskable interrupt (NMI) to processor A.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field).

51.3 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.

- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 4 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

51.3.1 Submodules

51.3.1.1 MUA side

MUA receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

NOTE

Processor B should not access MUA registers. Processor C, if exist, should also not access MUA registers. TRDC might be needed to prevent such illegal access of Processor B or C to MUA registers.

51.3.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

NOTE

Processor A should not access MUB registers. Processor C, if exist, should also not access MUB registers. TRDC might be needed to prevent such illegal access of Processor A or C to MUB registers.

51.3.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

51.3.3 Clocking

Table 432. MU clocks

Clock name	Description
Bus clock MUA	Used only for bus accesses to MUA control and configuration registers
Bus clock MUB	Used only for bus accesses to MUB control and configuration registers

51.3.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

51.3.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

Table 433. Exceptions to asynchronous system reset

MUA-side exceptions	MUB-side exceptions
MUB_SR[MURS] MUB_CSSR0/MUB_CSR0	MUA_CCR0[BOOT] MUA_SR[MURS] MUA_CSSR0/MUA_CSR0

51.3.4.2 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors, monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

NOTE

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

51.3.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register. These interrupts are Ored into a single interrupt for each MUA or MUB, please consult the interrupt map file attached to this document.
- 4 general-purpose interrupts (asserted when the GIP flags are set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))
- One non-maskable interrupt (NMI) flag (asserted when the NMI flag is set in Core Control 0 (CCR0))

All interrupts except NMI are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupts) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

- Wait mode
- Stop mode
- Power-down mode

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flags (GSR[GIP*n*]) to deassert the request to the interrupt controller.

The software must also clear the NMI by writing CSSR0[NIMC] (as a part of the interrupt handler) to deassert the NMI request.

When a processor writes to the general-purpose interrupt (GCR[GIR*n*]), MU synchronizes the write event to the other processor to set the general-purpose interrupt request pending flag (GSR[GIP*n*]). When GSR[GIP*n*] is set and the general-purpose interrupt is enabled on the receiving side (GIER[GIE*n*] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP*n*]. The interrupt is deasserted as soon as the write to GSR[GIP*n*] occurs. MU synchronizes the write event of GSR[GIP*n*] to the other processor. The synchronized signal writes 0 to the GIR*n* interrupt.

Before writing 1 to GCR[GIR*n*], verify that the field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

51.4 External signals

This module has no external signals.

51.5 Initialization

MU does not require initialization.

51.6 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.
- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

51.6.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When *n* = 0, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For *n* = 3, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
    a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
    b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
    a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
    b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 434 and Figure 207 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

Table 434. Interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A writes data.	RR*n* on processor B's side reflects a data write to TR*n* by processor A.
2	Clear the transmitter empty flag and set the receiver full flag.	The data write to TR*n*: • Clears TSR[TE*n*] on the processor A side. • Sets RSR[RF*n*] on the processor B side.

Table continues on the next page...

Table 434. Interrupt messaging protocol (generalized) (continued)

Step	Action	Description
3	Generate the receive interrupt request.	Setting RSR[RF*n*] generates a receive interrupt request to processor B.
4	Processor B reads the data.	After receiving the receive interrupt request, processor B performs a data read of RR*n*.
5	Clear the receiver full flag and set the transmitter empty flag.	Reading the data from the RR*n* register: • Clears RSR[RF*n*] on the processor B side. • Sets TSR[TE*n*] on the processor A side.
6	Generate the transmit interrupt request.	Setting TSR[TE*n*] generates a transmit interrupt request to processor A.

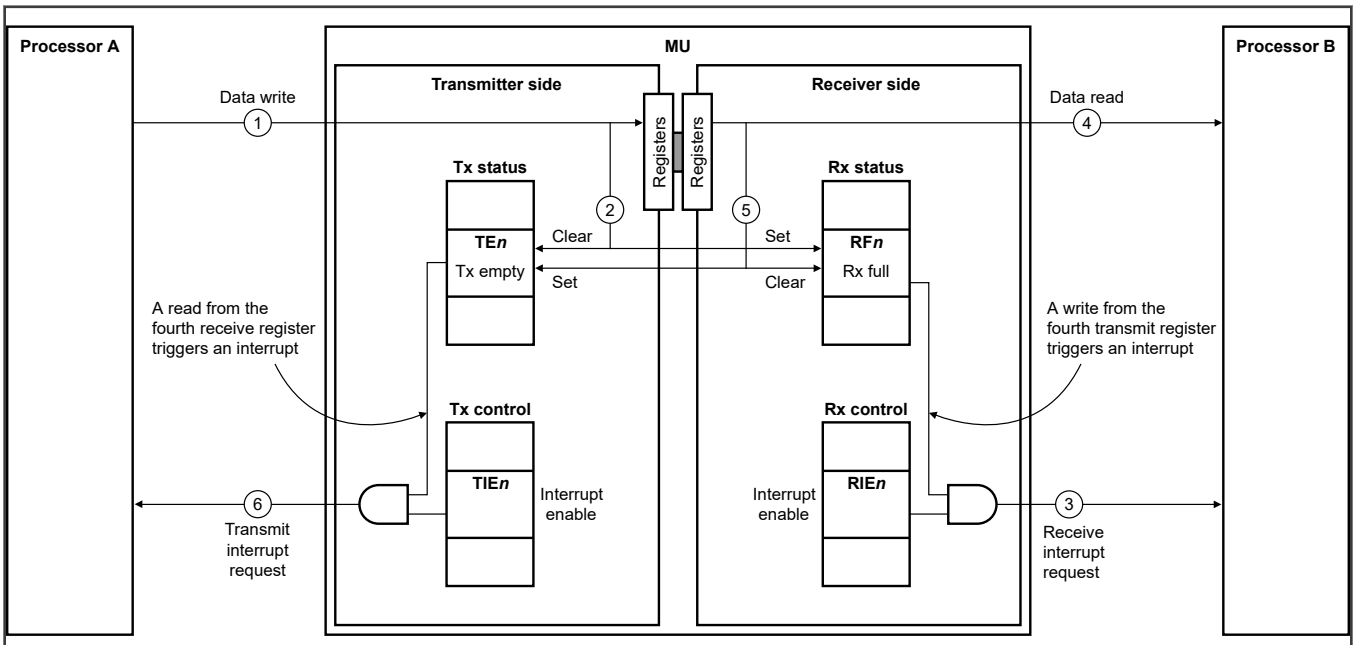

Figure 207. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

51.6.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 435 and Figure 208 describe the event steps when the processor triggers a general-purpose interrupt.

Table 435. General-purpose interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A sets its associated general-purpose interrupt request flag.	Processor A sets GCR[GIR*n*].
2	The general-purpose interrupt request pending status flag is set.	GSR[GIP*n*] is set.
3	MU generates the general-purpose interrupt request to processor B.	Setting GSR[GIP*n*] generates the general-purpose interrupt request to processor B. GIER[GIE*n*] must be set for processor B.
4	Processor B reads the status register.	Processor B reads GSR[GIP*n*].
5	Processor B services the interrupt.	—
6	Processor B sets GSR[GIP*n*] to clear the interrupt.	Processor B writes 1 to the corresponding GSR[GIP*n*] flag to clear the interrupt.
7	GCR[GIR*n*] is cleared.	Setting GSR[GIP*n*] clears GCR[GIR*n*] on the processor A side.

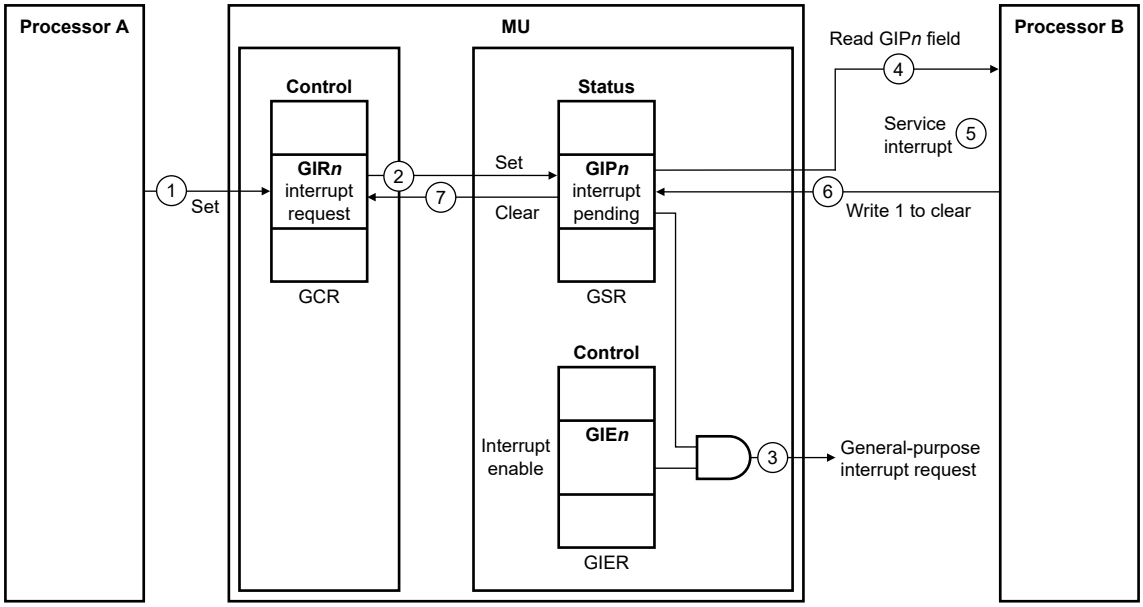

Figure 208. Messaging model using a general-purpose interrupt

51.6.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 436 shows processor A performing an exclusive access to shared memory.

- Table 437 shows processor B scanning for transaction information.
- Table 438 shows processor B accepting exclusive access from processor A.
- Table 439 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR*n*], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

Table 436. Processor A performs an exclusive access to shared memory

Step	Action	Description
1	Processor A sends the GIR*n* request to processor B using the processor A control register.	Before processor A performs an exclusive access to the shared memory, it sends a GIR*n* request to processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TR*n*).	Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from processor B.	Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding.
4	Processor A accesses the shared memory.	After receiving a dedicated interrupt from processor B, processor A proceeds.

Table 437. Processor B scans for transaction information

Step	Action	Description
1	Processor B receives an interrupt from a receive data register (RR*n*).	—
2	Processor B reads the receive data register (RR*n*).	—
3	Processor B scans the receive data register contents.	Processor B scans for transaction information (whether processor A has requested exclusive access).

Table 438. Processor B accepts exclusive access from processor A

Step	Action	Description
1	Processor B triggers a dedicated interrupt.	Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A.
2	Processor B sends a code message to processor A.	With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory.

Table 439. Processor B rejects exclusive access from processor A

Step	Action	Description
1	Processor B ignores the request from processor A for exclusive access.	If processor B does not provide permission to processor A, processor B ignores the exclusive-access request.

51.6.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

Table 440. Packet data transfer sequence

Step	Action	Description
1	Processor B requests DMA.	Processor B sends a DMA request to initiate the packet data transfer.
2	DMA data transfer	DMA acknowledges.
3		DMA starts transferring data from the specified processor B memory location to the specified shared memory.
4		DMA interrupts processor B to signal that the packet transfer has finished.
5	Processor B informs processor A that data is in shared memory.	Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data.
6	Processor A receives an interrupt.	Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory.
7	Processor A reads data, then writes data.	Processor A reads or processes packet data from shared memory.
8		Processor A writes the result from packet processing to a separate buffer.
9	Processor A informs processor B that the transfer is finished.	After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*).
10	Processor A sends an interrupt to processor B (a request for more data).	Processor B receives the next interrupt from processor A, in which processor A requests more packet data.

51.6.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

Table 441. Freeing a processor from deadlock

Processor mode	Technique	Description
—	Processor issues an interrupt.	The other processor can interrupt the processor by issuing one of the 12 (general purpose, receive, or transmit) interrupts.
Normal	Processor issues a non-maskable interrupt.	If a processor is in Normal mode, the other processor can issue a non-maskable interrupt (NMI). You can configure the NMI routine to execute a diagnostic routine that is predefined for such an event.

51.7 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 209 shows the schematic for MU registers.

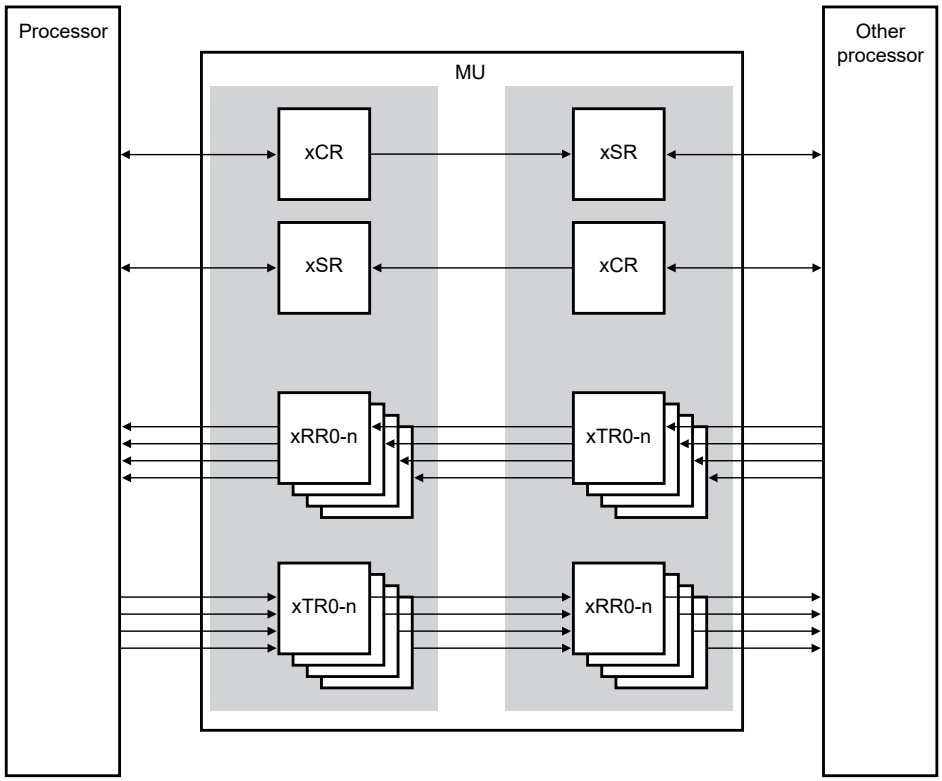

Figure 209. MU registers

51.7.1 MUA register descriptions

This section contains the detailed register descriptions for MUA registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

The only exception to this behavior is the MUA SR register. No transfer error occurs when accessing this location.

51.7.1.1 MUA memory map

MU.MUA base address: 4005_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VER)	32	R	0309_000Fh
4h	Parameter (PAR)	32	R	0304_0404h
8h	Control (CR)	32	RW	0000_0000h
Ch	Status (SR)	32	R	See section
10h	Core Control 0 (CCR0)	32	RW	0000_0014h
14h	Core Interrupt Enable 0 (CIER0)	32	RW	0000_0000h
18h	Core Sticky Status 0 (CSSR0)	32	RW	See section
1Ch	Core Status 0 (CSR0)	32	R	0000_0004h
100h	Flag Control (FCR)	32	RW	0000_0000h
104h	Flag Status (FSR)	32	R	0000_0000h
110h	General-Purpose Interrupt Enable (GIER)	32	RW	0000_0000h
114h	General-Purpose Control (GCR)	32	RW	0000_0000h
118h	General-purpose Status (GSR)	32	RW	0000_0000h
120h	Transmit Control (TCR)	32	RW	0000_0000h
124h	Transmit Status (TSR)	32	R	0000_000Fh
128h	Receive Control (RCR)	32	RW	0000_0000h
12Ch	Receive Status (RSR)	32	R	0000_0000h
200h - 20Ch	Transmit (TR0 - TR3)	32	RW	0000_0000h
280h - 28Ch	Receive (RR0 - RR3)	32	R	0000_0000h

51.7.1.2 Version ID (VER)

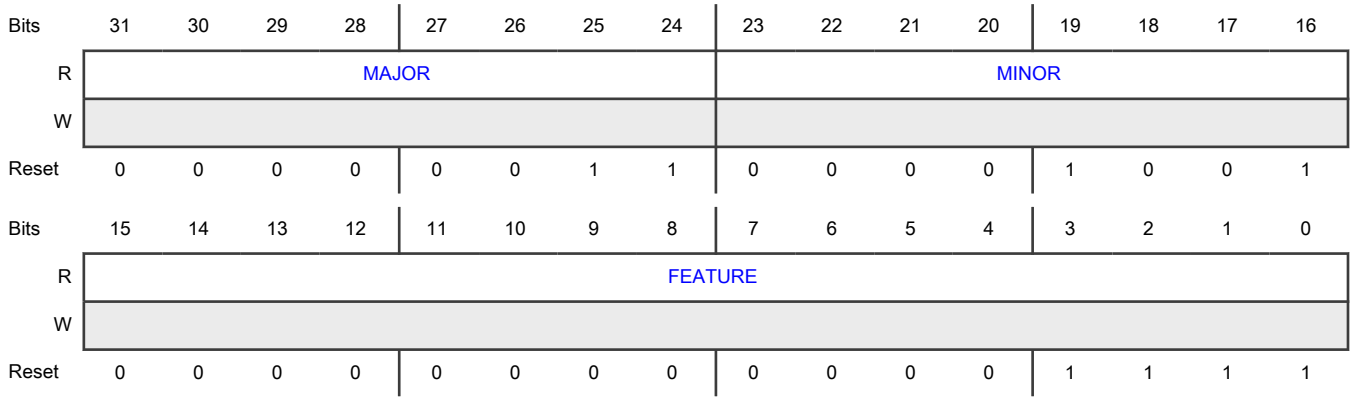
Offset

Register	Offset
VER	0h

Function

Determines the version ID and feature set number of MUA.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. Each bit of this field specifies a different feature: • If FEATURE[0] = 1: Standard features are implemented. • If FEATURE[1] = 1: RAIP and RAIE fields are implemented. • If FEATURE[2] = 1: Core Control and Status registers are implemented in MUA and MUB. • If FEATURE[3] = 1: Expand the number of TR*n* and RR*n* registers. • FEATURE[4] - FEATURE[15]: Reserved for future use.

51.7.1.3 Parameter (PAR)

Offset

Register	Offset
PAR	4h

Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FLAG_WIDTH								GIR_NUM							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RR_NUM								TR_NUM							
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

51.7.1.4 Control (CR)

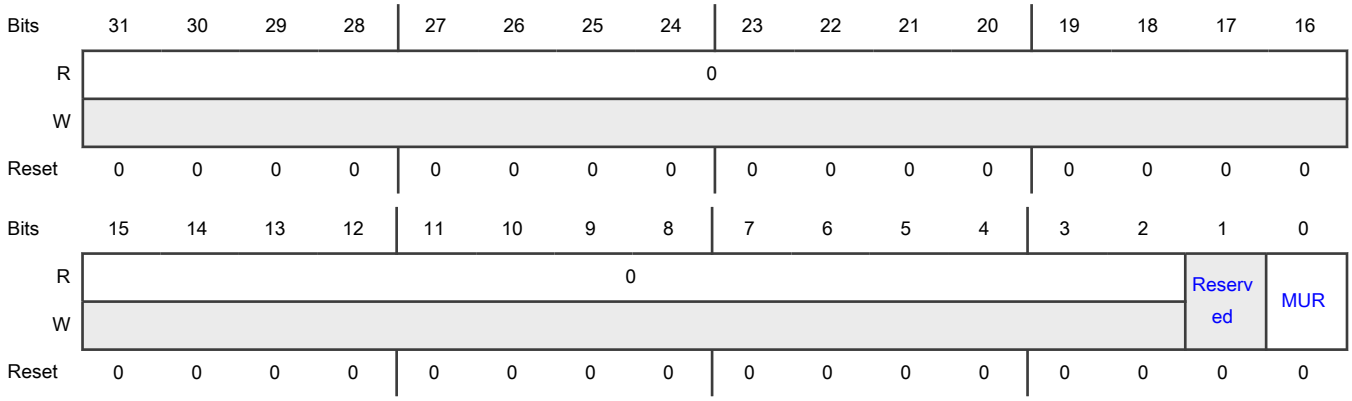
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 —	Reserved
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUA/B_CCR0 registers; MURS in MUA/B_SR registers and the MUA/B_CSSR0/CSR0 registers). Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program. After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended. You can only write 1 to MUR when processor B is not in Stop mode or Power-Down mode. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

51.7.1.5 Status (SR)

Offset

Register	Offset
SR	Ch

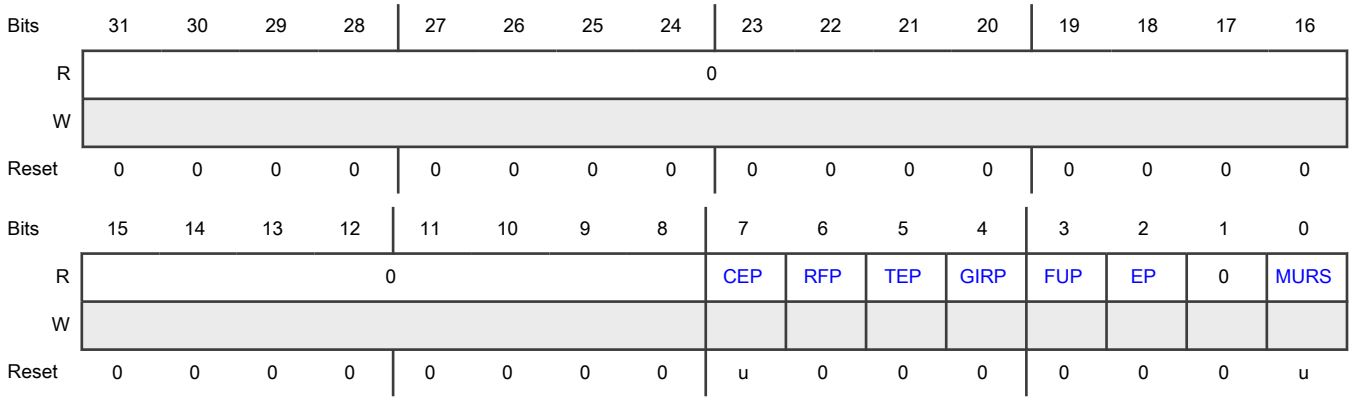
Function

Shows the status of MU resets and the status of pending events and requests.

NOTE

Writing to this register does not generate a transfer error.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 CEP	Processor B Event Pending Indicates whether a processor event is pending. This field becomes 1 when MU detects any core operation mode entry event. After this field becomes 1, MU checks the CSSR0 register to determine which core operation mode entry event in Processor B occurs. This field becomes 0 when all core operation mode entry events are serviced by writing 1 to CSSR0[WAIT] and CSSR0[HRIP]. The reset value of this field is chip-specific. 0b - No event pending 1b - Event pending
6 RFP	MUA Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it. This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset. 0b - Not pending; MUB is not writing to a Transmit register 1b - Pending; MUB is writing to a Transmit register
5 TEP	MUA Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it. This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - No MUA transmit empty event pending 1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUA General-Purpose Interrupt Pending Indicates that MUB has sent a general-purpose interrupt request. This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUA_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUA Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR. This field becomes 1 when the MUA side sends a flag update request to the MUB side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUA) 1b - Pending update flags (initiated by MUA)
2 EP	MUA Side Event Pending Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUB before entering Stop mode, verify that this field is 0. If it is 1, wait and continue to poll this field before entering Stop mode until it becomes 0. Reading MUA_SR[EP] must be the last access to MUA. Perform this read operation before entering Stop or Wait mode. Otherwise, subsequent actions may cause this field to become 1. If MUB is in Stop mode and the MUA event is triggered, this field remains 1 until MUB wakes up.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not pending 1b - Pending
1 —	Reserved
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

51.7.1.6 Core Control 0 (CCR0)

Offset

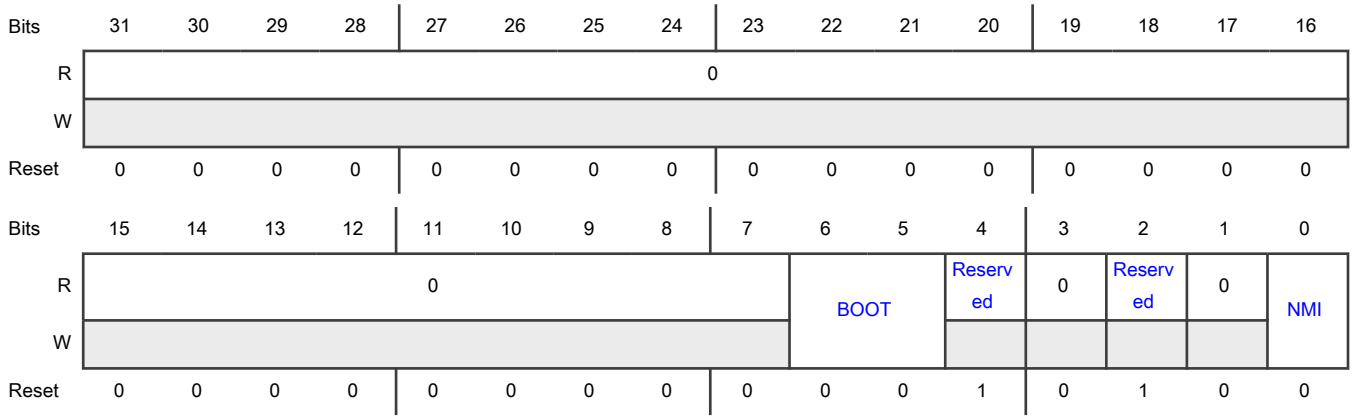
Register	Offset
CCR0	10h

Function

Allows MUA to control the processor on the MUB side.

Also allows control of the processor A hardware reset mask.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-5 BOOT	Target Processor B Boot Configuration Configures the boot source for processor B when it is the target core. See the chip-specific details for more information on boot options. 00b - Processor Boot option 0 = 0x2002_0000 01b - Processor Boot option 1 = 0x2002_8000 10b - Processor Boot option 2 = 0x2003_0000 11b - Processor Boot option 3 = Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 NMI	MUB Nonmaskable Interrupt Request Indicates whether Processor A has issued a nonmaskable interrupt to Processor B. When this field becomes 1, it initiates a nonmaskable interrupt to processor B. This field becomes 0 after 1 is written to MUB_CSSR0[NMIC] to clear that field. After this field becomes 0, MUA can initiate another nonmaskable interrupt to MUB. This field is cleared when MU resets. 0b - Nonmaskable interrupt not issued 1b - Nonmaskable interrupt issued

51.7.1.7 Core Interrupt Enable 0 (CIER0)

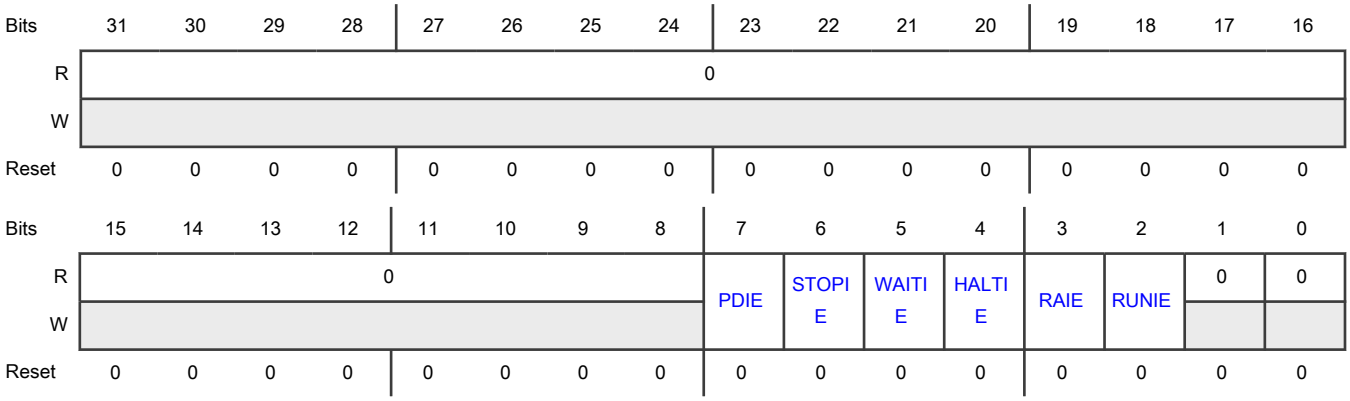
Offset

Register	Offset
CIER0	14h

Function

Controls interrupt enables.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 PDIE	Processor B Power-Down Mode Entry Interrupt Enable Enables processor A Power-Down Mode Entry Interrupt request due to Processor B Power-Down mode entry. If the value of this field is 1, an MU Power-Down mode Entry Interrupt is issued to Processor A when MUA_CSSR0[PD] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[PD] and no MU Power-Down mode Entry Interrupt is issued. 0b - Disable 1b - Enable
6 STOPIE	Processor B Stop Mode Entry Interrupt Enable Enables Processor A Stop Mode Entry Interrupt request due to Processor B Stop mode entry. If the value of this field is 1, an MU Stop Mode Entry Interrupt is issued to Processor A when MUA_CSSR0[STOP] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[STOP] and no MU Stop Mode Entry Interrupt is issued. 0b - Disable 1b - Enable
5 WAITIE	Processor B Wait Mode Entry Interrupt Enable Enables Processor A Wait Mode Entry Interrupt request due to Processor B Wait Mode Entry.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the value of this field is 1, an MU Wait Mode Entry Interrupt is issued to the processor A when MUA_CSSR0[WAIT] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[WAIT] and no MU Wait Mode Entry Interrupt is issued. 0b - Disable 1b - Enable
4 HALTIE	Processor B Halt Mode Entry Interrupt Enable Enables Processor A Halt Mode Entry Interrupt request due to Processor B Halt Mode Entry. If the value of this field is 1, an MU Halt Mode Entry Interrupt is issued to the Processor A when MUA_CSSR0[HALT] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[HALT] and no MU Halt Mode Entry Interrupt is issued. 0b - Disable 1b - Enable
3 RAIE	Processor B Reset Assertion Interrupt Enable Enables Processor A Reset Assertion Interrupt request due to Processor B reset assertion. If the value of this field is 1, an MU reset interrupt is issued to Processor A when MUA_CSSR0[RAIP] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[RAIP] and no MU reset interrupt is issued. 0b - Disable 1b - Enable
2 RUNIE	Processor B Run Mode Entry Interrupt Enable Enables Processor A Run Mode Entry Interrupt request due to Processor B Run Mode Entry. If the value of this field is 1, an MU Run Mode Entry Interrupt is issued to Processor A when MUA_CSSR0[RUN] = 1. If the value of this field is 0, MU ignores the value of MUA_CSSR0[RUN] and no MU Run Mode Entry Interrupt is issued. 0b - Disable 1b - Enable
1 —	Reserved
0 —	Reserved

51.7.1.8 Core Sticky Status 0 (CSSR0)

Offset

Register	Offset
CSSR0	18h

Function

Shows the status of interrupts pending (W1C).

The reset value is chip-specific.

Fields

Field	Function
31-8 —	Reserved
7 PD	Processor B Power-Down mode Entry Interrupt Pending Flag Indicates to Processor A whether Processor B has entered Power-Down mode. This flag is set after Processor B enters Power-Down mode. If CIER0[PDIE] enables the interrupt, the Processor A Power-Down mode Entry Interrupt request is issued when Processor B enters Power-Down mode. Clearing this flag also clears the MU Power-Down mode Entry Interrupt request. 0b - Processor B did not enter Power-Down mode. 1b - Processor B entered Power-Down mode.
6 STOP	Processor B Stop Mode Entry Interrupt Pending Flag Indicates to Processor A whether Processor B has entered Stop mode. This flag is set after Processor B enters Stop mode. If CIER0[STOPIE] enables the interrupt, the Processor A Stop Mode Entry Interrupt request is issued when Processor B enters Stop mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Clearing this flag also clears the MU Stop Mode Entry Interrupt request. 0b - Processor B did not enter Stop mode. 1b - Processor B entered Stop mode.
5 WAIT	Processor B Wait Mode Entry Interrupt Pending Indicates to Processor A whether Processor B has entered Wait mode. This flag is set after Processor B enters Wait mode. If CIER0[WAITIE] enables the interrupt, the Processor A Wait Mode Entry Interrupt request is issued when Processor B enters Wait mode. Clearing this flag also clears the MU Wait Mode Entry Interrupt request. 0b - Processor B did not enter Wait Mode. 1b - Processor B entered Wait Mode.
4 HALT	Processor B Halt Mode Entry Interrupt Pending Flag Indicates to Processor A whether Processor B has entered Halt mode. This flag is set after Processor B enters Halt mode. If CIER0[HALTIE] enables the interrupt, the Processor A Halt Mode Entry Interrupt request is issued when Processor B enters Halt mode. Clearing this flag also clears the MU Halt Mode Entry Interrupt request. 0b - Processor B did not enter Halt Mode. 1b - Processor B entered Halt Mode.
3 RAIP	Processor B Reset Asserted Interrupt Pending Flag Indicates to Processor A whether Processor B has entered reset. This flag is set after Processor B enters reset. If CIER0[RAIE] enables the interrupt, the Processor A reset interrupt request is issued when Processor B enters reset. Clearing this flag also clears the MU reset interrupt request. When Processor A leaves reset, this flag is cleared. Processor A then monitors the reset of processor B and sets this flag when its reset asserts. 0b - Processor B did not enter reset. 1b - Processor B entered reset.
2 RUN	Processor B Run Mode Entry Interrupt Pending Flag Indicates to Processor A whether Processor B has entered Run mode. This flag is set after Processor B enters Run mode. If CIER0[RUNIE] enables the interrupt, the Processor A Run Mode Entry Interrupt request is issued when Processor B enters Run mode. Clearing this flag also clears the MU Run Mode Entry Interrupt request. 0b - Processor B did not enter Run mode. 1b - Processor B entered Run mode.
1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
0 NMIC	Processor A Nonmaskable Interrupt Clear Clears the nonmaskable interrupt (NMI) request from the MUB side. The MUA-side NMI service routine uses this field. Writing 1 to this field clears MUB_CCR0[NMI], deasserting the NMI request and enabling MUB_CCR0[NMI] to trigger another NMI request. This field always reads as 0, so you cannot poll it. You can only use this field as part of the NMI service routine, in which you must write 1 to this field only once. This field is cleared when MU resets. 0b - Default 1b - Clear MUB_CCR0[NMI]

51.7.1.9 Core Status 0 (CSR0)

Offset

Register	Offset
CSR0	1Ch

Function

Shows the status of core events.

3-0	MUA General-Purpose Interrupt Request Pending

Table continues on the next page...

Table continued from the previous page...

Field	Function
GIPn	Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUA that MUB_GCR[GIR*n*] changed from 0 to 1. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor A. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUA_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUA side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

51.7.1.15 Transmit Control (TCR)

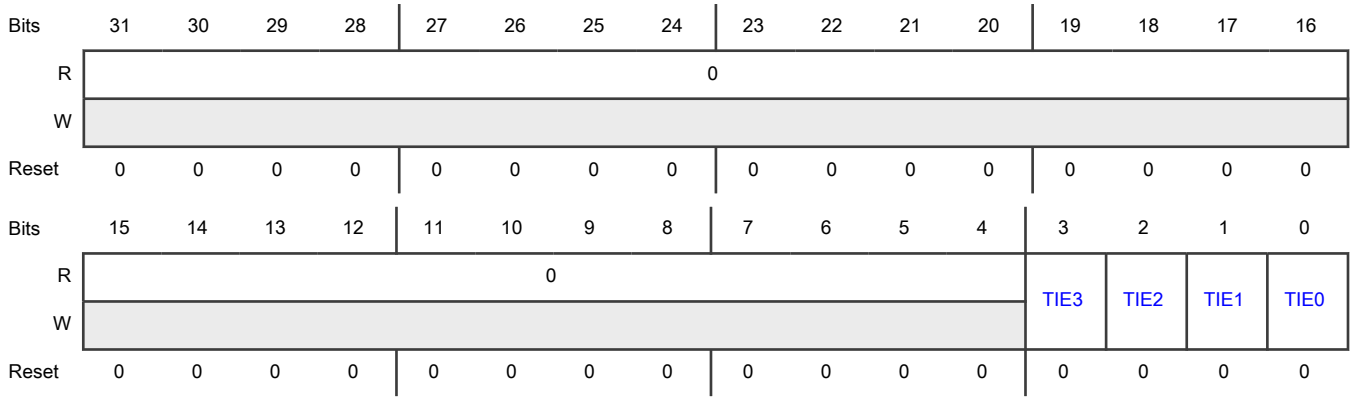
Offset

Register	Offset
TCR	120h

Function

Contains the MUA transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUA Transmit Interrupt Enable Enables MUA transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA transmit interrupt *n* request is issued when MUA_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUA_TSR[TE*n*], and no MUA transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

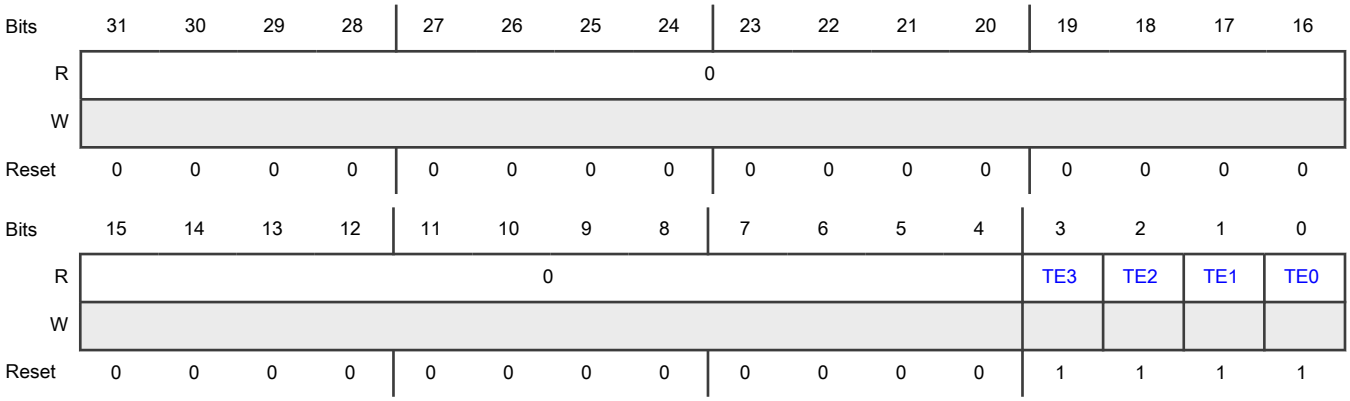
51.7.1.16 Transmit Status (TSR)

Offset

Register	Offset
TSR	124h

Function
Indicates whether the MUA transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 TEn	MUA Transmit Empty Indicates whether MUA Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUB_RR*n* register is read on the MUB side. When TE*n* = 1, it indicates to the MUA side that the MUA_TR*n* register is ready to be written on the MUA side. If MUA_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUA side. This field becomes 0 after the MUA_TR*n* register is written to on the MUA side. After this field becomes 0, if MUA_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUA side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

51.7.1.17 Receive Control (RCR)

Offset

Register	Offset
RCR	128h

Function
Contains the MUA receive interrupt enables.

Diagram

Table continued from the previous page...

Field	Function
3-0 RIEn	MUA Receive Interrupt Enable Enables MUA receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA receive interrupt *n* request is issued when MUA_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUA_RSR[RF*n*], and no MUA receive interrupt request is issued. 0b - Disable 1b - Enable

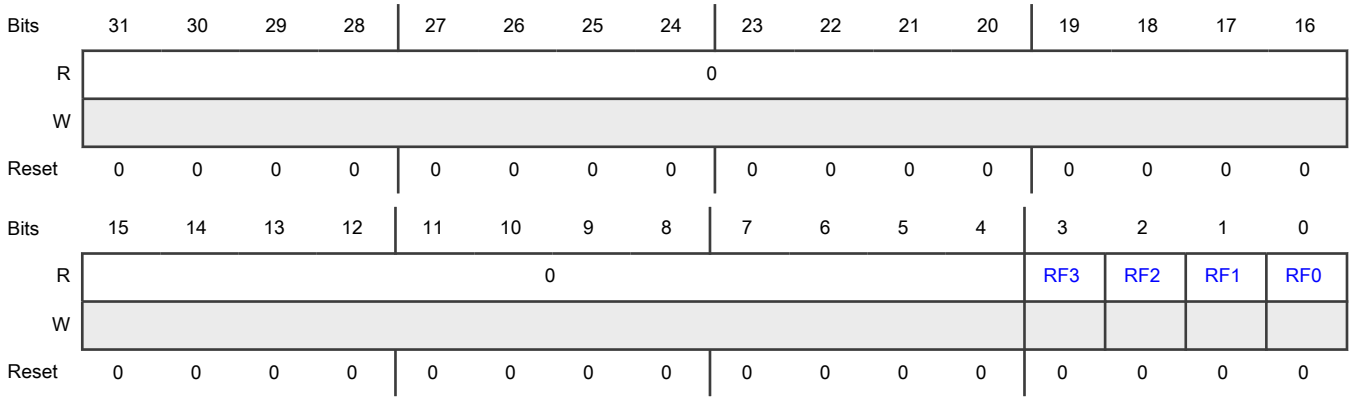
51.7.1.18 Receive Status (RSR)

Offset

Register	Offset
RSR	12Ch

Function
Indicates whether the MUA receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUA Receive Register Full Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RF*n* becomes 1 when the MUB_TR*n* register is written to on the MUB side. When RF*n* is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side. RF*n* becomes 0 when the MUA_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side. 0b - Not full 1b - Full

51.7.1.19 Transmit (TR0 - TR3)

Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function
Contains MUA transmit data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W	TR_DATA

R	0															
W	TR_DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0	MUA Transmit Data

Table continues on the next page...

Field	Function
TR_DATA	Contains MUA transmit data. MUB_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side. You can write to this register only when MUA_TSR[TE*n*] = 1. Reading this register returns all zeroes.

51.7.1.20 Receive (RR0 - RR3)

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUA receive data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RR_DATA	MUA Receive Data Reflects the data written to MUB TR*n*.

Table continues on the next page...

Field	Function
	Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side. You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUA.

51.7.2 MUB register descriptions

This section contains the detailed register descriptions for MUB registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

51.7.2.1 MUB memory map

MU.MUB base address: E000_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VER)	32	R	0309_000Fh
4h	Parameter (PAR)	32	R	0304_0404h

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
280h - 28Ch	Receive (RR0 - RR3)	32	R	0000_0000h

51.7.2.2 Version ID (VER)

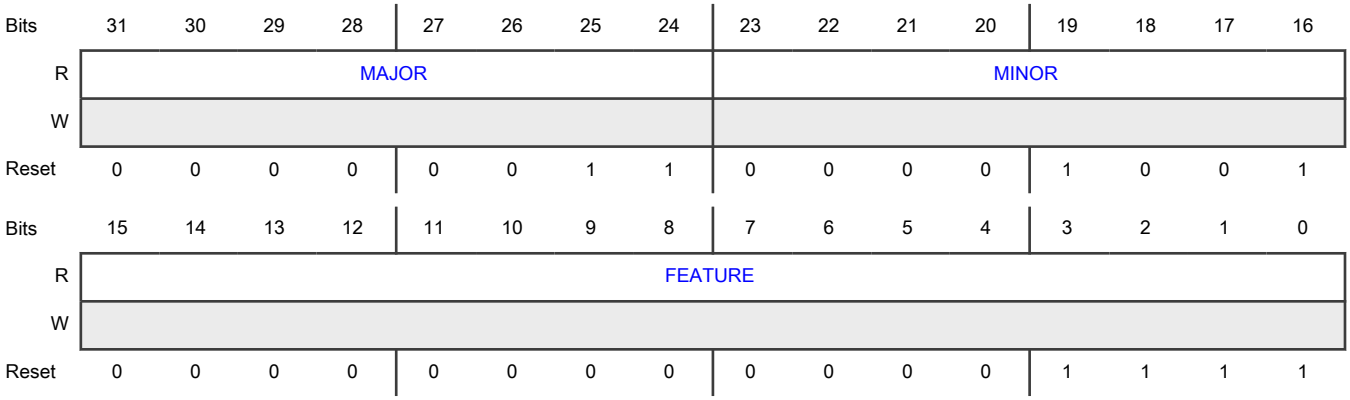
Offset

Register	Offset
VER	0h

Function

Determines the version ID and feature set number of MUB.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. MU implements: • Standard features • Expanded number of TR*n*/RR*n* registers

51.7.2.3 Parameter (PAR)

Offset

Register	Offset
PAR	4h

Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FLAG_WIDTH								GIR_NUM							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RR_NUM								TR_NUM							
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

51.7.2.4 Control (CR)

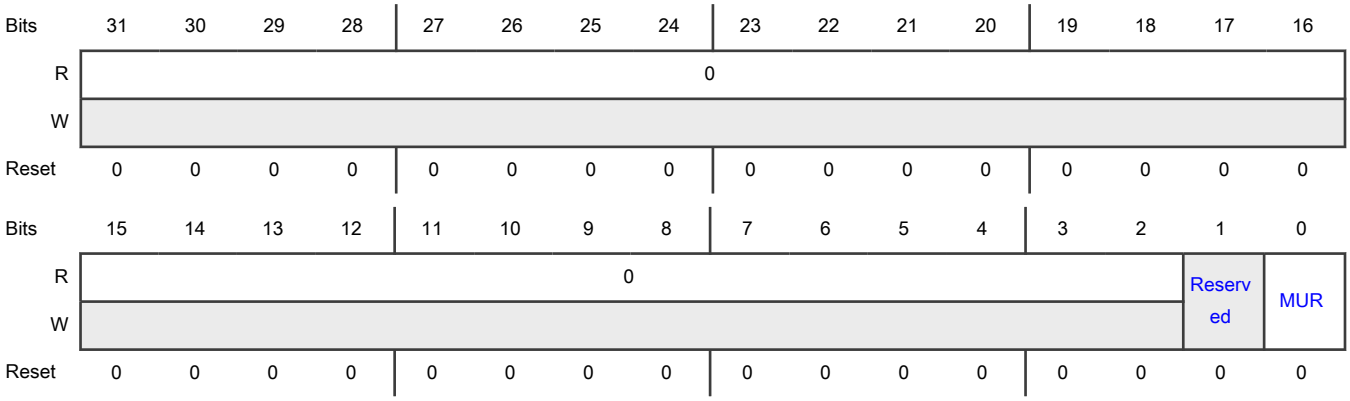
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 —	Reserved
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except in MUB/A_CCR0 registers; MURS in MUB/A_SR registers). Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program. After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

51.7.2.5 Status (SR)

Offset

Register	Offset
SR	Ch

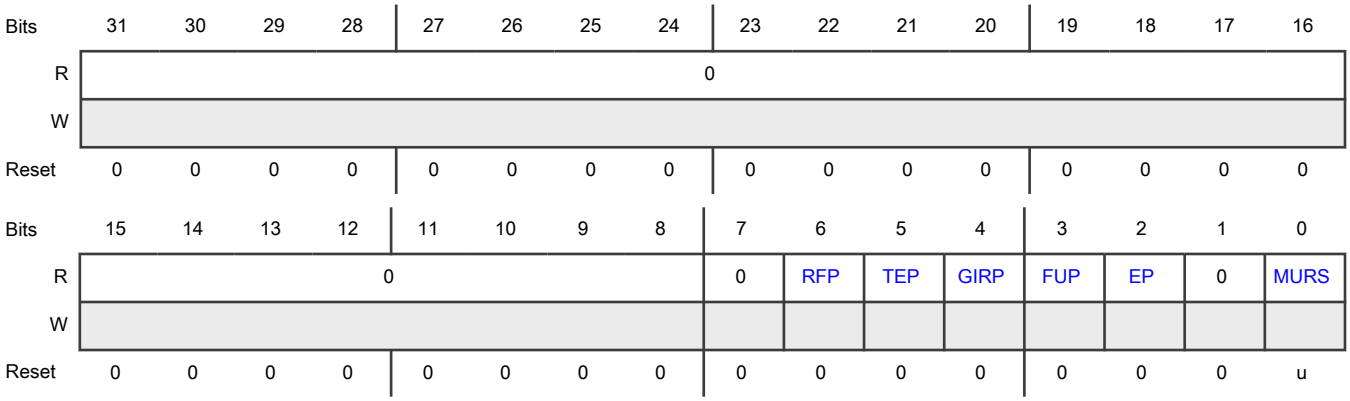
Function

Shows the status of MU resets and the status of pending events and requests.

NOTE

Writing to this register does not generate a transfer error.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 RFP	MUB Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it. This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset. 0b - Not pending; MUA is not writing to a Transmit register 1b - Pending; MUA is writing to a Transmit register
5 TEP	MUB Transmit Empty Pending Indicates whether a transmit empty message is pending. This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it. This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - No MUB transmit empty event pending

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUB General-Purpose Interrupt Pending Indicates that MUA has sent a general-purpose interrupt request. This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUB Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUB_FCR. This field becomes 1 when the MUB side sends a flag update request to the MUA side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUB_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUB) 1b - Pending update flags (initiated by MUB)
2 EP	MUB Side Event Pending Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUA, verify that this field is 0. If it is 1, wait and continue to poll this field until it becomes 0. 0b - Not pending 1b - Pending
1 —	Reserved
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

51.7.2.6 Core Control 0 (CCR0)

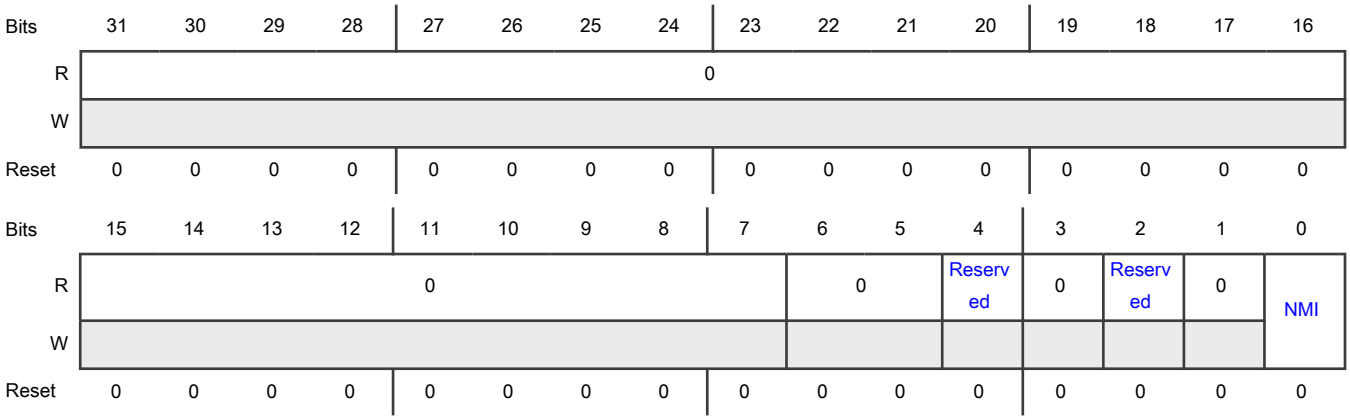
Offset

Register	Offset
CCR0	10h

Function

Allows MUB to control the processor on the MUA side.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-5 —	Reserved
4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 NMI	MUA Nonmaskable Interrupt Request Indicates whether Processor B has issued a nonmaskable interrupt to Processor A. When this field becomes 1, it initiates a nonmaskable interrupt to processor A. This field becomes 0 after 1 is written to MUA_CSSR0[NMIC] to clear that field. After this field becomes 0, MUB can initiate another nonmaskable interrupt to MUA. This field is cleared when MU resets. 0b - Nonmaskable interrupt not issued 1b - Nonmaskable interrupt issued

51.7.2.7 Core Interrupt Enable 0 (CIER0)

Offset

Register	Offset
CIER0	14h

Function
Controls interrupt enables.

Diagram

0 —	Reserved

51.7.2.8 Core Sticky Status 0 (CSSR0)

Offset

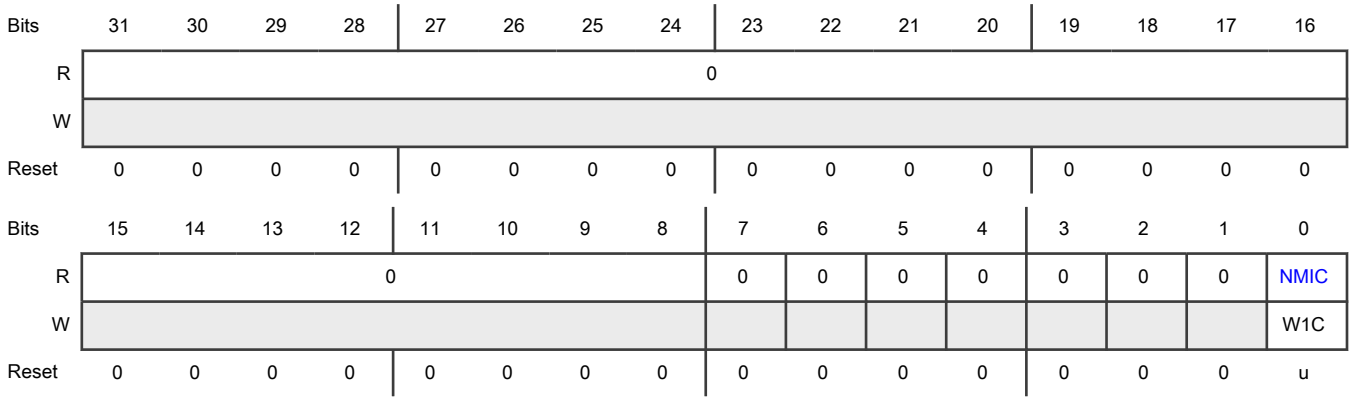
Register	Offset
CSSR0	18h

Function

Shows the status of interrupts pending (W1C).

The reset value is chip-specific.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 —	Reserved
6 —	Reserved
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 NMIC	Processor B Nonmaskable Interrupt Clear Clears the nonmaskable interrupt (NMI) request from the MUA side. The MUB-side NMI service routine uses this field. Writing 1 to this field clears MUA_CCR0[NMI], deasserting the NMI request and enabling MUA_CCR0[NMI] to trigger another NMI request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field always reads as 0, so you cannot poll it. You can only use this field as part of the NMI service routine, in which you must write 1 to this field only once. This field is cleared when MU resets. 0b - Default 1b - Clear MUA_CCR0[NMI]

51.7.2.9 Flag Control (FCR)

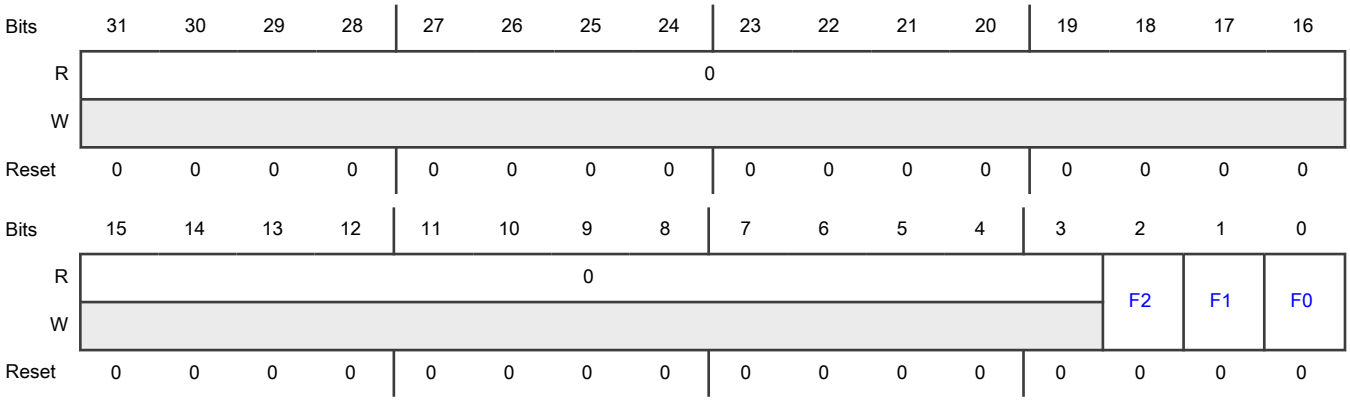
Offset

Register	Offset
FCR	100h

Function

Configures MUA_FSR[F*n*] flags.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUB to MUA Flag Configures MUA_FSR[F*n*] flags, where *n* = 0 to 2. F*n* configures the corresponding MUA_FSR[F*n*] flag. F*n* becomes 0 when MU resets.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Clear MUA_FSR[Fn] 1b - Set MUA_FSR[Fn]

51.7.2.10 Flag Status (FSR)

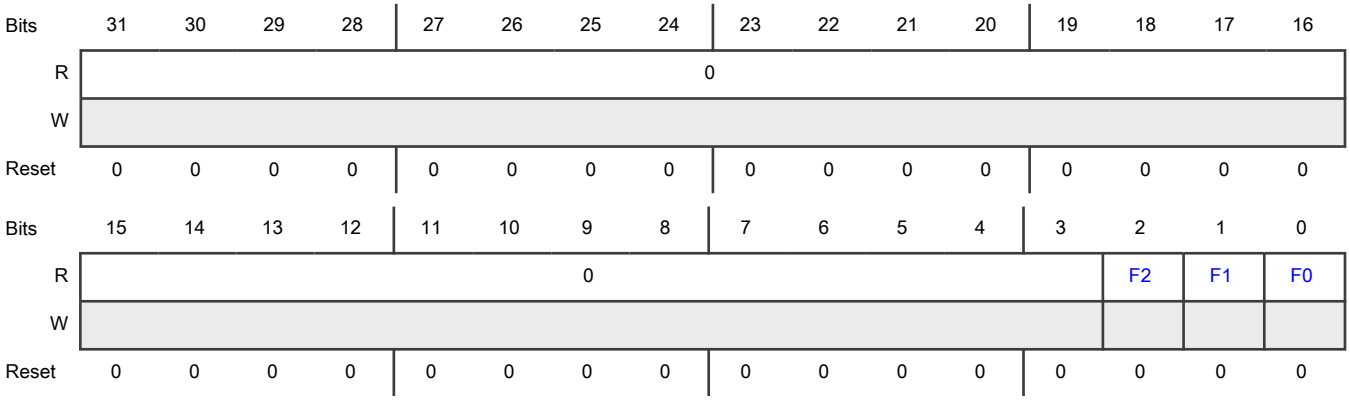
Offset

Register	Offset
FSR	104h

Function

Contains flags configured by the values written to MUA_FCR[F*n*].

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUA to MUB-Side Flag Contains flags configured by the values written to MUA_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUB-side flag configured by the values written to MUA_FCR[F*n*]. When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0b - MUA_FCR[Fn] = 0 1b - MUA_FCR[Fn] = 1

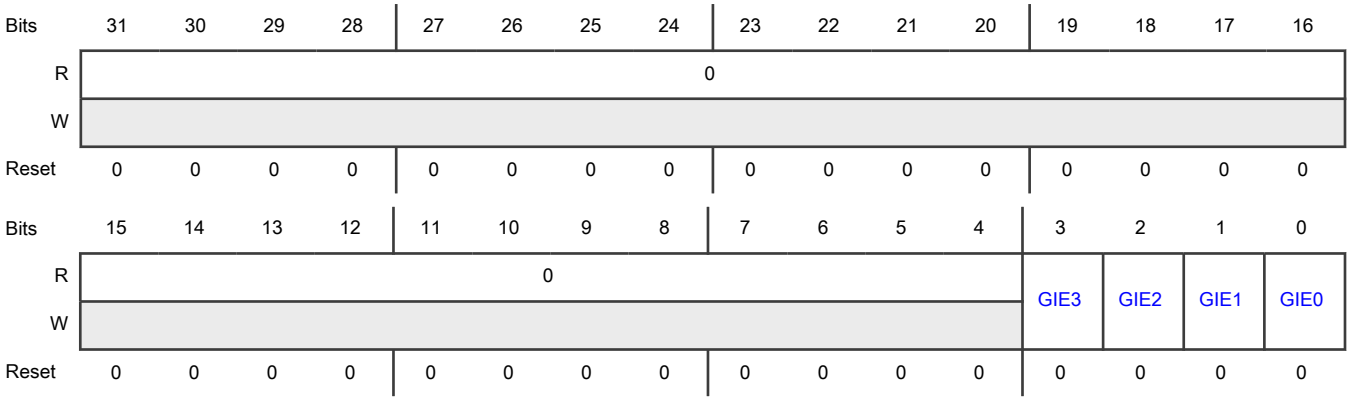
51.7.2.11 General-Purpose Interrupt Enable (GIER)

Offset

Register	Offset
GIER	110h

Function
Contains the MUB general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIEn	MUB General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor B when MUB GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0b - Disable 1b - Enable

51.7.2.12 General-Purpose Control (GCR)

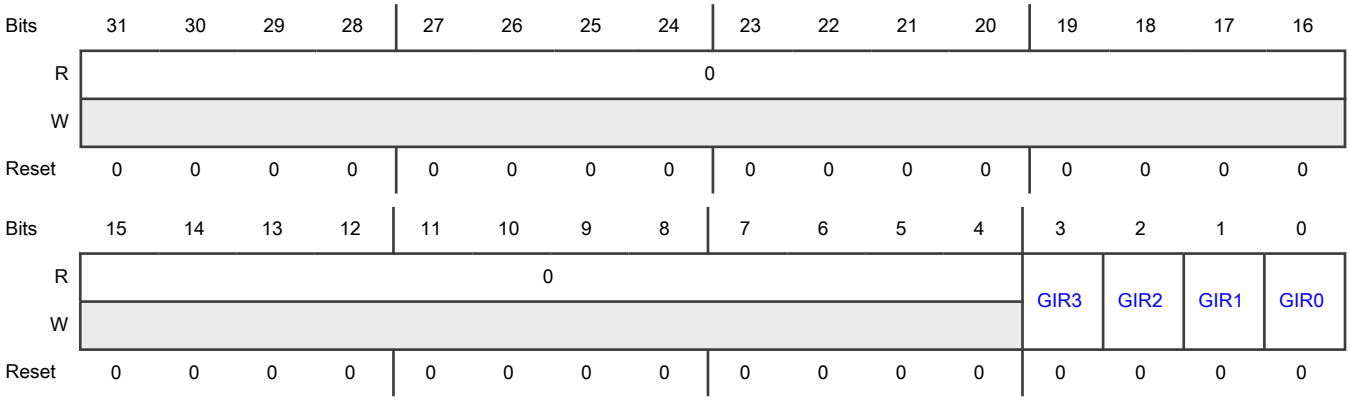
Offset

Register	Offset
GCR	114h

Function

Contains the MUB general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIRn	MUB General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUA. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A. This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

51.7.2.13 General-purpose Status (GSR)

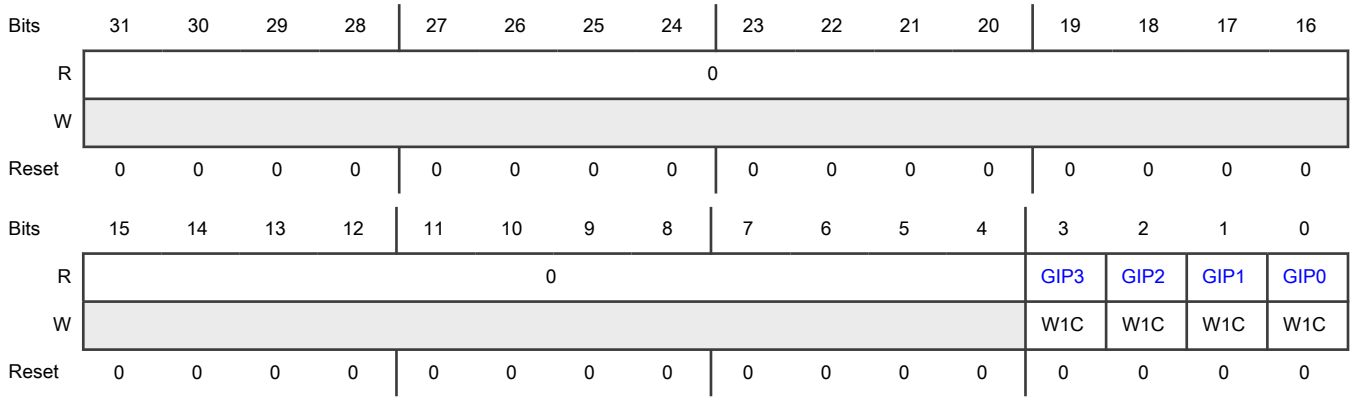
Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUB general-purpose interrupt pending requests.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIPn	MUB General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUB that MUA_GCR[GIR*n*] changed from 0 to 1. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor B. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUB_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUB side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

51.7.2.14 Transmit Control (TCR)

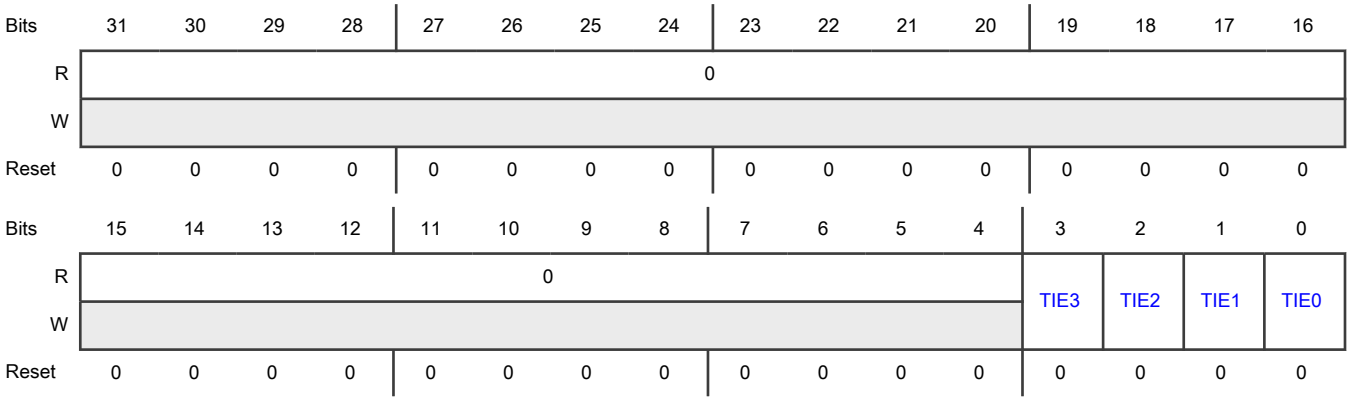
Offset

Register	Offset
TCR	120h

Function

Contains the MUB transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUB Transmit Interrupt Enable Enables MUB transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB transmit interrupt *n* request is issued when MUB_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUB_TSR[TE*n*], and no MUB transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

51.7.2.15 Transmit Status (TSR)

Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUB transmit registers are empty.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUB Transmit Empty Indicates whether MUB Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUA_RR*n* register is read on the MUA side. When TE*n* = 1, it indicates to the MUB side that the MUB_TR*n* register is ready to be written on the MUB side. If MUB_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUB side. This field becomes 0 after the MUB_TR*n* register is written to on the MUB side. After this field becomes 0, if MUB_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUB side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

51.7.2.16 Receive Control (RCR)

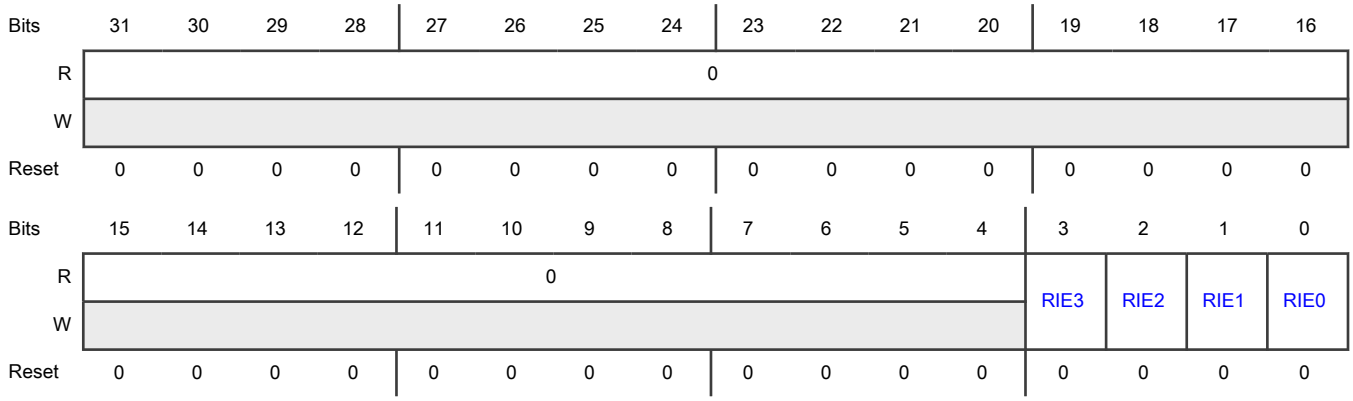
Offset

Register	Offset
RCR	128h

Function

Contains the MUB receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUB Receive Interrupt Enable Enables MUB receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB receive interrupt *n* request is issued when MUB_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUB_RSR[RF*n*], and no MUB receive interrupt request is issued. 0b - Disable 1b - Enable

51.7.2.17 Receive Status (RSR)

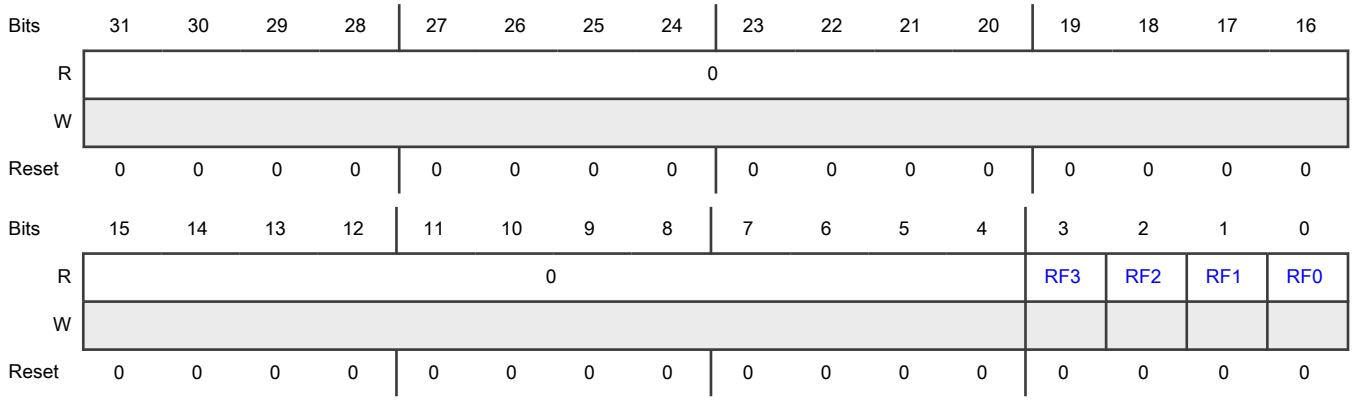
Offset

Register	Offset
RSR	12Ch

Function

Indicates whether the MUB receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUB Receive Register Full Indicates whether MUB Receive register (RR*n*) is full, where *n* = 0 to 3. RF*n* becomes 1 when the MUA_TR*n* register is written to on the MUA side. When RF*n* is 1, it indicates to the MUB side that new data in the MUB_RR*n* register is ready for MUB to read it. If MUB_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUB side. RF*n* becomes 0 when the MUB_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUB_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUB side. 0b - Not full 1b - Full

51.7.2.18 Transmit (TR0 - TR3)

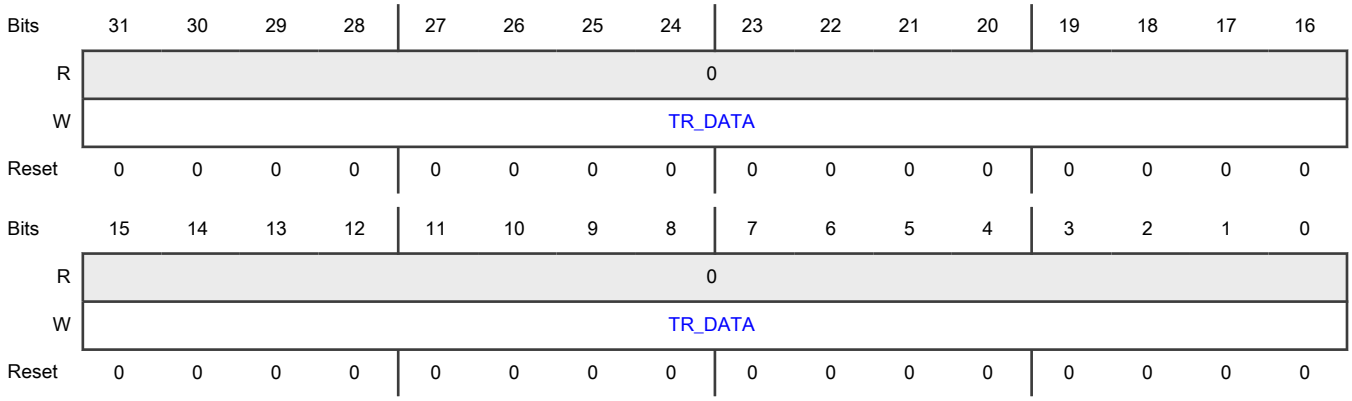
Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function

Contains MUB transmit data.

Diagram



Fields

Field	Function
31-0 TR_DATA	MUB Transmit Data Contains MUB transmit data. MUA_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUB_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUB_TSR[TE*n*] on the transmitter side, and sets MUA_RSR[RF*n*] on the receiver side. You can write to this register only when MUB_TSR[TE*n*] = 1. Reading this register returns all zeroes.

51.7.2.19 Receive (RR0 - RR3)

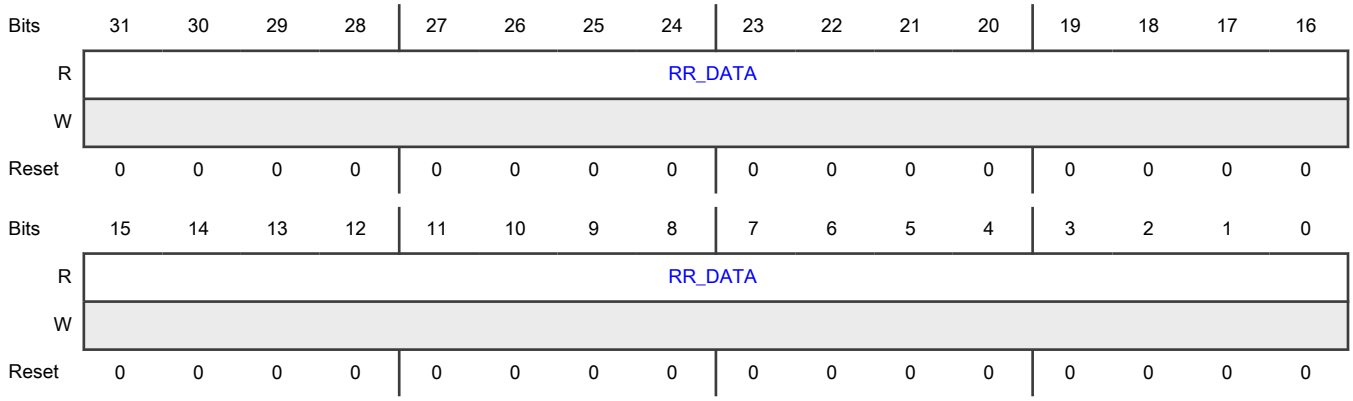
Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUB receive data.

Diagram



Fields

Field	Function
31-0 RR_DATA	MUB Receive Data Reflects the data written to MUA TR*n*. Reading this register clears MUB_RSR[RF*n*] on the receiver side, and sets MUA_TSR[TE*n*] on the transmitter side. You can read this register only when MUB_RSR[RF*n*] = 1. Reading it before MUB_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUB_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUB.

Chapter 52
Radio Platform

52.1 Chip-specific Radio Platform information

52.1.1 XTAL_OUT_EN

The XTAL_OUT_EN in this chapter is the RF_XTAL_OUT_ENABLE in the Package pinout.

52.2 Introduction

52.2.1 Introduction

The 2.4GHz Multi-Protocol Radio supports concurrent operation in the 2.4GHz bands.

The 2.4GHz band radio covers 2.36-2.4835GHz and is built to support multiple protocols.

- Bluetooth Low Energy v6.0 with support for optional features
  - Channel Sounding: Mandatory and Optional Features
  - 1Mbps
  - 2Mbps
  - Long Range 125kbps & 500kbps
- IEEE 802.15.4-2006 compliant PHY & MAC
  - Thread
  - Zigbee
- IEEE 802.15.4j-2012 Medical Body Area Network (MBAN) frequency bands spanning from 2360-2400MHz.
- Generic 2-level FSK/GFSK/MSK/GMSK
  - 250kbps
  - 500kbps
  - 1000kbps
  - 2000kbps
- Concurrent 802.15.4 and Bluetooth LE operation

The Radio block diagram is provided for illustration of the internal organization of the radio.

The Narrowband Unit (NBU) is a dedicated compute subsystem for the Narrowband Radio. The NBU is comprised of an Arm Cortex-M33 and associated peripherals that, in conjunction with the Bluetooth Unit, support the Bluetooth LE protocol. Among the supporting peripherals are timers, a messaging unit, and dedicated flash (distinct from the SoC flash). While the NBU allows for flexibility for evolving requirements, firmware to implement radio protocols is intended to be developed and delivered by NXP.

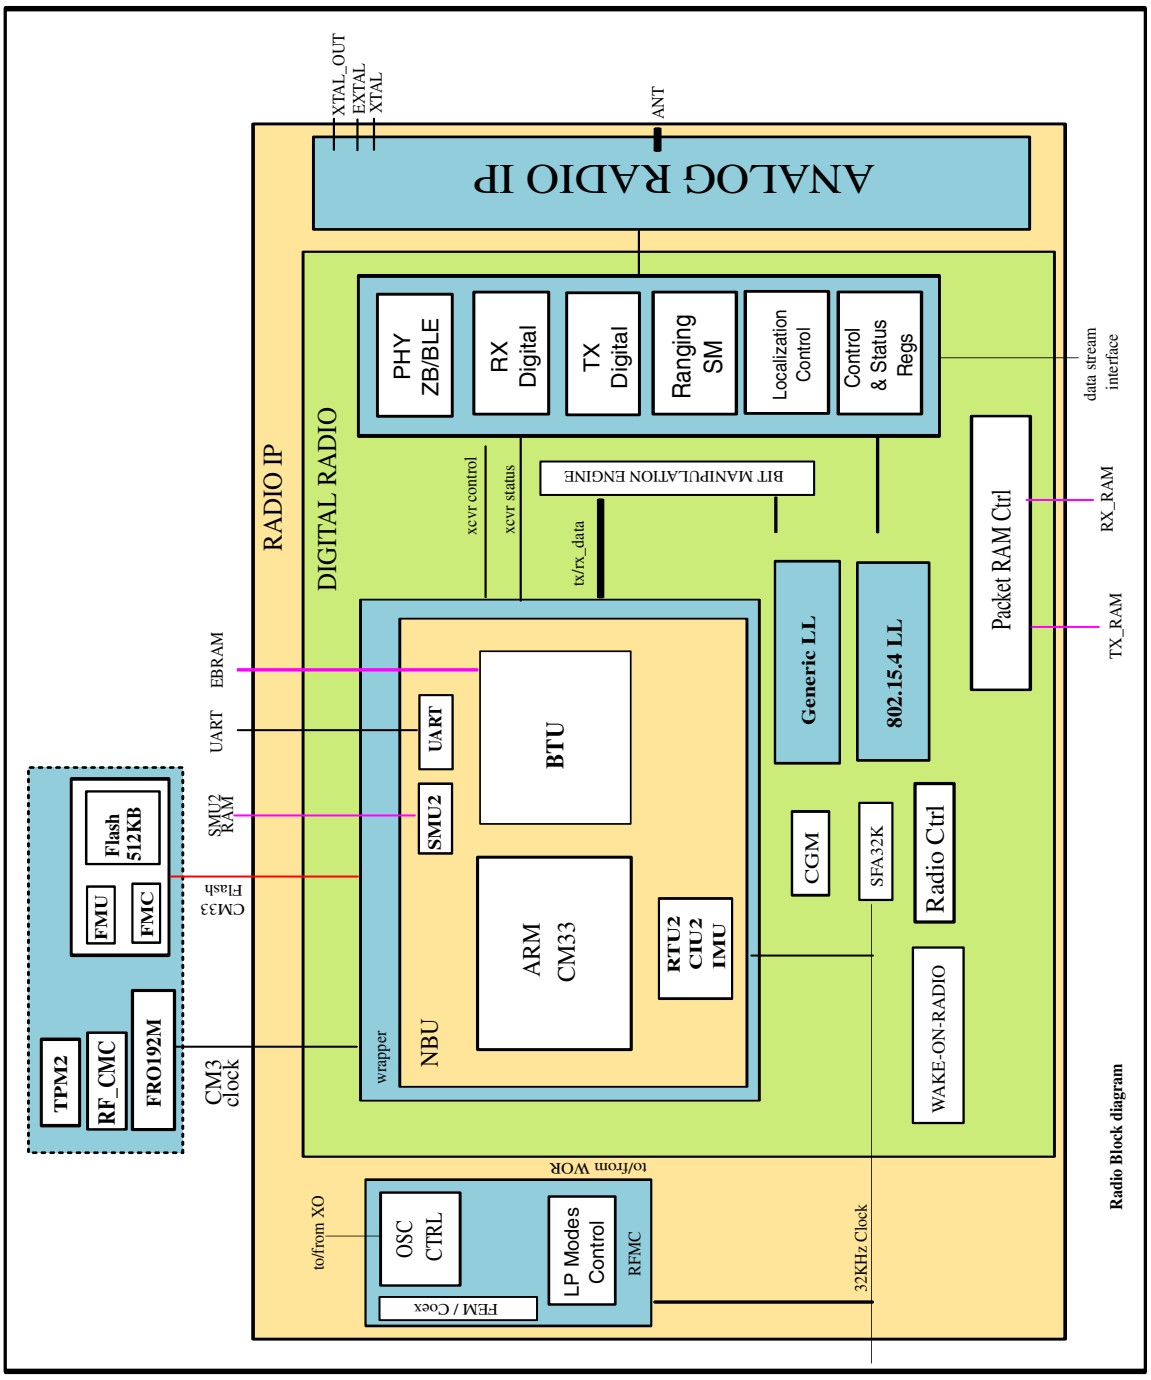


Figure 210. Radio Block diagram

52.2.2 Interface Specification

52.2.2.1 I/O Ports

This section describes all ports of the Radio IP at the top level.

52.2.2.1.1 Ports for XO and RFMC

The table below shows signals which are related to the XO or the RFMC .

Table 442. I/O Ports

Name	Size	Direction	Pad/ GPIO	Domain	ISO safe state value	Typ Switch Freq	Clock Domain	Test	Description
Analog/Power Interface									
EXTAL		IO	Pad	LDO_XO		40MHz	EXTAL		Input crystal waveform or square wave clock in bypass
XTAL		IO	Pad	LDO_XO		40MHz	EXTAL		Square wave oscillator output
XTAL_OUT		IO	Pad	LDO_XO			EXTAL		Buffered clock out for use by external device
DGO Interface - clock control									
ipp_do_xo_req_1p8v		O	GPIO	1p8v					To device external to the SoC to request clk to be input to RF XO.
ipp_ibe_xosc_ext_en_1p8v		O	GPIO	1p8v					Input Buffer Enable for above signal
ipp_ind_xosc_ext_en_1p8v		I	GPIO	1p8v					From device external to the SoC to request the RF Osc be enabled, for instance from WiFi chip.
DGO Interface - Coexistence / LANT / FAD									
ipp_ind_rf_nallowed_1p8v		I	GPIO	1p8v					Signal from external device indicating RF operation is not allowed
ipp_ibe_rf_nallowed_1p8v		O	GPIO	1p8v					Input Buffer Enable for above signals

52.2.2.1.2 Ports for 2.4GHz Radio

The table below shows signals which are specific to the 2.4GHz radio.

Table 443. I/O Ports

Name	Size	Direction	Pad/ GPIO	Domain	ISO safe state value	Typ Switch Freq	Clock Domain	Test	Description
Analog/Power Interface									
ANT		IO	Pad	VPA		2.4GHz			Antenna
GANT		IO	Pad	GND					Ground node for antenna to integrated balun
VDD_RF		IO	Pad	VDD_RF					Supply for Radio except for PA
GND_RF		IO	Pad	GND					Ground for Radio

52.3 RFMC

52.3.1 Overview

The Radio Mode Controller (RFMC) is responsible for sequencing the power mode of the 2.4GHz radio domain and controlling the radio crystal oscillator (XO).

52.3.1.1 Block Diagram

The following diagram gives a high-level overview of the RFMC.

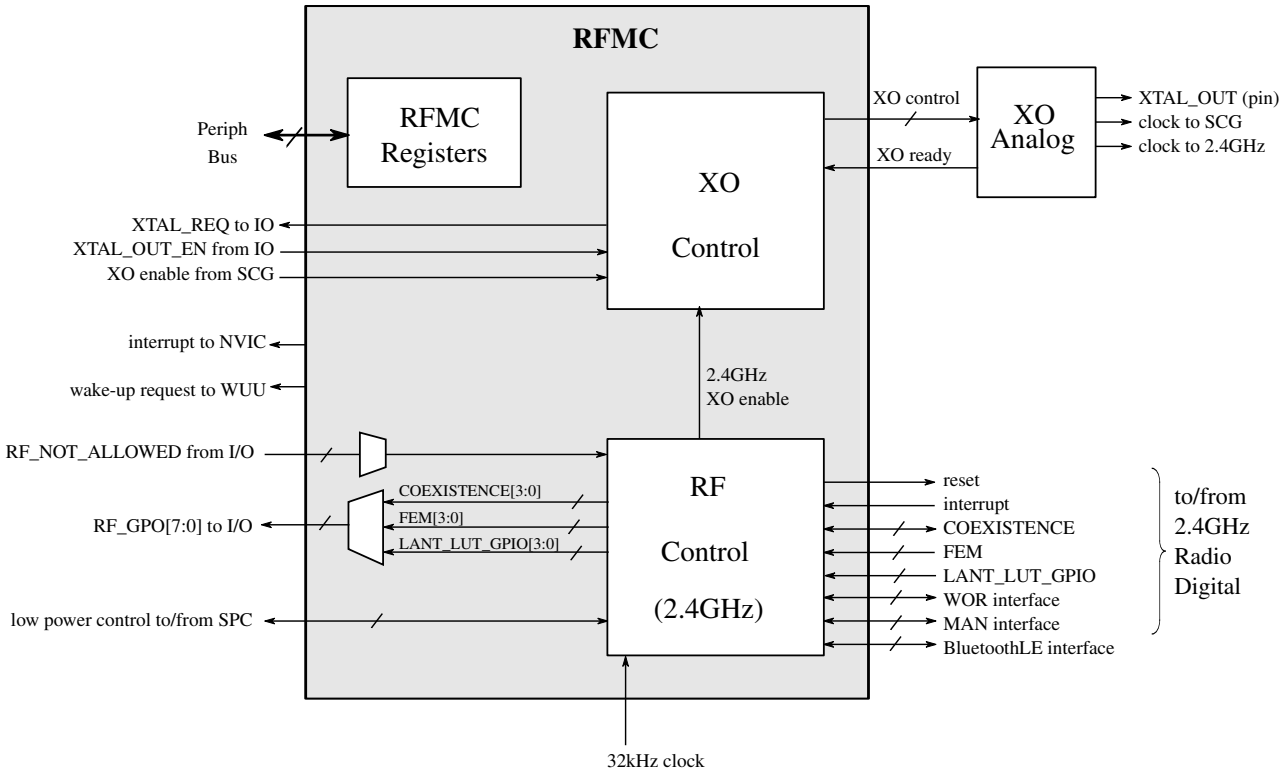

Figure 211. RFMC Block Diagram

52.3.1.2 Features

The Radio Mode Controller (RFMC) is responsible for sequencing the power mode of the 2.4GHz radio domain and controlling the radio crystal oscillator (XO). Specifically, it supports the following features:

- Support for Deep Sleep and Power Down modes.
- Low power mode entry/exit for the 2.4GHz radio power domain.
- Enable of XO supported from both internal and external sources.
- Support for external coexistence interface for 2.4GHz frequency band
- 32kHz timer to control low power entry/exit times via Wake on Radio (WOR) or Manual (MAN) counters.
- Timer offsets to ensure XO and radio power restored prior to WOR/MAN exit event.
- Interrupts supported for XO and low power radio wakeup events.

52.3.2 Functional description

52.3.2.1 XO Control

The XO Control sub-module is responsible for enabling the XO analog oscillator in response to a request from either the 2.4GHz radio, System Clock Generator (SCG) or an external request (XTAL_OUT_EN pin asserted). The clock output from the XO analog oscillator can be independently driven to 3 different clocking domains under RFMC control: 2.4GHz radio digital, SCG and XTAL_OUT pin. (Additional XO clock output(s) to the 2.4GHz radio analog blocks are not shown in the figures; this is enabled by TSM.) The figure below illustrates the logic implemented by the XO control sub-module to drive each of these domains.

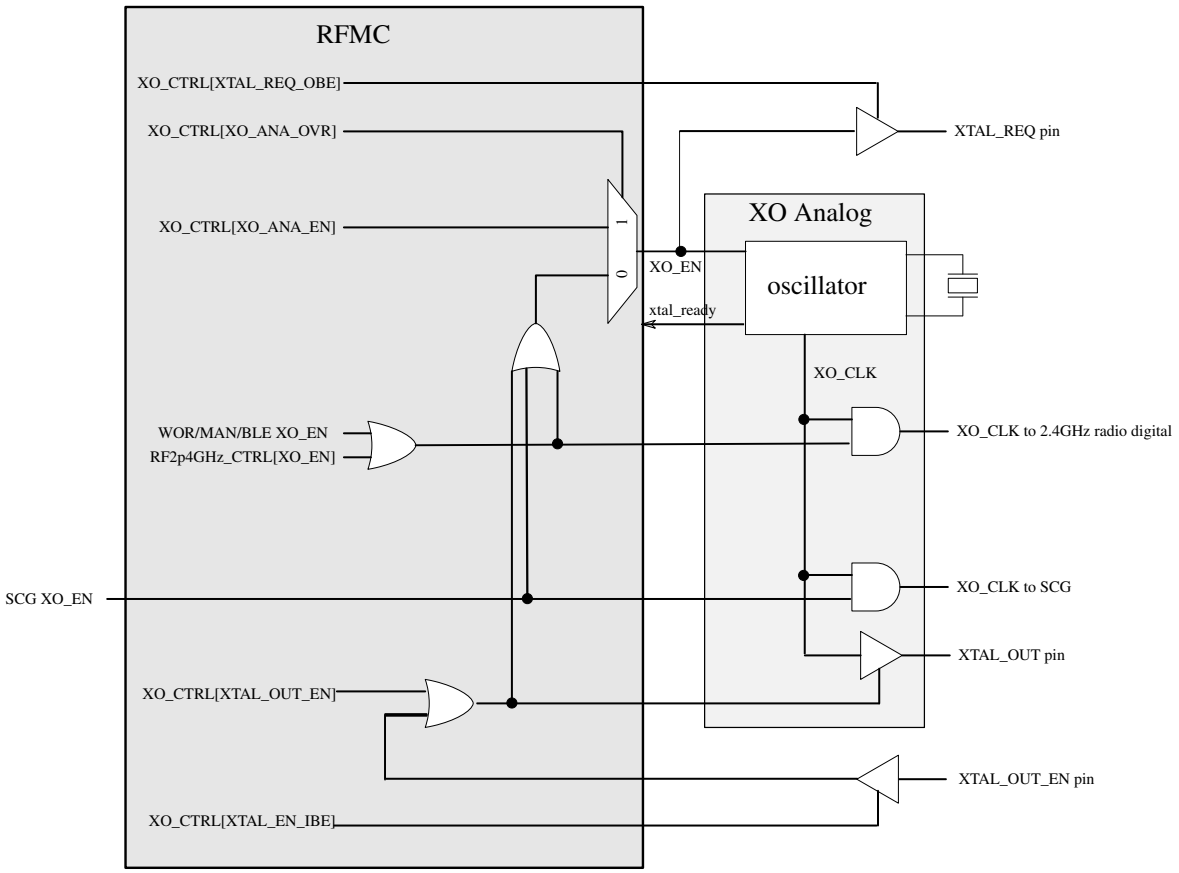

Figure 212. XO Control logic

The XO_CTRL[WKUP_OFFSET] can be used to pre-emptively enable the XO during a MAN/WOR wakeup sequence. This ensures the XO is ready and stable before the link layer begins operation at the designated MAN/WOR wakeup time.

Three flags with optional interrupts can be generated by the XO Control sub-module:

- RDY_FLAG: sets after the XO output is ready.
- INT_FLAG: sets when an internal source (SCG, 2.4GHz radio) has requested the XO.
- EXT_FLAG: sets when an external source (XTAL_OUT_EN pin) has requested the XO.

52.3.2.2 Low Power Mode Controllers

A major function of the RFMC is to control the power mode of the 2.4GHz radio . The RFMC itself resides in the system power domain and remains fully functional in all power modes except for Deep Power Down.

The 2.4GHz sub-module within the RFMC contains the following power controllers, any of which can be used to control low power entry/exit for the 2.4GHz radio:

- The MAN power controller can be used in conjunction with the Generic Link Layer or the 802.15.4 Link Layer. This controller is used to control the low power mode entry/exit time by programming the entry and wakeup time in the RFMC.
- The WOR power controller can be used in conjunction with the Generic Link Layer or the 802.15.4 Link Layer. This controller enters low power mode when directed -- and for the duration specified -- by the radio's WOR scheduler. The WOR scheduler is capable of scheduling multiple low power entry/exit and radio events.
- The Bluetooth LE power controller can only be used in conjunction with the Bluetooth LE Link Layer in the 2.4GHz radio. This power controller enters and exits low power as directed by the Bluetooth LE link layer in the radio. (Note that the Bluetooth

LE link layer controls a small amount of logic residing in the system power domain and which uses the 32kHz clock to keep track of time during low power mode.)

In addition to the power controllers, software can also set/clear the RF*_CTRL[LP_ENTER] bit to enter/exit low power mode.

When software or the power controller directs the radio to enter low power, the low power mode will be as selected as programmed by the RF*_CTRL[LP_MODE] bit field, which selects between the following:

- Deep Sleep: low power static mode with clocks gated, but all radio digital logic and SRAM state is retained.
- Power Down: full power down of all radio digital logic and SRAM.

Following a POR/LVD event, RF*_CTRL[LP_ENTER] is set and RF*_CTRL[LP_MODE] is configured such that both radios will initially be in Power Down mode until the RF*_CTRL[LP_ENTER] field is cleared.

The MAN, WOR and Bluetooth LE power controllers in the RFMC each implement its own state machine to sequence the radio in and out of low power modes. Each state machine implements the following states, which are also observable by reading the RF*_STAT[MAN/WOR/BLE_STATE] register fields:

- RESET: controller reset, waiting for controller to be enabled. Outputs set to XO_EN=0, RF_ACTIVE=0, LP_REQ=0.
- ACTIVE: radio in active mode. Outputs set to XO_EN=1, RF_ACTIVE=1, LP_REQ=0.
- SLEEP: radio in low power mode. Outputs set to XO_EN=0, RF_ACTIVE=0, LP_REQ=1.
- WKUP: radio begins transition to active mode. Outputs set to XO_EN=1, RF_ACTIVE=1 (after RF*_COEXT[RFACT_WKUP_DLY]), LP_REQ=0 (after RF*_CTRL[LP_WKUP_DLY]).

The following diagram shows the transitions between states for the power controllers.

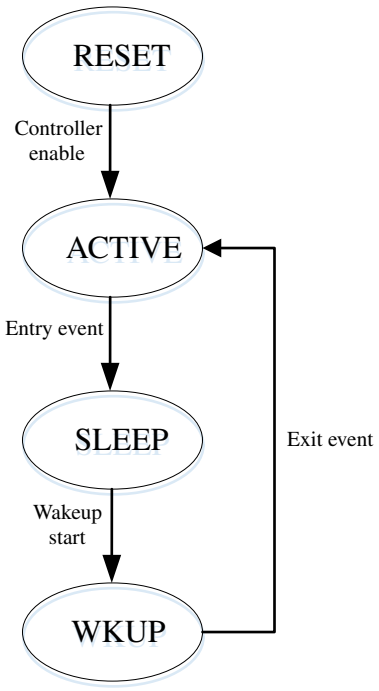

Figure 213. MAN/WOR/Bluetooth LE power control state diagram

Note that the transition from ACTIVE to SLEEP also depends on a "sleep ready" signal from the RF_CMC module, which ensures that other logic in the radio (especially the flash) is ready for the RFMC to put the radio is low power mode. This RF_CMC signal is reflected in the RF*_STAT[SLP_RDY_STAT] bit.

On transition from WKUP state to ACTIVE state, each power controller selected via RF*_CTRL[SFA_TRIG_EN] asserts a trigger to the SFA in the radio for one 32kHz clock cycle which will (if the SFA is properly configured) start a calibration cycle for the FRO32K clock.

To ensure correct sequencing of the radio power modes, it is recommended that only one of the power controllers be enabled at any given time. However, the RFMC does allow the MAN and WOR power controllers to be concurrently enabled in which case the radio will only enter low power when MAN and WOR power controllers both request low power.

The MAN/WOR/Bluetooth LE power controllers operate using the 32kHz OSC clock, and this clock must be available before enabling any of the power controllers for low power entry/exit.

52.3.2.2.1 MAN Power Controller

To enable the MAN power controller, the RF*_MAN2[MAN_EN] bit must be set. The RF*_TIMER[TIM_EN] must also be set to enable the 32kHz timer used by the MAN power control. For the 2.4GHz radio, the MAN must be assigned to a specific link layer in the 2.4GHz radio. In the WOR, the ENTER_TIME and WKUP_TIME for MAN should be programmed with the desired low power entry and exit time, respectively.

The low power entry/exit sequence is illustrated in the figure below. After the link layer has requested deep sleep entry (man_sleep_req in figure below, and reflected in the RF*_MAN1[ENTER_REQ] status bit) a MAN low power entry event is triggered when the RF*_TIMER[TIME] counter matches ENTER_TIME. Low power exit is scheduled to complete when the RF*_TIMER[TIME] counter matches WKUP_TIME. Prior to the WKUP_TIME, the MAN controller will enable the XO (xo_en) at XO_CTRL[WKUP_OFFSET] 32kHz cycles before WKUP_TIME, and request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion) at RF*_CTRL[LP_WKUP_DLY] 32kHz cycles after XO is enabled. It is expected that the WKUP_OFFSET is programmed to allow sufficient time for the XO to warmup and assert the xtal_ready signal. Likewise, the LP_WKUP_DLY is programmed to allow enough time for the SPC to bring the radio out of low power mode before WKUP_TIME. RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG] and RF*_STAT[MAN_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at WKUP_TIME, respectively. Before the MAN power controller will enter ACTIVE state, TIME must reach WKUP_TIME and man_sleep_req must be de-asserted. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the MAN power controller reaches the ACTIVE state. The MAN power controller's state is reflected in RF*_STAT[MAN_STATE] for use as needed by software.

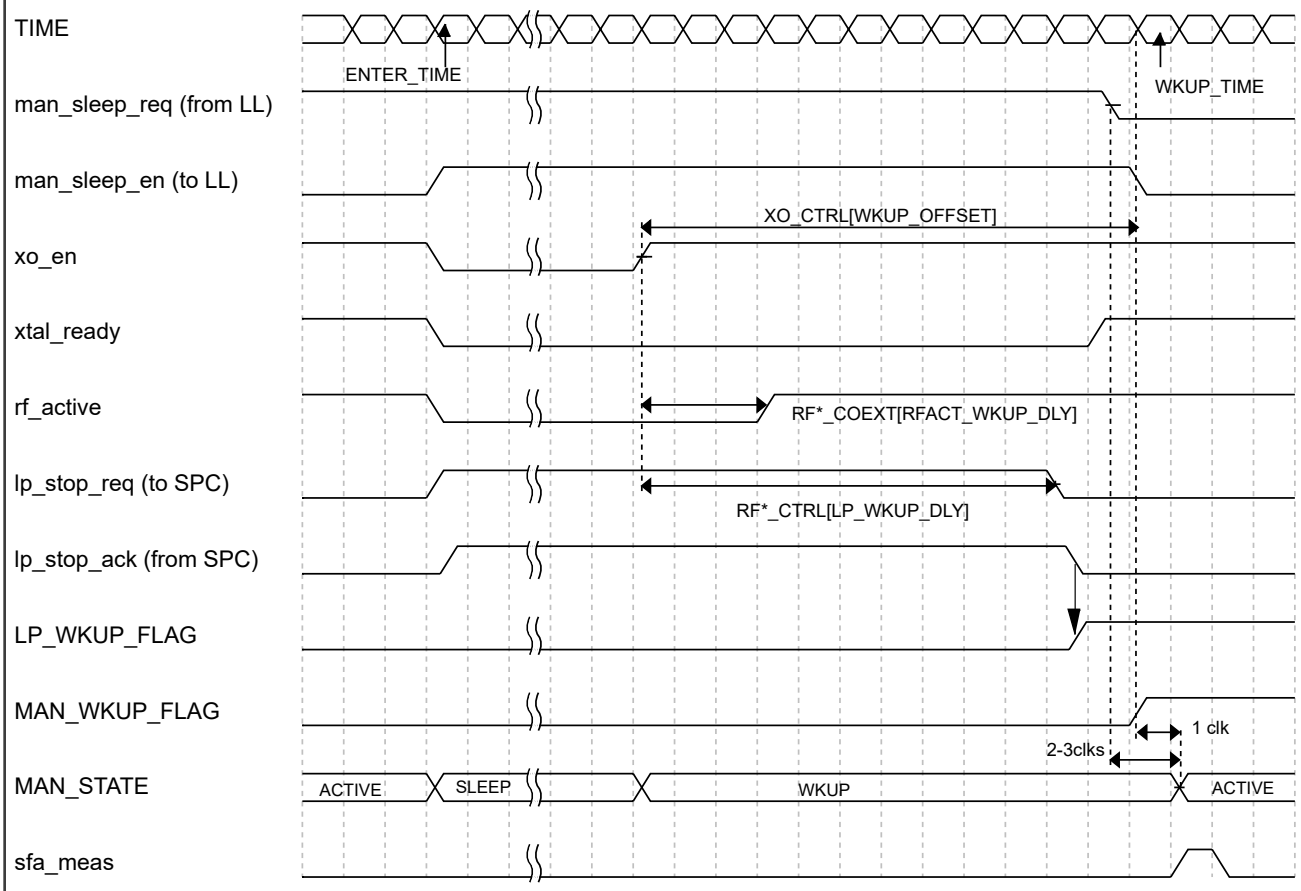

Figure 214. Low Power entry/exit for MAN Power Controller

If for some reason the radio needs to be woken before WKUP_TIME has been reached, the RF*_MAN2[MAN_WKUP] bit can be set by software to wake the radio prematurely. The radio can also be woken before WKUP_TIME has been reached if a debug request is raised from outside the radio by setting pin rfmc_radio_debug_req_1p8v.

52.3.2.2.2 WOR Power Controller

To enable the WOR power controller, the RF*_WOR2[WOR_EN] bit must be set. For the 2.4GHz radio, the WOR must be assigned to a specific link layer by programming the WOR_CTRL[WOR_PROTOCOL] in the 2.4GHz radio. The WOR low power entry is controlled by wor_sleep_req (reflected in RF*_WOR1[ENTER_REQ] bit) from the "WOR scheduler" (the WOR logic in the radio domain), and the desired low power duration (wor_sleep_duration -- reflected in RF*_WOR1[DURATION_TGT]) is also an input to the RFMC from the WOR scheduler.

The low power entry/exit sequence is illustrated in the figure below. Prior to low power entry, the WOR scheduler pulses the wor_sleep_duration_clr to clear the DURATION counter (RF*_WOR2[DURATION]) in the WOR power controller, then asserts wor_sleep_req. The WOR power controller needs to synchronize this request to the 32kHz clock domain, so after 2-3 cycles, low power mode is entered. Low power exit is scheduled to complete when the DURATION counter matches wor_sleep_duration. Prior to this time, the WOR controller will enable the XO (xo_en) at XO_CTRL[WKUP_OFFSET] 32kHz cycles before wor_sleep_duration, and request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion) at RF*_CTRL[LP_WKUP_DLY] 32kHz cycles after XO is enabled. It is expected that the WKUP_OFFSET is programmed to allow sufficient time for the XO to warmup and assert the xtal_ready signal. Likewise, the LP_WKUP_DLY is programmed to allow enough time for the SPC to bring the radio out of low power mode before WKUP_TIME. RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG]

and RF*_STAT[WOR_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at wor_sleep_duration, respectively. The WOR power controller does not move to ACTIVE state until after the WOR scheduler de-asserts the wor_sleep_req signal. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the WOR power controller reaches the ACTIVE state. The WOR power controller's state is reflected in RF*_STAT[WOR_STATE] for use as needed by software.

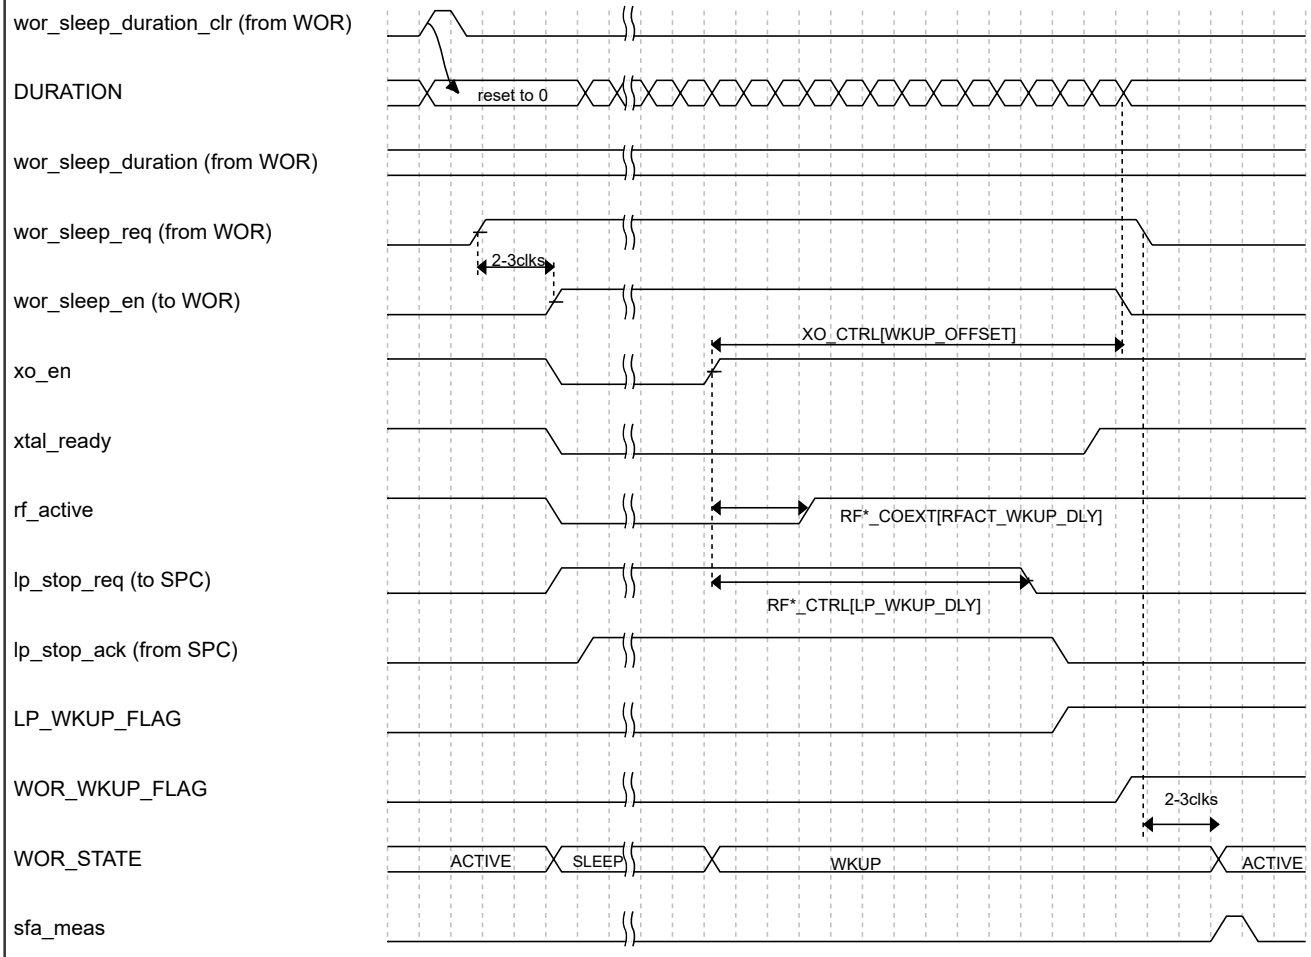

Figure 215. Low Power entry/exit for WOR Power Controller

If for some reason the radio needs to be woken before wor_sleep_duration has been reached, the RF*_WOR2[WOR_WKUP] bit can be set by software to wake the radio prematurely. The radio can also be woken before wor_sleep_duration if a debug request is raised from outside the radio by setting pin rfmc_radio_debug_req_1p8v.

52.3.2.2.3 Bluetooth LE Power Controller

To enable the Bluetooth LE power controller, the RF2p4GHz_CTRL[BLE_LP_EN] bit must be set. A Bluetooth LE low power entry and exit event is then controlled by the Bluetooth LE link layer (see Bluetooth LE link layer programming model).

NOTE

The 32kHz clock used by both the Bluetooth LE power controller and the Bluetooth LE link layer is enabled by setting RF2p4GHz_CTRL[BLE_LP_EN]. If for some reason the Bluetooth LE link layer needs this clock to be active while the Bluetooth LE power controller is not enabled (BLE_LP_EN bit not set), software can program RF2p4GHz_CTRL[CLK_OVR] to force the clock to be enabled.

The low power entry/exit sequence is illustrated in the figure below. When the Bluetooth LE link layer wants to enter low power, it de-asserts the bt_clk_req input to RFMC (this signal is reflected in RF*_STAT[BLE_WKUP_STAT]). When the Bluetooth LE link layer wants to exit low power, it asserts bt_clk_req. At that time, the Bluetooth LE power controller will enable the XO (xo_en), and after RF*_CTRL[LP_WKUP_DLY] 32kHz cycles it will request the SPC to wake the radio domain from low power mode (lp_stop_req de-assertion). It is expected that the LP_WKUP_DLY is programmed such that the SPC will complete bringing the radio out of low power mode near the time when the XO becomes ready (xtal_ready). However, in several cases, CM33 will want to have access to radio memory without using the radio. In that case, there is no need to start, and hence wait, for the XO. For this purpose, RF*_CFG[BLE_FAST_WKUP] bit can be set to 1. In this case, the Bluetooth LE power controller will request the SPC to wake the radio domain from low power mode without wakeup delay. RF_ACTIVE can also be programmed to assert at RF*_COEXT[RFACT_WKUP_DLY] after XO is enabled. Flags RF*_STAT[LP_WKUP_FLAG] and RF*_STAT[BLE_WKUP_FLAG] (with optional interrupts) are set after the lp_stop_ack (from SPC) de-asserts and at xo_en, respectively. The Bluetooth LE power controller moves to ACTIVE state in the cycle after lp_stop_req is de-asserted. If properly configured in RF*_CTRL[SFA_TRIG_EN], a trigger (sfa_meas) will be issued to the radio SFA after the Bluetooth LE power controller reaches the ACTIVE state. The Bluetooth LE power controller's state is reflected in RF*_STAT[BLE_STATE] for use as needed by software.

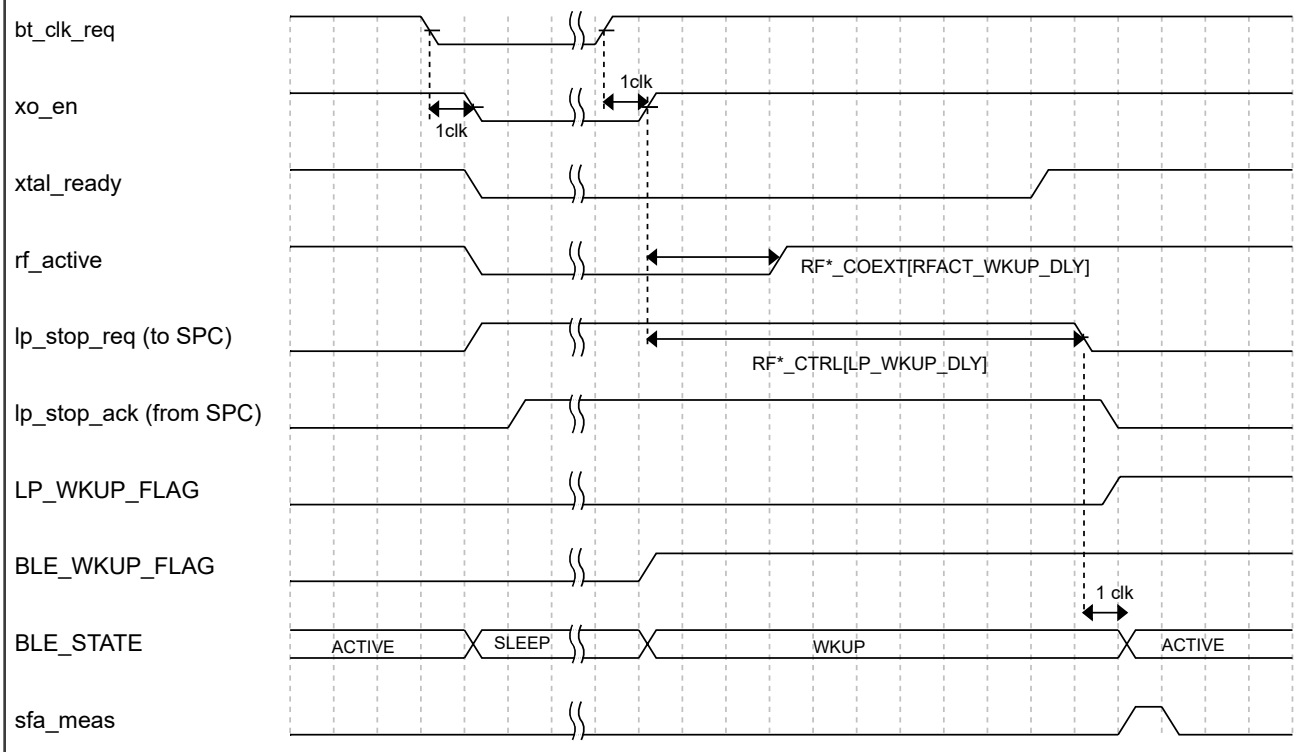

Figure 216. Low Power entry/exit for Bluetooth LE Power Controller

If for some reason the radio needs to be woken before the Bluetooth LE link layer is scheduled to assert bt_clk_req, the RF2p4GHz_CTRL[BLE_WKUP] bit can be set by software to wakeup the radio prematurely.

The Bluetooth LE power controller behavior is a bit different than the MAN and WOR power controllers. In particular

- The XO_CTRL[WKUP_OFFSET] bitfield is not used by the Bluetooth LE power controller. Instead the Bluetooth LE link layer has its own programmable bitfield "Osc_startup_delay" which is used to delay when the Bluetooth LE link layer switches timing control from the low power clock to the XO
- The Bluetooth LE power controller does not have a counter to keep track of the low power duration; that is handled in the Bluetooth LE link layer

- The BLE_WKUP_FLAG asserts at WKUP state, whereas the MAN_WKUP_FLAG and WOR_WKUP_FLAG assert at the end of the requested low power duration

The radio can also be woken earlier in one of these cases :

- One of the two external wakeup signals on pins rfmc_ext_wakeup_2p4GHz_1p8v[1:0] is set
- Debug request is raised from outside the radio by setting pin rfmc_radio_debug_req_1p8v

Because nbu core and soc host core can go to low power independently, Software needs to give indication to the other core for some information. For this purpose, specific mirror registers in always on domain are available so both cores can communicate without the need for one to wakeup the second. In the RFMC, these registers are RF 2.4GHz Buffer from Host to Radio (RF2p4GHz_HOST2RADIO) and RF 2.4GHz Buffer from Radio to Host (RF2p4GHz_RADIO2HOST). The equivalent mirror registers are in the Transceiver module.

52.3.2.3 Radio Coexistence

The 2.4GHz radio implements external IO signals to support coexistence with an external RF device operating within the same frequency band. The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the coexistence outputs {RF_ACTIVE, RF_STATUS, and RF_PRIORITY[1:0]} from the 2.4GHz radio, provides additional control for the RF_ACTIVE signal, and provides control for the RF_NOT_ALLOWED coexistence input. The next few paragraphs discuss RFMC control of the RF_NOT_ALLOWED and RF_ACTIVE signals. For more information on coexistence refer to the Coexistence Interface and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

For RF_NOT_ALLOWED, the RFMC provides programmable control (RF*_COEXT[RFNA_IE] bitfield) so that this coexistence signal can be sourced from any of 5 device pins, or disabled. Some status bits related to RF_NOT_ALLOWED are also available in XCVR_MISC->RSM_INT_STATUS register of the Transceiver.

For RF_ACTIVE, the RFMC provides programmable control (RF*_COEXT[RFACT_SRC] bitfield) to select whether this coexistence output is sourced by the RFMC, the Bluetooth LE bt_clk_req signal, or a mux of the TSM's RF_ACTIVE signal and the active link layer's REQUEST signal. If RF_ACTIVE is sourced by the RFMC (RF*_COEXT[RFACT_SRC]=00), this signal relies on the RFMC’s low power controllers (one of the RFMC’s low power controllers should be enabled); in this configuration the RF_ACTIVE behavior is as follows:

- If RF*_COEXT[RFACT_IDIS]=0
  - Asserts during the RFMC low power controller's wakeup sequence, RF*_COEXT[RFACT_WKUP_DLY] 32kHz clock cycles after the XO is enabled
  - De-asserts when the RFMC low power controller requests that the radio enters a low power mode
  - Software can cause RF_ACTIVE to be asserted during a low power mode by setting the RF*_COEXT[RFACT_EN] bitfield
- If RF*_COEXT[RFACT_IDIS]=1
  - Asserts when the TSM is busy
  - De-asserts when the TSM is idle

Also related to RF_ACTIVE are the QUIET_REQ outputs. These also indicate when the radios are active, but are used inside the SOC to suppress SOC Core flash and/or RF Core flash activity if needed. These outputs have configurable behavior using the RF*_COEXT register's QREQ_SRC, QREQ_SOC_EN and QREQ_RF_EN bits.

52.3.2.4 Radio FEM Control

The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the FEM (front-end module) signals {ANT_A, ANT_B, RX_SWITCH, and TX_SWITCH} from the 2.4GHz radio, but does not otherwise make use of, or affect these signals. For more information on these signals, refer to the Transceiver Localization and Antenna Control section of the Transceiver chapter and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

52.3.2.5 Radio Localization Antenna Select

The RFMC provides mux control (via RFMC's RF_GPO[7:0] output) for the LANT_LUT_GPIO[3:0] (localization antenna select) signals from the 2.4GHz radio, but does not otherwise make use of, or affect these signals. For more information on these signals, refer to the Transceiver Localization and Antenna Control section of the Transceiver chapter and Coexistence/FEM/LANT connections sections of the Radio Control chapter.

52.3.2.6 Clocking

The RFMC uses the following clock sources :

- ipg_clk : provided at SOC level at radio top's ipg_clk_s_1p8v pin to control Read/Write operations to registers.
- 32 kHz clock : provided from SOC level at radio IP's clk_32k_1p8v pin, it is the functional clock of the RFMC
- 32 kHz clock : provided from SOC level at radio IP's clk_32k_nbu_1p8v pin, it is gated then provided to the radio digital part

Those clocks are managed only at SOC level.

52.3.2.7 Reset

The RFMC and 2.4GHz radio are reset on any system reset event or by setting the RFMC_CTRL[RFMC_RST] bit, with the exception of the following registers bits which are only reset on a POR/LVD event: RFMC_CTRL[RFMC_RST] (resets to 0) and RFMC_CTRL[RST_MSK] (resets to 0).

The RFMC can also generate software resets for the 2.4GHz radio via the RF*_CTRL[RF_POR], RF*_CTRL[RST] and RF*_CTRL[CPU_RST] bits. Setting RF*_CTRL[RF_POR], RF*_CTRL[RST], or RF*_CTRL[CPU_RST] will have no effect on the RFMC itself however. The reset associated with RF*_CTRL[CPU_RST], ipg_async_cpu_reset_lv, is used primarily to hold the CM3 core in reset for flash loading. The reset associated with RF*_CTRL[RF_POR], ipg_async_por_2p4GHz_b_lv, provides POR for the LV domain logic. On exit from Power Down or Deep Power Down low power modes, a signal from the SPC (spc_pd_pwrdwn_exit) asserts all of the LV resets.

There is also a RF*_CTRL[CPU_RST_LOCK] bit associated with the RF*_CTRL[CPU_RST]. If the CPU_RST_LOCK bit is set, the CPU_RST bit cannot be cleared until the next system reset (ipg_async_reset_1p8v). The lock bit is used by boot ROM code to force the radio CPU to remain in reset if the radio flash verification fails.

The radio also needs to be held off until the flash has finished its initialization (its IFR outputs are valid, and it is ready to accept read requests) after a reset. The radio flash output signal msf_core_hold is used by the RF_CMC module for this purpose: the RF_CMC delays de-assertion of the non-POR resets used by the radio.

For testing purposes, the RFMC and radio power domains can be isolated from system reset events by setting the RFMC_CTRL[RST_MSK] register bit. Note that the RFMC_CTRL[RFMC_RST] and RF*_CTRL[RST] register bits are still functional when the RFMC_CTRL[RST_MSK] bit is set.

The figure below illustrates reset bits and signals for the RFMC, RF_CMC and radio. The ipg_async_reset_rfmc_1p8v is an output from the RFMC to use to reset any other 1.8v logic in the radio power domain.

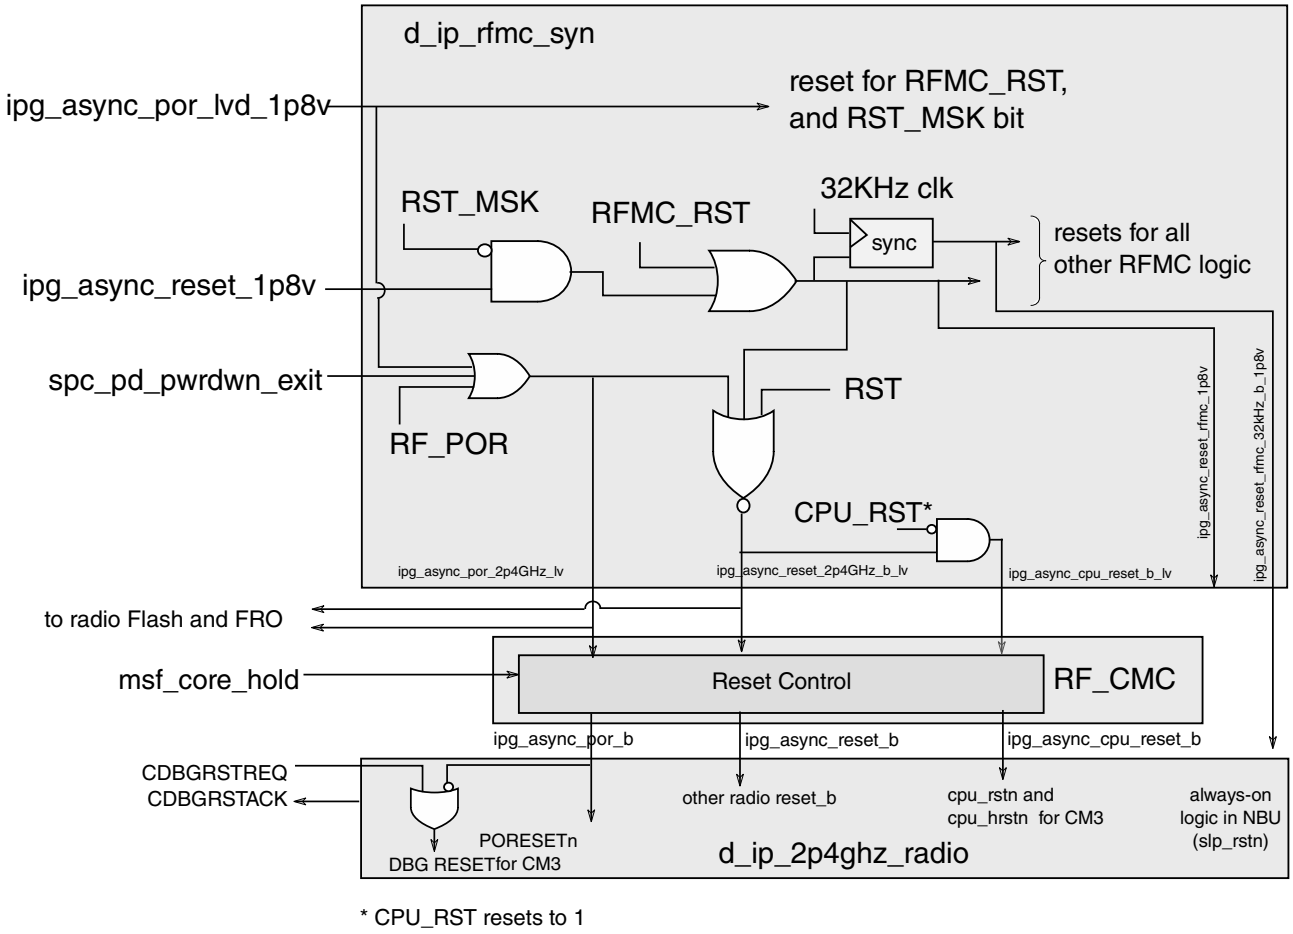

Figure 217. Reset

52.3.2.8 Interrupt and wake-up request

The RFMC generates an output for the SOC's interrupt controller (NVIC) and a wake-up request for the SOC's wake-up unit (WUU). As shown in the figure below, all enabled interrupt sources within the RFMC -- from the XO control and the 2.4GHz low power controllers -- are combined to generate the rfmc interrupt. The wake-up request for the WUU combines enabled interrupt requests from the Bluetooth LE, WOR and MAN low power controllers within the RFMC with interrupt requests from the 2.4GHz radio .

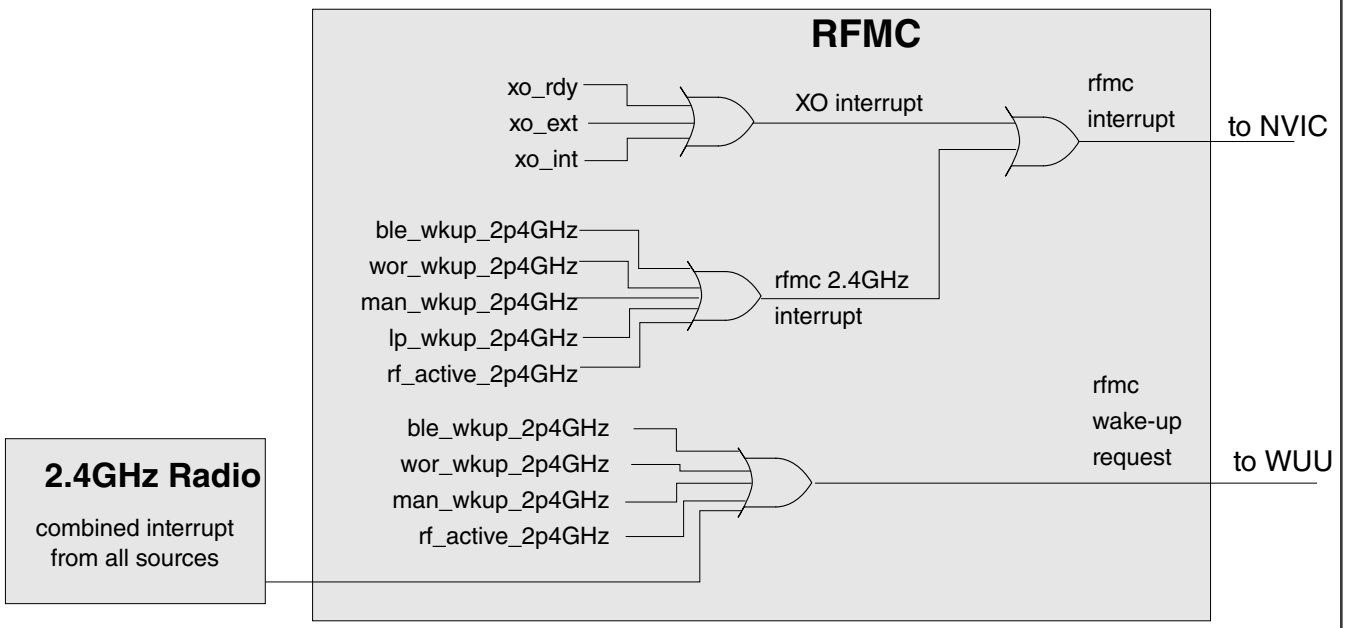

Figure 218. Interrupt and wake-up request

52.3.2.9 Power-on Sequence

After a POR/LVD event, the RFMC is released from reset, the 2.4GHz radio is powered up and released from reset, but the XO is disabled and the NBU CPU is held in reset . The following steps are needed by software. (Note that steps 1-3 may optionally be supported by the SOC boot ROM.)

1. Configure the XO. Program the EXT_MODE, XTAL_REQ_OBE and other bits in the XO_CTRL register as needed
2. Set RF*_CTRL[XO_EN] to enable the XO, or enable of the RFMC's low power controllers to allow it to enable the XO.
3. Clear the RF*_CTRL[CPU_RST] bit to release the NBU CPU from reset.
4. Wait for XO_STAT[RDY_FLAG] to be set. An RFMC interrupt is also associated with this event. Software can access the radio modules which use the XO clock after the XO is ready. (Software can access the radio modules which use the radio FRO clock before the XO is ready.)

52.3.3 External signals

Table 444. RFMC external I/O

Signal	Description	I/O
XO Interface		
XTAL_REQ	Request to enable an external crystal when internal XO is bypassed.	O
XTAL_OUT_EN	Enable from an external source to activate internal XO.	I
Radio Coexistence, FEM Control, and Localization Antenna Select Interfaces		
RF_GPO[7:0]	Software can select any two of {4 Coexistence signals, 4 FEM Control signals, 4 Localization Antenna Select signals} on this 8bit output.	O

Table continues on the next page...

Table 444. RFMC external I/O (continued)

Signal	Description	I/O
RF_NOT_ALLOWED[4:0]	Software can select 1 of 5 input pins to use for the "RF not allowed" Coexistence signal, which blocks radio activity when asserted.	I

52.3.4 Initialization

RFMC does not require any special initialization.

In order to start the NBU CM33 core, the RF2p4GHz_CTRL[CPU_RST] needs to be de-asserted, so that its reset gets released.

52.3.5 Application Information

As RFMC is managing the power modes transition for the Radio power domain, here it given the typical LowPower entry and exit sequences. Low power mode entry is always initiated by the Radio itself, while Wakeup sequence can be triggered either internally by the Radio using internal timers, or by the main power domain (i.e. to access SMU for sending messages to the Radio).

For Low Power entry/exit, the following parameters need initially to be configured:

- RF2p4GHz_CTRL[BLE_LP_EN] should be set, it will enable the BLE LP state machine.
- RF2p4GHz_CTRL[LP_WKUP_DLY] is defining the startup time of the Radio XO. Typical value is 0x10, translating into a XO startup time of 488us. This parameter ensures that XTAL is up and running prior to Low Power mode exit.
- RF2p4GHz_CTRL[LP_MODE] configures the LP mode entered when requested. Unless Radio is used, target LP_MODE is set to 0x3, corresponding to Deep Sleep: low power static mode with retention of digital logic and SRAMs.
- Inside RF_CMC, RADIO_LP[SLEEP_EN] should also be set to ungate LP entry after Radio CM33 WFI deepsleep request

Table continued from the previous page...

Field	Function
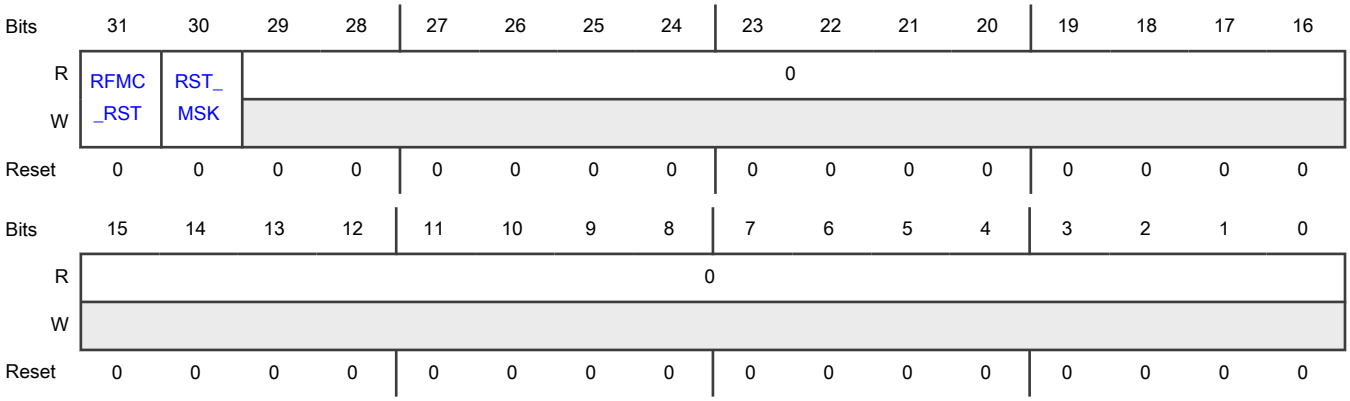
0 RF2p4GHz_EN	Indicates whether 2.4GHz radio is enabled (as determined by fuse bit). When disabled, the 2.4GHz radio will remain in Power Down. 0b - 2.4GHz radio disabled 1b - 2.4GHz radio enabled

52.3.6.1.4 RFMC Control Register (CTRL)

Offset

Register	Offset
CTRL	8h

Diagram



Fields

Field	Function
31 RFMC_RST	S/W System Reset for RFMC This causes a system reset for the RFMC. It resets all registers in the RFMC except for the RST_MSK and RFMC_RST register bits. This also resets the 2.4GHz radio. Note, the RFMC_RST bit is only reset on a POR/LVD event. 0b - Release the RFMC from reset 1b - Hold the RFMC in reset
30 RST_MSK	Reset Mask When set, masks system reset events (does not include POR/LVD) from resetting the RFMC, and 2.4GHz radio. Note the RFMC_RST bit is still functional, but will not reset the RST_MSK bit. The RST_MSK bit is only reset on a POR/LVD event.

Fields

Field	Function
31 XO_ANA_EN	XO Analog Enable When the XO_ANA_OVR bit is set, this bit will control the XO analog enable. Note this bit only enables the XO analog, but will not enable its output to the SCG, XTAL_OUT pin, or 2.4GHz radio domain. 0b - XO analog disabled 1b - XO analog enabled
30 XO_ANA_OVR	XO Analog Enable Override When set, allows the XO_ANA_EN bit to override any internal or external requests for the XO. 0b - XO analog enable not overridden 1b - XO analog enable overridden by XO_ANA_EN bit
29 XO_LDO_EN	XO LDO Enable When the XO_LDO_OVR bit is set, this bit will control the XO LDO enable.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - XO LDO disabled 1b - XO LDO enabled
28 XO_LDO_OVR	XO LDO Enable Override When set, allows the XO_LDO_EN bit to override any internal or external requests for the XO LDO. 0b - XO LDO enable not overridden 1b - XO LDO enable overridden by XO_LDO_EN bit
27-24 SPARE	XO Spare Registers Bit 3:1 - Reserved Bit 0 - Bypass CLK_AUX_DRV_LDO
23 XTAL_RDY_OVR	XTAL Ready Override When the XTAL_RDY_OVR_EN bit is set, this bit will override the XTAL ready signal from the XO analog.
22 XTAL_RDY_OVR_EN	XTAL Ready Override Enable When set, allows the XTAL_RDY_OVR to override the XTAL ready signal from the XO analog.
21 EXT_MODE	External Clock Mode 0b - DC coupled external clock mode (amplifier powered down). 1b - AC coupled external clock mode or crystal mode (amplifier powered up).
20 LDO_BYPASS	XO LDO Bypass
19 XTAL_OUT_INV	XO Clock Output Invert Inverts the polarity of the XTAL_OUT clock relative to the internal XO clock. Also referred to as AUX_DRV_FLIP. 0b - XTAL_OUT not inverted 1b - XTAL_OUT inverted
18 RDY_CNT_OFF	XTAL Ready Count Disable 0b - XTAL Ready Count Enabled 1b - XTAL Ready Count Disabled
17-16 RDY_CNT	XTAL Ready Count Configures the ready counter value (in number of XO clock cycles) for XO startup time. 00b - 1024

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - 2048 10b - 4096 11b - 8192
15-14 —	Reserved
13-8 WKUP_OFFSET	XO Wakeup Offset Configures number of 32kHz reference clocks before a MAN/WOR wakeup event to enable the XO.
7 —	Reserved
6 XTAL_EN_IBE	XTAL_OUT_EN Input Pin Enable Enables an external source to request the XO to be enabled (see chip configuration chapter for pin mapping). 0b - XTAL_OUT_EN input pin disabled 1b - XTAL_OUT_EN input pin enabled
5 XTAL_REQ_OBE	XTAL_REQ Output Pin Enable Enables output pin for XO request (see chip configuration chapter for pin mapping). 0b - XTAL_REQ output pin disabled 1b - XTAL_REQ output pin enabled
4 XTAL_OUT_EN	XTAL_OUT Output Pin Enable Enables the XO clock and drives it to the XTAL_OUT output pin (see chip configuration chapter for pin mapping). 0b - XTAL_OUT output disabled 1b - XTAL_OUT output enabled
3 —	Reserved
2 EXT_IE	XO External Request Interrupt Enable Configures the XO to generate an interrupt when the EXT_FLAG is set. 0b - XO external request interrupt disabled 1b - XO external request interrupt enabled
1	XO Internal Request Interrupt Enable Configures the XO to generate an interrupt when the INT_FLAG is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
INT_IE	0b - XO internal request interrupt disabled 1b - XO internal request interrupt enabled
0 RDY_IE	XTAL Ready Interrupt Enable Configures the XO to generate an interrupt when the RDY_FLAG is set. 0b - XTAL ready interrupt disabled 1b - XTAL ready interrupt enabled

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 RST	S/W Reset for 2.4GHz Radio When set, the RST bit will cause a reset of the 2.4GHz radio domain. Note, setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Release the 2.4GHz radio from reset 1b - Hold the 2.4GHz radio in reset
30 RF_POR	S/W Power-on-Reset for 2.4GHz Radio When set, the RF_POR bit will cause a power-on-reset of the 2.4GHz radio domain. Note, setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - Release the 2.4GHz radio from power-on-reset 1b - Hold the 2.4GHz radio in power-on-reset
29 CPU_RST	S/W Reset for 2.4GHz Radio CPU When set, the CPU_RST bit will cause a reset of the 2.4GHz radio CPU. Note that this bit is set after a system reset, so SOC Core software will have to clear it to bring the 2.4GHz radio CPU out of reset. Setting this bit has no effect on the RFMC's registers and this bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - Release the 2.4GHz radio CPU from reset 1b - Hold the 2.4GHz radio CPU in reset
28 CPU_RST_LOCK	LOCK for CPU_RST When set, the CPU_RST bit will be locked and unable to be reprogrammed until the next system reset. Note that this bit is not affected by the RST bit in this register, or by the RFMC CTRL[RFMC_RST] bit. This bit remains functional even when the RFMC_CTRL[RST_MSK] bits is set. 0b - CPU_RST bit is not locked 1b - CPU_RST bit is locked
27-24 CLK_OVR	Clock Gating Override Controls whether low power mode controller clocks are gated off when the logic is not enabled (default), or whether the clocks are on regardless of whether the logic is enabled. 0xxxb - Bluetooth LE power controller clock (and 32kHz clock used by Bluetooth LE link layer) only enabled when BLE_LP_EN=1 (default) 1xxxb - Bluetooth LE power controller clock (and 32kHz clock used by Bluetooth LE link layer) always enabled x0xxb - WOR power controller clock only enabled when WOR_EN=1 (default) x1xxb - WOR power controller clock always enabled xx0xb - MAN power controller clock only enabled when MAN_EN=1 (default) xx1xb - MAN power controller clock always enabled xxx0b - TIMER clock only enabled when TIM_EN=1 xxx1b - TIMER clock always enabled
23	XO Enable for 2.4GHz Radio

Table continues on the next page...

Table continued from the previous page...

Field	Function
XO_EN	Software enable of the XO analog and output to the 2.4GHz radio domain. Note that this software enable is logically or'd with enables from the 2.4GHz MAN/WOR/Bluetooth LE power controllers. 0b - XO software enable deasserted 1b - XO software enable asserted
22 XO_EN_GLITCH_DIS	XO_EN Glitch Disable for 2.4GHz Radio If set, this disables logic added to suppress potential glitches on the xo_en signal to the analog when both MAN and WOR power controllers are enabled.
21 LP_STOP_REQ_GLITCH_DIS	LP_STOP_REQ Glitch Disable for 2.4GHz Radio If set, this disables logic added to suppress potential glitches on the lp_stop_req signal to the SPC when both MAN and WOR power controllers are enabled.
20-18 SFA_TRIG_EN	SFA Trigger Enable Selects which low power controllers can cause an SFA trigger on transition from WKUP to ACTIVE state 0xxb - Bluetooth LE Low Power Controller is not allowed to cause an SFA trigger. 1xxb - Bluetooth LE Low Power Controller is allowed to cause an SFA trigger. x0xb - WOR Low Power Controller is not allowed to cause an SFA trigger. x1xb - WOR Low Power Controller is allowed to cause an SFA trigger. xx0b - MAN Low Power Controller is not allowed to cause an SFA trigger. xx1b - MAN Low Power Controller is allowed to cause an SFA trigger.
17-12 LP_WKUP_DLY	LP Wakeup Delay Configures number of 32kHz reference clocks following enable of the XO to initiate SPC recovery for a MAN/WOR/Bluetooth LE wakeup event. Note, LP_WKUP_DLY should always be set to a value greater than or equal to XO_CTRL[WKUP_OFFSET].
11-8 LP_MODE	Radio Low Power Mode Configures the radio low power mode entered after any request is asserted e.g. from S/W, MAN or WOR. The mode bits should not be changed while the radio is in or transitioning through power modes (LP_REQ_STAT and LP_ACK_STAT status bits should be clear). 0000b - Active: clock gating only (only intended for debug) 0001b - Sleep: clock gating, PMC in low power mode(only intended for debug) 0011b - Deep Sleep: low power static mode with retention of digital logic and SRAMs. 0111b - Power Down: power down of radio digital logic, optional SRAM retention. 1111b - Deep Power Down: power down of radio digital logic and SRAMs.
7 LP_ENTER	S/W Low Power Entry Request Software initiated request to enter low power mode. Note that the LP_ENTER bit is clear after a POR/LVD event, resulting in the radio defaulting to a powered up state.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Deassert S/W request for low power mode entry 1b - Assert S/W request for low power mode entry
6 BLE_LP_EN	Bluetooth LE Low Power Enable Enable the Bluetooth LE power controller's wakeup output to initiate Radio low power mode entry/ wakeup. 0b - Bluetooth LE wakeup request disabled 1b - Bluetooth LE wakeup request enabled
5 BLE_WKUP	Bluetooth LE Wakeup Force early Bluetooth LE wakeup from low power mode. 0b - Bluetooth LE low power mode wakeup deasserted 1b - Bluetooth LE low power mode wakeup asserted
4 LP_WKUP_IE	Low Power Wakeup Interrupt Enable Configures the radio to generate an interrupt when the LP_WKUP_FLAG is set. 0b - Low Power wakeup interrupt disabled 1b - Low Power wakeup interrupt enabled
3 RFACT_IE	RF_ACTIVE Interrupt Enable Configures the radio to generate an interrupt when the RFACT_FLAG is set. (It is not recommended to use RFACT_IE or RFACT_FLAG except when RFACT_SRC=2'b00.) 0b - RF_ACTIVE interrupt disabled 1b - RF_ACTIVE interrupt enabled
2 BLE_WKUP_IE	Bluetooth LE Wakeup Interrupt Enable Configures the radio to generate an interrupt when the BLE_WKUP_FLAG is set. 0b - Bluetooth LE wakeup interrupt disabled 1b - Bluetooth LE wakeup interrupt enabled
1 MAN_WKUP_IE	MAN Wakeup Interrupt Enable Configures the radio to generate an interrupt when the MAN_WKUP_FLAG is set. 0b - MAN wakeup interrupt disabled 1b - MAN wakeup interrupt enabled
0 WOR_WKUP_IE	WOR Wakeup Interrupt Enable Configures the radio to generate an interrupt when the WOR_WKUP_FLAG is set. 0b - WOR wakeup interrupt disabled 1b - WOR wakeup interrupt enabled

Fields

Field	Function
31-23 —	Reserved
22-21 —	Reserved
20-18 BLE_STATE	Bluetooth LE Low Power State Returns the current state of the RFMC's Bluetooth LE low power controller. 000b - RESET state (BLE_LP_EN=0). 001b - ACTIVE state (XO enabled, RF_ACTIVE asserted, LP request deasserted). 010b - SLEEP state (XO disabled, RF_ACTIVE deasserted, LP request asserted). 011b - WAKEUP state (XO enabled, RF_ACTIVE asserted after RFACT_WKUP_DLY, LP request deasserted after LP_WKUP_DLY).
17-15 MAN_STATE	MAN Low Power State Returns the current state of the MAN low power controller. 000b - RESET state (MAN_EN=0). 001b - ACTIVE state (XO enabled, RF_ACTIVE asserted, LP request deasserted).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - SLEEP state (XO disabled, RF_ACTIVE deasserted, LP request asserted). 011b - WAKEUP state (XO enabled, RF_ACTIVE asserted after RFACT_WKUP_DLY, LP request deasserted after LP_WKUP_DLY).
14-12 WOR_STATE	WOR Low Power State Returns the current state of the WOR low power controller. 000b - RESET state (WOR_EN=0). 001b - ACTIVE state (XO enabled, RF_ACTIVE asserted, LP request deasserted). 010b - SLEEP state (XO disabled, RF_ACTIVE deasserted, LP request asserted). 011b - WAKEUP state (XO enabled, RF_ACTIVE asserted after RFACT_WKUP_DLY, LP request deasserted after LP_WKUP_DLY).
11 —	Reserved
10 BLE_WKUP_STAT	Bluetooth LE Wakeup Status Returns the current status of the Bluetooth LE wakeup request (bt_clk_req) to the RFMC.
9 LP_ACK_STAT	Low Power Acknowledge Status Returns the current status of the Radio low power acknowledge from the SPC. Note that the LP_ACK_STAT bit will be set after a POR/LVD event
8 LP_REQ_STAT	Low Power Request Status Returns the current status of the Radio low power request to the SPC. Note that the LP_REQ_STAT bit will be set after a POR/LVD event
7 FRO_CLK_VLD_STAT	FRO Clock Valid Status Returns the current status of the FRO Clock Valid signal.
6 RST_STAT	Reset Status Returns the current status of the RF_CMC's reset output. 0b - Reset is not asserted. 1b - Reset is asserted.
5 SLP_RDY_STAT	RF_CMC Sleep Ready Status Returns the current status of the Sleep Ready signal from RF_CMC.
4	Low Power Wakeup Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
LP_WKUP_FLAG	Flag which sets after deassertion of the Radio low power acknowledge from the SPC, indicating radio power domain wakeup is complete (write 1 to clear). Note, this flag will assert for all sources of radio wakeup e.g. MAN/WOR/Bluetooth LE controller or software clear of LP_ENTER bit.
3 RFACT_FLAG	RF_ACTIVE Flag This flag is associated with the RF_ACTVE pin, but only when RFACT_SRC=2'b00. (It is not recommended to use this flag for other settings of RFACT_SRC.) Write 1 to clear.
2 BLE_WKUP_FLAG	Bluetooth LE Wakeup Flag Flag which sets when Bluetooth LE low power controller transitions to WAKEUP state during a Bluetooth LE wakeup event (write 1 to clear).
1 MAN_WKUP_FLAG	MAN Wakeup Flag Flag which sets when MAN low power controller transitions to ACTIVE state after a MAN wakeup event (write 1 to clear).
0 WOR_WKUP_FLAG	WOR Wakeup Flag Flag which sets when WOR low power controller transitions to ACTIVE state after a WOR wakeup event (write 1 to clear).

Field	Function
31 —	Reserved
30-28 RFNA_IBE	RF_NOT_ALLOWED Input Buffer Enables Enables input pin for RF_NOT_ALLOWED. 000b - RF_NOT_ALLOWED input pin disabled 001b - RF_NOT_ALLOWED input pin uses PTA16 010b - RF_NOT_ALLOWED input pin uses PTA17 011b - RF_NOT_ALLOWED input pin uses PTA22 100b - RF_NOT_ALLOWED input pin uses PTC7 101b - RF_NOT_ALLOWED input pin uses PTD6
27 —	Reserved
26 QREQ_RF_EN	QUIET_REQ Enable for Radio CPU Flash Enables QUIET_REQ to suppress Radio CPU Flash activity. 0b - QUIET_REQ is not enabled for Radio CPU Flash 1b - QUIET_REQ is enabled for Radio CPU Flash
25 QREQ_SOC_EN	QUIET_REQ Enable for SOC Core Flash Enables QUIET_REQ to suppress SOC Core Flash activity. 0b - QUIET_REQ is not enabled for SOC Core Flash 1b - QUIET_REQ is enabled for SOC Core Flash
24 QREQ_SRC	QUIET_REQ Source Selects the QUIET_REQ source from the RFMC or TSM/LL outputs. 0b - QUIET_REQ is driven by the RFMC 1b - QUIET_REQ is driven by the TSM/LL
23-22 —	Reserved
21-16 RFACT_WKUP_DLY	RF_ACTIVE Wakeup Delay If RFACT_SRC=2'b00, this configures number of 32kHz reference clocks following enable of the XO to assert the RF_ACTIVE pin for a MAN/WOR/Bluetooth LE wakeup event. Note, RFACT_WKUP_DLY should always be set to a value less than or equal to XO_CTRL[WKUP_OFFSET].
15 RFACT_EN	S/W Enable of RF_ACTIVE pin If RFACT_SRC=2'b00 and RFACT_IDIS=0, this can be used by software to assert the RF_ACTIVE pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Take no action 1b - Assert RF_ACTIVE pin
14 RFACT_IDIS	RF_ACTIVE Idle Disable if RFACT_SRC=2'b00, this configures the RF_ACTIVE pin to deassert when TSM is idle. 0b - RF_ACTIVE does not deassert when TSM is idle (will deassert on next low power mode entry) 1b - RF_ACTIVE will deassert when TSM is idle
13-12 RFACT_SRC	RF_ACTIVE Source Selects the RF_ACTIVE source from the RFMC, TSM/LL or Bluetooth LE wakeup request. 00b - RF_ACTIVE is driven by the RFMC 01b - RF_ACTIVE is driven by the TSM/LL 10b - RF_ACTIVE is driven by the Bluetooth LE wakeup request (bt_clk_req) 11b - Reserved
11 PORTA_PWR	PORTA Power Some of the coexistence or FEM control pins are mapped to PORTA pin in the SOC. This bit controls whether PORTA pins (in the CORE_WAKE domain) remain powered when the MCU is in Deep Power Down 0b - PORTA pins do not remain powered (default behavior) 1b - PORTA pins remain powered
10-8 RFGPO_SRC	RF_GPO Source Selects the Source for RF_GPO[7:0]. 52.4 2.4GHz Radio

52.4.3 Overview

The radio supports the following bus interfaces to allow software access to radio peripherals and memories:

1. RADIO(NBU) CM33 interface to the RADIO(NBU) CM33 memories, the memory-mapped peripherals inside the NBU, access to the radio resources (Generic LL, XCVR, etc.) outside of the NBU via the radio's PBRIDGE, access to resources (radio flash, TPM2, RF_CMC, radio FRO192M) related to -- but outside of -- the radio via NBU PBRIDGE, and access to HOST CM33 peripherals (e.g., DSB, EdgeLock Secure Enclave, SEMA42, and RFMC) via AXBS PBRIDGE0. (For a detailed list of peripherals accessible via PBRIDGE0, refer to the Peripheral Bridge section of the Core overview chapter of this Reference Manual.)
2. HOST CM33 access some NBU resources, and NBU PBRIDGE resources. Note that this path only allows access to certain regions of the NBU/RADIO CM33 memory space, and (unlike #1 above) it is not allowed access to the radio PBRIDGE or the AXBS's PBRIDGE0.
3. CM33 access to the radio PBRIDGE to access radio resources (Generic LL, XCVR, etc.) outside of the NBU
4. HOST CM33 and NBU CM33 access to RFMC registers. The NBU CM33 access is via AXBS PBRIDGE0 (#1 above).

52.4.3.1 Block Diagram

The 2.4 GHz Radio Block Diagram is shown in the picture below:.

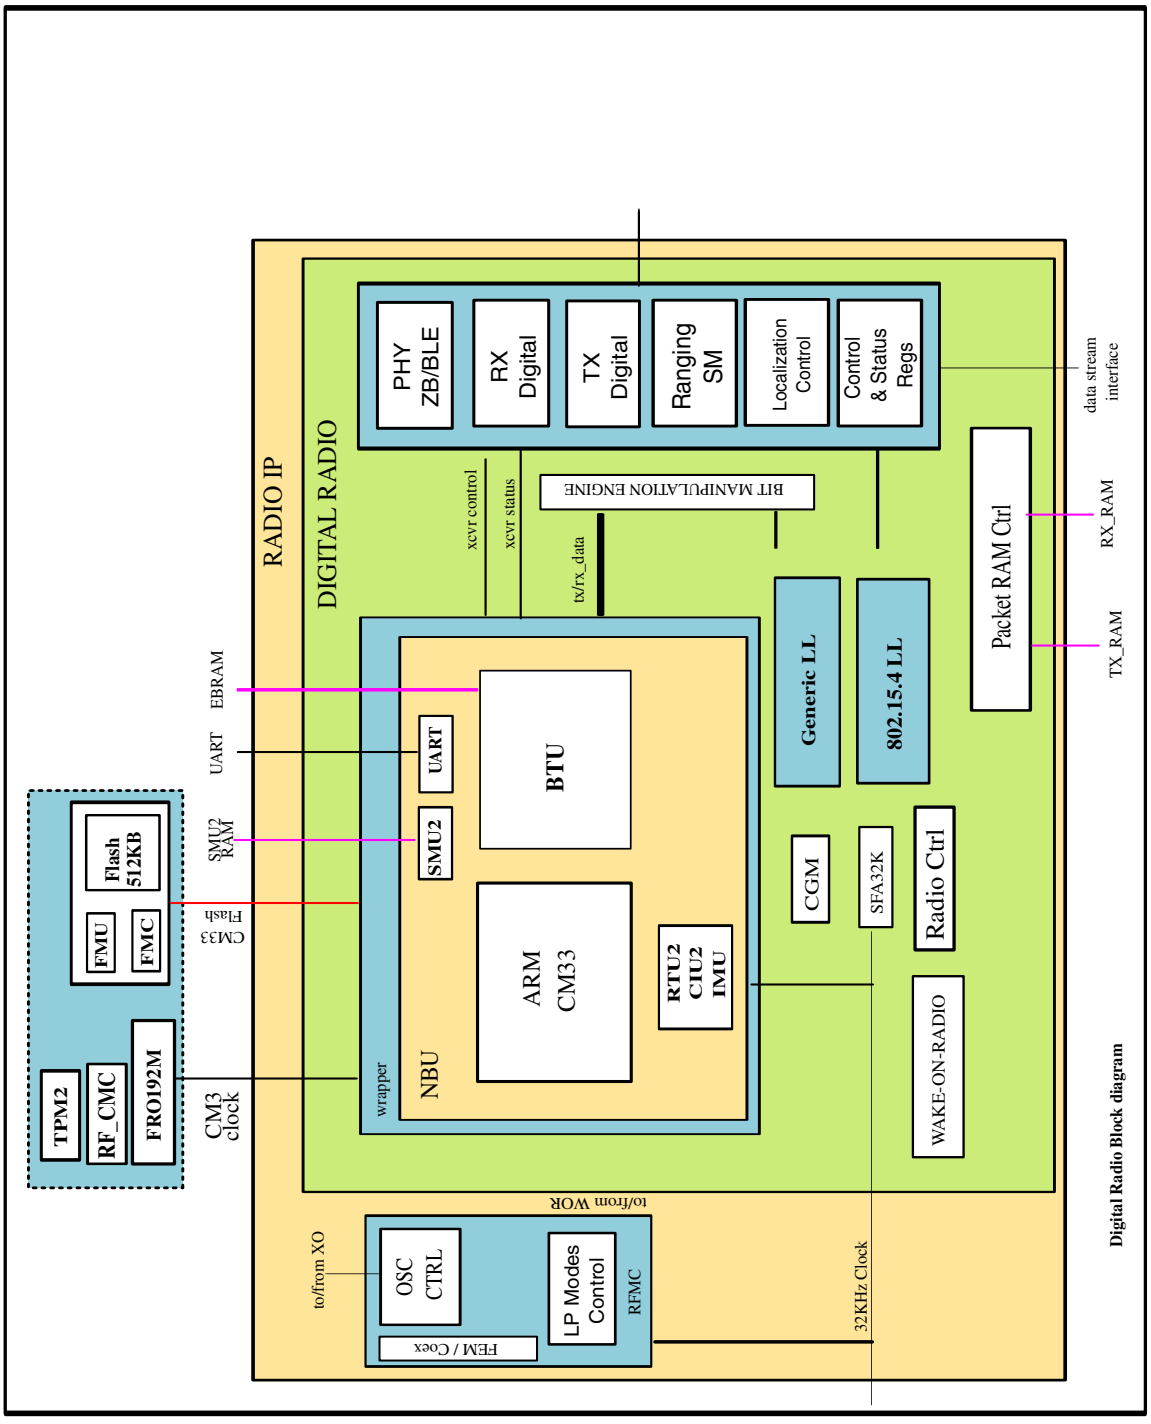

Figure 219. Radio Block Diagram

The block diagram highlights the different bus interfaces

52.4.3.2 Features

The Digital Radio IP provides the logic to drive the 2.4GHz multi-protocol radio, and it supports the following protocols:

1. Bluetooth Low Energy v6.0, supporting all mandatory features
   - Channel Sounding
   - 1Mbps
   - 2Mbps
   - Long Range (125kbps and 500kbps)
2. IEEE 802.15.4-2006 compliant PHY and MAC
   - Thread
   - Zigbee
3. Generic 2-level FSK/GFSK/MSK/GMSK
   - 250kbps
   - 500kbps
   - 1000kbps
   - 2000kbps
4. Concurrent IEEE 802.15.4 and Bluetooth Low Energy operation

52.4.4 Functional Description

52.4.4.1 Radio Control

52.4.4.1.1 Wake On Radio

52.4.4.1.1.1 Overview

The 2.4GHz Wake-On-Radio (WOR) Scheduler, is a hardware automation block, intended to reduce radio and SoC dynamic power consumption, and facilitate radio frequency hopping.

Wake-On-Radio (WOR) substantially increases the autonomy of the radio within the SoC, taking advantage of the separated power domains for the MCU and the Radio in the SoC, by providing sufficient hardware automation to ensure very long MCU low-power intervals, encompassing multiple RF operations, whenever possible.

52.4.4.1.1.1.1 Block Diagram

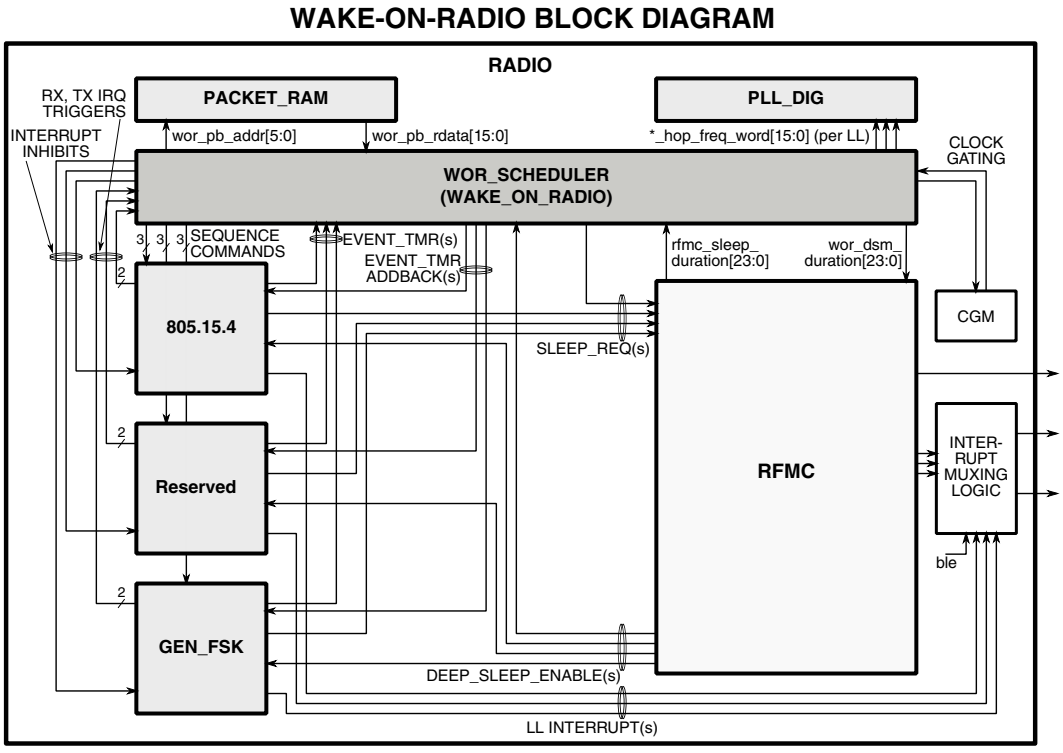

Figure 220. WAKE-ON-RADIO BLOCK DIAGRAM

52.4.4.1.1.1.2 Features

The 2.4GHz Radio Wake-On-Radio Scheduler provides hardware automation for the following operations:

- Insertion of the radio digital logic into Deep Sleep Mode (DSM), and subsequent DSM exit
- Sequencing of RF operations, both TX and RX, between DSM cycles, without MCU intervention.
- RF Frequency Hopping

Two different scheduling methods are supported:

- Timeslot-based scheduling
- Constant-Interval scheduling

WOR supports the radio's 802.15.4, and GENERIC_FSK protocol engine(s), and interfaces to the radio's RFMC (Radio Mode Controller) for the scheduling of DSM entry/exit.

WOR also provides the following features:

- Divide future RF operations into "timeslots", which can occur at regularly-, or non-regularly-scheduled intervals.
- Descriptor-based format for software to program timeslot information.
- Interaction with the protocol engines to dynamically manage radio interrupts, allowing link layer interrupts to propagate only when it is necessary to notify the MCU of required action.

52.4.4.1.1.2 Functional Description

52.4.4.1.1.2.1 Assign To Protocol

The 2.4GHz radio supports multiple protocols, each with its own protocol engine. All protocols can benefit from scheduling in advance several RF operations and DSM cycles, with the radio conducting the successive operations autonomously, allowing the MCU to remain in low power state for the duration. This is the concept behind Wake-On-Radio (WOR).

The WOR function can be assigned to any one of the following protocol(s): 802.15.4, GENERIC_FSK. (Bluetooth LE has its own, internal DSM and wake-on-radio control scheme, as well as hardware-controlled frequency hopping, built into the IP, so it does not interact with the WOR Scheduler).

Assigning WOR to a protocol is done by way of the WOR_PROTOCOL register, as shown in the following table:

WOR_PROTOCOL[2:0]	ASSIGNED PROTOCOL ENGINE
0	Not Assigned
1	802.15.4
2	GENERIC_FSK
3	Reserved

Assigning to protocol means that the assigned Link Layer's WOR interface signals are routed, exclusively, to and from the WOR state machine. WOR interface signals include the event timers, sequence start- and stop-command signals, interrupt inhibits, and event timer addback commands. These interface signals are covered in more details in later sections.

The following diagram illustrates how 1 of the 3 WOR-capable Link Layers is assigned to the WOR function:

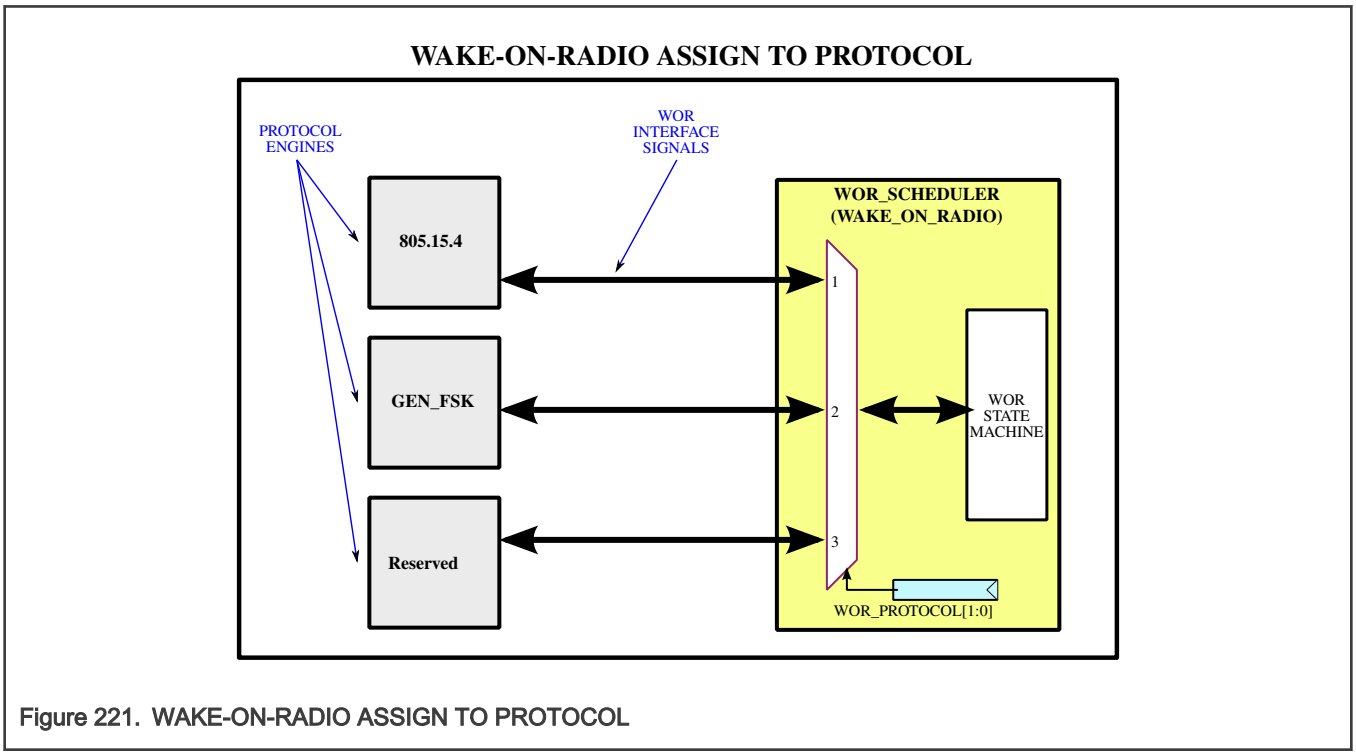

Figure 221. WAKE-ON-RADIO ASSIGN TO PROTOCOL

In a multi-protocol setting, assigning a protocol to Wake-On-Radio does not mean that unassigned protocols are incapable of DSM. There is a back-up method, Manual DSM, which uses software-driven DSM entry and exit. In a multi-protocol setting, any 2 of the radio's protocols can be assigned to different DSM control scheme, with the control schemes being Wake-On-Radio, Manual DSM, and Bluetooth LE DSM.

52.4.4.1.1.2.2 Scheduling Modes

For maximum flexibility in scheduling future RF operations and Deep Sleep cycles, Wake-On-Radio (WOR) defines 2 scheduling modes: Timeslot Mode, and Constant Interval Mode. These modes are described in the sections below.

Timeslot Mode

Timeslot mode is desirable when the schedule for RF transactions is sporadic, varies over time, or is otherwise non-periodic. Timeslot mode is based loosely on the TSCH (Timeslotted Channel Hopping) concept, first defined in IEEE Std 802.15.4-2015. Key principles of TSCH are adopted by WOR, but far short of full adherence.

In TSCH, time is divided into slots of fixed duration. Slots are grouped into slotframes, containing fixed number of slots. Once a TSCH PAN (network) is established, slotframes will repeat forever, back-to-back. Devices can be assigned to 1 or more slots within a slotframe. For any given device on any given slot, the assigned slot can be TX or RX. One device can be assigned to transmit in a given slot; another device can be assigned to receive in the same slot. Assigning Device A to Transmit, and Device B to Receive, in the same slot, creates a link. Links can be dedicated (one TX and one RX device assigned). Or, links can be shared (multiple TX devices, using CSMA, and multiple RX devices). Typically, each slot uses a different hop frequency.

Slotframes are TDMA structures, with time on one axis and hop frequency on the other. The diagram below shows one "row" of a typical slotframe, with links established for Devices A, B, and C, all on the same hop frequency. This slotframe consists of 3 timeslots: TS0, TS1, and TS2.

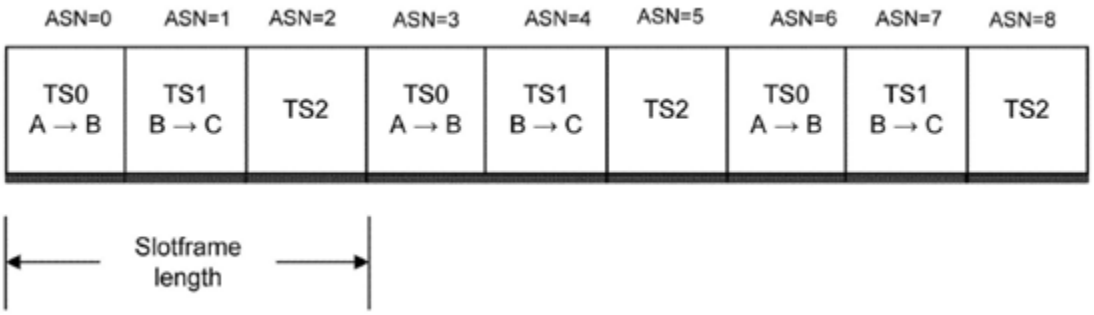

Figure 222. IEEE Std 802.15.4 TSCH 1-D SLOTFRAME

Another diagram below, shows a slotframe of 2 dimensions. The time axis has 100 slots, and the frequency axis has 4 indices into a table of available hop frequencies. Devices A, B, C, and D are assigned to various slots, and links are created amongst them.

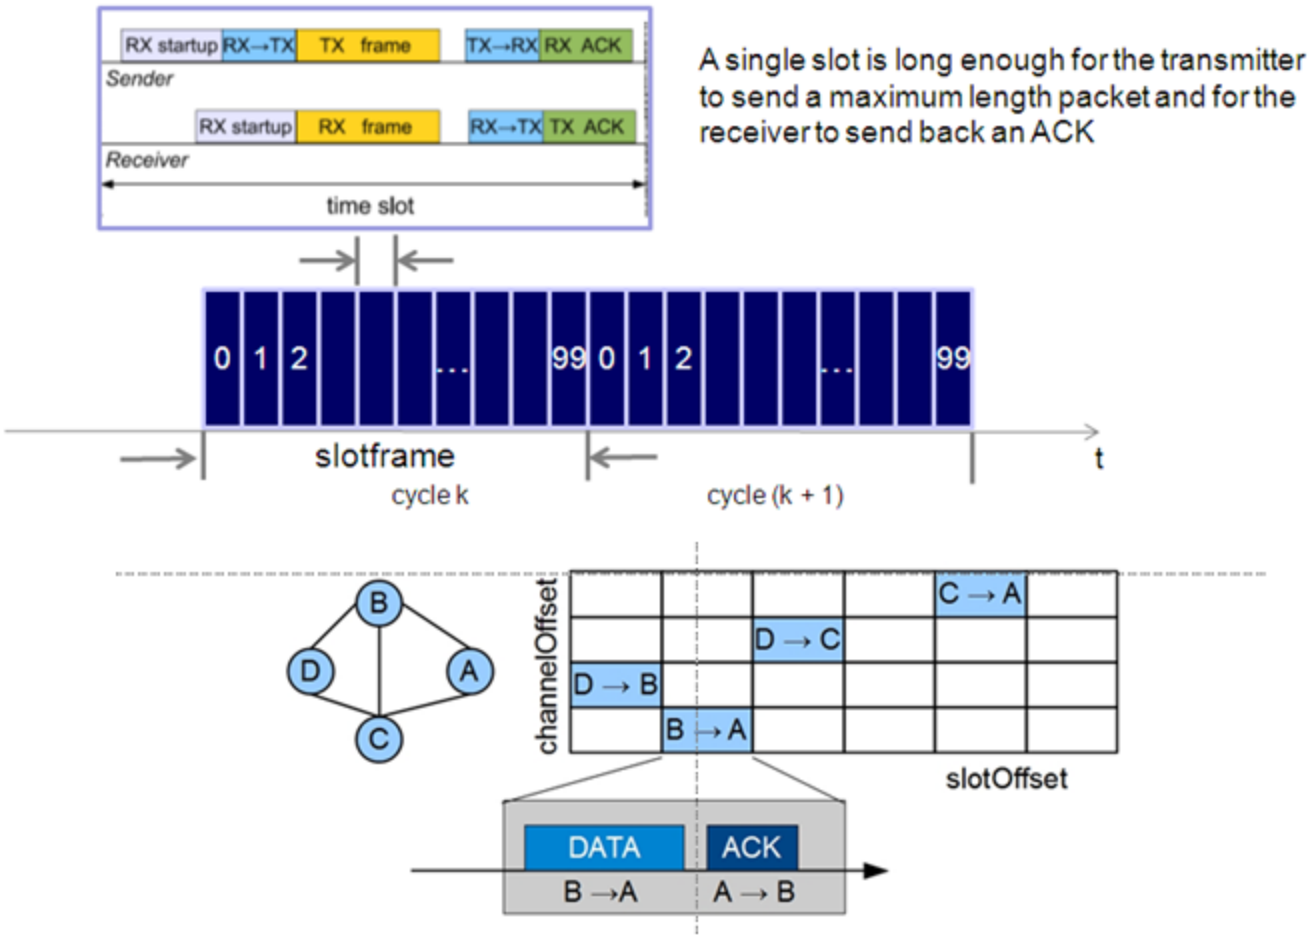

Figure 223. IEEE Std 802.15.4 TSCH 2-D SLOTFRAME

When RF operations are to be scheduled using Wake-On-Radio in a TIMESLOT context, the start times for the next *N* operations are programmed into the descriptor table to assign them to slots. One field of each slot descriptor, START_TIME, holds this information for WOR. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. *N* is the number of slots used, and can be any integer from 2 to 4. The register SLOTS_USED is programmed with this value. The start times programmed into the descriptors, are relative to the Event Timer of the assigned Link Layer. WOR software will read the Event Timer, add to this value the desired time-to-next-event, and write the sum into the descriptor START_TIME. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the START_TIME field of the current slot's descriptor, WOR hardware will initiate an RF sequence. The type of sequence is determined by the descriptor's FUNCTION field, and can be TX or RX or RT or TR. The RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for TIMESLOT scheduling mode is determined by the RECEIVE_TIMEOUT[15:0] register. The units of this register are microseconds. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME + RECEIVE_TIMEOUT,

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relevant to TX sequences, since these always self-terminate. The following diagram depicts how the WOR hardware processes the descriptor table, the assigned Event Timer, and the RECEIVE_TIMEOUT register, to start and terminate an RF operation.

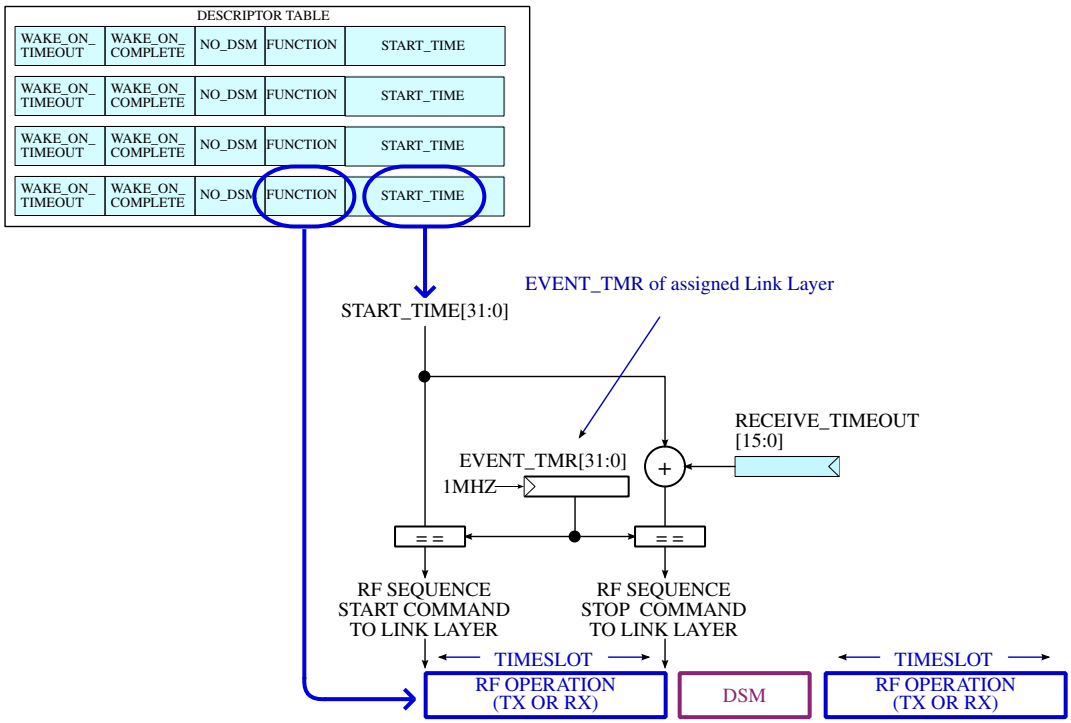

Figure 224. EVENT SCHEDULING IN TIMESTLOT SCHEDULING MODE

If the assigned protocol engine is 802.15.4 or GENERIC_FSK, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 or GENERIC_FSK Link Layer.

In any timeslot, if the assigned FUNCTION is RX or RT, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

To execute the function RT, Link Layer should be configured with **AUTOACK** set. When Event Timer match, WOR will assert **wor_rx_start_ext signal** to Link Layer to start the RX sequence. After Link Layer completes the Auto-ACK sequence, it will send the signal **tx_irq_trig** to WOR to advance to the next state. If the RX operation timeout occurs, either nominal or delayed, WOR will assert **wor_seq_stop_ext** to the assigned Link Layer, causing an immediate abort of the RX sequence. RT function is effected by the window widening feature. A TIMESTAMP is captured in the RT sequence.

To execute the function TR, when Event Timer match, WOR will assert **wor_tx_start_ext** signal as well as **wor_function_is_tr** signal to Link Layer to start the TR sequence. After Link Layer completes the TR sequence, it will send signal **rx_irq_trig** to WOR to advance to the next state. If the RX operation timeout occurs, either nominal or delayed, WOR will **assert wor_seq_stop_ext** to the assigned Link Layer, causing an immediate abort of the RX sequence. TR function is not effected by the window widening feature. A TIMESTAMP is captured in the TR sequence.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

In Timeslot Scheduling mode, the MCU *must* be awakened at least once every *N* slots, to refresh the descriptor table (or at least, to refresh the START_TIME's), with *N* being the value of SLOTS_USED. This periodic wakeup requirement must be enforced by

appropriate setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT fields of the 4 slot descriptors. This is a requirement imposed on WOR software. (The same period wakeup requirement does not necessarily apply to Constant Interval scheduling mode. See next section.)

Constant-Interval Mode

Constant-Interval mode is appropriate when the schedule for RF transactions is perfectly periodic. A good example of such a scheduling regime, is the Bluetooth Low Energy Scanning State. In this state, a SCAN_INTERVAL is defined, which sets the interval between receive operations, and a SCAN_WINDOW is defined, which sets the duration of receiver "ON" time within the SCAN_INTERVAL. Wake-On-Radio adopts the principles of Bluetooth LE SCAN_INTERVAL and SCAN_WINDOW, broadening their scope to apply to any type of RF operation (TX or RX), and modifying the nomenclature to better represent the nature of the operations, to WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW.

Instead of programming timeslot START_TIME's into the slot descriptors, Contant-Interval requires that WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW be programmed instead. An additional parameter, WOR_EVENT_START, determines the instant of the first RF operation of the Constant-Interval WOR session, in case the desired start time is not immediate. WOR_EVENT_START is also programmed into the descriptor table. In Constant-Interval scheduling mode, WOR hardware processes the descriptors, and uses WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, to calculate the start time (Event Timer match), for the first RF operation, as well as all subsequent RF operations, on a rolling basis. WOR software is not required to refresh the descriptor table on a periodic basis, and would only intervene in the descriptors if a change was required to any parameter (e.g., a Bluetooth LE "Anchor Point Move" during a connection would require descriptor updates). In Constant-Interval mode, the start of WOR_EVENT_WINDOW always aligns to the start of WOR_EVENT_INTERVAL.

Aside from replacing the Timeslot descriptor START_TIME parameters with WOR_EVENT_INTERVAL, WOR_EVENT_WINDOW, and WOR_EVENT_START, the descriptor format is identical across the 2 scheduling modes, and the descriptor storage space (registers) is completely shared, since only 1 scheduling mode can be in effect at any given time. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor, and how the descriptor table is shared between the 2 scheduling modes.

A diagram depicting an example of Constant-Interval scheduling mode is shown below. In this diagram, the scanning device is in Constant-Interval mode, with the WOR_EVENT_INTERVAL and WOR_EVENT_WINDOW indicated.

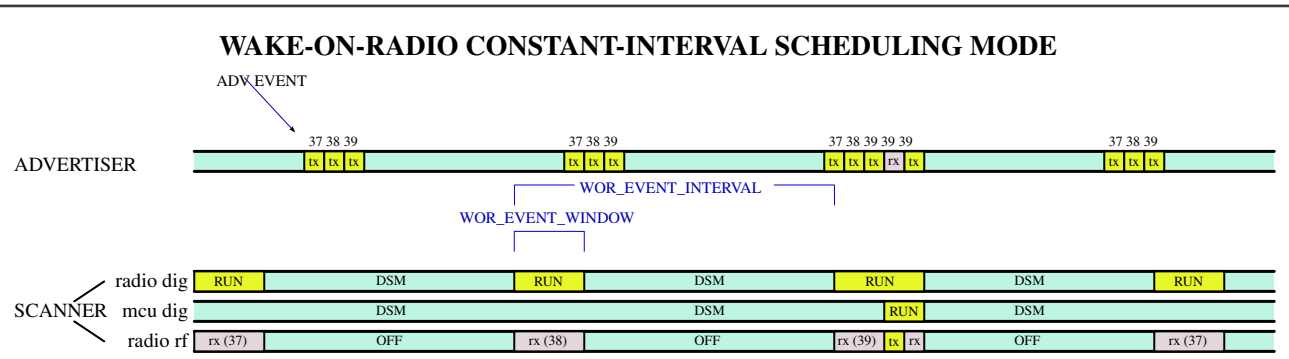

Figure 225. CONSTANT-INTERVAL SCHEDULING MODE EXAMPLE

When RF operations are to be scheduled using Wake-On-Radio in a Constant-Interval context, the WOR_EVENT_START, WOR_EVENT_INTERVAL, and WOR_EVENT_WINDOW parameters for the Constant-Interval operation are programmed into the descriptor table. These need be programmed only once, unless a change in network timing require an on-the-fly change to one of these parameters. The units for all 3 WOR_EVENT parameters are microseconds. See Section Descriptor Format for more information on the descriptor fields, and how they are packed into the descriptor. WOR hardware will process these 3 parameters to calculate the initial start time, and all subsequent start times, on a rolling basis. The start times computed by WOR hardware, are relative to the Event Timer of the assigned Link Layer. WOR hardware will monitor the assigned Link Layer's Event Timer; when it matches the next computed start time, WOR hardware will initiate an RF sequence. The type of sequence is determined by the current slot descriptor's FUNCTION field, and can be TX or RX. The RF operation will be allowed to continue, until it either self-terminates, or a timeout is reached. The timeout period for Constant-Interval scheduling mode is determined by the WOR_EVENT_WINDOW descriptor field. If a timeout is reached, i.e.,

EVENT_TMR = START_TIME (computed) + WOR_EVENT_WINDOW (descriptor),

WOR hardware will terminate the sequence. Timeout applies to RX sequences only. RX sequences may result in no packet being received, a packet being received which is not addressed to the device, or a packet which is received corruptly. Any of these scenarios will result in a timeout and a WOR shutdown of the sequence. A correctly received packet addressed to the device will self-terminate the RX sequence before the timeout is reached. Timeout is not relevant to TX sequences, since these always self-terminate. The concept of slots still applies to Constant-Interval Mode. The number of slots used can be any integer from 3 to 4 for Constant-Interval mode. The register SLOTS_USED is programmed with this value. Consecutive RF operations are assigned to consecutive slots, with the slot descriptor's parameters (e.g. FUNCTION, or WAKE_ON_COMPLETE) applying to the current slot. As in Timeslot mode, in Constant-Interval mode, WOR hardware will increment the slot number for each new RF operation, modulo SLOTS_USED.

In any timeslot, the assigned FUNCTION is a simple TX or RX operation. There is no automatic acknowledgement of packets. If acknowledgement is required during a timeslot, the MCU must be awakened (by setting the WAKE_ON_COMPLETE bit of the slot's descriptor), and the software must handle the acknowledgement, using standard Link Layer (not WOR) resources, within the turnaround time requirement (if any). WOR hardware will hold its state and wait for software to complete the acknowledgement, and other required tasks, before advancing to the next slot on software command.

If the assigned protocol engine is 802.15.4 or GENERIC_FSK, an autosequence is available which is a TX sequence preceded by a CCA (Clear Channel Assessment). If the CCA results in a busy channel, the autosequence terminates without transmission; otherwise the transmission proceeds. This autosequence can be used in WOR Timeslot mode by appropriately configuring the 802.15.4 or GENERIC_FSK Link Layer.

In any timeslot, if the assigned FUNCTION is RX, a TIMESTAMP can be captured to record the instant the packet's Access Address or SFD arrives at the Link Layer packet processor. There are 4 TIMESTAMP registers, once for each slot; hence, timestamps for the last 4 slots during which packets are received, can be recorded. See Section Timestamps for more details.

Typically, for RX timeslots, it is desirable to wake the MCU on good packets only. Thus, the slot descriptor's WAKE_ON_COMPLETE field should be set to 1. If it is desired to wake the MCU on no-packet, or on incorrecty-received packets, the WAKE_ON_TIMEOUT descriptor field can be set to 1. If WAKE_ON_TIMEOUT is set to 1 on any slot's descriptor, the WAKE_ON_COMPLETE field is *implied* to be set to 1 as well, regardless of its actual programmed value.

Typically, for TX timeslots, it is desirable to wake the MCU after each transmission, to service the Packet Buffer. In such scenarios, WAKE_ON_COMPLETE should be set to 1. If it is required to transmit the same packet repeatedly, across multiple slots, such that the Packet Buffer does not require regular service, WAKE_ON_COMPLETE can be set to 0, to skip the MCU wakeup, on any slot.

Unlike Timeslot mode, in Constant-Interval mode, it is not required to wake up the MCU at least every *Nth* slot to refresh the descriptor start times, because WOR hardware is able to compute all future start times on a rolling basis. If all slots are of the same type (same FUNCTION, TX or RX, and same descriptor information), there is no hard limit on the number of consecutive slots that can be executed between MCU wakeups. To set such a upper limit, the WAKE_ON_NTH_SLOT[7:0] register can be programmed with a value. When the number of slots elapsed after setting SLOTS_USED to a non-zero value to begin a WOR session, reaches the value of WAKE_ON_NTH_SLOT, the MCU will automatically be awakened at the end of the current slot, regardless of the setting of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits in the descriptor. The WAKE_ON_NTH_SLOT register is only relevant to Constant-Interval scheduling mode, and has no effect in Timeslot mode. In Constant-Interval mode, if automatic wake on *Nth* slot is not desired, set WAKE_ON_NTH_SLOT=0 to disable this wakeup upper-limit. However, if a zero setting is used, software *must* program at least one of the slot descriptors to schedule an MCU wakeup by setting the either WAKE_ON_COMPLETE or WAKE_ON_TIMEOUT fields of the descriptor to 1; otherwise a situation could arise where the MCU is never awakened by WOR.

52.4.4.1.1.2.3 Descriptor Format

As mentioned in previous sections, Wake-On-Radio allows the next several RF operations to be scheduled in advance. For scheduling purposes, each of the next, several RF operations is assigned to a slot. Each slot is associated with a descriptor, which is a hardware-based data structure containing information about the characteristics of the slot, and instructions for how WOR hardware should execute it. Characteristics include start time of the RF operation, and type (function) or operation to be conducted by WOR. Software schedules the next *N* RF operations (slots) by programming the next *N* descriptors with the slots' characteristics. Software then sets the SLOTS_USED register to *N* to begin a WOR session. WOR hardware includes a 2-bit slot counter that cycles through the slots, in order, starting with SLOT 0; the slot counter is used to select the "current descriptor". The current descriptor's slot characteristics are forwarded to the WOR state machine, which executes the RF operation per the

instructions in the descriptor. After the RF operation is complete, the slot counter is incremented by 1 (modulo SLOTS_USED), and the next slot's descriptor becomes the "current" one. The process repeats indefinitely until the WOR session is ended by setting SLOTS_USED=0. WOR hardware automatically inserts (unless instructed otherwise in the descriptor) a DSM cycle, after the current slot's RF operation completes, with a DSM duration that lasts until the start time of the *next* slot, so that time between RF operations is always filled with DSM, for maximum power savings. After setting SLOTS_USED to a non-zero value to begin a WOR session, the MCU can be put into a low power state, and remain there, until the last (*Nth*) slot completes, assuming Timeslot scheduling mode. (For Constant Interval mode, MCU wake up on the *Nth* slot is not required. See Section Scheduling Modes for information on when and how the MCU is to be awakened for Constant-Interval mode.)

The descriptor format for Timeslot scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

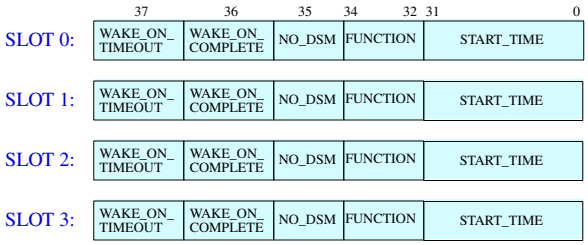

Figure 226. DESCRIPTOR FORMAT (TIMESLOT MODE)

The descriptor format for Constant-Interval scheduling mode is shown in the diagram below, indicating the various fields in the descriptor, and the bits assigned to each field:

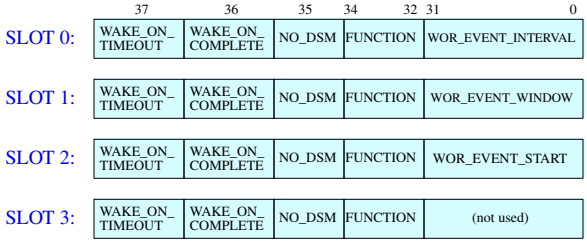

Figure 227. DESCRIPTOR FORMAT (CONSTANT-INTERVAL MODE)

The descriptor formats for Timeslot and Constant-Interval scheduling modes are almost identical, and so the descriptor hardware is almost completely shared by the 2 scheduling modes, as shown in the diagram below:

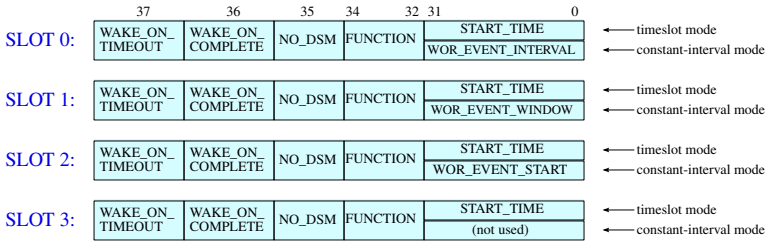

Figure 228. DESCRIPTOR FORMAT (SHARED)

Descriptor fields are described in the table below:

FIELD	DESCRIPTION
START_TIME	The instant at which to begin the current slot's RF operation. START_TIME is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see START_TIME programming information later in this section. Applies to Timeslot mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_INTERVAL	Sets the interval between the start of RF operations for consecutive slots. Units are microseconds. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_WINDOW	Maximum duration of the transceiver "ON" time for the current slot. "ON" time will be less than this if the RF operation self-terminates. Units are microseconds. Applies to Constant-Interval mode only. The start of the WOR_EVENT_WINDOW aligns to the start of the WOR_EVENT_INTERVAL. WOR hardware will automatically adjust this value with window-widening, if enabled.
WOR_EVENT_START	The instant at which to begin the RF operation for the first SLOT 0 of the WOR session. WOR_EVENT_START is relative to the assigned Link Layer's Event Timer. Units are microseconds. Because the Event Timers' bit widths vary with protocol, see WOR_EVENT_START programming information later in this section. Applies to Constant-Interval mode only. WOR hardware will automatically adjust this value with window-widening, if enabled.
FUNCTION	This 3 -bit field defines the RF function of the slot: 0: No RF 1: TX 2: RX 3: RT 4: TR 5~7: Reserved
NO_DSM	By default, a DSM cycle is automatically entered at the end of the current slot's RF operation, and the DSM cycle is timed to expire just before the start time of the next consecutive slot. If this field is set to 1, DSM is not entered, and the WOR state machine holds the radio in RUN state until the start time of the next slot is reached. NO_DSM can be used to execute back-to-back, or closely spaced RF operations, such as a Bluetooth LE 3-channel advertising event.
WAKE_ON_COMPLETE	Instructs the WOR state machine to permit an interrupt to wake up the MCU at the end of a successfully completed

Table continues on the next page...

Table continued from the previous page...

FIELD	DESCRIPTION
	RF operation. RX operations are successfully completed if a packet is received before the timeout, which passes CRC and packet filtering rules. TX operations are always successfully completed. A successfully completed operation with WAKE_ON_COMPLETE=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's RF interrupts (RXIRQ, TXIRQ, and/or SEQ_END_IRQ) to propagate, resulting in an MCU wakeup. If WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE is *implied* to be 1 as well, regardless of the setting of this field.
WAKE_ON_TIMEOUT	Instructs the WOR state machine to permit an interrupt to wake up the MCU at the point of timeout of an RX operation. For Timeslot mode, timeout is determined by the RECEIVE_TIMEOUT[15:0] register; for Constant-Interval mode, timeout is determined by WOR_EVENT_WINDOW descriptor field. In either case, window-widening will automatically adjust the timeout instant, if enabled. A timeout which occurs with WAKE_ON_TIMEOUT=1 will cause the WOR state machine to temporarily remove its Link Layer interrupt inhibits, allowing the assigned Link Layer's SEQ_END_IRQ to propagate, resulting in an MCU wakeup, with a notification of timeout.

Event Timer bit width various across protocols. For 802.15.4, Event Timer is 28 bits; for GENERIC_FSK, Event Timer is 32 bits. In all cases, the Event Timer clock rate is 1MHz.

When FUNCTION is set to "NO_RF", no RF operation is performed during the slot. In this scenario, the WOR state machine will wait until the slot's programmed (or computed) START_TIME, and then automatically re-enter DSM until the next consecutive slot's START_TIME is reached. This allows multiple (up to 4) DSM-only slots which effectively extends the maximum DSM duration fourfold, to 1073 seconds (about 18 minutes), for the 802.15.4 and GENERIC_FSK protocol. However the RF Oscillator is activated briefly at each slot's START_TIME so that the WOR can process the current slot descriptor, and update the assigned Link Layer's Event Timer. Extending the DSM duration using the "NO_RF" method is referred to as "DSM cascading".

During an RX operation on any slot, if an AA or SFD has been detected at the point of timeout, the timeout (and the automatic shut-down of the sequence by the WOR state machine) is *deferred* until either:

1: The packet is fully received and determined to be good. In this case the WAKE_ON_COMPLETE bit determines if the MCU is to be awakened.

2: The packet is fully received and determined not to be good. In this case the WAKE_ON_TIMEOUT bit determines if the MCU is to be awakened.

There are no time restrictions on programming the descriptor table. All descriptor fields can be modified at any time. Needless to say, caution should be exercised with modifying descriptor START_TIME, and other parameters, for the *current* slot; START_TIME (or WOR_EVENT_START) must be in the future, and FUNCTION should not be modified once the START_TIME has been reached.

52.4.4.1.1.2.4 State Machine

In Wake-On-Radio, future RF operations are scheduled by programming instructions into the WOR Descriptor table. Based on descriptor specifications, WOR hardware organizes the scheduled RF operations into slots, with one RF operation per slot. The slot includes more than just the RF operation. Idle time between the current time, and the start of the RF operation, is filled

with DSM. WOR hardware must compute the required DSM duration, and request DSM from RFMC (Radio Mode Controller). A diagram showing how WOR hardware processes the descriptor table, and organizes the required operations into consecutive slots, encompassing both DSM and RF, is shown below.

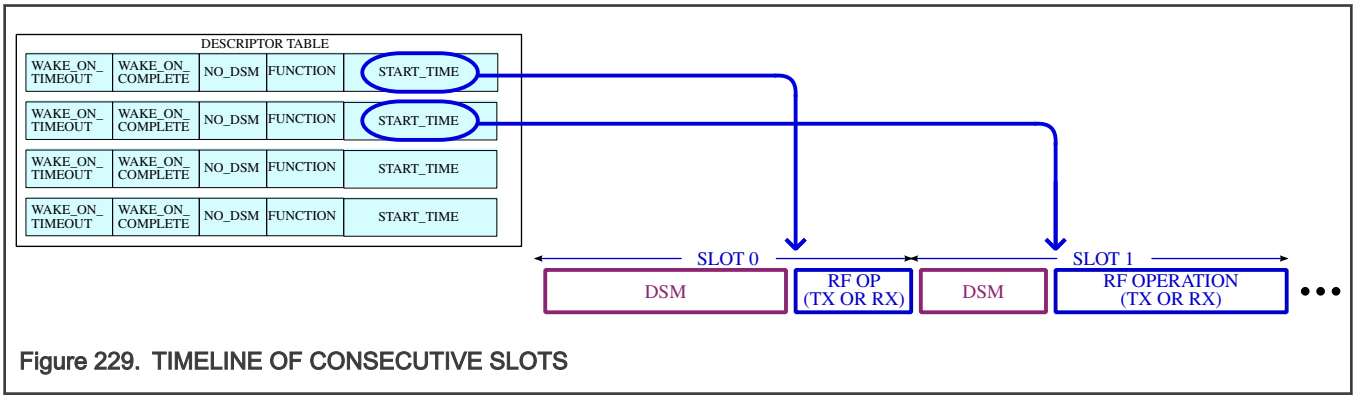

Figure 229. TIMELINE OF CONSECUTIVE SLOTS

Once a WOR session has been initiated by setting SLOTS_USED to a non-zero value, the timeline of consecutive slots shown, will repeat indefinitely, with the slot number increasing by 1 after each slot, modulo SLOTS_USED.

During each slot, WOR hardware must perform a series of tasks, e.g., computing the DSM duration, commanding the assigned Link Layer to start and stop the RF sequence, etc. Some of the required WOR hardware tasks are superimposed on the slot timeline, in the diagram below.

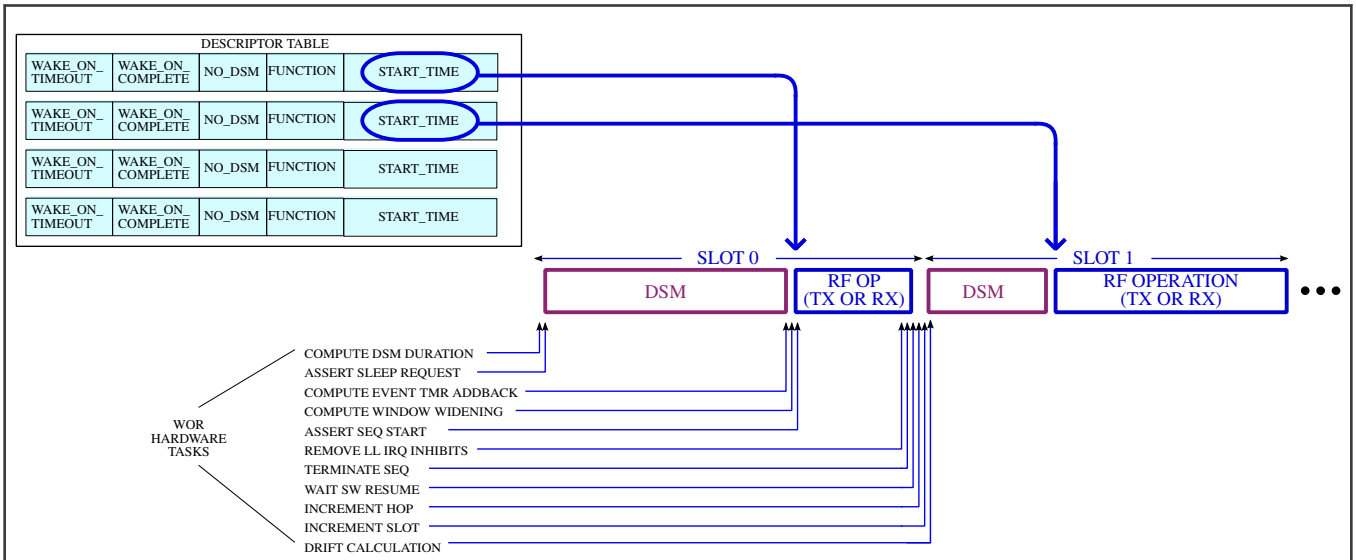

Figure 230. SLOT TIMELINE WITH HARDWARE TASKS

The WOR state machine is responsible for processing the descriptor table, and performing all the required tasks during each slot. The 11 -state machine interfaces with the assigned Link Layer for sequence operations, and with RFMC for DSM operations. The state machine also controls the incrementing of the slot counter, and the frequency hop table index. A state diagram of the WOR state machine is shown below.

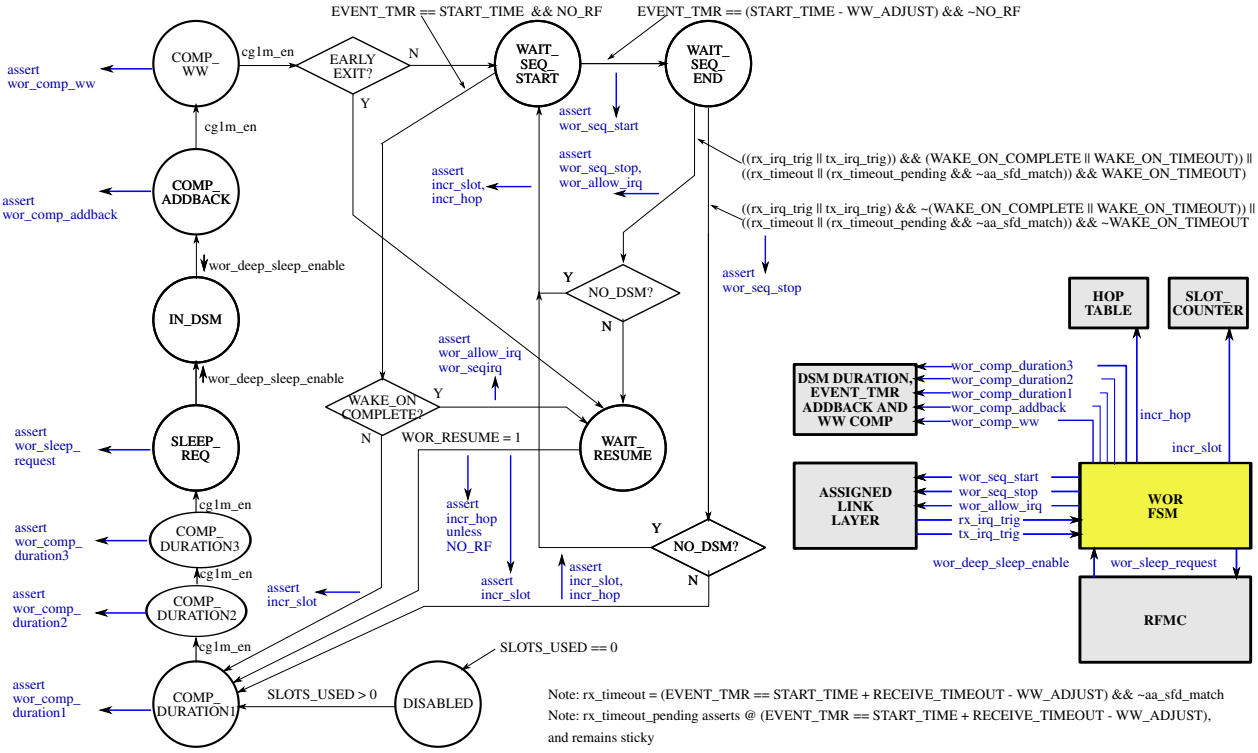

Figure 231. WAKE-ON-RADIO STATE DIAGRAM

A description of the WOR states follows.

DISABLED

WOR is in its disabled state whenever SLOTS_USED=0. WOR can be taken to "DISABLED" from any state by setting SLOTS_USED=0. WOR can be enabled by setting SLOTS_USED to a non-zero value, which initiates a new WOR "session".

COMP_DURATION1

WOR must compute the duration of the upcoming DSM cycle. This is done in 3 stages (states). COMP_DURATION1 is the first stage. Whenever the slot counter is incremented to begin a new slot, the slot's (descriptor's) START_TIME is in the future. In most cases, the START_TIME is distant enough that DSM is justified. During COMP_DURATION1, WOR computes the time to the next START_TIME, by subtracting both the current time (the assigned Link Layer's Event Timer) and the time-accumulated window-widening (if enabled) from the slot descriptor's START_TIME. (See Section Window Widening for more details on this feature.) The result of this subtraction is MICROSECONDS_TO_START_TIME[27:0]. This value must be converted to 32.768KHz cycles to be of use to RFMC. The multiplier is (549755 / 2^24), which is an approximation to the ideal conversion factor. The product is truncated to integer, the result represents the number of 32.768KHz cycles to remain in DSM prior to the next START_TIME. The hardware computations which take place during COMP_DURATION1 are shown in the following diagram.

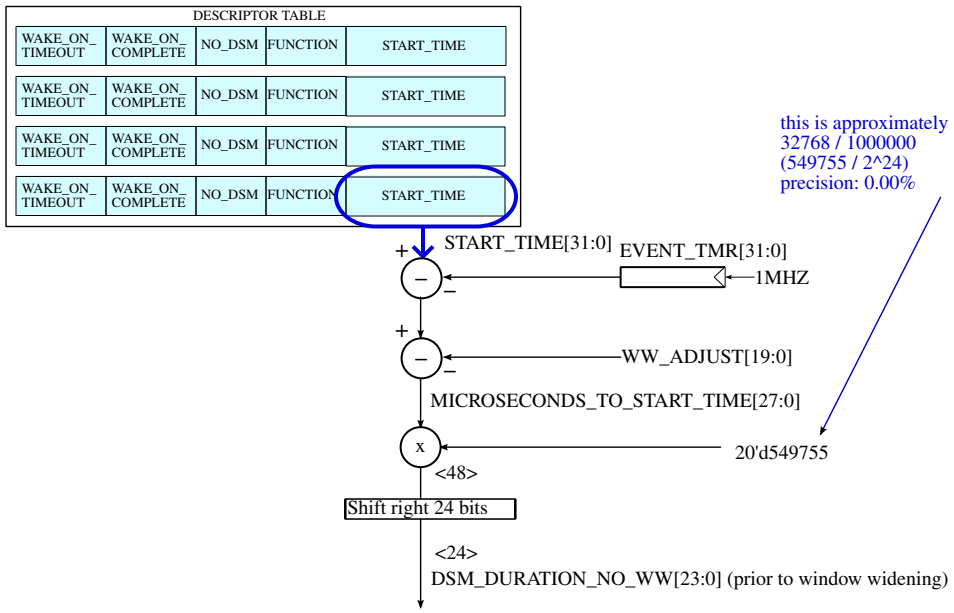

Figure 232. COMP_DURATION1

However this intermediate result does not account for the fact that window-widening for the upcoming DSM cycle itself, must be subtracted from this product. This is separate from the "accumulated" window-widening which has built up during the WOR session so far, which has already been accounted for. The estimate for the next DSM cycle's window widening is handled in the next state, COMP_DURATION2

The WOR output wor_clr_dsm_duration is asserted in this state, which is sent to the RFMC to proactively clear the DSM Duration Counter, which becomes active in the IN_DSM state (see below). The wor_clr_dsm_duration is an active-high, registered (glitch-proof) output signal.

COMP_DURATION2 and COMP_DURATION3

If window-widening is enabled, the DSM duration computed during COMP_DURATION1 may be long enough that it will need to be shortened slightly to account for window-widening which will accumulate during the DSM cycle itself. The computation for this window-widening is performed during this state. (See Section Window Widening for more details on this computation, and the usage of WW_DSM_FACTOR.) The (intermediate) duration from COMP_DURATION1 is multiplied by the DSM window-widening factor, and the product is subtracted from the duration estimate. The difference is a more accurate duration that accounts for window-widening during the DSM cycle. In a final step, a guardband is subtracted from the DSM duration. The guardband, with units of 32.768KHz clock cycles, guarantees that the DSM will complete on time before the next START_TIME is reached, accounting for RFMC synchronization and other delays in processing the WOR's sleep request. The guardband, which applies to all DSM cycles initiated by WOR, is determined by the register DSM_GUARDBAND[3:0]. The result of this step, is the final DSM duration (wor_dsm_duration[23:0]) which is then sent to the RFMC, which is responsible for radio DSM entry and exit. The hardware computations which take place during COMP_DURATION2 and COMP_DURATION3(alongside those covered by COMP_DURATION1) are shown in the following diagram.

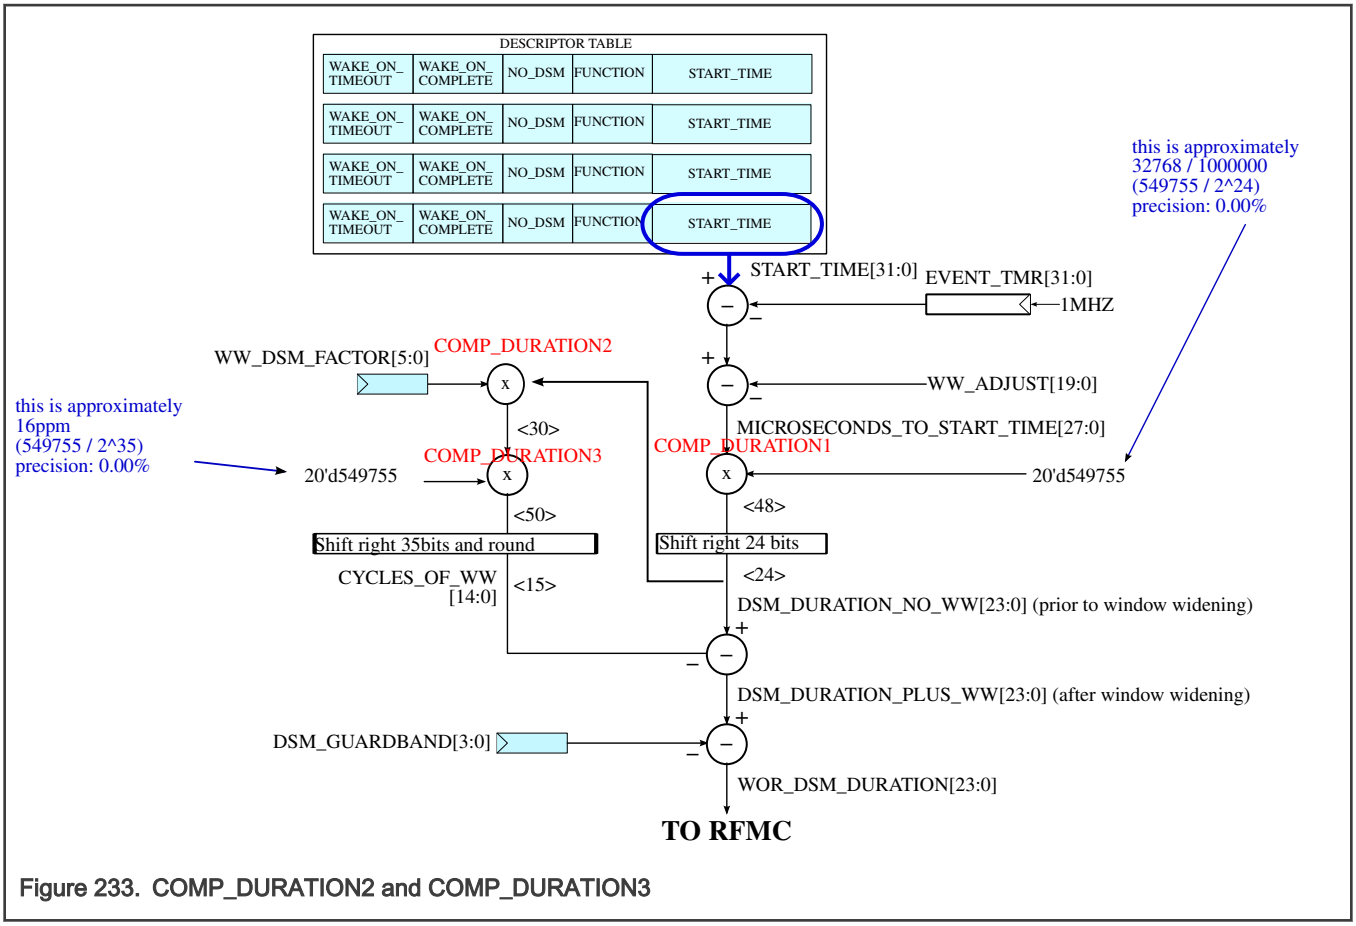

Figure 233. COMP_DURATION2 and COMP_DURATION3

SLEEP_REQ

In this state, WOR asserts its sleep request (wor_sleep_request) to the RFMC. This is a level, active-high, and registered (glitch-proof) signal to RFMC to indicate a DSM cycle is being requested of precise duration wor_dsm_duration[23:0], which was computed during the prior 2 WOR states. The units of wor_dsm_duration[23:0] are 32.768KHz clock cycles. RFMC shall synchronize wor_sleep_request into the 32.768KHz clock domain, and use it to activate the RFMC's DSM state machine. The RFMC DSM state machine shall place the radio in DSM, and simultaneously assert the output: wor_deep_sleep_enable. This signal is the precise indicator of DSM being "in effect", and is used to gate the assigned Link Layer's clocks and freeze its Event Timer.

IN_DSM

DSM is in effect during this state. Because the RF Oscillator has been disabled, there are no clocks to WOR, including its state machine, or the Link Layer, in this state. This is merely a holding state that prevails until DSM exits and the clocks to WOR and Link Layer are restarted. During this state, RFMC will use wor_deep_sleep_enable to enable a 24-bit counter which counts out the precise number of cycles in wor_dsm_duration[23:0]. When this counter reaches wor_dsm_duration, RFMC shall exit DSM and de-assert wor_deep_sleep_enable. RFMC shall provide the final count of the 24-bit counter which was used to time the DSM, using output signal rfmc_sleep_duration[23:0]. In most cases, rfmc_sleep_duration will be an exact match to wor_dsm_duration; the exceptional case is an unscheduled, early exit of DSM (see Section DSM Early Exit.) The interface signals between WOR and RFMC, and a high-level description of the hardware tasks performed by RFMC during IN_DSM state, is shown in the following diagram.

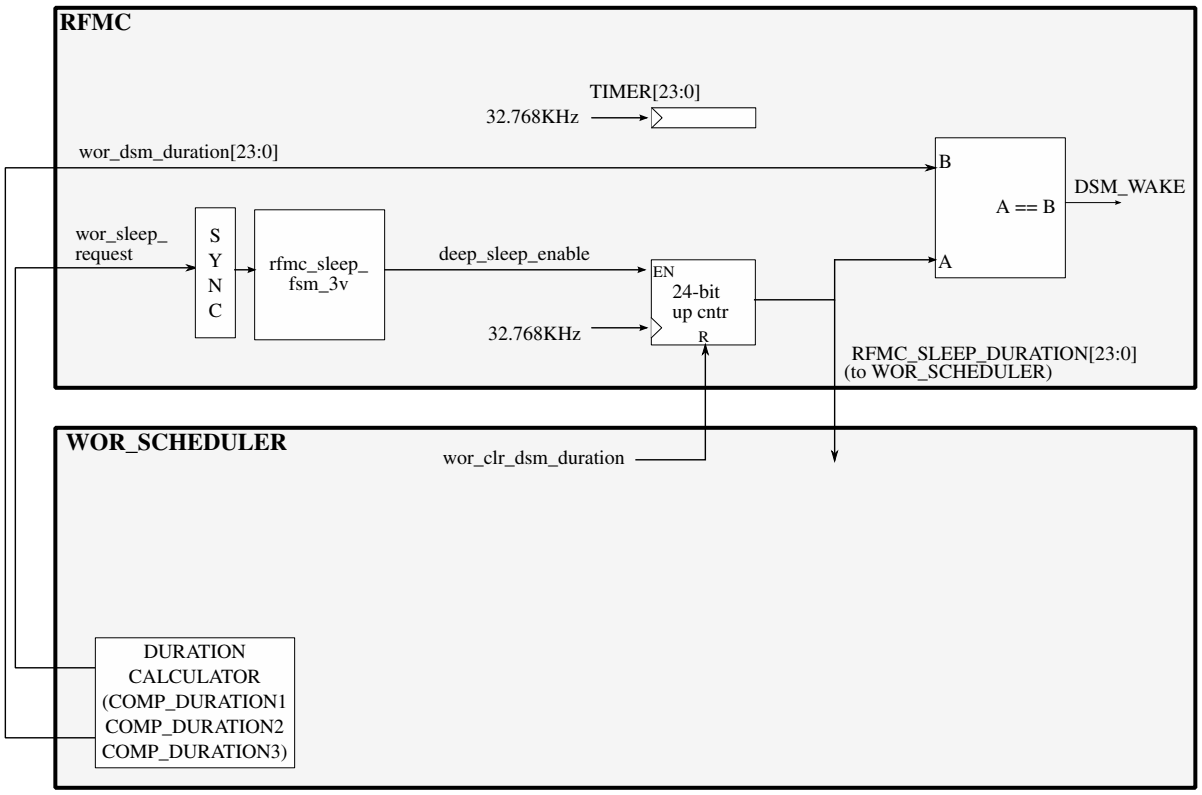

Figure 234. IN_DSM

COMP_ADDBACK

During the previous state, IN_DSM, the Reference Oscillator was disabled, and so the Event Timer of the assigned Link Layer was frozen. After DSM completes, clocks are restored and Event Timer resumes counting, but it is "behind" by the amount of time that the radio was in DSM. WOR hardware must compute the amount of DSM time, convert it to microseconds, and "add it back" to the Event Timer, so that after the addback, the Event Timer timebase is restored to where it would have been, had there been no DSM. (Note: there is a maximum of 1us of "loss of precision" upon every DSM exit; this timebase error is random and will not accumulate, it will average out over many DSM cycles). In this state, WOR computes the addback value by multiplying the rfmc_sleep_duration[23:0] (the precise number of 32.768KHz clock cycles during which RFMC held the radio in DSM) by 30.517578125 (the number of microseconds per 32.768KHz clock cycle). The 30.517578125 is an unsigned 14-bit value with 5 integer bits. The other multipicand, rfmc_sleep_duration is an unsigned integer. The product is the DSM elapsed time in microseconds, a 38 unsigned bit value with 29 integer bits. The product is rounded to the nearest integer and the 1 MSB's are discarded, resulting in the final wor_addback[27:0] value. At the end of this state, this result is sent to the assigned Link Layer's Event Timer, along with the wor_addback command (pulse), indicating to the Link Layer that it must add this amount to the current state of its Event Timer. After this point the protocol's timebase has been restored and operations can now be performed referencing the Event Timer. The following diagram depicts the hardware tasks performed in the COMP_ADDBACK state.

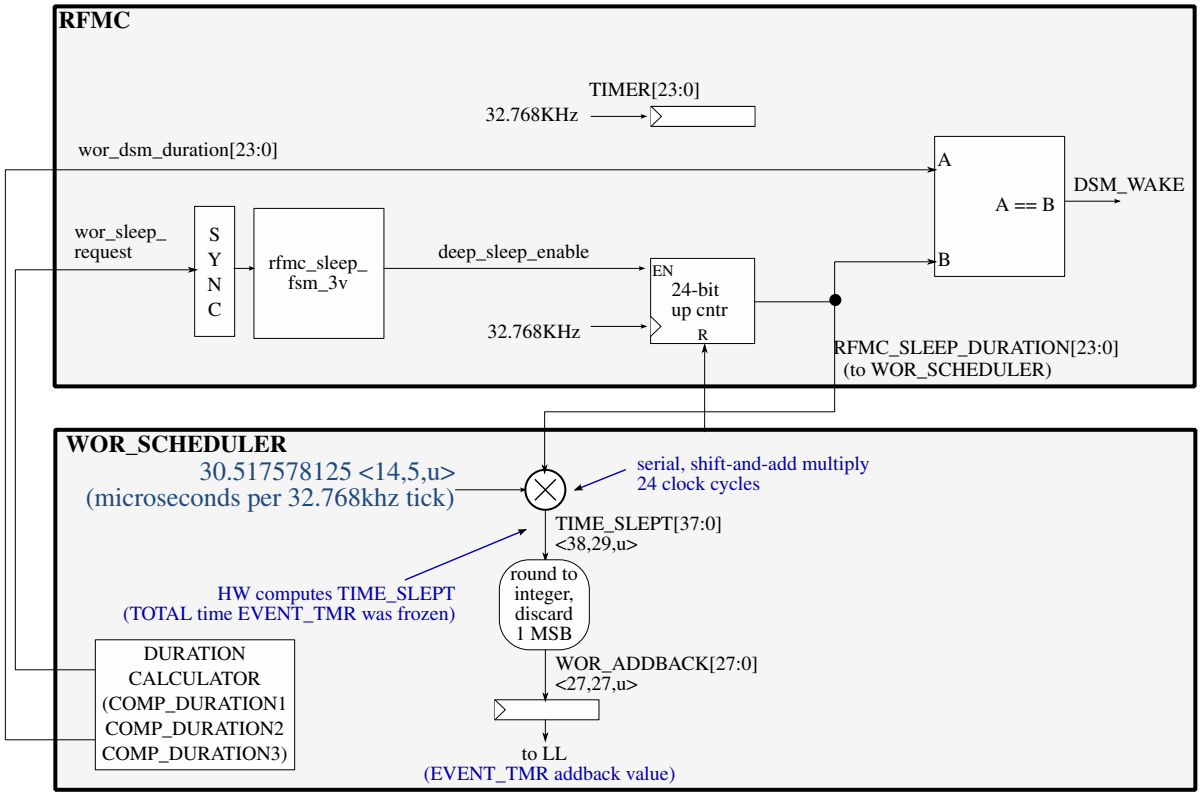

Figure 235. COMP_ADDBACK

COMP_WW

If window-widening is enabled, WOR must compute how much to increase the receive window by, based on the duration of the just-completed DSM cycle, so that this early-start offset to the receive window is ready in advance of the slot descriptor's START_TIME. The window-widening increment is computed during this state. Details of this hardware task are described in Section Window Widening.

WAIT_SEQ_START

After COMP_WW state, the WOR is ready to command an RF operation, and is only waiting for the slot descriptor's START_TIME to arrive. This start time will be in the near future since the DSM duration was timed to wake up "just in time" to start the RF operation, with sufficient guardband to guarantee that a DSM wake up can never occur too late. The WAIT_SEQ_START state merely waits for the assigned Event Timer to match the current slot descriptor's START_TIME. If the slot's FUNCTION is RX or RT, and window widening is enabled, START_TIME is modified by the hardware to be:

START_TIME - ww_adjust[19:0],

where ww_adjust[19:0] is the time-accumulated window-widening "early start" amount for the RX operation (see Section Window Widening.) If the FUNCTION is not RX or if window-widening is disabled, START_TIME is unmodified. Once a START_TIME match to the Event Timer occurs, WOR asserts the Link Layer interface signal wor_tx_start_ext (if FUNCTION is TX or TR), or wor_rx_start_ext (if FUNCTION is RX or RT). Neither interface signal is asserted if FUNCTION is NO_RF. The assigned Link Layer will commence an RF operation, TX or RX, based on this WOR command. At this point, the WOR state machine arrives at a fork:

- If FUNCTION = NO_RF and the descriptor WAKE_ON_COMPLETE=1, the next state is WAIT_RESUME
- Else if FUNCTION = NO_RF and WAKE_ON_COMPLETE=0, the next state returns to COMP_DURATION1 to begin the next slot. The slot counter and hop table index are incremented.
- Else, this is an RF operation that must be waited for. The state machine advances to the WAIT_SEQ_END state.

WAIT_SEQ_END

This state has been reached because an RF operation was launched during the previous state, and WOR is waiting for that operation to end. There are 3 ways for an RF operation to end:

- A TX operation self-terminates, indicated when the Link Layer asserts tx_irq_trig to WOR.
- A RX operation self-terminates due to a good packet reception, indicated when the Link Layer asserts rx_irq_trig to WOR.
- A RXor RT or TR operation times out. The rx_irq_trig is not asserted before the timeout. See Section Scheduling Modes for a description on the 2 methods WOR uses to compute the point-of-timeout, based on Scheduling Mode.

If either tx_irq_trig or rx_irq_trig is asserted, WOR advances to the next state (see below). If a point-of-timeout is reached without an rx_irq_trig, WOR hardware checks to see if Access Address Match has occurred or if SFD has been detected. If either is the case, timeout is deferred until either:

- The rx_irq_trig is ultimately asserted to indicate a good packet was received. This is a delayed good packet reception.
- The packet reception underway at point-of-timeout ultimately results in a CRC- or filtering-violation. This will automatically trigger a Link Layer RX recycle which will negate the AA-match or SFD-match indicator. WOR will detect this negation and declare a delayed timeout at this point.

If a timeout occurs, either nominal or delayed, WOR will assert wor_seq_stop_ext to the assigned Link Layer, causing an immediate abort of the RX sequence. This abort shall be handled by the protocol engine like a software abort. The wor_seq_stop_ext will not assert for a deferred timeout which results in a delayed good packet reception.

Nominally, WOR blocks the assigned Link Layer's RF-related interrupts from propagating to the MCU, to prevent unintended MCU wakeups during a WOR session. The RF-related interrupts for the supported protocol engines, are nearly identical in function across a 3 protocols, and are called RXIRQ, TXIRQ, and SEQ_END_IRQ. At the conclusion of an RF operation on a slot, WOR must decide whether to temporarily remove the Link Layer interrupt inhibits, to allow the Link Layer interrupt to be asserted to wake the MCU, based on which of the 5 outcomes to the RF operation occurred, and the state of the WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT descriptor fields. The following table specifies whether WOR blocks, or allows, the RF interrupts to propagate, at the conclusion of the RF operation.

RF OPERATION OUTCOME	WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=0	WAKE_ON_TIMEOUT=0, WAKE_ON_COMPLETE=1	WAKE_ON_TIMEOUT=1, WAKE_ON_COMPLETE=x
tx_irq_trig	BLOCK	ALLOW	ALLOW
rx_irq_trig (nominal)	BLOCK	ALLOW	ALLOW
rx_irq_trig (delayed)	BLOCK	ALLOW	ALLOW
no rx_irq_trig @ nominal timeout	BLOCK	BLOCK	ALLOW
no rx_irq_trig @ delayed timeout	BLOCK	BLOCK	ALLOW

At the conclusion of the RF operation, the WOR next state is a function of whether the Link Layer RF interrupts were BLOCKED or ALLOWED (see previous table), as well as the NO_DSM descriptor field as illustrated in the following table.

RF OPERATION OUTCOME	INTERRUPTS BLOCKED, NO_DSM=0	INTERRUPTS ALLOWED, NO_DSM=0	NO_DSM=1
tx_irq_trig	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
rx_irq_trig (nominal)	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)

Table continues on the next page...

Table continued from the previous page...

RF OPERATION OUTCOME	INTERRUPTS BLOCKED, NO_DSM=0	INTERRUPTS ALLOWED, NO_DSM=0	NO_DSM=1
rx_irq_trig (delayed)	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
no rx_irq_trig @ nominal timeout	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)
no rx_irq_trig @ delayed timeout	COMP_DURATION1 (increment slot, hop idx)	WAIT_RESUME	WAIT_SEQ_START (increment slot, hop idx)

WAIT_RESUME

If WOR has allowed the MCU to be awakened (interrupted) by temporarily negating the RF interrupt inhibits, WOR must enter a state which permits the MCU executing WOR or Link Layer software, to complete all its assigned tasks on the slot. These tasks may include processing and decrypting a received packet, servicing the packet buffer, and formulating and transmitting an acknowledge packet. The WAIT_RESUME state serves that purpose. The WAIT_RESUME state is reached whenever all of the following conditions are met:

- Current state is WAIT_SEQ_END
- FUNCTION is TX or RXor RT or TR
- RF operation completes with any outcome (rx_irq_trig, tx_irq_trig, nominal, or delayed timeout)
- NO_DSM=0
- RF Interrupts are ALLOWED (see table, WAIT_SEQ_END state)

WAIT_RESUME is also reached whenever all of these following conditions are met:

- Current state is WAIT_SEQ_START
- FUNCTION is NO_RF
- START_TIME match to the assigned Link Layer's Event Timer
- WAKE_ON_COMPLETE=1

Once WAIT_RESUME is reached, WOR software must authorize WOR hardware to resume the WOR session and advance to the next slot, by setting the WOR_RESUME register bit to 1. When WOR_RESUME is set to 1 in WAIT_RESUME state, WOR hardware takes the following steps:

1. Advances to the next slot (slot counter++ % SLOTS_USED)
2. Increments the frequency hop table index *unless* FUNCTION = NO_RF
3. Enters COMP_DURATION1 state on the new slot
4. Reimposes Link Layer interrupt inhibits

52.4.4.1.1.2.5 Window Widening

OVERVIEW

Because a device in a connected state is not receiving all the time, its timebase will invariably drift with respect to the timebase of other device(s) in the network, due to finite crystal oscillator tolerances amongst the networked devices. Reducing the duty cycle of the receiver, albeit necessary to achieve power savings, exacerbates the drift problem.

To compensate for drift, Receive Window Widening can be employed. As time elapses in a network connection between successful packet receptions, the window-widening algorithm gradually moves future receiver turn-on times to the left (advance) and the turn-off time to the right (retard) to allow the transmitted packet to fall within the receiver's window in the presence of a

drifting timebase. The effect of window-widening on successive receive cycles, none of which result in a good packet reception, is illustrated in the following diagram.

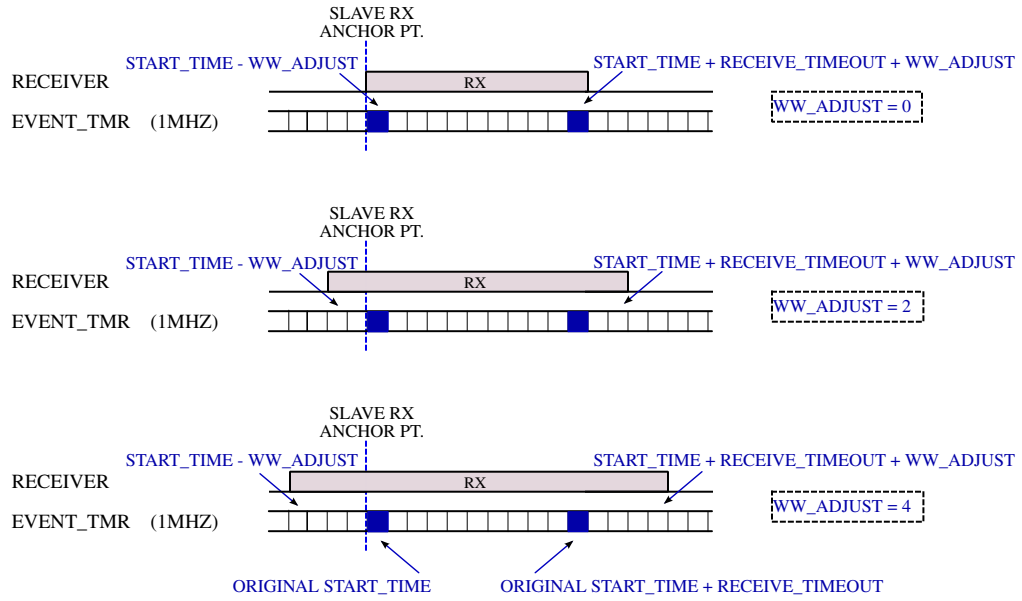

Figure 236. EFFECT OF WINDOW WIDENING ON RECEIVE WINDOW

Window widening is typically applicable only to the slave device(s) in a network, as the master (coordinator) of the network is normally the master of network timing. Thus, in Wake-On-Radio, window widening is optional, enabled by the by setting the WW_EN register bit to 1.

The Window widening algorithm needs to take into account the "Sleep Clock Accuracy" of the devices in the network. Sleep Clock Accuracy (SCA) is a *Bluetooth Low Energy* concept, and the Bluetooth LE nomenclature is adopted by Wake-On-Radio, and extrapolated to all supported protocols.

In Bluetooth LE, drift encountered by a slave device must be compensated by accounting for the SCA of both the master and the slave (self). The master transmits its SCA to the slave in the connection request (CONNECT_REQ), an advertising channel packet which informs an advertising slave of the master's desire to form a connection with it; the parameters on the CONNECT_REQ include the master's SCA. The slave device knows its own SCA, so the composite SCA is known at the point of connection establishment. Wake-On-Radio adopts this concept, although the precise method of informing the slave of Master SCA is protocol-dependent and takes place at a higher level, beyond the scope of this document.

Bluetooth LE subdivides the allowed Master SCA into coarse ranges, to reduce the number of over-the-air bits required to inform the slave. The ranges are shown in the following diagram.

SCA	masterSCA
0	251 ppm to 500 ppm
1	151 ppm to 250 ppm
2	101 ppm to 150 ppm
3	76 ppm to 100 ppm
4	51 ppm to 75 ppm
5	31 ppm to 50 ppm
6	21 ppm to 30 ppm
7	0 ppm to 20 ppm

Figure 237. SCA RANGES

The slave SCA must be accounted for as well, so the maximum composite SCA is 1000ppm. For Wake-On-Radio, this is the maximum allowed drift as well, and window-widening programmability will allow for drift amounts within these ranges to be compensated.

FACTS

In the WOR hardware, the window-widening adjustment, is a value, ww_adjust[19:0], that is subtracted from the receiver START_TIME, and added to the receiver TIMEOUT, when the slot's FUNCTION = RX, as shown in the diagram below.

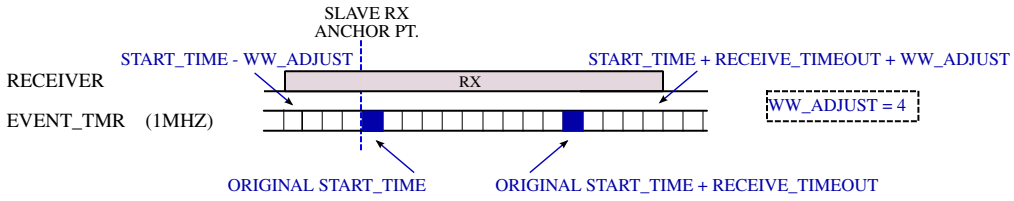

Figure 238. WINDOW WIDENING EFFECT ON RX SEQUENCE

The ww_adjust[19:0] adjustment, has no effect on START_TIME for slots using FUNCTION TX or NO_RF.

After system reset, if window-widening is enabled using WW_EN, ww_adjust[19:0] will increase linearly over time.

The adjustment, ww_adjust[19:0], will be reset to 0 under any of the following conditions:

1. system reset
2. good packet received (CRC verified and packet filtering passes)
3. Software writes a 1 to WW_NULL register bit

The reset-on-good-packet (item #2 above), can be inhibited by setting register bit WW_RESET_ON_RX=0. By default this bit is set.

The adjustment, ww_adjust[19:0], consists of 2 components, which are summed together:

1. **DSM adjustment:** computed at the conclusion of every DSM cycle based on rfmc_sleep_duration[23:0]
2. **RUNTIME adjustment:** computed by periodically incrementing a binary counter by 1 every *N* EVENT_TMR ticks whenever NOT in DSM

The rates at which window-widening accumulates during DSM and RUNTIME, are controlled by 2 programmable registers. The programmed values of these registers should be informed by the combined (master + slave) SCA.

The 2 components of the window-widening adjustment, and the reset conditionality, are illustrated in the following diagram:

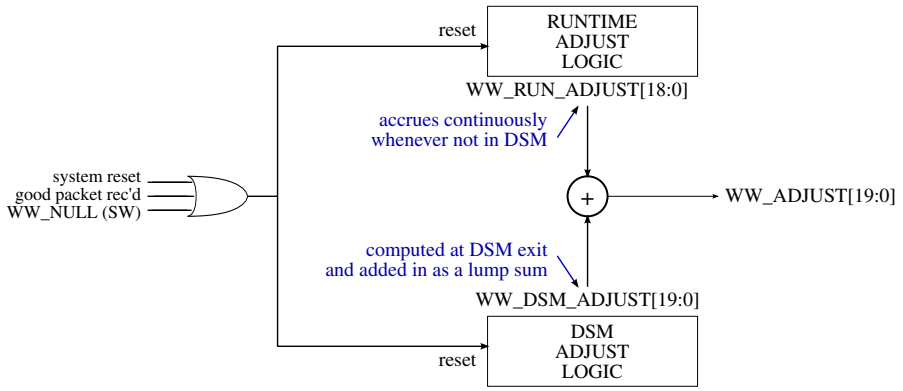

Figure 239. WINDOW WIDENING COMPONENTS AND RESET CONDITIONALITY

WINDOW WIDENING DSM ADJUSTMENT

In Wake-On-Radio, every slot includes a DSM cycle (unless NO_DSM=1 in the descriptor). WOR hardware computes the window-widening DSM adjustment after the DSM cycle completes, during the WOR COMP_WW state. This state immediately follows the COMP_ADDBACK state which updates the Event Timer for time-slept. The WW DSM adjustment, ww_dsm_adjust[19:0], is computed, and then added to the composite, accumulated adjustment, ww_adjust[19:0], as a lump sum. During COMP_WW state, WOR hardware multiplies rfmc_sleep_duration[23:0], which is the precise number of 32.768KHz cycles for which the RFMC held the radio in DSM, by a programmable factor which represents the number of microseconds per 32.768KHz clock cycle, scaled by the combined SCA of the master and slave (drift), i.e.,

DSM_DURATION (from RFMC) * (masterSCA + slaveSCA), converted to µs

Programmable register WW_DSM_FACTOR maps the composite SCA (masterSCA + slaveSCA), in parts per million, to a multiplicand which represents

N *** 16ppm * 30.5178125µs,**

where *N* = WW_DSM_FACTOR, and

30.5178125 is the *precise* number of microseconds per 32.768KHz tick, not an approximation.

Register WW_DSM_ADJUST allows SCA to be applied in coarse ranges, as described earlier in this section. Each LSB of WW_DSM_ADJUST is worth 16ppm of 30.5178125µs. Valid values are 0 ≤ WW_DSM_FACTOR ≤ 63. Consider the table below as a guide for selecting WW_DSM_FACTOR based on composite SCA:

masterSCA + slaveSCA	Use this WW_DSM_FACTOR
251 ppm to 500 ppm	16 (256ppm) - 32(512ppm)
151 ppm to 250 ppm	10 (160ppm) - 16(256ppm)
101 ppm to 150 ppm	7 (112ppm) - 10(160ppm)
76 ppm to 100 ppm	5 (80ppm) - 6 (96ppm)
51 ppm to 75 ppm	4 (64ppm)
31 ppm to 50 ppm	3 (48ppm)
21 ppm to 30 ppm	2 (32ppm)
0 ppm to 20 ppm	1 (16ppm)

Figure 240. WW_DSM_FACTOR BASED ON COMPOSITE SCA

A summary of all the hardware tasks performed to compute ww_dsm_adjust[19:0] during the COMP_WW state, is shown in the diagram below.

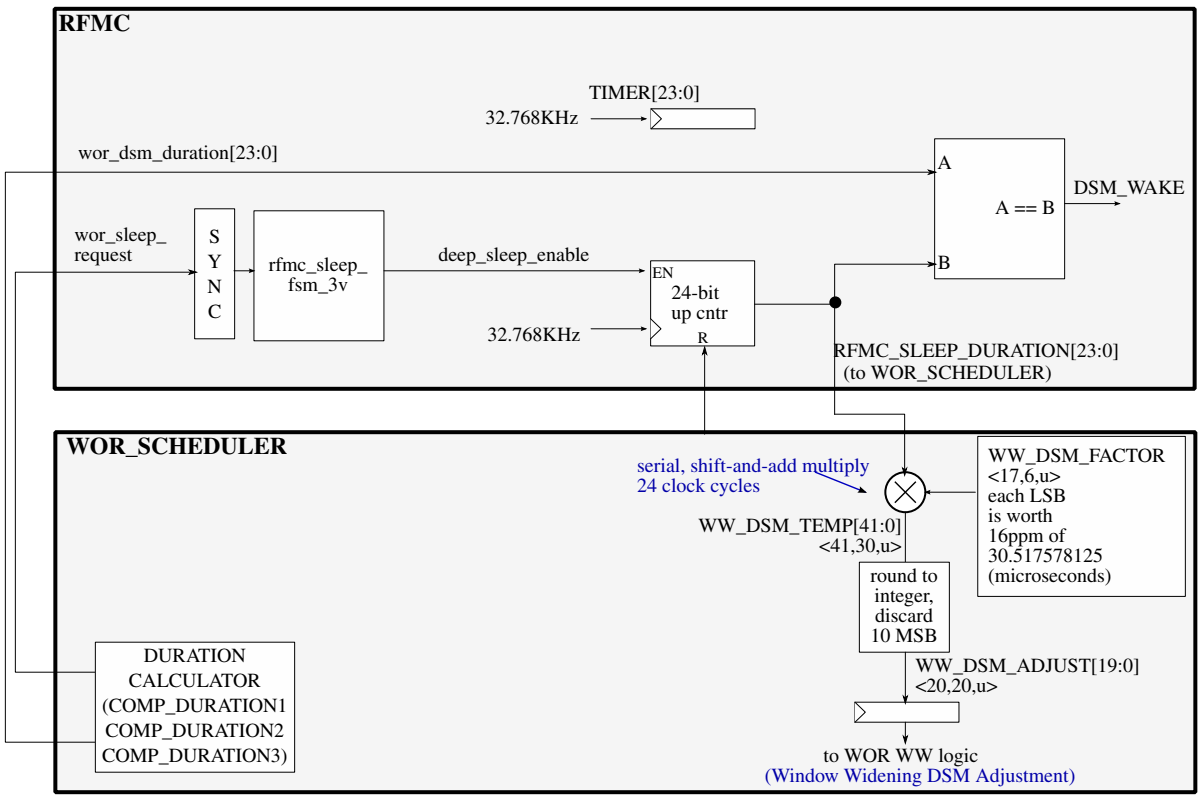

Figure 241. HARDWARE TASKS DURING COMP_WW STATE

WINDOW WIDENING RUNTIME ADJUSTMENT

The window-widening RUNTIME adjustment is computed by incrementing a binary counter every *N* EVENT_TMR ticks whenever NOT in DSM (i.e., EVENT_TMR is running). *N* is a variable based on programmable register WW_RUN_ADJUST[4:0]. The programmable resolution, or granularity, of the DSM adjustment (16ppm), will be matched by the RUNTIME adjustment. Unlike the DSM adjustment, the RUNTIME adjustment is an approximation to the ideal value of *N*, since *N* is the result of a division operation whose quotient is not always an integer number of microseconds. However, the objective in Wake-On-Radio is to spend as little time in RUN between events as possible, so the DSM adjustment will dominate the sum. Therefore, additional resolution in the RUNTIME adjustment, although achievable, would have little benefit in overall power savings.

N is a modulo for the binary counter which tracks the runtime adjustment, and represents the ideal number of microseconds between each increment to the adjustment, which is simply the reciprocal of the composite SCA, i.e.,

***N* = 1 / (master SCA + slave SCA)**

Using an example of composite SCA = 192ppm,

***N* = 1 / 192e-6 = 5208.333**

For implementation, each SCA range (the same table of ranges defined for the DSM adjustment) becomes an input to a look-up table (LUT) which approximates this division, rounding the quotient to the nearest integer. SCA range is represented by the WW_RUN_FACTOR. If WW_RUN_FACTOR=0, the RUNTIME adjustment never increments (special case). Valid values are 0 ≤ WW_RUN_FACTOR ≤ 16.

Every time the modulo *N* is reached, the binary counter resets to 0, and the RUNTIME adjustment is incremented by 1, meaning that the start of the next receive operation, has been advanced by 1µs. The hardware which implements the window widening RUNTIME adjustment is shown in the following diagram.

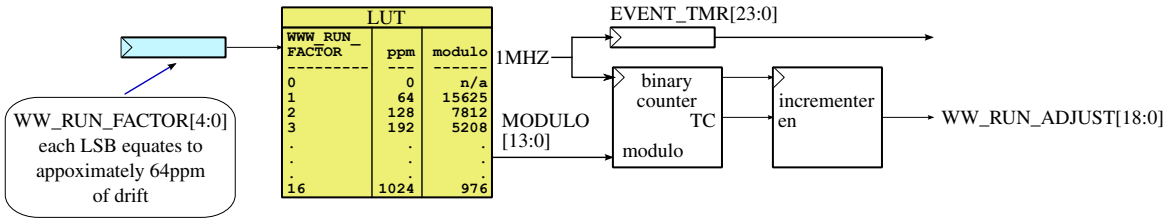

Figure 242. WINDOW WIDENING RUNTIME ADJUSTMENT

COMPENSATING DSM DURATION FOR WINDOW WIDENING

In executing each slot as specified by the WOR descriptor, there is one other instance where window widening must be accounted for. During the COMP_DURATION1 state, WOR computes the DSM duration based on descriptor START_TIME and current (Event Timer) time. This duration is timed to complete the DSM cycle as close as possible to the desired START_TIME, but with sufficient guardband to ensure wakeup can never occur too late. But the duration computed during this state may be sufficiently long that the desired START_TIME needs to be advanced, due to drift within the DSM cycle itself. Thus, window widening needs to be estimated and subtracted from this computation. This window widening estimation is used only for the purpose of the duration estimation, and does not accumulate from one DSM cycle to the next (i.e., from one slot to the next). This window widening compensation to DSM duration occurs during the COMP_DURATION2 and COMP_DURATION3 state. See Section State Machine for a description of WOR states.

The difference between this window widening computation, and the computation during COMP_WW, is that the result must be in units 32.768KHz clock cycles, because it is targeted for RFMC, instead of microseconds for an Event Timer offset. The COMP_DURATION2 and COMP_DURATION3 computation multiplies the DSM duration (in 32K cycles) computed in COMP_DURATION1 by an estimate of the SCA (drift), to arrive at a product which represents the number of 32.768KHz cycles by which to foreshorten the upcoming DSM cycle due to the widening requirement. So there is no conversion of units.

CYCLES_OF_WW[14:0] = DSM_DURATION_NO_WW[23:0] (result of COMP_DURATION1, neglecting widening) * *WW_DSM_FACTOR* * 549755 / 2^35

This product is subtracted from the DSM duration estimate, along with the DSM_GUARDBAND[3:0], to arrive at the final wor_dsm_duration[23:0] sent to RFMC for execution:

WOR_DSM_DURATION[23:0] = DSM_DURATION_NO_WW[23:0] - CYCLES_OF_WW[14:0] - DSM_GUARDBAND[3:0].

The following diagram illustrates all of the hardware tasks performed during COMP_DURATION2 and COMP_DURATION3 state:

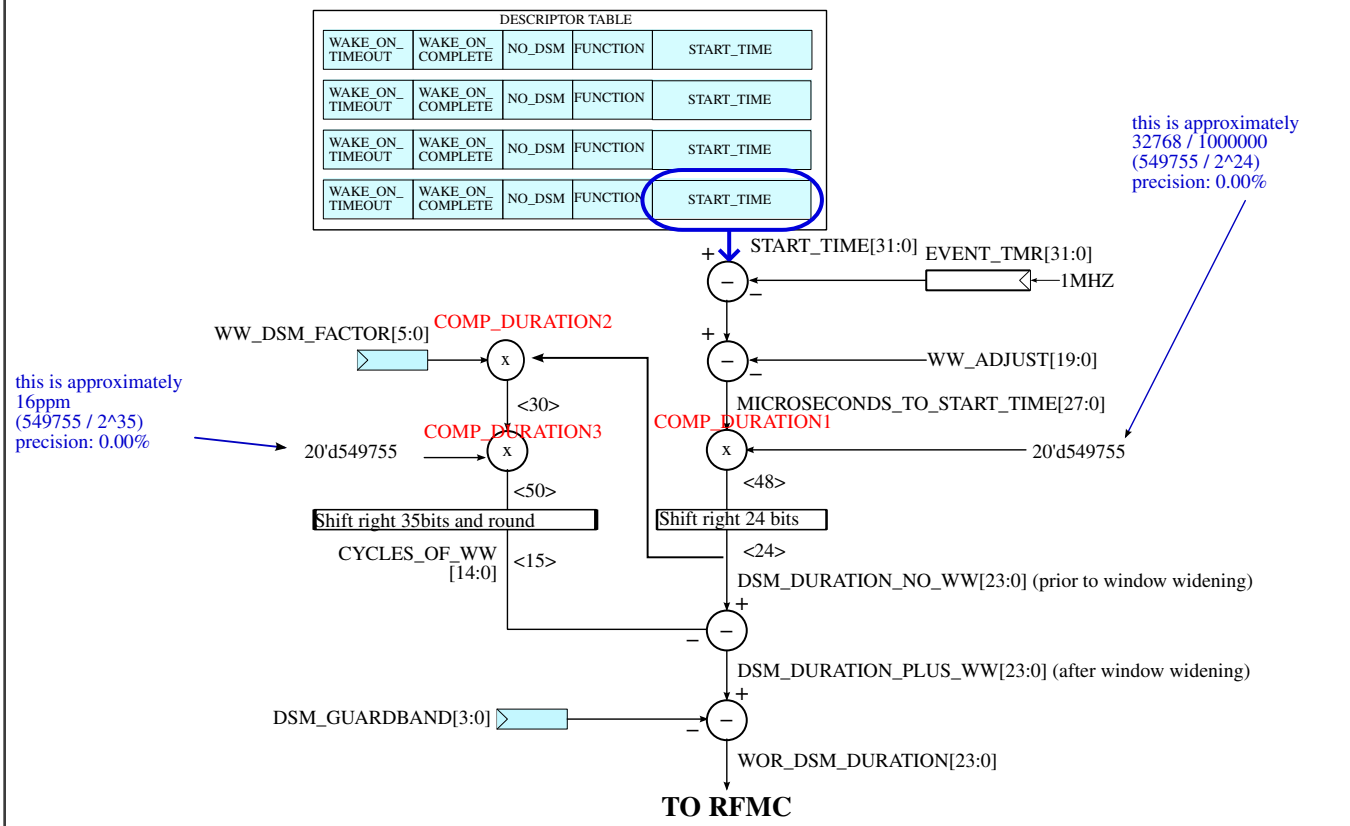

Figure 243. COMP_DURATION2

APPLYING THE WINDOW WIDENING

Now that the window-widening adjustment has been computed, it must be put into effect, by modifying the START_TIME of the RF operation to advance it by the number of microseconds in ww_adjust[19:0], which is the combined DSM and RUNTIME window widening adjustment. This occurs during the WAIT_SEQ_START state. The same adjustment is applied again, by modifying the TIMEOUT of the RF operation (assuming timeout is reached), by delaying it by the same number of microseconds that START_TIME was advanced by. This occurs during the WAIT_SEQ_END state. The following diagram illustrates how window-widening is applied in Timeslot Scheduling mode.

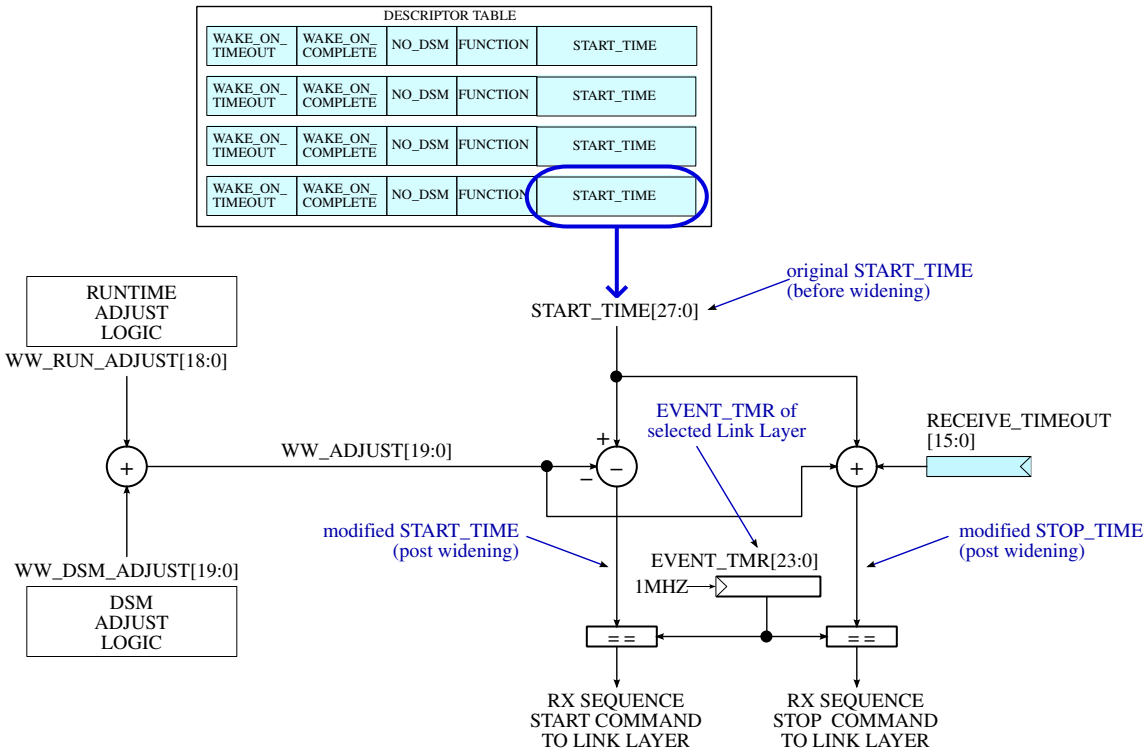

Figure 244. APPLYING WINDOW WIDENING (TIMESLOT MODE)

The application of window-widening in Constant-Interval scheduling mode, is largely the same as Timeslot mode; however the way the WOR hardware determines START_TIME and TIMEOUT is different, these need to be computed by WOR on a slot-by-slot basis. The following diagram illustrates how window-widening is applied in Constant-Interval Scheduling mode.

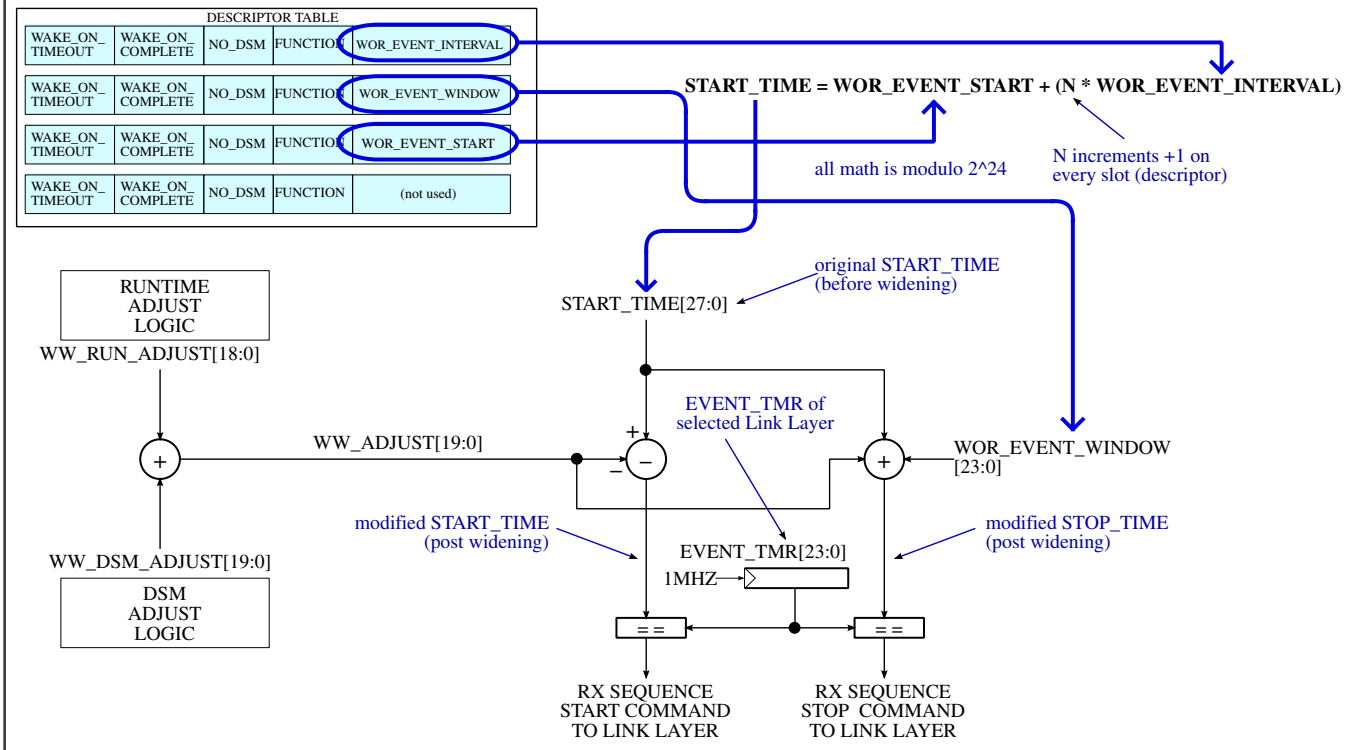

Figure 245. APPLYING WINDOW WIDENING (CONSTANT-INTERVAL MODE)

NOTE

When dealing with the combination of high SCA (Sleep Clock Accuracy) as well as long requested DSM intervals, it is the responsibility of software to guarantee that the accumulation of window widening does not become excessively large. Window widening should not be allowed to accumulate to such an extent that the adjusted START_TIME is advanced so much that it moves to the left of the *previous* slot's START_TIME, or that the TIMEOUT is retarded so much that is moves to the right of the *next* slot's START_TIME, especially in scenarios where no good packets are received for an extended period of time. Software should periodically monitor window widening accumulation using mandatory MCU wakeups after every third or fourth slot (timeslot mode), or WAKE_ON_NTH_SLOT (constant interval mode), and use caution when scheduling long DSM intervals (distance between START_TIME on consecutive slots) with high WW_DSM_FACTOR values.

52.4.4.1.1.2.6 Auto DSM Drift Calculation

Usually, the combination of SCA (Sleep Clock Accuracy) is hard to get, so for Window Widening, user has to set a big enough WW_DSM_FACTOR to cover the worst case. This makes the window larger enough to receive the packets but also wastes power. And also, the accumulation of window widening may become excessively large after many slots.

The "Auto Drift Calculation" feature is used to solve these shortcomings. This feature can only be used in Constant-Interval mode and it is enabled by register AUTO_CAL set when WW_EN is also enabled.

Its basic concept is that (the timestamp of the packet arrives - expected) is proportional to (the set drift - the actual drift). Based on this theory, hardware can calculate the actual drift after received a packet and then apply the calculated drift to the next slot to get the optimized window to save power. The detailed process is as follows.

1. Theory of Drift Calculation

Below figure shows a 4 slots receive case in Constant-Interval mode. After the reception of the first packet which is called the synchronization packet, software configures the WOR to the Constant-Interval mode and enables the Window Widening feature.

The term Rx(x=sync, 0~3) denotes the timestamp recorded in the link layer's Event Timer when the packet actually arrives, and Sx(x=0~3) denotes the expected timestamp which is calculated by the WOR hardware. RX_ENx(x=0~3) denotes the RX_EN signal assertion time.

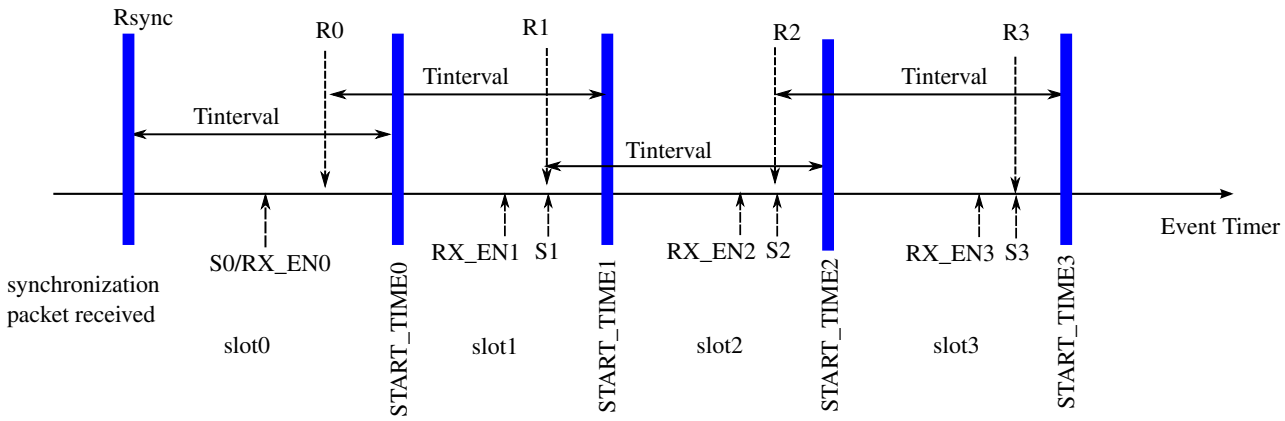

Figure 246. Auto Drift Calculation Algorithm

Software programs the START_TIME(WOR_EVENT_START) of the slot0 as

START_TIME0 = Rsync + Tinterval, Tinterval is WOR_EVENT_INTERVAL,

because if there is no clock drift, this is the next packet arrive time.

Since the START_TIME is the time which WOR hardware informs the Link Layer to assert the RX_EN signal, so it should consider the RX warm up time and the Preamble-SFD delay. The precise START_TIME should be

START_TIME0 = Rsync + Tinterval - AA_SFD_DLY,

where AA_SFD_DLY is a programmable register which counts for the RX warm up time and the Preamble-SFD delay.

AA_SFD_DLY does not effect the drift calculation, so for simplicity, it is ignored in the discussion below.

In this example, at slot0, user will set an initial WW_DSM_FACTOR to cover the worst case drift. If ignore the RUNTIME adjustment, the window will open WW_DSM_ADJUST0(Tsleep0 * drift_set0) earlier before the START_TIME. Due to the combination of SCA, the real packet arrive time is R0, it is (Tsleep0 * drift_real0) earlier than the START_TIME. That is to say,

the expected packet arrive time is:

S0 = START_TIME0 - WW_DSM_ADJUST0

= START_TIME0 - Tsleep0 * drift_set0 / 1000000, where drift_set0 = WW_DSM_FACTOR * 16 (ppm), Tsleep0 is the sleep time in slot0,

the real packet arrive time is:

R0 = START_TIME0 - Tsleep0 * drift_real0 / 1000000, where drift_real0 is the real drift during slot0, the unit is ppm

Hardware uses the delta time between S0 and R0, delta_time0, to get the drift_real0 as:

delta_time0 = R0 -S0

= Tsleep0 * (drift_set0 - drift_real0) / 1000000 (us)

drift_real0 = drift_set0 - (delta_time0 / Tsleep0 * 1000000) (ppm)

In the above formula, It is difficult for the hardware to calculate the division, so an approximate method is using Tinterval instead of Tsleep0:

drift_real0 = drift_set0 - (delta_time0 / Tinterval * 1000000) (ppm)

Convert drift_real0 to 16ppm unit as:

drift_real0_factor = drift_real0 / 16

= drift_set0_factor - (delta_time0 / Tinterval * 1000000 / 16) (LSB), where drift_set0_factor = WW_DSM_FACTOR

If user calculates the 1000000/Tinterval/16 and programs the result into register TINT_DIV_MILLION, hardware can simplify division into multiplication as,

drift_real0_factor = drift_set0_factor - (delta_time0 * TINT_DIV_MILLION) (LSB)

To cover the whole range of Tinterval, which is about 500 us to 2^28 us, the actual value programmed to the TINT_DIV_MILLION is

TINT_DIV_MILLION = (1000000 / Tinterval / 16) * 2^17

The hardware will take this extension into account and handle it accordingly.

The calculated drift_real_factor is readable by register **CAL_DSM_FACTOR** which is a signed register of two's complement value. A negative value means the packet comes later than expected.

2. START_TIME Calculation for Each Slot

To calculate and track the drift in each slot, the START_TIME calculation is different with the normal Constant Interval Mode.

In normal Constant Interval Mode, the slot1's START_TIME is calculated as,

START_TIME1 = START_TIME0 +Tinterval

When AUTO_CAL is set, and if Link Layer received a packet in slot0, WOR calculates the next START_TIME as

START_TIME1 = R0 + Tinterval,

and the expected packet arrive time is:

S1 = START_TIME1 - WW_DSM_ADJUST1

= START_TIME1 - Tsleep1 * drift_set1 / 1000000, where drift_set1 = drift_real0, Tsleep1 is the sleep time in slot1,

and the real packet arrive time is:

R1 = START_TIME1 - Tsleep1 * drift_real1 / 1000000, where drift_real1 is the real drift during slot1, the unit is ppm

So, drift_real1 can be calculated as:

drift_real1 = drift_set1 - (delta_time1 / Tsleep1 * 1000000)

By this way, at each slot, hardware repeats to calculate and track the drift.

Ideally, the drift_real in slot0 and slot1 is same, so S1 is equal to R1. This means the packet may come at the exact time when the window opens. This achieves the longest sleep time.

But due to the drift calculation error in slot0 or/and drift change between the slots, the packet may come a little bit earlier(like in slot2) or later than the expected time. To make sure that the packet is received, the real window open time is TIME_MGN earlier than the calculated point, Sx, where TIME_MGN is a user programmable register with us unit.

TIME_MGN can be calculated as:

TIME_MGN = (drift_calculation_err + inter_slot_drift_change) * Tinterval

The real Window Open time for slot 1 is

RX_EN1 = S1 - TIME_MGN

and the real STOP_TIME, i.e., Window Close time is

STOP1 = S1 + WOR_EVENT_WINDOW + TIME_MGN

For summary, for slot n, if there is a packet received in the previous slot n-1,

START_TIME(n) = R(n-1) + Tinterval

S(n) = START_TIME(n) - WW_DSM_ADJUST(n)

RX_EN(n) = S(n) - TIME_MGN

STOP(n) = S(n) + WOR_EVENT_WINDOW + TIME_MGN

3. Packet Missed Case

When a slot missed a packet due to some reasons, like drift sudden changes or RF signal is blocked, it will impact the drift calculation process.

Below figure shows the case that a packet is missed at slot 0. The basic idea is to apply the initial WW_DSM_FACTOR to slot 1, after received in slot 1, then apply the initial WW_DSM_FACTOR to slot2, after received in slot 2, the drift_real2 is calculated.

Since packet is missed in slot0, the initial WW_DSM_FACTOR is still used in slot1 and there is no margin time applied to START/STOP_TIME.

For slot1,

START_TIME1 = S0+Tinterval

RX_EN1 = START_TIME1 - WW_DSM_ADJUST1

STOP1 = RX_EN1 + WOR_EVENT_WINDOW + 2 * WW_DSM_ADJUST

WW_DSM_ADJUST is the accumulated DSM adjust,

WW_DSM_ADJUST = WW_DSM_ADJUST0 + WW_DSM_ADJUST1

WW_DSM_ADJUST0 is the DSM adjust of slot0,

WW_DSM_ADJUST0 = Tsleep0 * drift_set0 / 1000000, drift_set0 = WW_DSM_FACTOR * 16 (ppm)

WW_DSM_ADJUST1 is the DSM adjust of slot1,

WW_DSM_ADJUST1 = Tsleep1 * drift_set1 / 1000000, drift_set1 = WW_DSM_FACTOR * 16 (ppm)

For slot2,

START_TIME2 = R1+Tinterval

RX_EN2(S2) = START_TIME2 - WW_DSM_ADJUST2,

STOP2 = RX_EN2 + WOR_EVENT_WINDOW + 2 * WW_DSM_ADJUST2,

WW_DSM_ADJUST2 is the DSM adjust of slot2,

WW_DSM_ADJUST2 = Tsleep2 * drift_set2 / 1000000, drift_set2 = WW_DSM_FACTOR * 16 (ppm)

R2 = START_TIME2 - Tsleep2 * drift_real2 / 1000000

Using R2 and S2, we can get the drift_real2 and apply it to slot3.

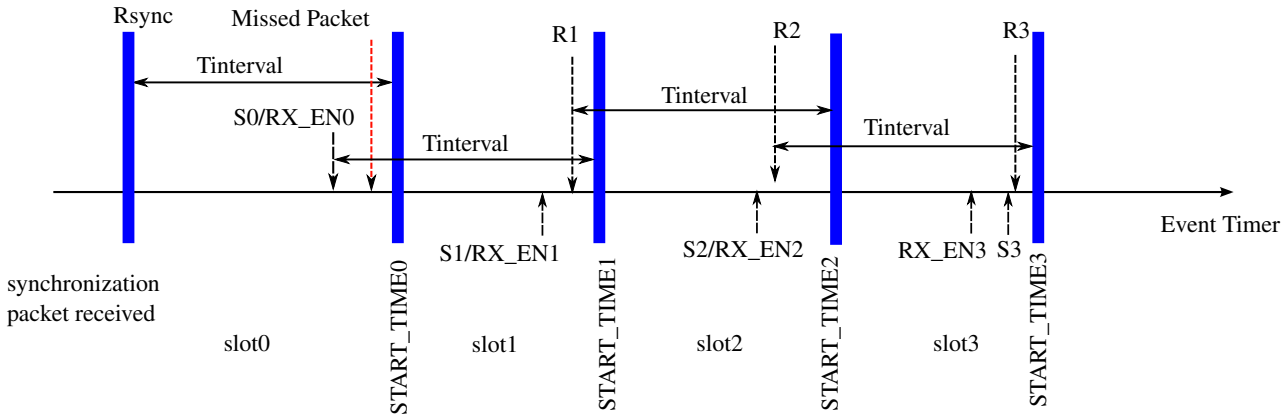

Figure 247. Handle of Missed Packet(Example 1)

As another example below, in slot0 packet is received, but in slot1, the packet is missed. The basic idea is to apply the drift_real0 to slot 2, after received in slot 2, then apply the initial WW_DSM_FACTOR to slot3, after received in slot 3, the drift_real3 is calculated..

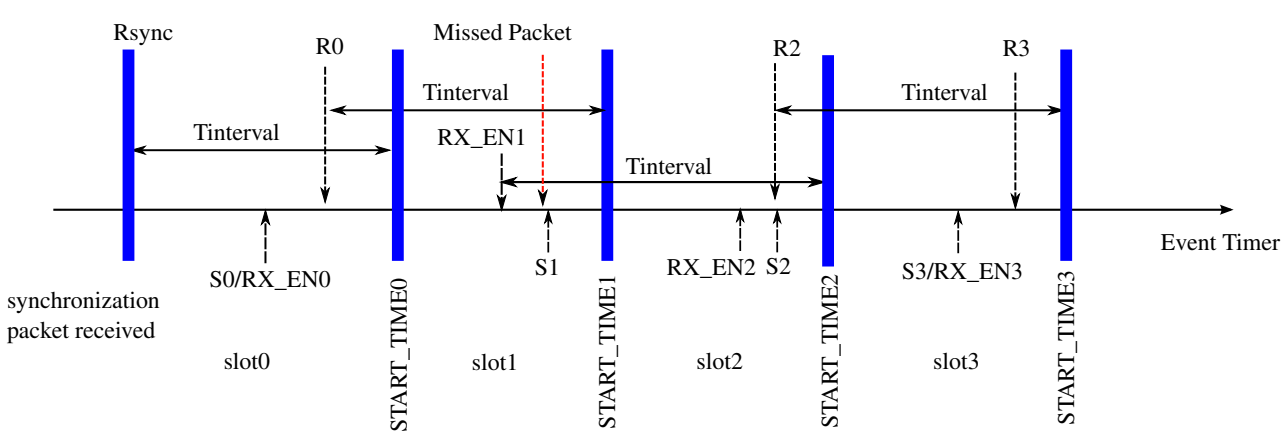

Figure 248. Handle of Missed Packet(Example 2)

Since packet is received in slot0, drift_real0 can be calculated.

For slot1,

START_TIME1 = R0+Tinterval

RX_EN1 = START_TIME1 - Tsleep1 * drift_real0 / 1000000 - TIME_MGN

STOP1 = RX_EN1 + WOR_EVENT_WINDOW + 2 * TIME_MGN

For slot2,

Then the START_TIME is calculated as:

START_TIME2 = RX_EN1+Tinterval

And hardware still applies the calculated drift_real0 to slot 2. Consider the drift change between slot0 and slot1, slot1 and slot2, the real window open point is TIME_MGN us before S2.

RX_EN2 = START_TIME2 - Tsleep2 * drift_real0 / 1000000 - TIME_MGN

and the real STOP_TIME, i.e., Window Close time is

STOP2 = RX_EN2 + WOR_EVENT_WINDOW + 4 * TIME_MGN

For summary, for slot n, if there is no packet received in the previous slot n-1,

START_TIME(n) = RX_EN(n-1) + Tinterval

RX_EN(n) = START_TIME(n) - Tsleep(n) * drift_set(n) / 1000000 - TIME_MGN

STOP(n) = RX_EN(n) + WOR_EVENT_WINDOW + 2 * (k+1) * TIME_MGN, where k is the number of missed slots since last received

In this example, in slot2, the packet is received. At this point, hardware does not calculate the drift_real for the next slot, because the calculation may be not correct since two slots passed. So hardware uses the initial WW_DSM_FACTOR for the next slot, slot3. and

START_TIME3 = R2 + Tinterval

So, if slot3 received a packet, the situation is like slot0, hardware get the drift_real for the next slot again.

S3 = START_TIME3 - Tsleep3 * drift_set3 / 1000000, where drift_set3 = WW_DSM_FACTOR * 16 (ppm)

R3 = START_TIME3 - Tsleep3 * drift_real3 / 1000000

drift_real3 = drift_set3 - (delta_time3 / Tsleep3 * 1000000) (ppm)

4. Slot with Function TX/TR/NO_RF

For slots with function TX/TR/NO_RF, they are not effected by the window widening. That is to say, for TX/TR, the TX_EN is asserted at the START_TIME_T:

START_TIME_T(n) = START_TIME_T(n-1) + Tinterval

START_TIME_T(0) = WOR_EVENT_START

For NO_RF, at the START_TIME_T, the WoR state machine jumps to next slot.

There is the case that TX/TR/NO_RF may be mixed with RX/RT function. In this case, the slot with TX/TR/NO_RF function is treated as "missed slot" since there is no packet received.

5. Handle of Missing Many Slots

In WoR operation, there may be some cases that many slots missed packets. The window will become larger and larger if missed so many packets and it is responsible for the WoR to wake up the MCU to check the fail condition and re-configure the radio block again.

WoR block provides a register **RX_SLOT_FAIL_THRESH**. When the number of missed slot is equal to this value plus 1, the WOR_RX_FAIL_IRQ is set. And when WOR_RX_FAIL_IRQ_ EN is set, the related interrupt will be sent to the MCU.

6. Software Do the Drift Calculation

Because the hardware uses Tinterval to approximate Tsleep, there is error. The WoR hardware provides a software interface that uses the MCU to calculate drift_real. When register **TIME_REC** is set with AUTO_CAL, some timing information is recorded to the Packet RAM. There can be at most 8 slots timing information can be recorded. WOR uses 160 bytes of Packet RAM for the timing information.

The timing information for one slot is as shown in below table.

Basically the drift_real can be calculated with:

drift_real_factor = drift_set_factor - (aa_match_time_delta_signed / Tsleep * 1000000 / 16) (LSB)

Where

Tsleep = rfmc_sleep_duration * 1000 / 32.768 (us)

Note, the calculation is only make sense when received a packet in a slot with the previous slot also received, or received a packet in the first slot.

This calculated drift factor can be programmed into register **SW_DRIFT_SET**, which is a two's complement value and each LSB is worth 16ppm.

Table 445. Timing Information for One Slot

Timing information word #	Timing information
Timing information word 0	{16'h0, packet_received, NO_DSM, 3'h0, wor_function[2:0], wor_slot_count[7:0]}
Timing information word 1	{{8{1'b0}}, rfmc_sleep_duration[23:0]}
Timing information word 2	TX_EN or RX_EN assert time
Timing information word 3	Packet arrived time, TimeStamp
Timing information word 4	{{11{1'b0}}, aa_match_time_delta_signed[20:0]} (aa_match_time_delta_signed is the delta time between Sx and Rx, two's complement value)

7. Calculation Error

There are many cases which will cause the calculation error. All these error can be covered by properly setting the register **TIME_MGN.**

7.1 Using Tinterval as Tsleep

Since the hardware are using Tinterval as Tsleep during the drift calculation, this will cause error.

7.2 Using 16ppm granularity

Since the hardware finally calculates the drift in 16ppm granularity, due to the round function, there may be 0.5 LSB(8 ppm) error

7.3 Drift change during slots

Due to the voltage or temperature change, the drift may change during slots.

7.4 The Event Timer Jitter after sleep

The event timer has a random ±1 us error after sleep. This error is caused and cannot be avoided by the fact that the 1MHz clock and the 32KHz clock are async. As shown in below waveform.

This will cause the delta_time ±1 us error, so will cause the calculation has error as:

When the Tinterval is 1ms, this 1us error will cause the calculated drift ±1000ppm error;

When the Tinterval is 10ms, ±100ppm error

When the Tinterval is 100ms, ±10ppm error

When the Tinterval is 1s, ±1ppm error

So the register TIME_MGN should be set to also consider this ±1 us error.

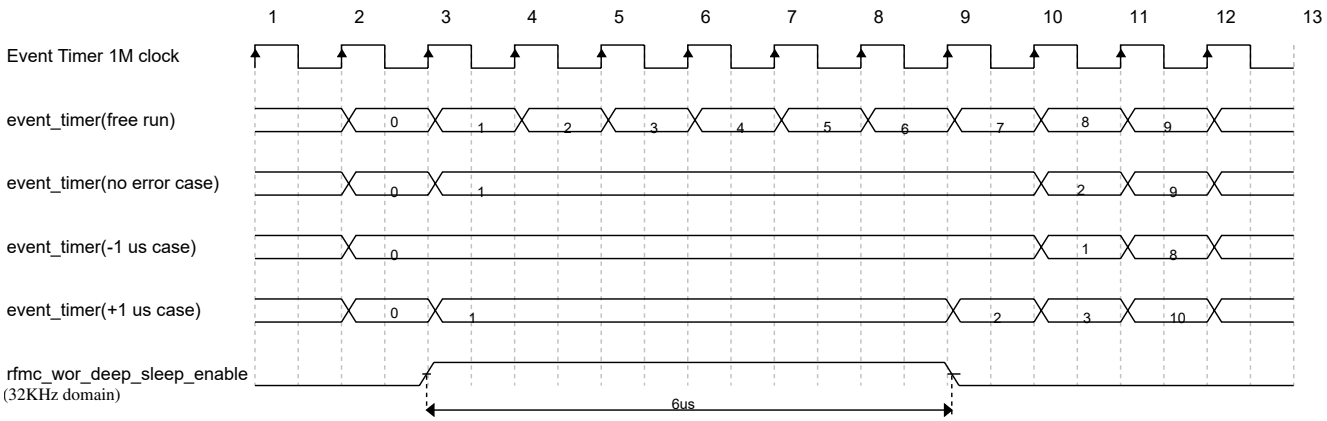

Figure 249. Event Timer Jitter

52.4.4.1.1.2.7 Timestamps

In Wake-On-Radio, every slot with FUNCTION=RX can capture a timeslot associated with any packet that is received in the slot. Any receive slot which results in an Access Address or an SFD detection will capture a timestamp into a register. Timestamps assist Link Layer software in maintaining and fine-tuning the network timebase across 2 or more networked devices.

Timestamp Capture

In Wake-On-Radio, each descriptor is associated with a slot. Any slot can be assigned an RX operation. RX operations require a timestamp to be captured. So, the timestamp can be thought of as being associated with the descriptor. The bit width of the timestamp is the same as the bit-width of the assigned Link Layer; i.e., 32 bits for GENERIC_FSK, and 28 bits for 802.15.4. Association of timestamps to descriptors is illustrated in the following diagram.

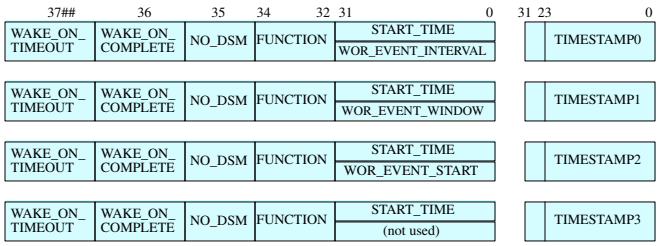

Figure 250. TIMESTAMP CAPTURE

Capture occurs at the instant AA or SFD is detected, and results in the current state of the assigned Link Layer's Event Timer being transferred to a TIMESTAMP register. WOR hardware does not apply any offset to the captured timestamp. A timestamp is captured for the last *N* RX operations, which result in (at least) one AA or SFD detection, where *N* = SLOTS_USED (typically 4).

Timestamp capture is area-intensive, due to:

- wide bit-width
- multiplicity (per descriptor)

Each of the supported protocol engines already has a TIMESTAMP register of the required bit-width. It is used for non-WOR (legacy) operations. To save area, when WOR is engaged, the TIMESTAMP register indigenous to the Link Layer, is used to capture the timestamp for WOR SLOT 0. Thus, in WOR mode (WOR_EN=1), the assigned Link Layer's TIMESTAMP register will only capture a timestamp when WOR SLOT=0, and will not change otherwise. If WOR is not engaged, the Link Layer TIMESTAMP register will capture all timestamps, the legacy behaviour. When WOR_EN, timestamps associated with SLOTS 1, 2, and 3 are captured in the TIMESTAMP1, TIMESTAMP2, and TIMESTAMP3 registers, respectively, which are new, and resident in the WOR scheduler. This distribution of timestamp register resources is illustrated in the following diagram.

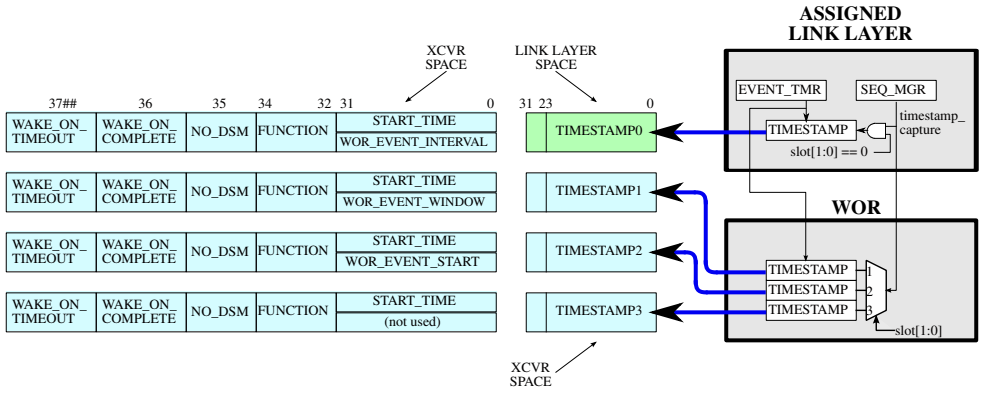

Figure 251. TIMESTAMP REGISTER DISTRIBUTION

Software should be aware of the fact that the designating the SLOT 0 timestamp to reside in the assigned Link Layer's TIMESTAMP register means that the TIMESTAMP registers in Wake-On-Radio, are not all in one address space: TIMESTAMP0 resides in the assigned Link Layer's address space, while TIMESTAMP1-3 register reside in XVCR address space, alongside all the other WOR registers.

TIMESTAMP STATUS

A timestamp will be captured into a TIMESTAMPx register on any slot assigned to FUNCTION RX, whenever an Access Address or SFD is detected during the receive window. Whenever a timestamp is captured as described above, a 3-bit read-only status register is updated with information regarding status of the reception which occurred during the slot. The timestamp status, TIMESTAMPx_STS[2:0], becomes valid, and final (for the current slot), at the end of the receive window, and is made available to MCU when it is next awakened, along with the TIMESTAMP itself. The status information can be used by software to ascertain the validity of the timestamp. The following diagram describes timestamp status.

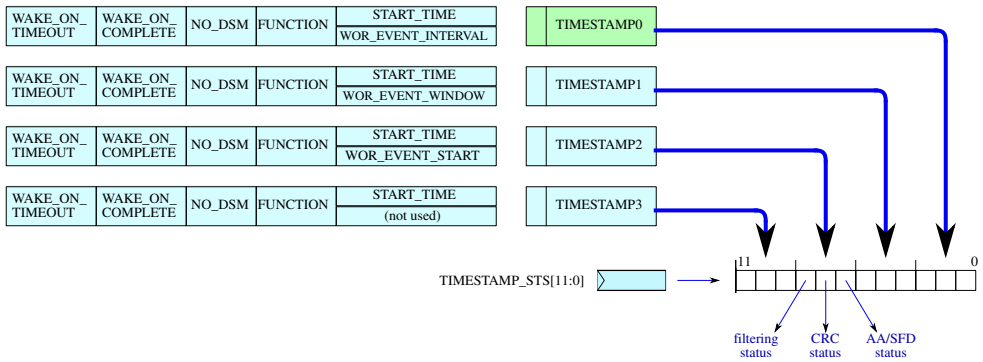

Figure 252. TIMESTAMP STATUS

A breakdown of the 3-bit status field, per timestamp, follows in the table below.

- 0: AA/SFD status
- 1: CRC status
- 2: Packet Filtering status

For any WOR slot assigned to RX, the 3-bit timestamp status field for that slot is cleared to 000 at the instant that WOR state WAIT_SEQ_START is reached. This is prior to the launch of the receive operation. (The bits are not cleared if the slot's function is not RX.) Once reception begins, the individual timestamp status bits are updated in realtime as the circumstances of the reception warrant. The 3-bit timestamp status is considered valid at the end of the receive window, and the bits reflect reception status per the following table.

TIMESTAMPx_STS bit	Meaning if 0	Meaning if 1
[0] AA/SFD status	No AA or SFD was detected during the receive window.	At least one AA or SFD was detected. RX recycles can lead to multiple occurrences.
[1] CRC status	For the packet associated with last (most recently) detected AA or SFD, CRC verification failed.	For the packet associated with last (most recently) detected AA or SFD, CRC verification passed.
[2] Packet Filter status	For the packet associated with last (most recently) detected AA or SFD, at least 1 packet filtering rule was violated.	For the packet associated with last (most recently) detected AA or SFD, all packet filtering rules passed.

Packet filtering rules, and hence the meaning of the TIMESTAMPx_STS[2] bit, vary across protocols, as summarized in the following table.

PROTOCOL	MEANING OF TIMESTAMP_STSx[2] (PACKET FILTER)
802.15.4	Reflects the Packet Processor FILTERFAIL flag
GENERIC_FSK	There are 3 packet filter criteria: 1. H0 matching 2. H1 matching 3. LENGTH_MAX compliance (maximum packet length verification)

Timestamp status bits are sticky. Once they become valid at the end of the receive window (end of WAIT_SEQ_END state), they remain valid until the *next* time the same slot number comes up again, and WOR reaches WAIT_SEQ_START state on that slot number.

In general, the MCU does not need to be notified on "bad packets." However, timestamp status may still be of value to WOR software even without Data Indication on any given slot. Notification policy can be modified at the protocol level, to enable RXIRQ on bad packets, mainly for debug purposes. If notification policy is modified by configuring the assigned Link Layer accordingly, this will affect Wake-On-Radio was well, as an rx_irq_trig will be generated on otherwise "bad" packets. See Section State Machine, specifically the WAIT_SEQ_END state, for details on how WOR responds to rx_irq_trig during this state, to determine how modifying notification rules would affect WOR response.

WOR software can use timestamp status to gauge the validity of the timestamp in any given slot. The following tables provides some guidelines.

TIMESTAMPx_STS	TIMESTAMPx REGISTER VALIDITY	MEANING
0b000	stale	No AA or SFD was received during this timeslot. The TIMESTAMPx register was not updated by HW and continues to hold the timestamp captured after the last AA or SFD detection on this slot number.
0bX01	invalid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification failed. TIMESTAMP register holds the EVENT_TMR captured for

Table continues on the next page...

Table continued from the previous page...

TIMESTAMPx_STS	TIMESTAMPx REGISTER VALIDITY	MEANING
		this reception. Because CRC failed, the TIMESTAMP should be deemed invalid, but this decision is left to the application.
0b011	valid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and can be deemed valid. However Packet Filtering failed, so typically there would be no Data Indication.
0b111	valid	At least 1 AA or SFD was detected during this timeslot. For the last (most recent) AA or SFD detected, CRC verification passed. TIMESTAMP register holds the EVENT_TMR captured for this reception, and is valid. Packet Filtering passed.

52.4.4.1.1.2.8 Interrupts

WOR hardware utilizes the assigned Link Layer's interrupts for all MCU wakeups and notifications. In Wake-On-Radio, the MCU is in a low-power state most of the time. So, interrupts are allowed to assert only when it is mandatory to wake the MCU out of its low power state, to tend to required Link Layer or WOR tasks. WOR hardware modifies the interrupt activity of the assigned Link Layer by dynamically blocking and/or allowing Link Layer interrupts to propagate to the MCU, under control of the current slot descriptor specifications. Each of the 3 supported protocol engines have been modified to allow WOR to manage its RF-related interrupts. The RF-related interrupts have nearly identical functions and meanings across the 3 protocols:

- TXIRQ (or TX_IRQ)
- RXIRQ (or RX_IRQ)
- SEQ_END_IRQ (or SEQIRQ)

The modifications to the protocol engines, involve an AND gate inserted between each interrupt trigger, and the interrupt status bit, allowing or blocking the trigger from asserting the status bit. A gating signal, wor_allow_irq, is provided by WOR to each protocol engine to enable/disable the AND gate. The gating signal is updated dynamically by the WOR state machine based on state, RF operation status, and the current descriptor's WAKE_ON_* fields. See Section State Machine, specifically the description of the WAKE_SEQ_END state, for more details on how and when WOR allows and blocks RF-related interrupts. For protocols not assigned to WOR, interrupts are always allowed.

The raw interrupt triggers themselves (the inputs to the AND gates), namely, tx_irq_trig and rx_irq_trig, are passed directly to WOR hardware, so that WOR state machine can react to RF operation status in realtime, and sequence through the states as specified by the current slot's descriptor.

WOR manages one other Link Layer interrupt, for non-RF-related notifications. Each protocol engine has an existing interrupt, WAKE_IRQ, to notify MCU on wakeup from Manual DSM mode (not Wake-On-Radio). See Section Manual DSM for more details on this DSM control scheme. For any protocol, Wake-On-Radio and Manual DSM are mutually-exclusive control schemes, so when a protocol is assigned to WOR, its WAKE_IRQ is re-purposed, and re-named, to WOR_IRQ.

Like the "allow/block" gating WOR uses to manage the RF-related interrupts, WOR uses 2 signals to either block or *force* a WAKE_IRQ / WOR_IRQ:

- **wor_block_wake_irq:** prevents the (legacy) WAKE_IRQ from asserting at DSM exit, this is *mandatory* for Manual DSM, but is *conditional* for WOR.
- **wor_force_wake_irq:** WOR needs to assert WOR_IRQ under 3 conditions (see below)

There are 3 conditions for which WOR needs to compel the Link Layer to assert WOR_IRQ. WOR maintains 3 read-only status flags to indicate each of these conditions. The status flags exist in XCVR (WOR) address space, even though the WOR_IRQ resides in the protocol-specific address space. The 3 conditions, and the associated status flag for each, are described in the following table.

- **WOR_NO_RF_FLAG:** START_TIME has been reached on a slot with FUNCTION = NO_RF and WAKE_ON_COMPLETE=1
- **WOR_MAX_SLOT_FLAG:** In Constant-Interval scheduling mode, the WOR_SLOT_COUNT[7:0] has reached WAKE_ON_NTH_SLOT[7:0]
- **WOR_DSM_EXIT_FLAG:** An unscheduled, asynchronous DSM "Early Exit" has occurred

To service an WOR_IRQ, the interrupt service routine should query the 3 read-only status flags to determine the cause of the MCU wake up. At least one of these flags will be set. It is possible that more than 1 of the flags is set. For the WOR_NO_RF_FLAG, WAKE_ON_COMPLETE would typically not be set on a NO_RF slot, since the purpose of NO_RF is to allow "DSM cascading"; only for debug purpose has this flag been provided. Servicing of the other 2 flags is beyond the scope of this document.

Clear the WOR_IRQ by writing a 1 to this bit in the protocol-specific address space. However the 3 WOR flags are "sticky". Any flag which is set will remain set until a new WOR session has begun, which means taking WOR to DISABLED by setting SLOTS_USED=0, followed by re-enabling by setting SLOTS_USED>0.

In initializing the assigned Link Layer for WOR operation, it is *essential* that software enable (unmask) the 3 RF-related interrupts, as well as WAKE_IRQ / WOR_IRQ. It is equally essential that all non-WOR related interrupt sources are *disabled* when a protocol is assigned to WOR, to prevent unnecessary MCU wakeups. The following tables describe all the Link Layer interrupts, their controllability (or lack of) by WOR, and the required enabling/unmasking by software.

INTERRUPT CONFIGURATION (802.15.4)

INTERRUPT	WOR CONTROL	SW INIT	COMMENTS
TXIRQ	gated by wor_irq_allow	ENABLE	Asserted after packet transmission when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT
RXIRQ	gated by wor_irq_allow	ENABLE	Asserted after good packet reception when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT
SEQIRQ	gated by wor_irq_allow	ENABLE	1. Asserted after any good packet transmission or reception when: WAKE_ON_COMPLETE || WAKE_ON_TIMEOUT 2. Asserted after bad (or no) packet reception when: WAKE_ON_TIMEOUT
CCAIRQ	unaffected	DISABLE	Not used in WOR

Table continues on the next page...

RX_WATERMARK_IRQ	unaffected	DISABLE	Not used in WOR

52.4.4.1.1.2.9 Channel Hop Table

Typically, in either Timeslot or Constant-Interval scheduling mode, RF operations on consecutive slots use different RF channels. Using Wake-On-Radio to program slot specifications for the next few RF operations in advance, would be of little value if the MCU had to wake up on every slot to program the assigned Link Layer's CHANNEL_NUM register. Thus, Wake-On-Radio provides hardware automation for channel hopping on a slot-by-slot basis.

A table of channel hop frequencies is maintained by hardware. The number of entries in the table (hop sequence length) is programmable. Prior to starting a WOR session, software will program the desired sequence of channel numbers into the table. After WOR is activated by setting SLOTS_USED>0, The WOR state machine controls the index (read pointer) into the table. The index is typically incremented at the end of every slot, when the slot counter is incremented. The increment is +1 modulo "hop sequence length". The RF operation on the current slot, is then carried out on the RF channel pointed to by the hop table index. If necessary, WOR or Link Layer software can update the hop table index at any time.

Rather than adding a channel number field to the descriptor, to save area, the hop table is decoupled from the descriptor table. The hop tables utilizes a small section of Packet RAM which is not otherwise used by the supported WOR protocols. WOR uses 128 bytes of Packet RAM for the channel hop table.

The channel information entered into the hop table, can use the (legacy) 7-bit "mapped channel" format, which allows channels to be specified on a 1MHz boundary; or one of 2 new 16-bit formats that allows channel frequency of higher resolution. The option for the legacy format, provides backwards compatibility to existing software, which does not use WOR, to program RF channel information the way it does today, without any changes. The inclusion of the new formats allows additional flexibility for programming channels which deviate from a 1MHz boundary, coupled with the automation built in to WOR. The format selected, determines:

1. how the hop table is organized in RAM
2. how software programs the hop table
3. how the WOR parses the table during execution of the current slot
4. and how the PLL digital block interprets the frequency word extracted from the table.

Selecting the hop table configuration is by way of the HOP_TBL_CFG[2:0] register. Based on this setting, the source of channel information, can either be the CHANNEL_NUM[6:0] bit register that exists in each protocol engine today (legacy), or the new hop table, according to the following table:

Source of RF channel information, based on HOP_TBL_CFG[2:0]:

0: Assigned Link Layer's CHANNEL_NUM register (legacy)

1: WOR Hop Table

2: WOR Hop Table

3: WOR Hop Table

4-7: Reserved

To allow for the legacy option, the 3 protocol-specific CHANNEL_NUM registers are now routed to WOR, which multiplexes them with the hop table output based on HOP_TBL_CFG and WOR_PROTOCOL settings. WOR then outputs 3 16 bit frequencies words, one per protocol, to PLL Digital, conveying the required channel information.

Hop table organization is determined by HOP_TBL_CFG, as per the following table:

Hop Table Organization, based on HOP_TBL_CFG[2:0]:

0: N/A

1: Table size is 128 entries. Two 7-bit CHANNEL_NUM fields are packed into a 16-bit hop frequency word for RAM storage

2: Table size is 128 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel

3: Table size is 128 entries. Each 16-bit hop frequency word in RAM contains a specification for a single RF channel

4-7: Reserved

The content of the hop frequency word provided to PLL Digital, and how it is interpreted by that block, also varies with HOP_TBL_CFG, as per the following table:

PLL Digital Interpretation of Hop Frequency Word, based on HOP_TBL_CFG[2:0]:

0: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0

1: Lower 7 bits of hop frequency word contain a mapped channel (legacy format). Upper 9 bits are 0

2: All 16 bits are valid. See Chapter *PLL Digital* for interpretation

3: All 16 bits are valid. See Chapter *PLL Digital* for interpretation

4-7: Reserved

The following diagram summarizes the routing of channel hop signalling amongst the supported protocol engines, the WOR scheduler, the PLL Digital, and Packet RAM. It also shows the 2 hop table configurations, and hop frequency word generation, based on HOP_TBL_CFG. The existing (legacy) configuration is on the left, and the new, WOR-based configuration is on the right.

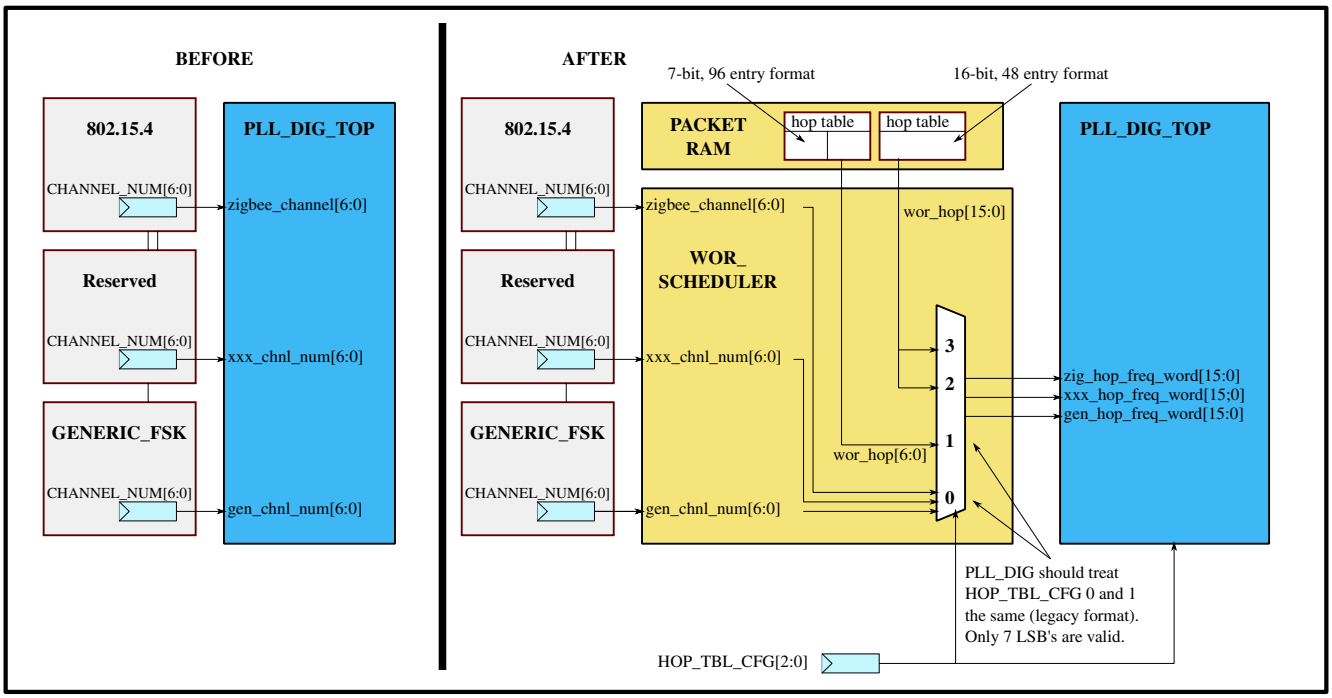

Figure 253. CHANNEL HOP SIGNAL ROUTING AND CONFIGURATION

The number of entries in the table is determined by programmable register HOP_SEQ_LENGTH[7:0]. If HOP_TBL_CFG=1, HOP_SEQ_LENGTH determines the number of 7-bit CHANNEL_NUM entries in the Packet RAM table, which are packed 2 per RAM word. HOP_SEQ_LENGTH must not exceed 128 in this case. If HOP_TBL_CFG=2 or HOP_TBL_CFG=3, HOP_SEQ_LENGTH determines the number of 16-bit format entries in the Packet RAM table, one per RAM word. HOP_SEQ_LENGTH must not exceed 128 in this case.

At the start of new WOR "session" (setting SLOTS_USED to a non-zero value), WOR hardware initializes the table index (read pointer) to 0. (Software can modify this index, see below.) After slot execution completes, as the WOR state machine increments the slot counter to service the next slot, the hop table index is incremented by +1 (modulo HOP_SEQ_LENGTH). An exception is made to this rule, if the FUNCTION field of the slot descriptor is set to NO_RF, the hop index is *not* incremented when the slot counter is incremented to advance to the next slot. The NO_RF function is used for "DSM cascading".

Software can take control of the hop table index at any time, by writing a new desired index to the NEW_HOP_IDX[6:0], and with the UPDATE_HOP_IDX register set to 1. These 2 steps can be performed as a single, atomic IPS bus write. WOR hardware will update the index accordingly. From this point forward, the hop-table hardware incrementing rules, discussed in the previous paragraph, apply. This way, software can execute a one-time "jump" in the hop table indexing.

The read-only register WOR_HOP_IDX[6:0] allows software to read the instantaneous, hardware-controlled hop table index at any time. Similarly, the read-only register WOR_HOP_FREQ_WORD[15:0] allows software to read the instantaneous, hardware-generated frequency word sent to PLL digital. This word is the output of the hop table configuration selection mux shown in the diagram above, the protocol-specific word currently selected by WOR_PROTOCOL.

A diagram showing the RAM-based, 128-entry hop table (HOP_TBG_CFG=1), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

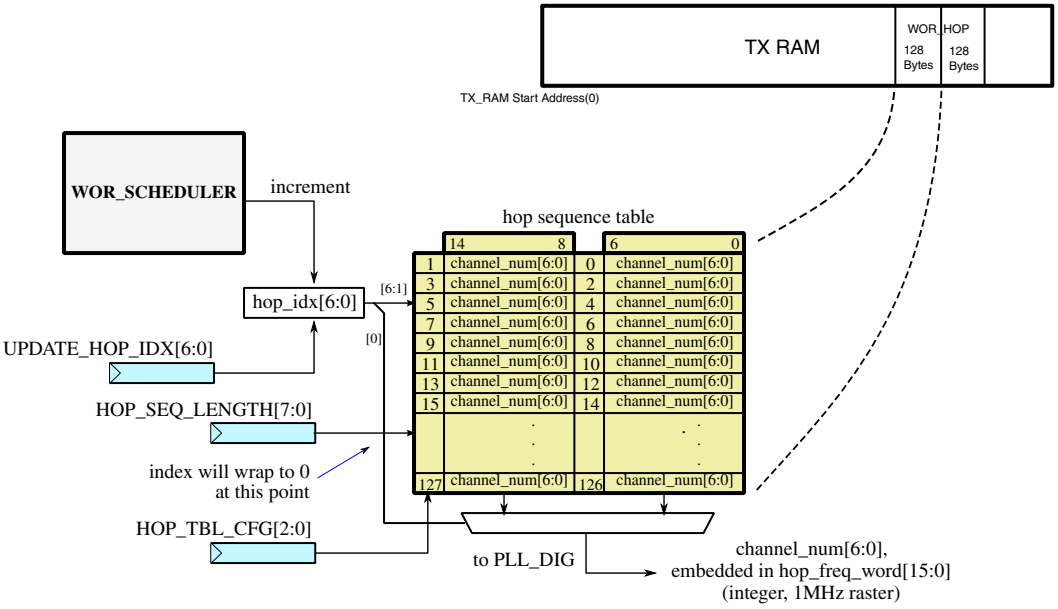

Figure 254. 128-ENTRY HOP TABLE

A diagram showing the RAM-based, 128-entry hop table (HOP_TBG_CFG=2 or 3), where it is situated in Packet RAM space, how the channel information is organized in the table, and how WOR hardware indexes the table, is shown below.

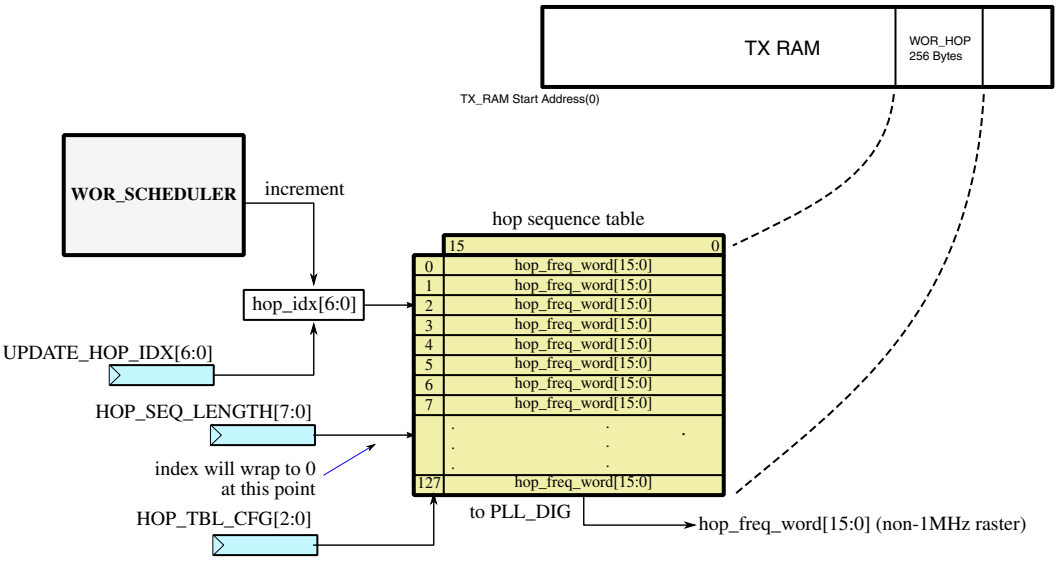

Figure 255. 128-ENTRY HOP TABLE

The 256 bytes of Packet RAM are reserved for the WOR hop table. The table is fixed in this position, and does not move based on HOP_TBL_CFG.

The WOR hop table should not be accessed (no writes or reads) while an RF operation is underway. There is no hardware to de-conflict RAM accesses with those originating in the protocol engines. Aside from this restriction, the hop table can be accessed at any time. A convenient time to modify the hop table, if required, would be during the WOR WAIT_RESUME state.

Follow the instructions below to program the WOR hop table.

1. Program the hop table

2. Program HOP_CTRL[HOP_SEQ_LENGTH] with the desired size of the hop sequence
3. Program HOP_CTRL[HOP_TBL_CFG] to select the desired table configuration and enable hopping during WOR

52.4.4.1.1.2.10 DSM Early Exit

As described in Section State Machine, for every slot, WOR hardware computes the duration of the upcoming DSM cycle based on descriptor START_TIME, current time, and window-widening, during the COMP_DURATION1 and COMP_DURATION2 states. WOR outputs the desired duration on wor_dsm_duration[23:0]. The Radio Mode Controller (RFMC) then executes this DSM for the prescribed number of 32.768KHz clock cycles, and when complete, sends the actual duration back to WOR using rfmc_sleep_duration[23:0]. Normally, these 2 durations will match precisely.

Conditions exist where the DSM cycle may occasionally need to be cut short, due to circumstances beyond the control of the radio. The SoC, starting with the MCU, must be awakened out of its low power state before the WOR DSM duration expires. When this happens, software handling the event which triggered the wakeup, will determine if the radio needs to be awakened as well. If this is the case, software will set the RFMC_WOR_WKUP bit. This will trigger an unscheduled wakeup process out of DSM by the RFMC deep sleep state machine. The wakeup will complete before the wor_dsm_duration[23:0] time has expired. RFMC will capture the *actual* DSM duration, cut short by the early exit, into rfmc_sleep_duration[23:0]

After DSM wakeup, WOR hardware always performs this check during the COMP_WW state:

rfmc_sleep_duration[23:0] == wor_dsm_duration[23:0]

If this check fails, WOR hardware declares an "DSM Early Exit", and takes the following steps:

1. Forces the assigned Link Layer to assert its WAKE_IRQ / WOR_IRQ (see Section Interrupts)
2. Sets the WOR_DSM_EXIT_FLAG in WOR space
3. Transitions to the WAIT_RESUME state and waits for software to service the WOR_IRQ.

Software should then take whatever steps are necessary to configure the radio to respond to the conditions which triggered the early exit. Servicing of a DSM early exit interrupt is beyond the scope of this document.

52.4.4.1.1.2.11 Manual DSM

Prior to Wake-On-Radio, implementation of the 2.4GHz used a software-driven, "manual" DSM. This DSM control scheme does not have any of the hardware automation associated with WOR, and software must perform such tasks as computing the Event Timer addback time, window-widening, etc.

Manual DSM still exists as an alternative to Wake-On-Radio. Manual mode can be of value in a multiprotocol setting. See Section Multiprotocol for more details.

Any of the 3 protocols supported by Wake-On-Radio, can utilize Manual DSM as an alternative to Wake-On-Radio. In short, Manual DSM works by programming a desired DSM start time into the ENTER_TIME register, and a desired DSM wake time into the WKUP_TIME register. The ENTER_TIME and WKUP_TIME registers are referenced to the 32.768KHZ TIMER, the radio's low-power (DGO) timer. ENTER_TIME, WKUP_TIME, and TIMER reside in RFMC address space.

When a match on TIMER to ENTER_TIME occurs, RFMC places the radio in deep sleep mode. The RF Oscillator is shut off, and the Link Layer's Event Timer is frozen in place. When a match on TIMER to WKUP_TIME occurs, the Event Timer resumes from where it left off. The RF Oscillator, is re-started as part of the DSM wake up process, and is running before WKUP_TIME is reached. At the instant the Event Timer resumes, the Link Layer asserts its WAKE_IRQ. The MCU should use the WAKE_IRQ ISR to compute the precise amount of time the radio was in DSM, convert this value to microseconds, and add this value to the current Link Layer Event Timer, to restore the timer to where it would have been, had DSM not occurred. There is a 1us loss-of-precision in the Event Timer timebase incurred on every DSM wakeup. This timebase error is random, and averages out over many DSM cycles.

Regarding the DSM wakeup process, there is additional programmability to configure the lead time for power-domain wakeup and oscillator re-start, relative to DSM exit (WKUP_TIME). This configurability is covered by the RFMC register. See the *Radio Mode Controller* chapter for more details.

52.4.4.1.1.2.12 Multiprotocol

The 2.4GHz radio supports 4 protocols, any 2 of which can be enabled for multiprotocol use on an alternating, time-shared basis. Both of the active protocols may require DSM. The following section describes the rules to be applied when assigning a protocol to a DSM control scheme.

The radio has 3 DSM control schemes:

1. Bluetooth LE-internal
2. Wake-On-Radio
3. Manual DSM

The Bluetooth LE-internal DSM controller applies to the Bluetooth LE protocol engine only, and is the only DSM option for Bluetooth LE.

Wake-On-Radio can be assigned to any one of the following protocols (see Section *Assign To Protocol*):

1. 802.15.4
2. GENERIC_FSK

Manual DSM can be assigned to any one of the following protocols (see Section *Manual DSM*):

1. 802.15.4
2. GENERIC_FSK

52.4.4.1.1.2.13 Hardware Multiplier

Wake-On-Radio requires 6 multiplies while executing each slot. The multiplications take place in the following WOR states (See Section State Machine):

1. COMP_DURATION1: to compute the upcoming DSM duration, excluding window widening
2. COMP_DURATION2 and COMP_DURATION3: to compute the subtractor to the upcoming DSM duration, for window widening
3. COMP_ADDBACK: to compute the Event Timer addback value based on RFMC-provided DSM duration
4. COMP_WW: to compute the DSM-component of window-widening incurred during the just-completed DSM cycle
5. DRIFT_CAL: to compute the clock drift

For maximum area and power saving, there is 1 hardware multiplier instance, which is timeshared for the 6 multiplies. Also, because the state machine has been architected to allow sufficient time to perform these computations before the results are needed, the multiplier uses a serial, add-and-accumulate construction. The multiplicands are 30 bits and 20 bits. The 30 bit operand is appropriately sized for the DSM_DURATION_NO_WW[23:0] * WW_DSM_FACTOR[5:0]. The 20 bit operand is appropriately sized to achieve the precision of the required calculations, as described in the earlier sections.

For each calculation, the multiplier requires 20 clocks (20 shifts). Each multiply takes place within the confines of a single state of duration 1µs. There are 32 periods of the reference oscillator during that period (26 for a 26MHz crystal), more than enough to complete the multiply. The clock to the multiplier runs at the reference oscillator rate, but runs only during the 6 1µs states listed above, to maximize power savings.

Depending on the calculation, the required precision, the positioning of the integer bits within the product, etc., the bits of the product tapped for each calculation varies. Also, depending on the calculation, combinational rounding or truncation of the product occurs, external to the multiplier.

52.4.4.1.1.2.14 Clocking

Because of the intensive interaction between Wake-On-Radio and 3 protocol engines it supports, the WOR hardware runs at 1MHz. This facilitates signalling between the WOR and the assigned Link Layers, with no additional pulse-stretching or signal-conditioning required. Like the protocol engines and the TSM, the CGM's cg1m_en gating signal is used to generate the common 1MHz, so the phasing of the clocks across all the communicating modules remains in sync.

All WOR clocks are conditioned on WOR_EN=1. This bit should be set, and remain set, whenever Wake-On-Radio is in use (it should not be toggled or modified dynamically by software, since module clock-gating is based on it). This bit should not be set if WOR is not in use; that way, the WOR hardware block will consume zero dynamic power.

In total, there are 4 clocks used by WOR hardware:

1. **ipg_clk_wor_1m**: Most of the WOR hardware runs off this 1MHz clock, including the state machine, descriptor processing, and hop table indexing. All link layer interface outputs are generated with this clock, and link layer inputs sampled by it.
2. **ipg_clk_wor_ww_1m**: Identical in timing to ipg_clk_wor_1m, but used only by functions that require window widening to be enabled. The additional clock gating granularity saves power when widening is disabled.
3. **ipg_clk_wor_comp**: This is the "compute clock" used by the serial multiplier. This clock runs at the reference oscillator frequency (derivative of xcvr_ref_clk_gated), but only during the 4 1µs-long states (per slot) during which the multiplier is in use; See Section Hardware Multiplier)
4. **ipg_clk_wor_timestamp**: This is the "timestamp clock". Because the protocol engines determine the timestamp-capture timing, based on AA/SFD detection, the clock-gate enable for the capture is sent to the CGM, which routes the resulting timestamp clock itself to WOR so that it can update its TIMESTAMP1,2, and 3 registers. This clock will typically pulse once per RX slot, and not at all for slots of other types.

All gating for the WOR clocks is performed in CGM. WOR provides the gating-enable signal, and CGM provides the clock.

All WOR clocks are in the Reference Oscillator domain. There are no clock domain crossings inside the module.

No WOR critical timing paths are anticipated, nor any timing exceptions (e.g., multicycle paths).

52.4.4.1.1.2.15 Reset

The WOR has a main asynchronous reset input (ipg_hard_async_reset_b) that clears all the logic.

In addition, some internal accumulators for window-widening can be reset by two other conditions:

- Software writes 1 to the WW_CTRL [WW_NULL] bit.
- Good Packet Reception. For more details on this condition, please check Window Widening section.

52.4.4.1.1.3 External signals

Some of the WOR I/O signals are shown in the table below.

Signal	I/O	Description
ipg_hard_async_reset_b	input	Async reset - active low
ipg_clk_wor	input	Reference CLK
scan_mode	input	Scan mode
ipg_clk_wor_1m	input	1Mhz CLK
ipg_clk_wor_comp	input	Module IP clock, for computation
ipg_clk_wor_timestamp	input	Module IP clock, for timestamp
ipg_clk_wor_1m	input	Module IP clock, for WW
cg1m_en	input	1MHz CLK gating enable, restes accumulator
ips_clk	input	IPS clock
ips_module_en	input	IPS module enable

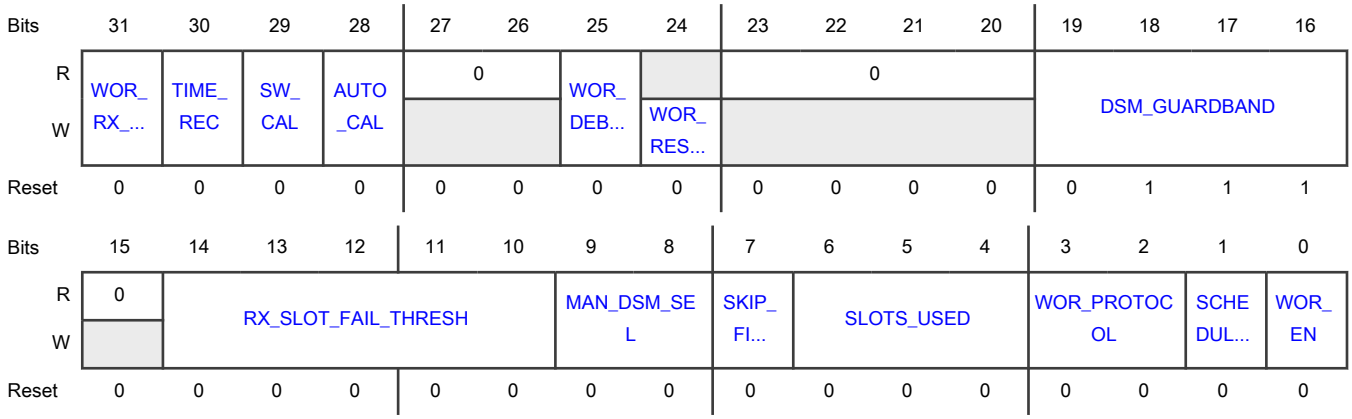
Diagram



Fields

Field	Function
31 WOR_RX_FAIL_IRQ_EN	WOR_RX_FAIL_IRQ Enable 1: WOR_RX_FAIL_IRQ interrupt is enabled 0: WOR_RX_FAIL_IRQ interrupt is not enabled
30 TIME_REC	Enable the WOR HW to record the timing information to the Packet RAM. 1: Record the timing information to the Packet RAM 0: Do not record the timing information to the Packet RAM.
29 SW_CAL	Enable the WOR SW to calculate the drift. Only when AUTO_CAL is set. Software can calculate the drift based on the timing information stored in the Packet RAM. When AUTO_CAL is enabled, this calculated drift can override the HW result. 1: Enable the software drift override. 0: Disable the software drift override.
28 AUTO_CAL	Auto calculate and track the drift enable Enable the WOR HW to auto calculate the drift. For Constant-Interval mode only. 1: Enable the drift auto calculation. 0: Disable the drift auto calculation.
27-26 —	Reserved
25 WOR_DEBUG_REG	WAKE-ON-RADIO Debug Register Enable WOR_DEBUG_REG alters the readback values of several read-only registers, for debug purposes. The registers which have a different readback value when WOR_DEBUG_REG=1 are:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• TIMESTAMP1 • TIMESTAMP2 • TIMESTAMP3 See the description of those registers, which indicates their nominal, and debug-mode readback values.
24 WOR_RESUME	WAKE-ON-RADIO Resume This bit causes the WOR state machine to advance from its WAIT_RESUME state. The state machine will enter WAIT_RESUME on any slot in which an MCU wakeup occurs (based on descriptor WAKE_ON_COMPLETE and/or WAKE_ON_TIMEOUT fields). After waking up (interrupting) the MCU, WOR will hold in WAIT_RESUME, giving software whatever time it needs to complete all required activity. Software then sets WOR_RESUME=1, causing the state machine to break out of WAIT_RESUME, advance to the next slot, and enter DSM. This bit is write-only. Writes of '0' have no effect. Readback value is always 0. Setting WOR_RESUME has no effect if WOR state machine is not in WAIT_RESUME. 1: Causes WOR state machine to advance out of WAIT_RESUME state, and begin the next slot 0: No effect.
23-20 —	Reserved
19-16 DSM_GUARDBAND	WAKE-ON-RADIO DSM Guardband Determines the number of 32.768KHz clock cycles of guardband used by the WOR state machine in computing duration of the DSM for any slot. Increasing this setting by 1 LSB causes WOR to shorten the DSM duration by 1 32.768KHz clock cycle. This guardband takes into account synchronization, and other, delays within the RFMC, and ensures that DSM will wakeup will never occur "too late" with respect to the slot descriptor's START_TIME field. The current default setting is 7. Values below 7 should not be used.
15 —	Reserved
14-10 RX_SLOT_FAIL_THRESH	RX Slot Fail Thresh When the number of missed slot is equal to (RX_SLOT_FAIL_THRESH + 1), the WOR_RX_FAIL_IRQ is set.
9-8 MAN_DSM_SEL	Manual DSM Selector Assigning Manual DSM to a protocol is done by way of the MAN_DSM_SEL[1:0] register, as shown in the following table: 0: Manual DSM Not Assigned 1: Manual DSM Assigned to 802.15.4 2: Manual DSM Assigned to GENERIC_FSK
7	WAKE-ON-RADIO Skip DSM On First Slot

Table continues on the next page...

Table continued from the previous page...

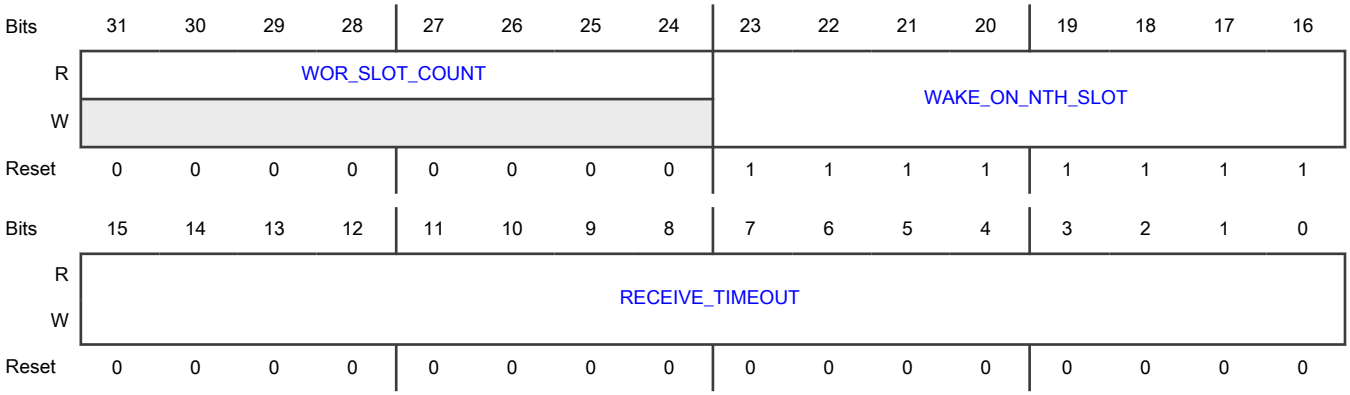
Field	Function
SKIP_FIRST_DSM	Setting this bit causes the WOR State Machine to skip the DSM entry/exit cycle for the first SLOT (SLOT 0) encountered after setting SLOTS_USED > 0, regardless of the setting of the NO_DSM field of the slot's descriptor. Subsequent slots, including SLOT 0 when it is re-encountered, will enter/exit DSM based on the descriptor NO_DSM. The SKIP_FIRST_DSM feature is useful, especially in Constant Interval Scheduling mode, when the desire is to begin RF operations immediately (at the start of the first EVENT_INTERVAL), as programmed in the descriptor START_TIME, without waiting out a DSM cycle 1: WOR skips DSM entry/exit on the first SLOT 0 after setting SLOTS_USED > 0, regardless of descriptor NO_DSM 0: WOR always obeys descriptor NO_DSM **Note:** SKIP_FIRST_DSM should not be used if the SLOT 0 descriptor FUNCTION is set to "NO_RF".
6-4 SLOTS_USED	WAKE-ON-RADIO Number Of Slots Used Determines the number of timeslots used to schedule future DSM and RF operations, for either scheduling mode. Up to 4 timeslots can be enabled. Increasing the number of timeslots used decreases average power consumption. Valid values are 0 ≤ SLOTS_USED ≤ 4. The SLOTS_USED register is the mechanism by which the WOR state machine is activated and de-activated. Setting SLOTS_USED to 0 disables the WOR state machine and puts the WOR functionality in an IDLE state. A subsequent write of a non-zero value to SL0TS_USED activates the state machine, initializing to SLOT 0, and starts a new WOR "session".
3-2 WOR_PROTOCOL	WAKE-ON-RADIO Protocol Selector Assigns the Wake-On-Radio function to one of the radio's protocol engines. 0: Not assigned 1: Assigned to 802.15.4 2: Assigned to GENERIC_FSK 3: Reserved
1 SCHEDULING_MODE	WAKE-ON-RADIO Scheduling Mode Determines the scheduling mode used by the WOR HW to organize future DSM and RF operations. 1: Constant-Interval Scheduling mode. 0: Timeslot Scheduling mode.
0 WOR_EN	WAKE-ON-RADIO Enable Wake-On-Radio Master Enable. In addition to enabling the block function, this bit gates the clock to the WOR module. This bit should be set, and remain set, whenever WOR is in use. 1: Wake-On-Radio is enabled. 0: Wake-On-Radio is disabled, and clocks to the module are gated off.

52.4.4.1.1.6.1.3 WAKE-ON-RADIO TIMEOUT (TIMEOUT)

Offset

Register	Offset
TIMEOUT	4h

Diagram



Fields

Field	Function
31-24 WOR_SLOT_COUNT	WAKE-ON-RADIO Absolute Slot Count This read-only register indicates the number of slots that have elapsed since SLOTS_USED was set to a non-zero value to activate the WOR state machine. WOR_SLOT_COUNT can be considered an Absolute Slot Number. WOR_SLOT_COUNT counts slots up to a maximum of 255. If the number of elapsed slots exceeds 255, WOR_SLOT_COUNT will remain at 255. WOR_SLOT_COUNT is "sticky" in the sense that it will hold its value after the WOR session has ended by setting SLOTS_USED=0; WOR_SLOT_COUNT will clear to 0 when a new WOR session is started by taking SLOTS_USED from 0 to any non-zero value.
23-16 WAKE_ON_NTH_SLOT	WAKE-ON-RADIO Force Wake On Nth Slot If the WAKE_ON_COMPLETE bit is not set in any descriptor, WOR will not awaken the MCU even after a number of good packets are received. Additionally, if WAKE_ON_TIMEOUT is also not set in any descriptor, WOR will not wake up the MCU under any circumstances, which would not be desirable. This register provides a backup method to awaken the MCU, after *N+1* slots have elapsed, where *N* = WAKE_ON_NTH_SLOT[7:0], regardless of whether or not any good packets have been received, and regardless of the setting of the WAKE_ON_* descriptor bits. Applies to Constant-Interval Mode only. (For Timeslot mode, at least one slot *must* have a WAKE_ON_* bit set in its descriptor).
15-0 RECEIVE_TIMEOUT	WAKE-ON-RADIO Receive Timeout For any RX slot, determines how long RX stays on after the descriptor's START_TIME is reached, in microseconds. A timeout is declared if a good packet is not received before the expiration of this time period (START_TIME + RECEIVE_TIMEOUT + WINDOW_WIDENING). Applies to TIMESLOT mode only.

52.4.4.1.1.6.1.4 WAKE-ON-RADIO TIMESTAMP 1 (TIMESTAMP1)

Offset

Register	Offset
TIMESTAMP1	8h

Function

Timestamp captured for a packet received on SLOT 1. During SLOT 1, any valid Access Address or SFD detection will result in the contents of the respective Link Layer's Event Timer being captured into this register at the instant of detection (there is no offset applied). TIMESTAMP1 remains "sticky" until a new AA or SFD detection occurs, during either the same, or a subsequent, SLOT 1.

Note: Timestamp for SLOT 0 is captured into the respective Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space.

Note: If WOR_DEBUG=1, this register instead reads back WOR_ADDBACK[27:0], which is the number of microseconds that the WOR state machine "added back" to the assigned Link Layer's Event Timer, to correct for the amount of time that Link Layer was in DSM (Event Timer frozen). The WOR_ADDBACK readback value applies to the most recently-completed DSM cycle.

Fields

Field	Function
31 WOR_RX_FAIL_IRQ	WOR RX Fail Interrupt Flag Will assert when the number of missed slot is equal to RX_SLOT_FAIL_THRESH.
30-24 —	Reserved
23-20 WOR_STATE	WAKE-ON-RADIO Current State This read-only register reflects the instantaneous state of the Wake-On-Radio state vector. A listing of the Wake-On-Radio states, along with the associated state vector, is below: • DISABLED (0) • COMP_DURATION1 (1) • COMP_DURATION2 (2) • COMP_DURATION3 (10) • SLEEP_REQ (3) • IN_DSM (4) • COMP_ADDBACK (5) • COMP_WW (6) • WAIT_SEQ_START (7) • WAIT_SEQ_END (8) • WAIT_RESUME (9)
19 —	Reserved
18 WOR_DSM_EXIT_FLAG	WAKE-ON-RADIO Early DSM Exit Flag This read-only flag indicates that, in the current slot, an event external to the radio has forced an early exit from DSM, before the WOR-computed DSM duration has expired. The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to an "DSM Early Exit wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "DSM Early Exit wakeup", software must set WOR_RESUME to advance to the next slot.
17 WOR_MAX_SLOT_FLAG	WAKE-ON-RADIO Maximum Slot Count Reached Flag This read-only flag indicates that, in the current slot, the following conditions have all been met: 1. SCHEDULING_MODE is set to 1 (Constant Interval) 2. WOR_SLOT_COUNT[7:0] (absolute slot number) has matched WAKE_ON_NTH_SLOT[7:0]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "Maximum Slot Reached wakeup", as described by the conditions above. The WOR_IRQ will become set, and the MCU awakened, even if the slot descriptor's WAKE_ON_COMPLETE and WAKE_ON_TIMEOUT bits are both set to 0. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "Maximum Slot Reached wakeup", software must set WOR_RESUME to advance to the next slot
16 WOR_NO_RF_FLAG	WAKE-ON-RADIO NO_RF Slot Flag This read-only flag indicates that, in the current slot, the following conditions have all been met: 1. The slot's descriptor FUNCTION is set to "NO_RF" 2. A DSM cycle has just completed (exited) during the slot 3. The slot's descriptor WAKE_ON_COMPLETE bit was set (or the WOR_SLOT_COUNT matched WAKE_ON_NTH_SLOT), requiring an MCU wakeup. The WOR_IRQ (WAKE_IRQ) interrupt inside the assigned Link Layer will become set under these conditions, and this flag indicates that the reason for WOR_IRQ was due to a "NO_RF wakeup", as described by the conditions above. The WOR state machine is holding in the WAIT_RESUME state, and once software has completed all activities pursuant to the "NO_RF wakeup", software must set WOR_RESUME to advance to the next slot
15-14 —	Reserved
13-12 SLOT	WAKE-ON-RADIO Current Slot This read-only register reflects the instantaneous state of the WOR's SLOT counter, indicating which SLOT is currently in service by the WOR state machine. Software can determine which of the 4 descriptors is currently in effect based on this register.
11-9 TIMESTAMP3_STS	WAKE-ON-RADIO Timestamp 3 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP3 register contents: **TIMESTAMP3_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occurred during the current, or most recent, SLOT 3 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP3 register. **TIMESTAMP3_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 3 RX operation **TIMESTAMP3_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 3 RX operation
8-6 TIMESTAMP2_STS	WAKE-ON-RADIO Timestamp 2 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP2 register contents:

Table continues on the next page...

Table continued from the previous page...

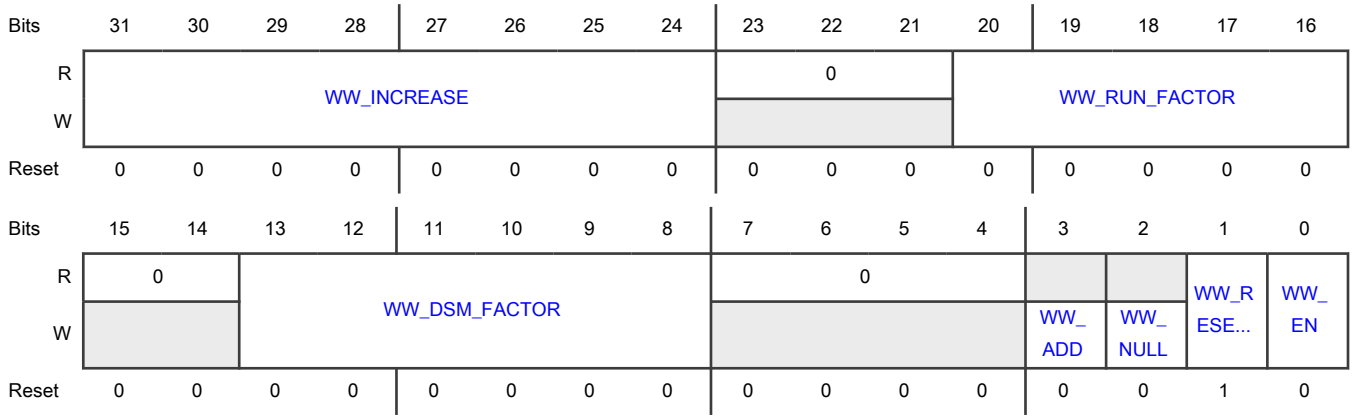
Field	Function
	TIMESTAMP2_STS[0] -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occurred during the current, or most recent, SLOT 2 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP2 register. **TIMESTAMP2_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 2 RX operation **TIMESTAMP2_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 2 RX operation
5-3 TIMESTAMP1_STS	WAKE-ON-RADIO Timestamp 1 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP1 register contents: **TIMESTAMP1_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occurred during the current, or most recent, SLOT 1 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP1 register. **TIMESTAMP1_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 1 RX operation **TIMESTAMP1_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 1 RX operation
2-0 TIMESTAMP0_STS	WAKE-ON-RADIO Timestamp 0 Status This read-only register comprises 3 bits which convey information about the validity of the TIMESTAMP0 register contents: **TIMESTAMP0_STS[0]** -- "AA/SFD Status". If set, this bit indicates at least 1 AA or SFD detection occurred during the current, or most recent, SLOT 0 RX operation, and therefore a timestamp, valid or not, was captured into the TIMESTAMP0 register. **TIMESTAMP0_STS[1]** -- "CRC Status". If set, this bit indicates a packet was received which passed CRC verification during the current, or most recent, SLOT 0 RX operation **TIMESTAMP0_STS[2]** -- "Filter Status". If set, this bit indicates a packet was received which passed Packet Filtering rules during the current, or most recent, SLOT 0 RX operation **Note:** TIMESTAMP0 register (timestamp for SLOT 0) is captured into the assigned Link Layer's TIMESTAMP register (external to WOR), and can be read from that Link Layer's address space. However TIMESTAMP0_STS[2:0], which applies to that register, resides in WOR address space.

52.4.4.1.1.6.1.8 WINDOW-WIDENING CONTROL (WW_CTRL)

Offset

Register	Offset
WW_CTRL	18h

Diagram



Fields

Field	Function
31-24 WW_INCREASE	Window-widening Manual Increase Amount This register allows software to increase (add to) the HW-computed window-widening adjustment. This incremental amount is added whenever a 1 is written to the WW_ADD register bit. The units of WW_INCREASE[7:0] are microseconds. It is an unsigned (positive only) addition. This is a one-time only addition (whenever WW_ADD is set), and the window-widening adjustment value continues to accumulate after the increment. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate.
23-21 —	Reserved
20-16 WW_RUN_FACTOR	Window-widening Runtime Factor Determines the rate of Window-widening that applies during RUNTIME (Reference Oscillator On). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 64ppm of SCA drift. Valid values are 0 -> 16. The lower this factor, the greater the power savings.
15-14 —	Reserved
13-8 WW_DSM_FACTOR	Window-widening DSM Factor WW_DSM_FACTOR[5:0]: Determines the rate of Window-widening that applies during DSM (Reference Oscillator Off). This setting should be based on the combined Sleep Clock Accuracy (SCA) of the Master + Slave. Each LSB is worth 16ppm of combined SCA drift. Valid values are 0 -> 63. The lower this factor, the greater the power savings.
7-4 —	Reserved
3 WW_ADD	Window-widening Add Command

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit allows software to increase (add to) the HW-computed window-widening adjustment. The incremental amount is determined by the WW_INCREASE[7:0] register. The capability to add to the HW-computed adjustment is intended for contingency or debug purposes only, as the HW-computed value should be accurate. This bit is write-only. Readback value is always 0. 1: Increase the HW-computed window-widening adjustment by amount WW_INCREASE[7:0]. 0: No effect
2 WW_NULL	Window-widening Null Command This bit allows software to reset the accumulated window-widening adjustment to 0. This bit is write-only. Readback value is always 0. 1: Reset the accumulated window-widening adjustment to 0. 0: No effect.
1 WW_RESET_ON_RX	Window-widening Reset on Received Good Packet Enable a good packet reception to reset the accumulated window-widening adjustment to 0. A good packet is one that passes CRC verification, and passes packet filtering rules. Filtering rules vary by protocol. 1: Allow good packet reception to reset window-widening adjustment. This is the default. 0: Block good packet reception from resetting window-widening adjustment.
0 WW_EN	Window-widening Enable Master Enable for Window Widening. Typically, only slave devices employ window widening. 1: Window Widening is enabled. 0: Window Widening is disabled.

52.4.4.1.1.6.1.9 FREQUENCY HOP CONTROL (HOP_CTRL)

Offset

Register	Offset
HOP_CTRL	1Ch

52.4.4.1.2 Radio Bit Manipulation Engine

52.4.4.1.2.1 Overview

This section provides an introduction to the Radio Bit Manipulation Engine (RBME) module. The RBME module is a group of configurable bit manipulation modules.

52.4.4.1.2.1.1 Block Diagram

52.4.4.1.2.1.1.1 TX-RBME Diagram

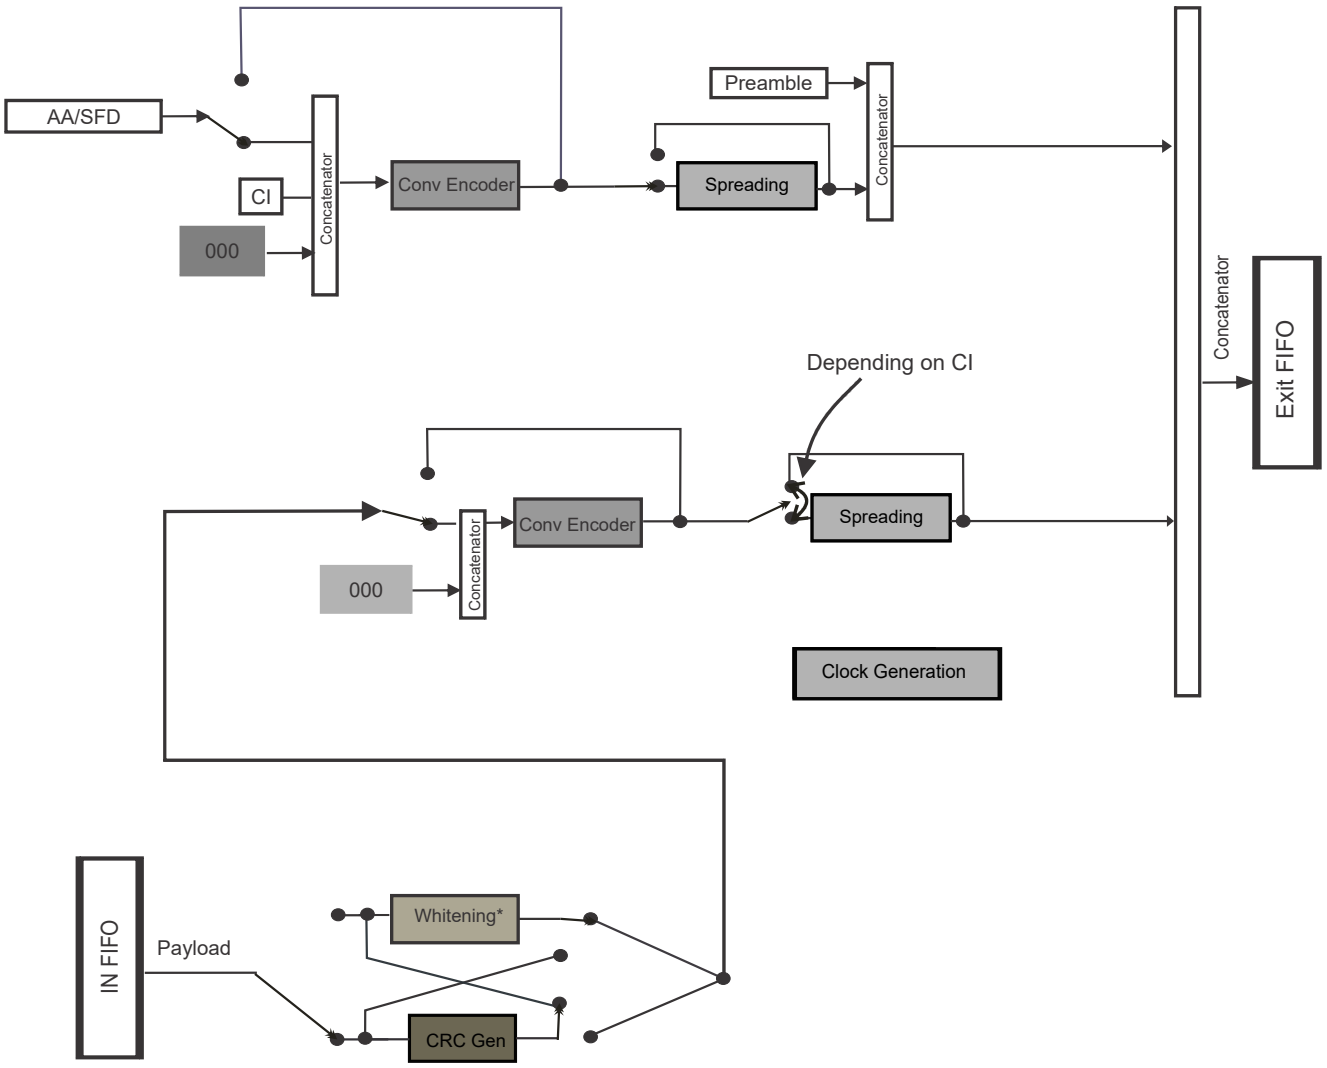

Figure 256. TX Diagram

52.4.4.1.2.1.1.2 RX-RBME Diagram

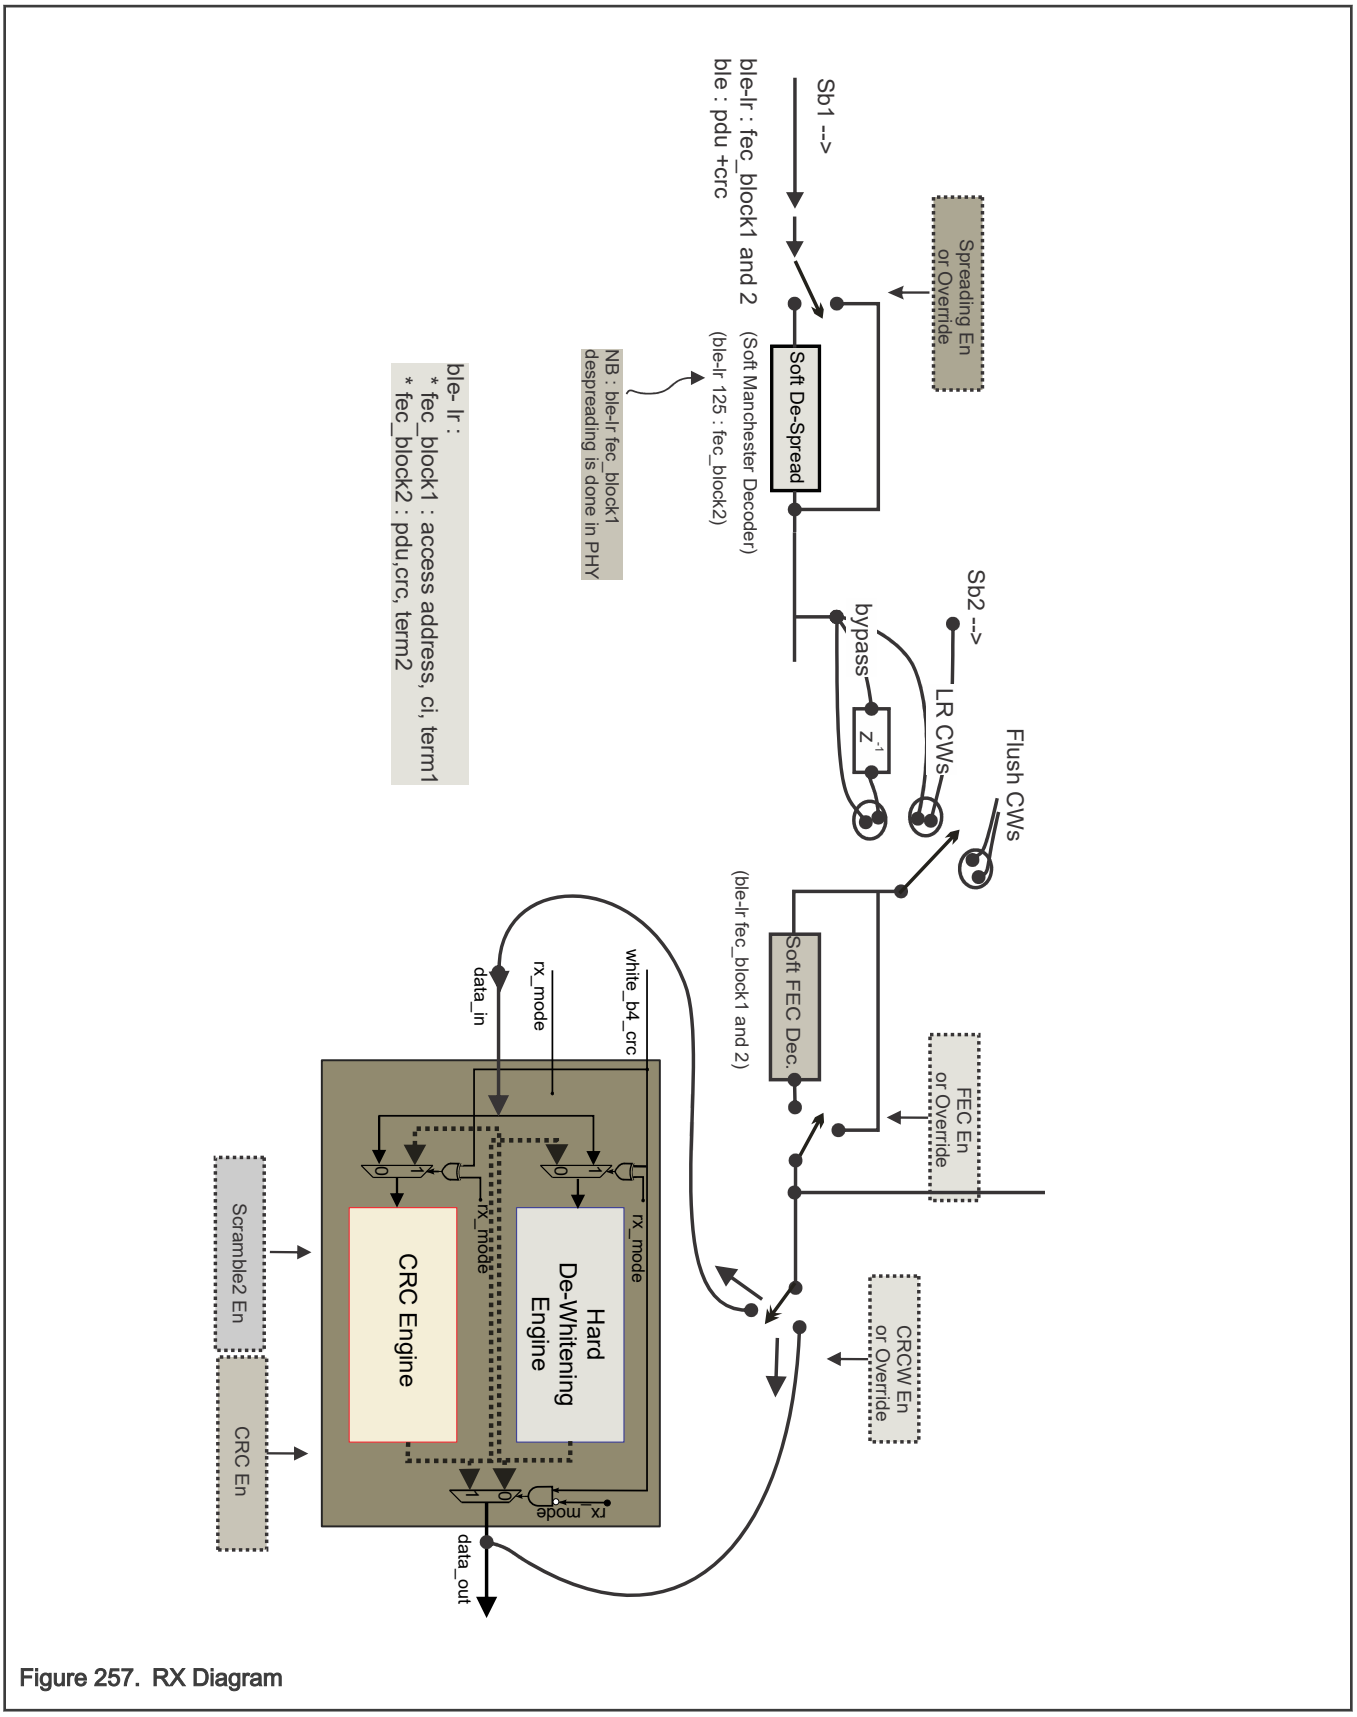

Figure 257. RX Diagram

52.4.4.1.2.1.2 Features

- FEC: Forward Error Correction
  - Support for Bluetooth LE and Bluetooth LE LR
    - Requires a two pass FEC, over the AA+CI and over the payload + CRC
    - These are called FECBlock1 and FECBlock2 respectively
- Spreading
  - Hard Spreader
  - Inclusive of hard Manchester encode and decode
- Configurable CRC and Whiten (CRCW)
  - CRC
    - Supports direct method only
    - Supports input byte reflection
    - Final XOR and checksum byte reflection
    - Multiple CRCs per packet is not currently supported
    - Programmable polynomial and seed values
  - Whitening Block
    - Hard whitening and de-whitening modes only
    - Programmable polynomial and seed values
    - Galois or Fibonacci type LFSR
  - CRC can switch on before or after the second whitening module
- RAM interface
  - Debug
  - Frame processing

NOTE

The RBME is fully functional with GEN-LL, while totally bypassed when 15p4-LL is activated. If the NBU is the active link-layer, the RBME only be enabled for receiving long-range (coded) packets. In this case, the RBME responsible for despreading and do FEC decode. The de-whitening and CRC calculation should be done inside the NBU

52.4.4.1.2.2 Functional description

52.4.4.1.2.2.1 Processing Order

TX-RBME Diagram shows the order of processing for the Transceiver (TX). The Receiver (RX) has the reverse order of processing shown in RX-RBME Diagram. The order of processing and the number of modules involved depends on:

1. The enable register for the block
   - Used to configure a block statically
   - Allows for configurability for a pre-known setup of the RBME
   - All TX modules only require a static enable as the configurations are known in advance
2. Override of the block (RX only)
   - Allows a dynamic override of the block enabling it regardless of the enable register
   - It requires that the appropriate override enable register be asserted

- It does not disable the block: if a block is to be enabled dynamically
  - Set enable register off
  - Set override enable on

3. Bypass of the (RX only)
   - It has the highest priority
   - It is used only internally
   - It is dynamic

52.4.4.1.2.2.1.1 RX Bluetooth LE LR Example

When the Coding Indicator (CI) bits are demodulated and decoded, the mode of Bluetooth LE LR is known. Therefore, dynamic override needs to be used for de-spreading. For this reason, the spreading is disabled and the override is enabled for the RX. Furthermore, the receive for Bluetooth LE LR requires special handling as the FEC is required twice. The following steps describe the RX flow.

1. RBME input mode from link layer has been set to 1 to let RBME prepare for a long range (LR) configuration before AAFound.
2. RBME_en is asserted once AAFound, from the PHY acquisition, has been asserted.
3. After reading the decoded CI bits, the PHY sends a one-bit CI indication.
   - CI_indicator NOT asserted for 125 kbps reception
   - CI_indicator asserted for 500 kips reception
4. The FEC processing must have the packet length from the link layer before the end of the packet for the CRC to be applied correctly. The processing counts the soft bits till Cnt = FECCounter2.
   a. FECCounter2 equals MaxPacketSize register until the LL updates the Frame length
   b. FECCounter2 = FrameLengthBits + NPHRBits + NCRCBits + FineTuneFECFlushBits
      i. FrameLengthBits is the number of bits from the link layer
      ii. NPHRbits = 16 for Bluetooth LE LR
      iii. NCRCbits = length of the CRC
      iv. FineTuneFECFlushBits is a register that allows for customization of the decoder length

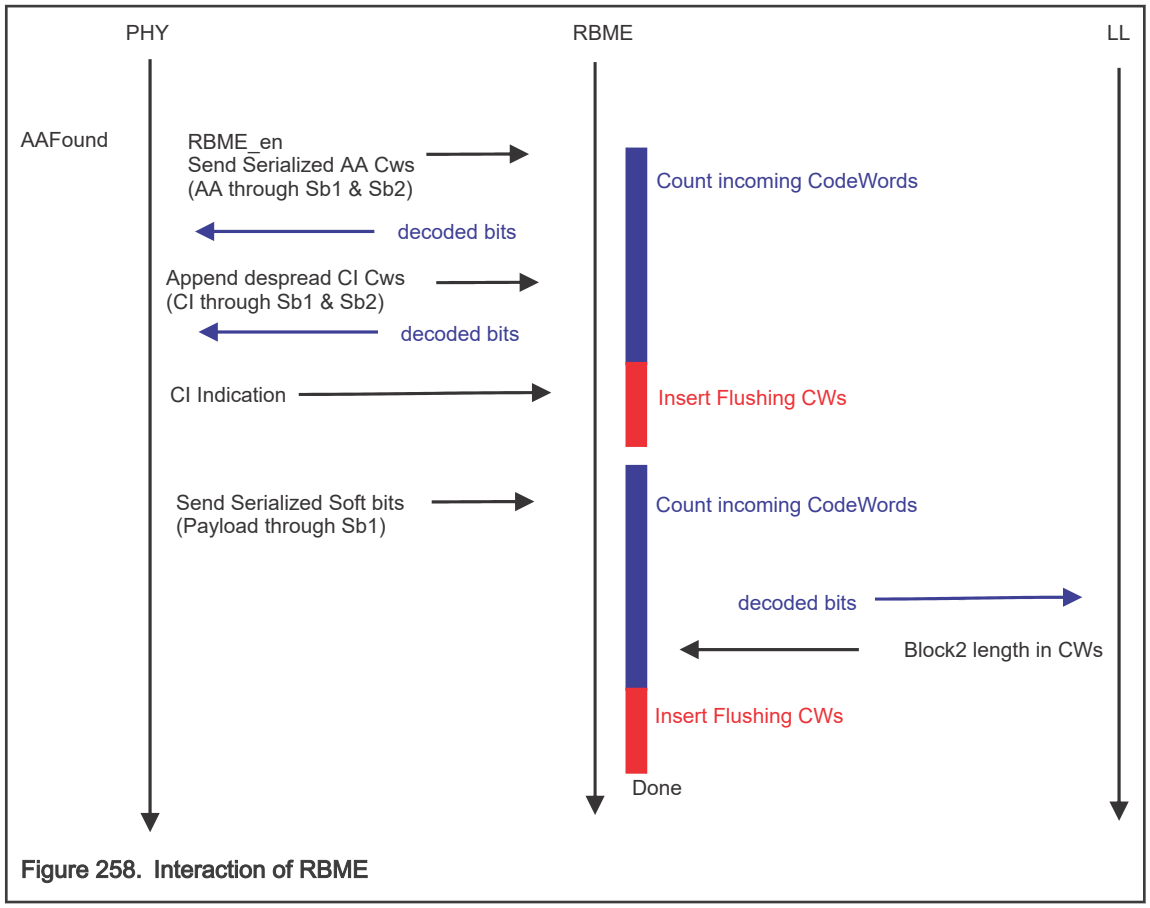

Figure 258. Interaction of RBME

The above figure (Interaction of RBME) shows the interaction among link layer, RBME, and PHY. The following table illustrates the Bluetooth LE LR packet format that RBME RX must account for. Note the separation into FEC Block1 and FEC Block2. Other important aspects are:

- AA+CI are spread with a spreading pattern of length 4
- AA+CI+TERM1 are combined as FECBlock1 as they need to be decoded together
- Header+Payload+CRC+TERM2 are combined as FECBlock2 as they need to be decoded together
- The de-spreading of AA+CI is done in the PHY for speed
- FECBlock2 may or may not need de-spreading depending on whether 125 kbps or 500 kbps are transmitted

Table 446. Standard Bluetooth LE LR Frame Format

10 Octets	4 Octets	2 bits	3 bits	Variable in Octets			24 bits	3 bits
Pre	AA	CI	TERM1	PDU			CRC	TERM2
				Header (16 bits)		Payload		
					Length (8 bits) L0:L7 Payload field length in octets. LSB first	ADV => 1:255 octets Data => 0:251 octets		
	FEC BLOCK 1			FEC BLOCK 2				

52.4.4.1.2.2.1.2 Frame delimiter before CRC Protocol (FCP) Example

An example of FCP frame packet is shown in the table below. It has the distinct characteristic that the Start Frame Delimiter (SFD) is passed through the CRC. This complicates the processing for the RX as there are two possibilities:

1. The ideal SFD is assumed for processing the CRC.
2. The decoded SFD is provided by the PHY.

   RBME assumes option 1, that is, the CRC presumes an ideal SFD. That ideal SFD is injected at the CRC buffer for processing, so no SFD bit errors will ever be caught. Another important feature of FCP is that whitening from a TX perspective is done before the CRC.

Table 447. FCP Frame Packet

1 octet	2 octets	5 octets		Variable in octets (8 -25)	2 octets
		RBME PHR		RBME Payload	
Pre	Net add	Device Address	Control (1 octet)	Data	CRC

52.4.4.1.2.2.2 RBME RAM And Interface

52.4.4.1.2.2.2.1 RAM Interface for RBME

RAM interface for RBME is important for debug and pre/post process frame. The only interrupt of RBME is generated by RAM interface. When packet RAM is filled completely with payload, the interrupt is sent to MCU in case of RAM_IF_IE set. The following figure (RBME TX RAM Interface) shows all the options, however, for simplicity the implementation of the RAM interface is in two developmental stages:

1. RAM-RBME-RAM only

   This interface is the simplest as it presumes that data into RBME and out of RBME comes and returns to the packet RAM.
2. RAM-RBME TX

   This interface writes single bit data from the packet RX RAM into RBME TX. The interface is like that of the generic LL using fast clock implicitly for the data rate and then switching internally to OTA derived clocks. For example, if FEC encoding alone is done, the input buffer is normally read at twice the OTA rate. TX_DIG normally dictates the OTA rate that is desired for the implementation. For the RAM equivalent, the read rate can be higher. The rate of RBME output may be higher than the equivalent OTA rate for the use case but must be smaller or equal to ref_clk/encoding_factor. The values for encoding factor are for example:

   a. For FEC encoding only

   b. 32 if a spreading factor of 16 was required and FEC was also required

   In Step2 of next figure (RBME RX RAM Interface), the data from TX RAM pre-processed is sent to link layer as normal case without RAM interface. Then RBME does the same way as usual.

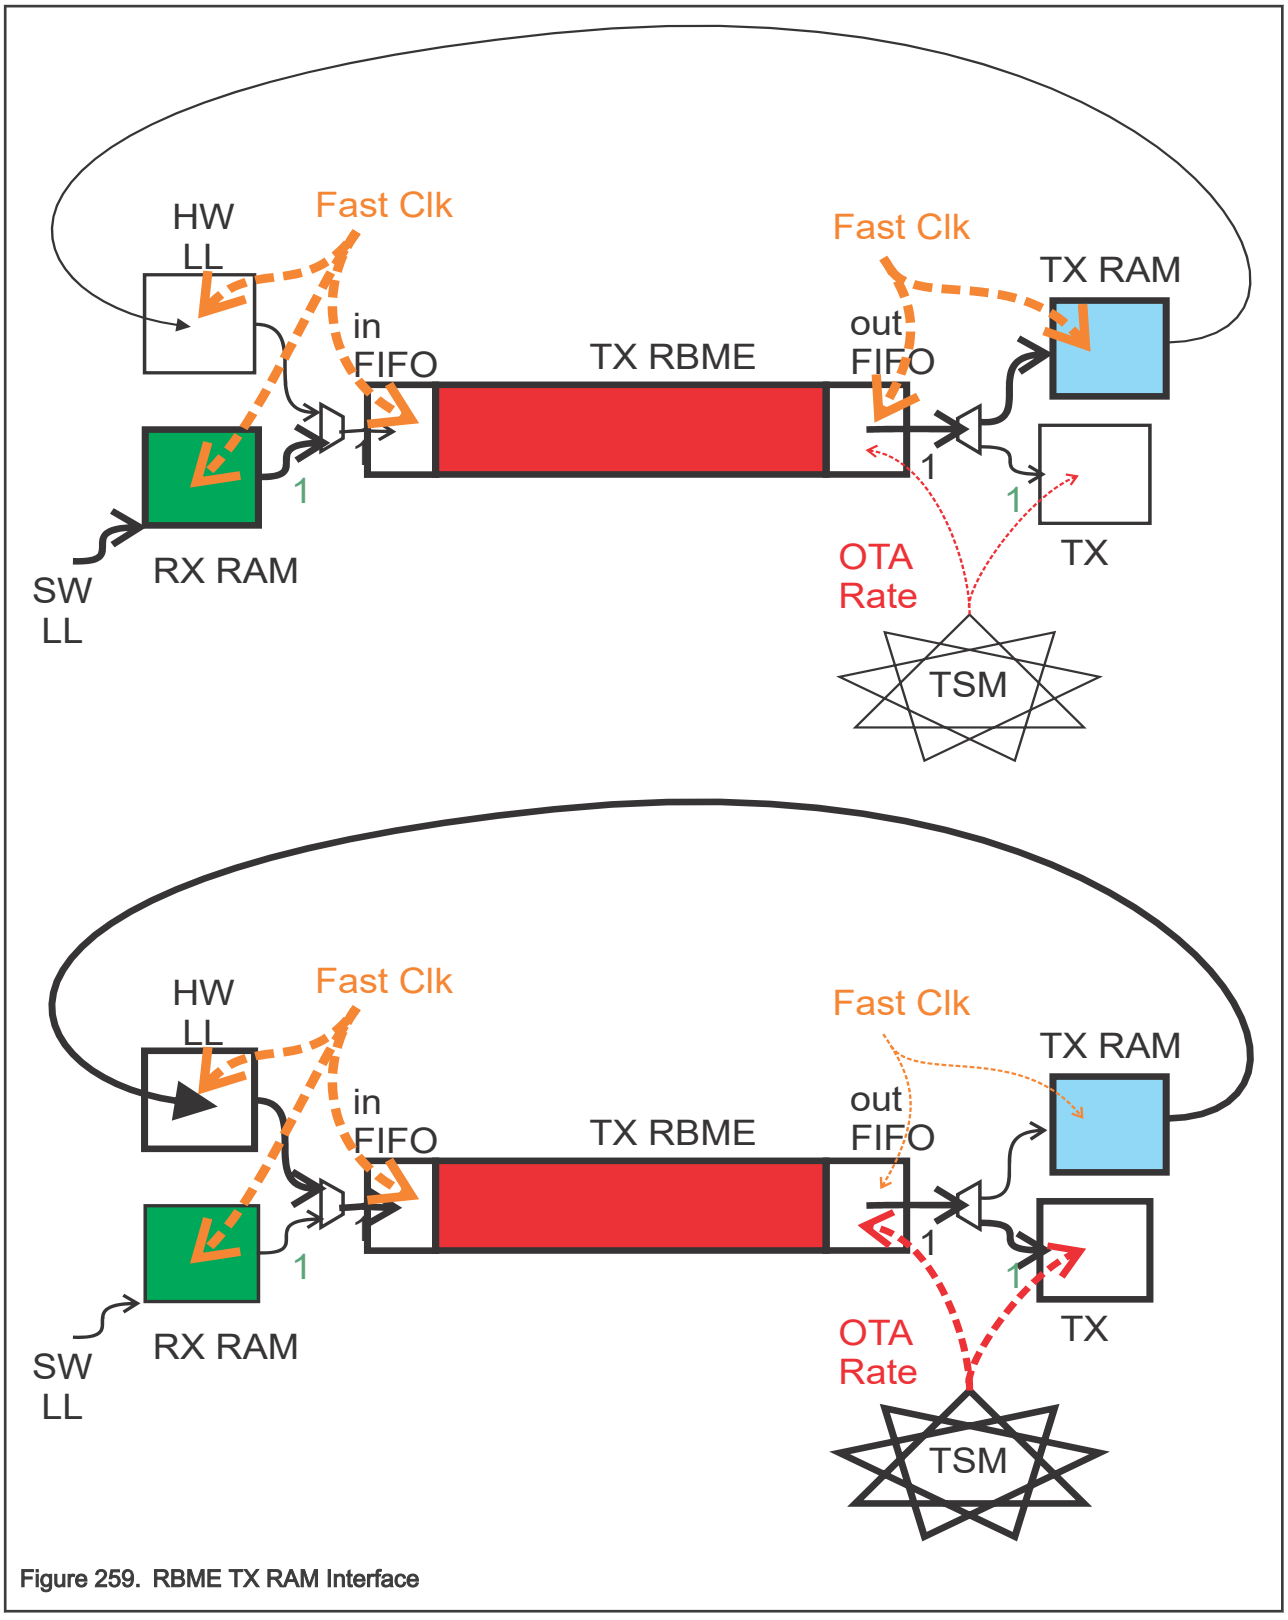

Figure 259. RBME TX RAM Interface

3. RAM-RBME RX

RBME RX processing: PHY ->[Despreading->FEC decoding->CRC & hard de-whitening]->LL Example: unsupported hard de-whitener with a different polynomial, interleaving and FEC plus soft de-spreading and CRC processing can be done in RBME RX.

1. First Pass: Use the PHY to RBME interface to process the data as normal but save the data to TX packet RAM before the de-whitener
    a. FEC decoding is enabled
    b. CRCW is bypassed
    c. Use software processing to do the soft de-whitening data
2. Second-Pass: Use the RAM interface to write 7-bit softbit words into RBME
    a. Do CRC decoding in RBME
    b. Use the RX RAM interface to read the CRC processed hard bit data

NOTE

A bypass from the PHY directly into packet RAM is needed if the de-spreader must be bypassed.

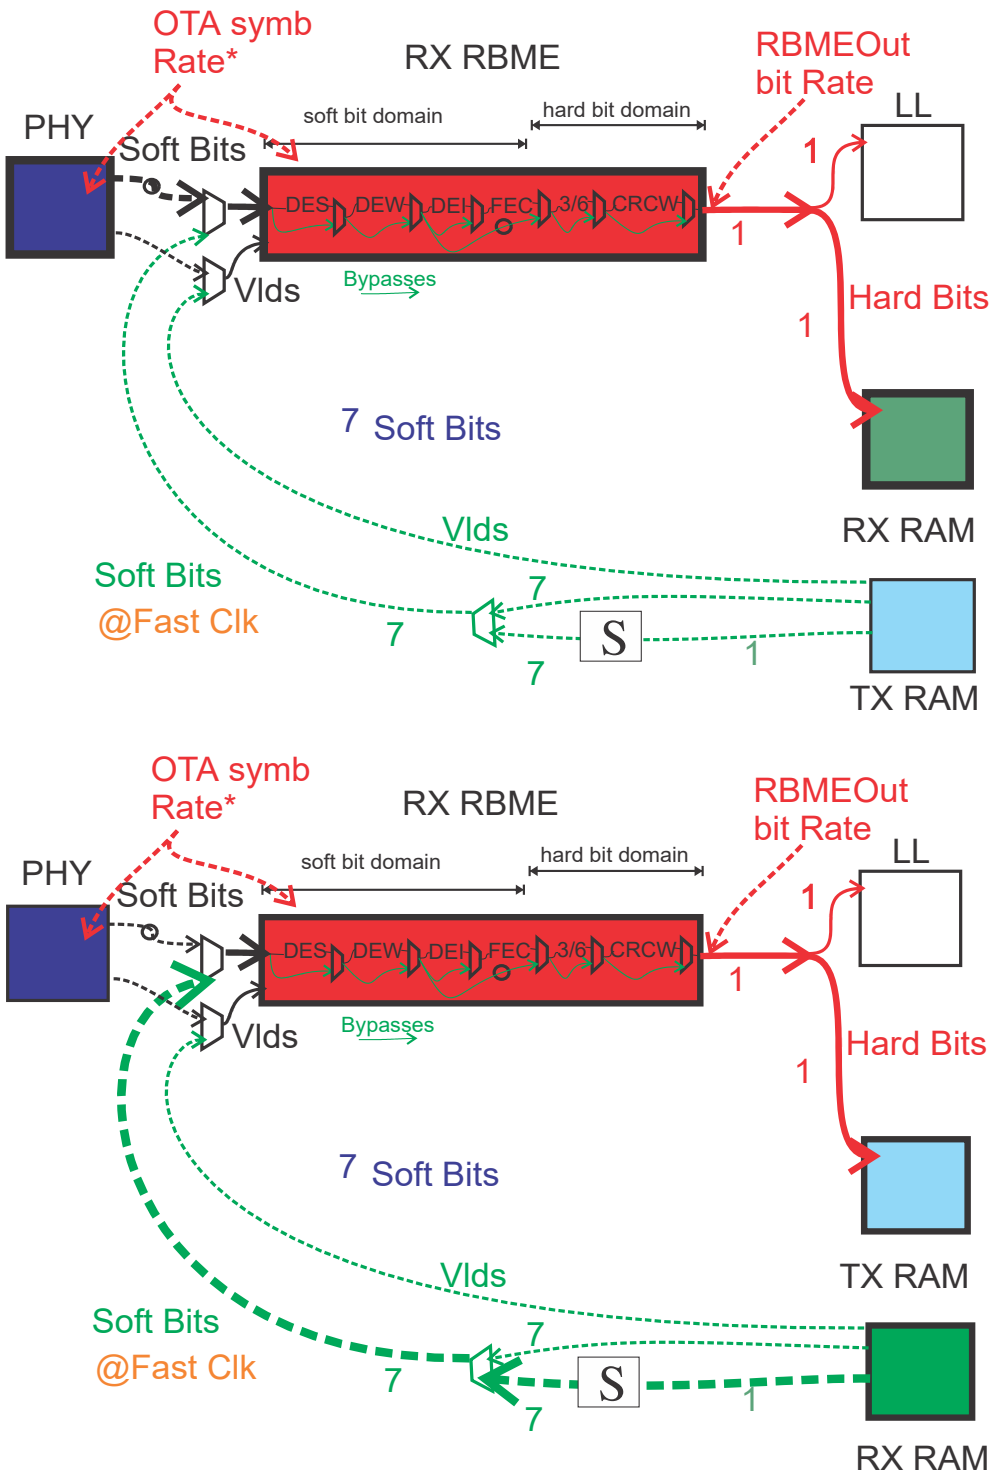

Figure 260. RBME RX RAM Interface

52.4.4.1.2.2.2.2 Internal Interfaces, Word Sizes, and Internal State Machines

For the TX, data and dataVld are single bits; for the RX and before the FEC, the data is in 7-bit words to describe softbits. The data format for CRCW for both TX and RX needs to be Boolean. In terms of clock valid management, every module internally controls its output clock valid (as opposed to a central control). This methodology makes the modules easier to interact with each other. Examples:

1. When bypassing a module, the data valid is equally bypassed.
2. If de-spreading by four is used, the output data valid(s) are four times slower at the output.

The FEC Decoder input is in codeword (CW) pairs. This is normal for a rate ½ FEC. For Bluetooth LE LR, the de-spreading is done at the PHY so that the input to RBME is CW pairs at FrefFreq/2 for speed. This means that a second seven-bit input word needs to be separately added to the input. In summary, the input to the RBME RX is either a seven-bit input or two seven-bit inputs (both associated with the same input data valid signal). For Bluetooth LE LR only, the two seven-bit inputs are expected during the decoding of the AA and CI. For all other cases, there is a single seven-bit input. The RBME may also decode data from external memory, such data are expected to be serialized outside the RBME. The single Sb1 input can be used for this, alternatively, both Sb1 and Sb2 inputs can be used for faster processing. The enable control for a module is tabulated in Table 448. Note that a bypass signal has priority. Block bypasses are internal to the RBME. External override access on the other hand, that is, for the Soft-Whitening module and the FEC module, is allowed as long as the corresponding override enable register is set.

Table 448. RBME Module Enable Truth Table

Enable (Register)	OverrideEnable (Register)	Override	Bypass*	Block Enabled
True	True	True	True	False
True	True	True	False	True
True	True	False	True	False
True	True	False	False	True
True	False	True	True	False

False	True	True	False	True
False	True	False	True	False
False	True	False	False	False
False	False	True	True	False
False	False	True	False	False
False	False	False	True	False
False	False	False	False	False

NOTE

Bypass signal is used internally, user does not need to program it.

52.4.4.1.2.2.3 FEC

The initial FEC originates from BL5 specifications related to the long-range feature. It is a part of 2.4 GHz Radio IP. The convolutional FEC encoder uses:

1. A non-systematic, non-recursive design
2. Code rate ½ with constraint length 4
3. The generator polynomials are:

$$G0(x) = 1 + x + x^2 + x^3$$

$$G1(x) = 1 + x^2 + x^3$$

52.4.4.1.2.2.3.1 Two-Pass FEC

The FEC encoder and decoder can run twice on a packet. For the TX and Bluetooth LE long range, it must encode the AA, CI + termination bits (FECBlock1), and then encode the payload and CRC (FECBlock2), see section "RX Bluetooth LE LR Example". For the RX, it must decode the two differently. To reduce latency, FECBlock1 is decoded with a fast clock once the AA is detected. FECBlock2 is decoded at the symbol rate.

52.4.4.1.2.2.3.2 TX FEC

FEC Encoder: Bluetooth LE-LR use case A shift register based representation of convolutional encoder is shown in the following figure.

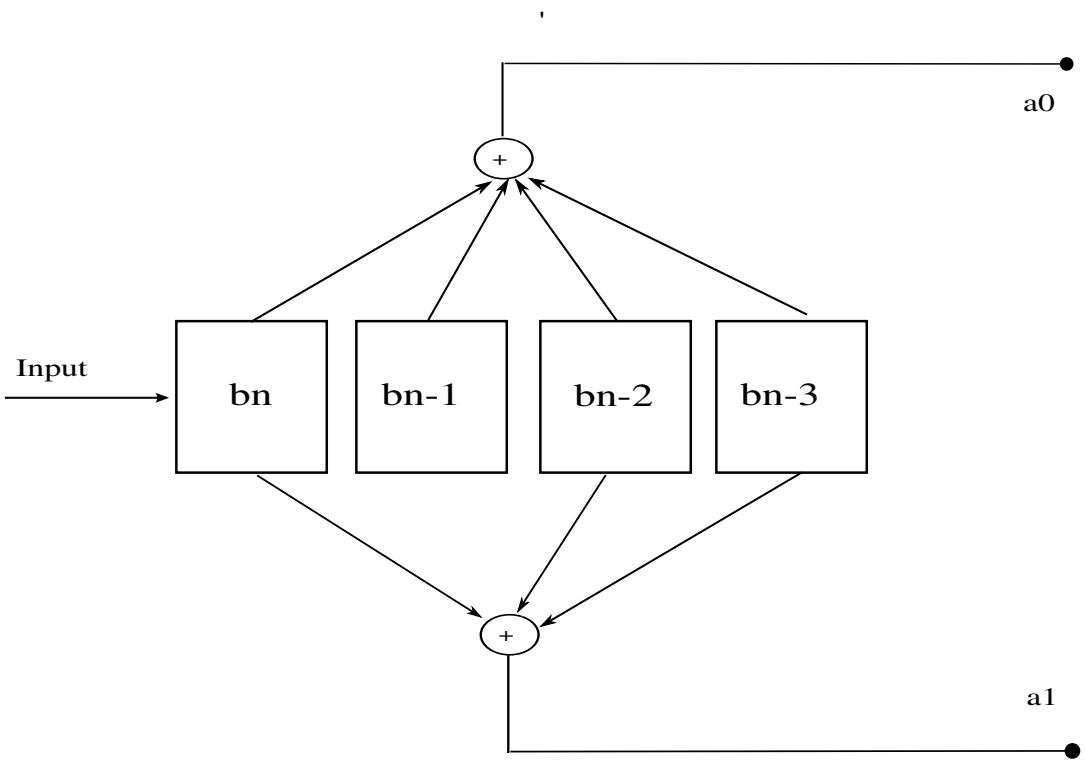

Figure 261. Bluetooth LE-LR FEC Encoder

Where:

- bn denotes the current bit, this is the input for the shift register.
- bn-i (i=1..3) are the previous bits sequence, they are referred to as the state or the memory of the encoder. The encoder produces two bits for each input bit.

The bit from generator polynomial G0 (a0) is transmitted first; the bit from generator polynomial G1 (a1) is transmitted second. The initial state of the convolutional FEC encoder is set to all zeros. An input sequence of three consecutive zeros always brings the convolutional FEC encoder back to its original state. This sequence is known as the termination sequence.

52.4.4.1.2.2.4 Spreader

TX Spreading

The spreading maps each input bit to P output bits (P = 2,4,8,16) symbols. The following table shows an example of Bluetooth LE LR where the choice for M is 4, depending on the coding scheme of protocols in use.

Table 449. Pattern Mapper inputs and outputs for Bluetooth LE LR spreading

Input from FEC encoder	Output sequence when P=1 (no spreading)	Output sequence when P=4
0	0	0011*
1	1	1100*
*The entries in the table are transmitted MSB first		

Manchester encoding is a subset of spreading with just two bits per input bit — see below figure. As the Manchester example illustrates, the clock rates (actually, clock valid signal rates) are affected by the Manchester encoding and decoding. The same applies to the spreader and de-spreader modules but with data rates changing by P = 2, 4, 8 or 16. Up to 16 are necessary to support all the 802.15.4 standards. The use of spreading means that output bits are serialized at P times the rate of the input bits. This is an important consideration as a clock valid on the output must be P times more often. That is, the data rate after the spreader is P times higher than that before the spreader. The data rate after the de-spreader in the RX is up to 16x smaller.

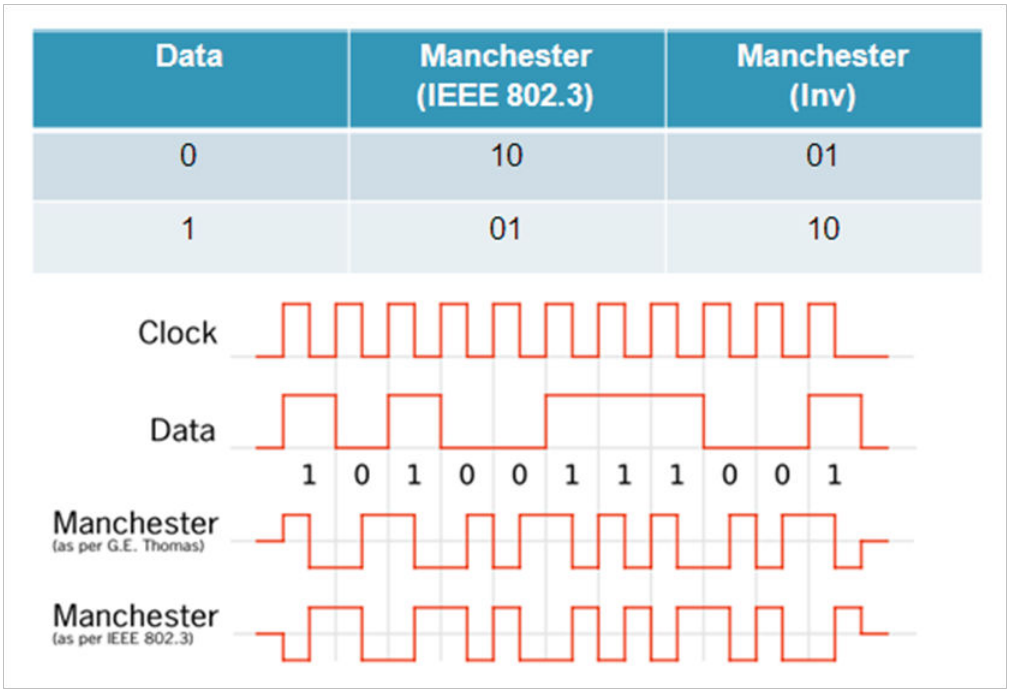

Figure 262. Manchester Encoding option for the Spreading Module

RX DE-Spreading

De-spreading is the dual of the spreading operation. De-spreading means correlating the soft bits provided by the demodulator with the reference sequence. This correlation needs to be done in a timely manner, that is, it has specific timing. For example, with a de-spreading of 4, four samples of the input generate the first output, the next four samples generate the second output and so on. The boundaries of de-spreading are fixed in the PHY.

52.4.4.1.2.2.5 Operation

The CRCW module contains the functionality to perform transmit CRC insertion, receive CRC checking, and data whitening. Additionally, the module can perform data error correction on received packets using the CRC syndrome if configured appropriately.

52.4.4.1.2.2.5.1 CRC Calculation

The CRC value is calculated using a configurable LFSR as depicted in Figure 263. The CRC calculation polynomial value is loaded into register *P*. The seed is loaded into register *SR* at initialization. The result is in register *SR* after all bits have been processed.

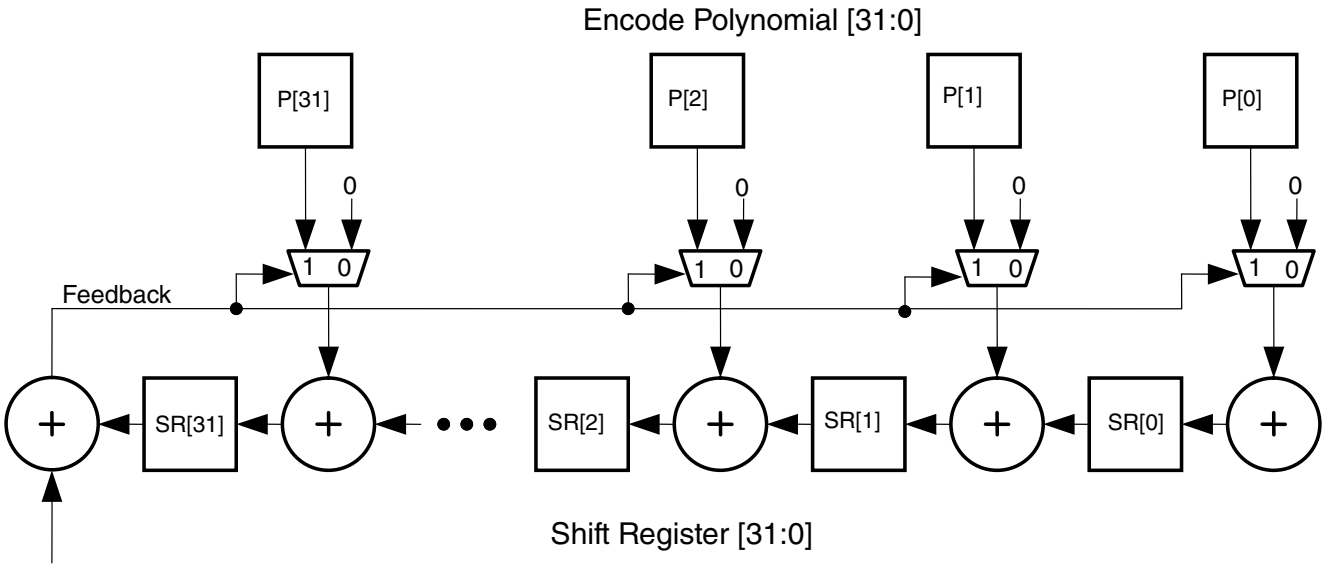

Figure 263. CRC Calculation Shift Register

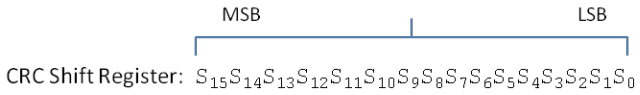
Data flows from the link layer function to the CRCW module during transmit before being sent to the radio physical layer. All bits in each packet are provided by the link layer function, including placeholder bits for the CRC value. The link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the CRC placeholder bits. The CRCW module overwrites the placeholder CRC bits with the CRC result, ordered as specified by the configuration options. Figure 264 is a list of example 16-bit CRC output modes.



REF IN	BYTE ORDER	REF OUT	Order of Transmitted Bits (shifted out first ..... shifted out last)
X	0	0	$P_0P_1P_2P_3P_4P_5P_6P_7P_8P_9P_{10}P_{11}P_{12}P_{13}P_{14}P_{15}$ $S_{15}S_{14}S_{13}S_{12}S_{11}S_{10}S_9S_8S_7S_6S_5S_4S_3S_2S_1S_0$

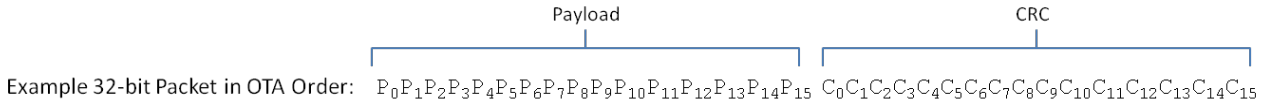
Figure 264. CRC Output Bit Order

52.4.4.1.2.2.5.2 CRC Check

During reception, data flows from the radio physical layer to the CRCW module before being sent to the link layer function. All bits in each packet are provided by the radio physical layer. Just as in transmit, the link layer function marks the CRC calculation start and stop points in the bit stream. The link layer also indicates the start of the received CRC bits.

The CRCW calculates the expected CRC result just as in transmit, but compares the received CRC bits as they arrive, ordered as specified by the configuration options, instead of inserting them into the packet. An early fail signal is asserted if a CRC bit miscompare is detected.

The CRC register contains the expected CRC when either of the *config_crc_byte_order* or *config_crc_ref_in* CRC configuration options are set. The CRC register contains the syndrome of the CRC error calculation when both options are not set.



REF IN	BYTE ORDER	REF OUT	Order of Bits Used in CRC Calculation (shifted in first ..... shifted in last)

Figure 265. CRC Input Bit Order

52.4.4.1.2.2.5.3 Data Whitening

The data whitener behaves identically in both transmit (whiten) and receive (de-whiten) operating modes. The LFSR used in this operation is designed to use either Fibonacci or Galois types of calculations. In either case, the LSB of the shift register is used to whiten each data bit as they are streamed through the CRCW.

An initialization signal for the data whiten logic loads the shift register with the seed value. The initialization signal can be used to re-initialize the shift register during a packet. A protocol-specific state machine controls a signal to mark the start and stop points for data whitening in the data stream.

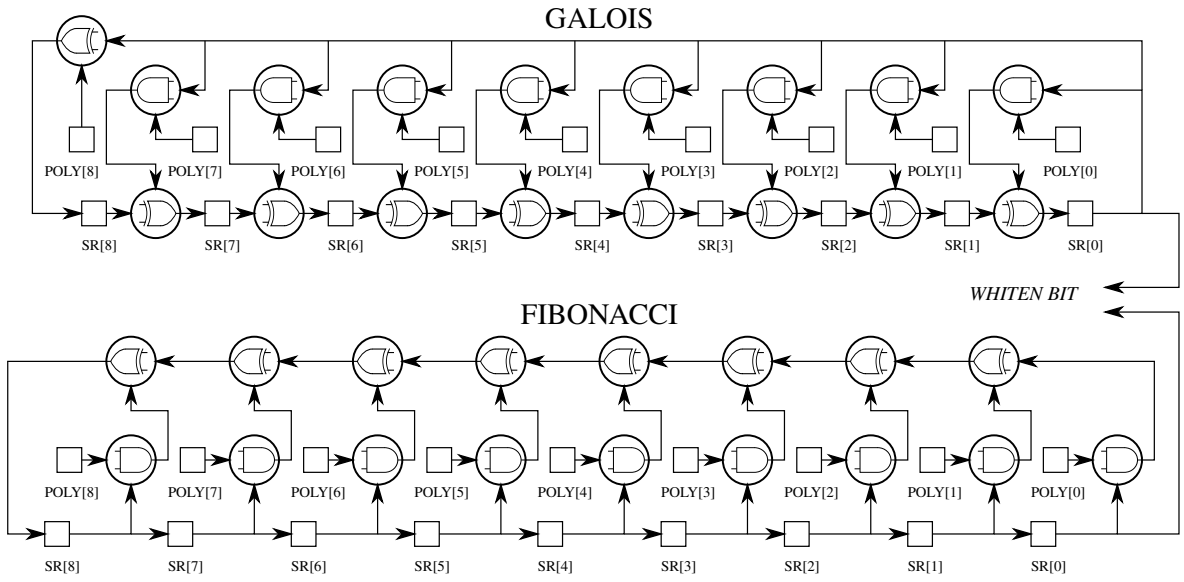

Figure 266. Data Whitening Shift Register

52.4.4.1.2.2.6 Clocking

The RBME has three clock sources: sysclk, radio_symb_clk and ipg_clk_s. The sysclk source is used directly or drives several clock gating inside rbme_cgm module, the radio_symb_clk is gated internally and used by internal blocks, while the ipg_clk_s is only used by the register access logic. The enable signals for clock gating are generated inside the rbme itself.

52.4.4.1.2.2.7 Reset

The RBME has a single asynchronous reset input, named ipg_hard_async_reset_. It clears all the logic inside the module.

52.4.4.1.2.2.8 Interrupts

The RBME block has an interrupt output signal rbme_irq, which indicates that the programmed number of payload bytes has been written to the RAM.

52.4.4.1.2.2.9 DMA

The RBME has no DMA.

52.4.4.1.2.3 Initialization

There is no particular sequence to initialize the Radio BME. The registers must be programmed as described in the Functional Description chapter

52.4.4.1.2.4 Application information

There is no specific procedures to be used by the application.

52.4.4.1.2.5 RBME register descriptions

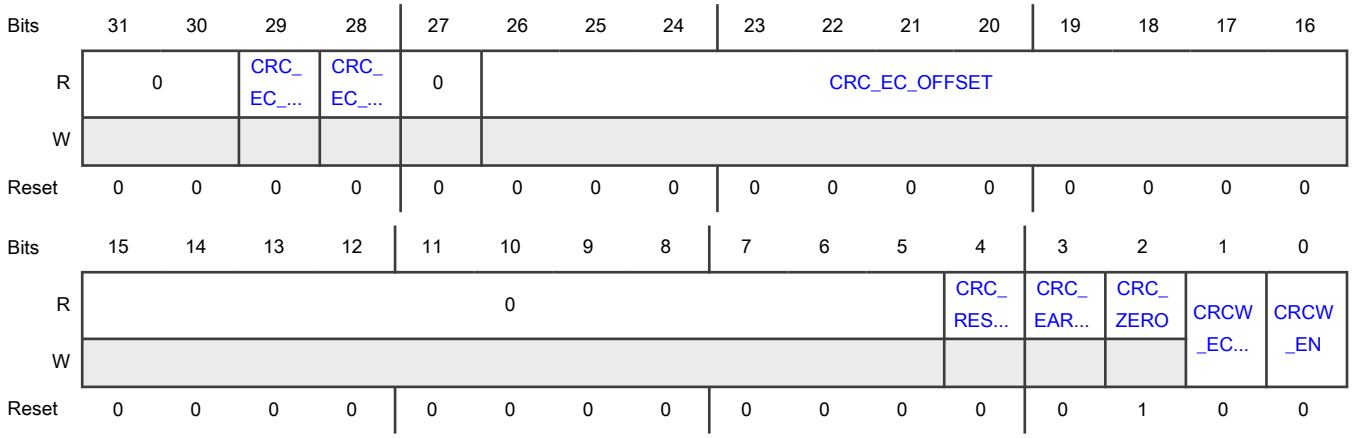
CRCW_CFG	0h

Diagram



Fields

Field	Function
31-30 —	Reserved
29 CRC_EC_FAIL	CRC error correction fail This signal is cleared when *crc_init* is asserted. It is set after the completion of a CRC error correction calculation that does not find a valid data correction solution or if error correction was disabled and the CRC check found an error.
28 CRC_EC_DONE	CRC error correction done This signal is cleared when *crc_init* is asserted. It is set after the error correction logic completes processing the syndrome. It is immediately set after a packet is received if no error was detected or if error correction is disabled. Otherwise, it can take up to N system clocks after the packet is received to assert, with N = number of bits used in the CRC calculation, including the CRC value.
27 —	Reserved
26-16 CRC_EC_OFFSET	CRC error correction offset This value provides the byte offset within the data packet to which the CRC error correction mask should be XOR-ed. This value is valid if the *crc_ec_done* signal is asserted and the *crc_ec_fail* signal is not asserted. The offset includes only the bytes used in the CRC calculation, including the CRC value.
15-5 —	Reserved
4 CRC_RES_OUT_VLD	CRC result output valid CRC result output valid
3	CRC error correction fail

Table continues on the next page...

52.4.4.1.3 SFA32K(Signal Frequency Analyser of 32KHz Clock)

52.4.4.1.3.1 Overview

The 32KHz clock source is used as the sleep timer clock source inside RFMC and Bluetooth LE Link Layer. So accuracy of the sleep timer depends on the accuracy of the 32KHz clock in the chip. In order to achieve a higher accuracy 32KHz clock source, the SFA module is used to measure the 32KHz clock source with RF OSC clock. The measurement result can be used by software to calibrate the 32KHz clock source.

The radio SFA module can be configured to measure the 32KHz clock source by a hardware trigger when radio exists from low power mode.

52.4.4.1.3.2 Overview

The Signal Frequency Analyser (SFA) provides functionality to perform measurements of clock frequency, clock period, and time between triggers.

52.4.4.1.3.2.1 Block Diagram

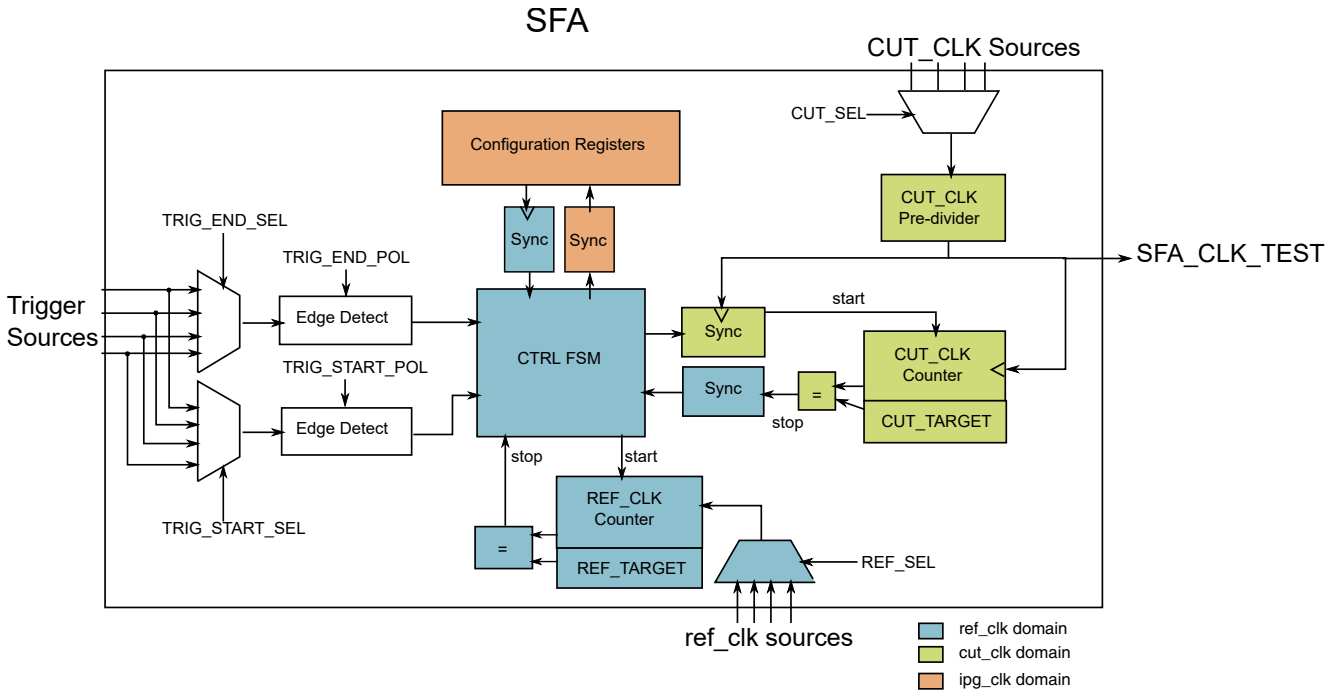

Figure 267. Signal Frequency Analyser Block Diagram

52.4.4.1.3.2.2 Features

The Signal Frequency Analyser includes the following features.

- Two 32-bit counters, one connected to the bus clock (REF clock), which serves as a reference, and the other connected to the clock under test (CUT).
- An 8-bit predivider is provided to divide down the CUT clock.
- A target count register for both the REF clock and CUT clock are provided to stop the counters.
- Trigger measurement mode to analyse the time between 2 edges (with configurable polarity) of either the same or different triggers. Note, the trigger pulse width must be at least 2 ref_clk cycles long to be properly registered.
- Selectable measurement modes to optimize test time by analysing either the frequency (for fast clocks), or the period (for slow clocks) of the CUT clock.
- Selectable sources for reference clock and CUT clock
- Support interrupt for CUT clk freq exceed setting freq limit

52.4.4.1.3.3 Functional Description

The Signal Frequency Analyser can be used to measure frequencies, periods, and time between events. The following use cases demonstrate how these capabilities can be used.

52.4.4.1.3.3.1 Frequency Measurements

The Signal Frequency Analyser can be used to measure the frequency of CUT CLK. The use cases below demonstrate how these capabilities can be used.

In general, either of the following methods may then be used to measure clock frequencies. To measure in frequency mode, register bit CTRL[MODE] must be set to 0x0 or 0x1.

Method 1 (when CUT frequency < REF frequency)(CTRL[MODE] == 0x0):

1. Set CUT and REF count targets
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it cleared
4. The next step can be completed using 2 different methods depending on the value of CTRL[SFA_TRIG_MEAS_EN]:
    a. SFA_TRIG_MEAS_EN = 0b0

       Perform a dummy write to the CUT counter. This triggers:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay

    b. SFA_TRIG_MEAS_EN = 0b1

       The SFA will stall processing until the trigger edge selected by CTRL[TRIG_START_SEL] and CTRL[TRIG_START_POL] has been received. Once the trigger has been received, the following sequence will occur:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When CUT counter reaches 1, MEAS_STARTED bit asserts after a ~2 REF cycle sync delay
6. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (a saved version of the current REF counter, which keeps running) will be written.
7. When CUT counter reaches target, CUT_STOPPED bit asserts after a ~2 REF cycle sync delay
8. Upon assertion of CUT_STOPPED, the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written.
9. The measurement is considered complete once the REF_STOPPED and CUT_STOPPED bits have been asserted in the CUT_CNT register. The user can either poll the REF_STOPPED and CUT_STOPPED bits or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when the measurement is complete.
10. Calculate CUT frequency by using the difference in the REF_COUNT_END_SAVED and REF_COUNT_ST_SAVED in comparison to the CUT target
11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

The following two figures represent two possible cases for frequency measurement with CTRL[MODE] = 0x0. The first image illustrates a complete frequency measurement. Note, it is assumed that the user has started the measurement some time before this waveform snapshot was taken. Therefore, the register writes to CUT counter and REF counter are omitted. In this example the CUT target of 0x0000_FFFF is reached before the REF target count is reached. The two significant measurement events occur when MEAS_STARTED is asserted and REF_CNT_STOPPED is asserted.

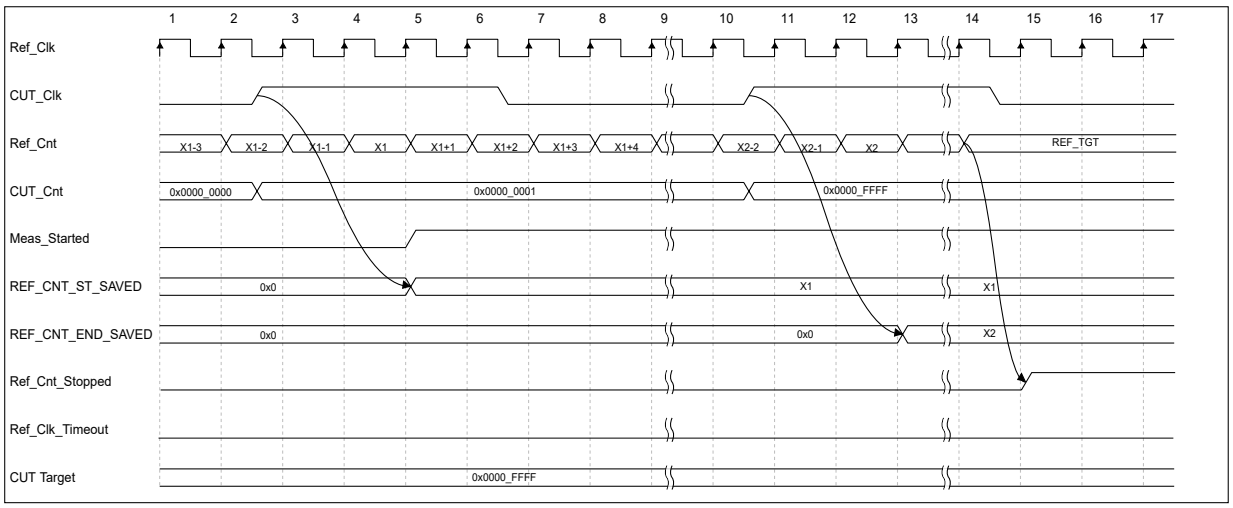

Figure 268. CUT Frequency Measurement with CUT Freq less than REF Freq

The next image illustrates the case when the frequency measurement is unable to be completed before REF_CNT_STOPPED is asserted. This is known as a reference clock timeout. In this example the CUT Target is set to 0x0000_FFFF; however, this value is never reached before REF_CNT = REF_CNT_STOPPED.

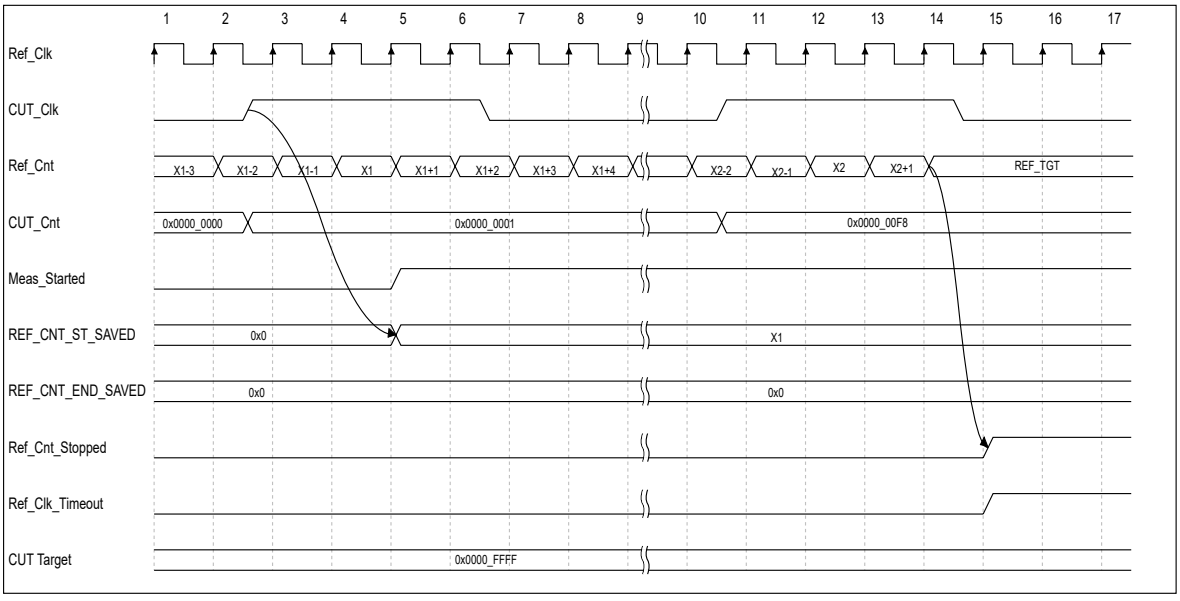

Figure 269. CUT Frequency Measurement Timeout with CUT Freq less than REF Freq

Method 2 (when CUT frequency > REF frequency)(CTRL[MODE] == 0x1):

1. Set CUT and REF count targets (Note: recommend CUT target be set to 0xFFFF_FFFF. There is no CUT_CNT_TIMEOUT flag.)
2. Perform a dummy write to REF counter (clears the *COUNT, *STARTED and *STOPPED bits)
3. Poll the CUT_STOPPED bit to make sure it is clear
4. The next step can be completed using 2 different methods depending on the value of CTRL[SFA_TRIG_MEAS_EN]:
    a. SFA_TRIG_MEAS_EN = 0b0

       Perform a dummy write to the CUT counter. This triggers:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay

    b. SFA_TRIG_MEAS_EN = 0b1

       The SFA will stall processing until the trigger edge selected by CTRL[TRIG_START_SEL] and CTRL[TRIG_START_POL] has been received. Once the trigger has been received, the following sequence will occur:

        i. REF counter starts counting immediately

        ii. CUT counter starts counting after a ~2 CUT cycle sync delay
5. When REF_COUNT reaches target, the CUT counter stops after a ~2 CUT cycle sync delay, and the CUT_STOPPED bit then sets after a ~2 REF cycle sync delay
6. Calculate CUT frequency by using the CUT_COUNT and REF target
7. To determine when the measurement has been completed, the user can either poll the CUT_STOPPED bit or enable SFA_IRQ_EN. An interrupt will be issued, if SFA_IRQ_EN is asserted and when both CUT_STOPPED and REF_STOPPED are asserted.
8. If the value CUT_CNT is greater than the value setting in CUT_HIGH_LIMIT_CNT , it means the measured cut clk frequency or trigger period is greater than maximum limit. If FREQ_GT_MAX interrupt flag is set, FREQ_GT_MAX IRQ will be generated.
9. If the value CUT_CNT less than the value setting in CUT_LOW_LIMIT_CNT , it means the measured cut clk frequency or trigger period is less than minimum limit, if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated

The following image represents an example frequency measurement with CTRL[MODE] = 0x1. In this case, the CUT frequency should be greater than the REF frequency. This measurement is used to count the number of CUT_CLK cycles that occur in REF_TARGET REF clk cycles. Note that registers REF_CNT_*_SAVED should not be read during this mode. It can be implied that REF_CNT_END_SAVED - REF_CNT_ST_SAVED = REF_TARGET.

When performing a CTRL[MODE] = 0x1 measurement, the CUT_TARGET should be set to the max value to prevent a CUT_TARGET timeout. The measurement will end when REF_CNT reaches the value stored in REF_TARGET. If CUT_TARGET is reached before REF_TARGET is reached, this will indicate an error condition. There is no flag to indicate a CUT_TARGET timeout. This is why CUT_TARGET should be set to the maximum value. The CUT_CNT timeout occurs when CUT_CNT is equal to CUT_TARGET. To detect that the CUT_CNT timeout did not occur, the CUT_CNT register should be less than CUT_TARGET at the end of a CTRL[MODE] = 0x1 measurement. When CUT_CNT is less than CUT_TARGET, the measurement stops when REF_TARGET is met.

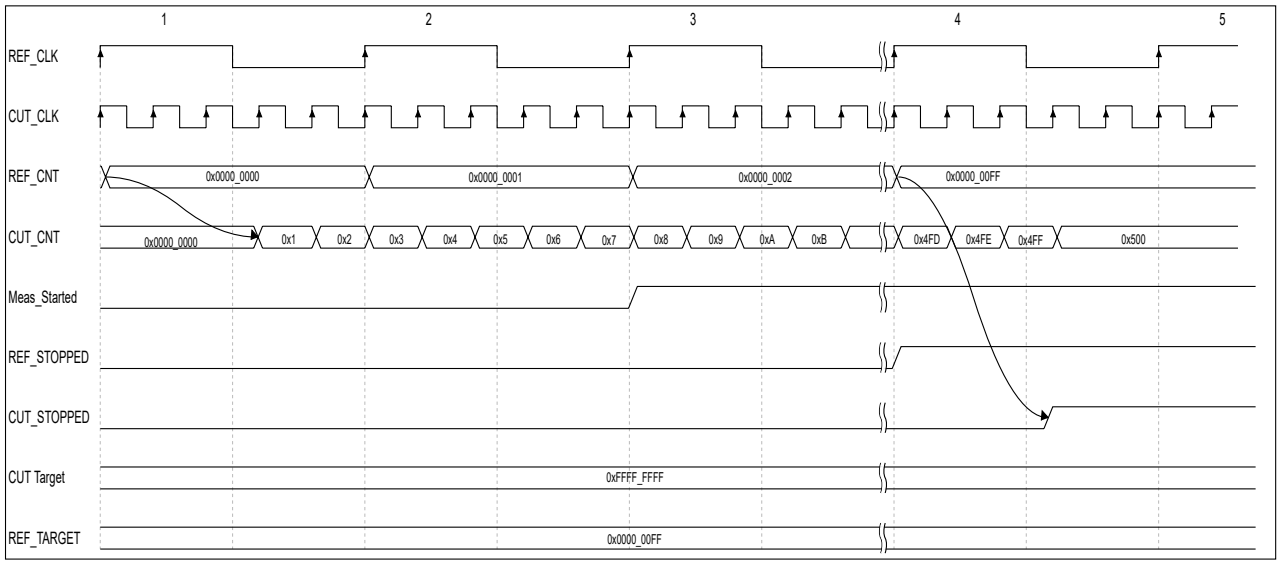

Figure 270. REF Frequency Measurement: CUT Freq greater than REF Freq

52.4.4.1.3.3.2 Clock Period Measurements

The signal frequency analyser has the capability to measure the period of CUT clock. To operate in clock period mode, the register CTRL[MODE] must be set to 0x2. This mode is used to count the number of REF CLK periods which occur during one period of CUT CLK.

Clock Period Measurement (CTRL[MODE] == 0x2). This mode is used to measure the period of CUT clock. It is assumed that CUT frequency < < REF frequency:

1. Select the source of CUT clock with CTRL[CUT_SEL], and configure any CUT pre-divide with CTRL[CUT_PREDIV].
2. Select a value for REF_TARGET. This value acts as a time-out function. The test will always end when REF_CNT == REF_TARGET.
3. Perform a dummy write to the REF counter. This triggers:
    a. REF counter starts counting immediately
    b. All previous counters will be cleared.
4. The MEAS_STARTED bit will indicate when the measurement sequence has begun.
5. The MEAS_STARTED bit is asserted on the first rising edge of the CUT after the dummy write to the REF counter. Upon assertion of MEAS_STARTED, the REF_COUNT_ST_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current REF_CNT value.
6. The REF_STOPPED bit will indicate when the measurement sequence has been completed.
7. Upon completion of one full period measurement (performed from one rising edge to the next rising edge), the REF_COUNT_END_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written with the current value of REF_CNT.
8. Note that REF_STOPPED may be set before the measurement has been completed. This may indicate the REF_CNT reached REF_TARGET before receiving a full period of CUT CLK. In this case, the CNT_STAT[REF_CNT_TIMEOUT] will be set to 0b1 to indicate that a time-out occurred.

9. Calculate the period width by using the difference between the values of REF_CNT_END_SAVED and REF_COUNT_ST_SAVED.
10. To determine when the measurement has been completed, the user can either poll the REF_STOPPED bit or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when REF_STOPPED is asserted.
11. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured cut clk frequency is less than minimum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
12. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured cut clk frequency is greater than maximum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

Figure 271 illustrates a CUT Clk period measurement cycle. It is assumed this timing diagram occurs sometime after beginning the measurement (dummy write to REF counter) with CTRL[MODE] == 0x2. In addition, it is assumed that SFA_IRQ_EN is asserted. In Figure 271 , the REF_TARGET register was set sufficiently high to receive a full period of CUT before REF_CNT timeout.

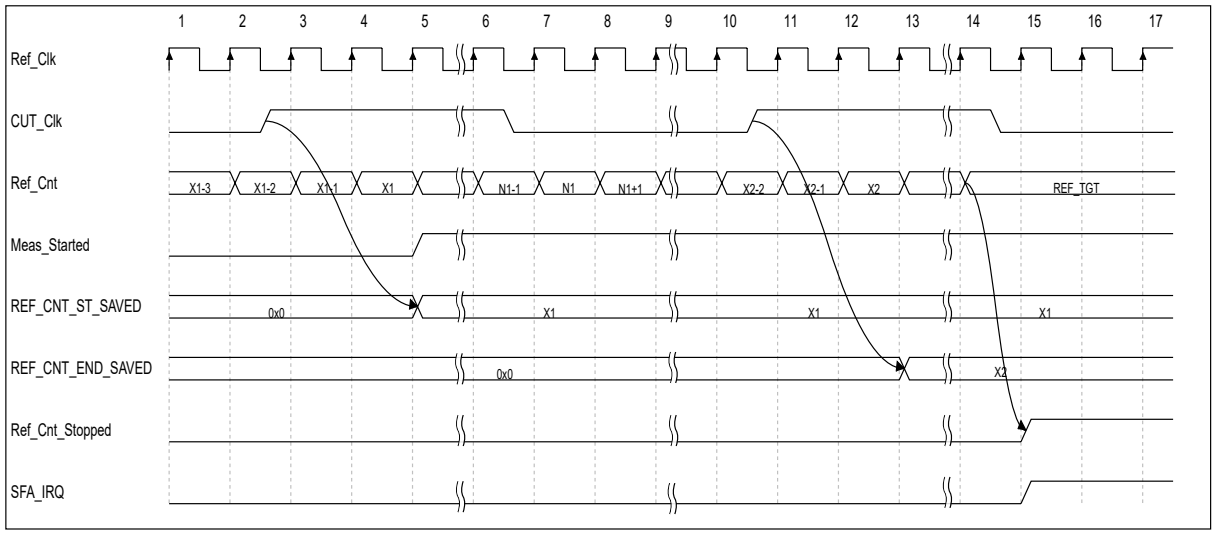

Figure 271. CUT Clk Period Measurement

Figure 272 illustrates what happens when REF_CNT reaches REF_TARGET before the SFA receives a full period of CUT Clk. The result will be an incomplete measurement, and REF_CNT_TIMEOUT will be asserted along with REF_STOPPED.

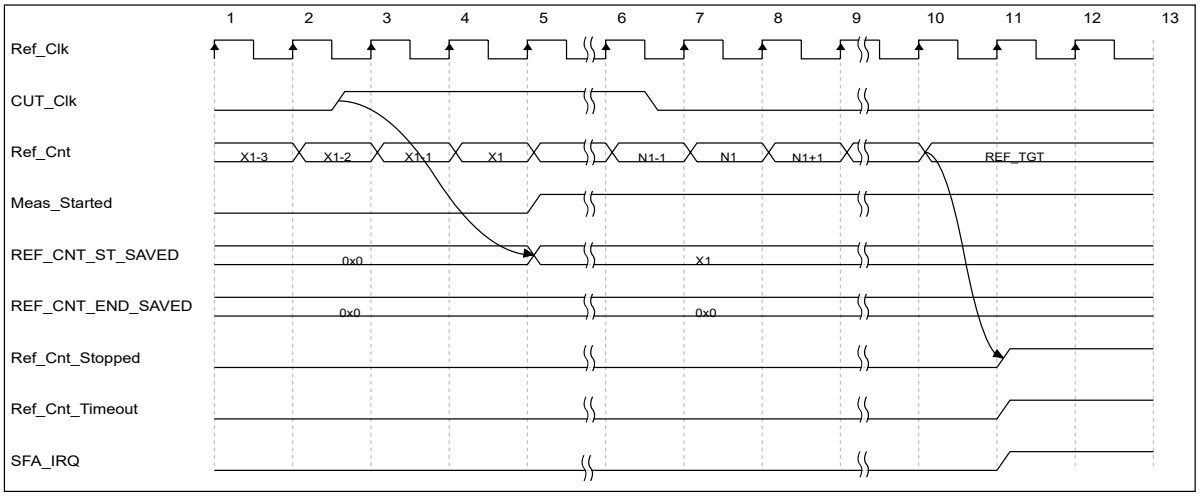

Figure 272. CUT Clk Period Timeout

52.4.4.1.3.3.3 Trigger Based Measurements

Triggered Measurement (CTRL[MODE] == 0x3). This mode is used to measure the time between two signal events. This measurement will count the number of REF clock periods between two triggers. Both the start trigger and end trigger can be selected from a bus interface. To select the start and end triggers, program the CTRL[TRIG_END_SEL] and CTRL[TRIG_START_SEL] fields. In addition, the polarity of each trigger can be selected to begin on rising or falling edge by programming CTRL[TRIG_END_POL] and CTRL[TRIG_START_POL]. It is assumed that the time between edges will be > > REF clock period:

1. Select the signal source which will begin the measurement with CTRL[TRIG_START_SEL].
2. Select a the polarity for TRIG_START_SEL by programming CTRL[TRIG_START_POL]. This will determine if the sequence begins on a rising or falling edge of TRIG_START_SEL.
3. Select both the signal source and edge polarity that will end the measurement, with CTRL[TRIG_END_SEL] and CTRL[TRIG_END_POL].
4. Select a value for REF_TARGET. This value will act as a time-out feature for the current measurement. The measurement will end when REF_CNT = REF_CNT_TARGET.
5. Perform a dummy write to the REF counter. This triggers:
    a. REF counter starts counting immediately
    b. All previous counters will be cleared.
6. The MEAS_STARTED bit will indicate when the selected TRIG_START_SEL edge has been triggered.
7. Upon assertion of MEAS_STARTED, REF_COUNT_ST_SAVED (which is a saved version of the actual REF counter, which keeps running) will be written.
8. The REF_STOPPED bit will indicate when the selected EDGE_COUNT_END edge has been triggered.
9. Upon assertion of REF_STOPPED, REF_CNT_END_SAVED (which is a saved version of the actual REF counter) will be written.
10. Note that REF_STOPPED may be set before the measurement has been completed. This may indicate the REF_TARGET is too low for the required measurement time. In this case, the CNT_STAT[REF_CNT_TIMEOUT] will be set to 0b1 to indicate that either TRIG_END_SEL or TRIG_START_SEL was never received.

11. Calculate the edge to edge time using the difference between the values of REF_COUNT_END_SAVED and REF_CNT_ST_SAVED.
12. To determine when the measurement has been completed, the user can either poll the REF_STOPPED bit or enable SFA_IRQ_EN. If SFA_IRQ_EN is asserted than an interrupt will be issued when REF_STOPPED is asserted.
13. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) greater than the value setting in REG_HIGH_LIMIT_CNT , it means the measured trigger period is greater than maximum limit,if according enable bit is set, the FREQ_LT_MIN_IRQ will be generated
14. If the value (REF_COUNT_END_SAVED-REF_COUNT_ST_SAVED) less than the value setting in REG_LOW_LIMIT_CNT , it means the measured trigger period is less than minimum limit, if according enable bit is set, the FREQ_GT_MAX_IRQ will be generated

The following two waveforms illustrate two possible cases for trigger based measurements. Note that it is assumed that the user completed the above steps 1 through 5 before these waveforms begin. In addition, it is assumed that SFA_IRQ_EN is asserted. The first waveform shows a completed trigger based measurement. The second waveform illustrates a ref counter timeout when attempting to complete a trigger based measurement. Notice the assertion of Ref_Cnt_Timeout upon completing the measurement cycle.

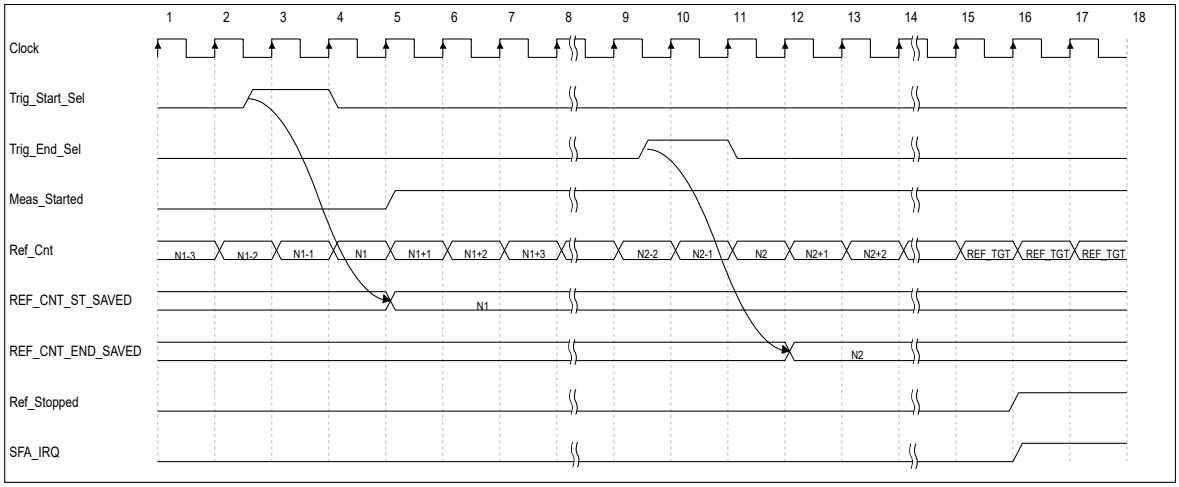

Figure 273. Trigger Based Measurement

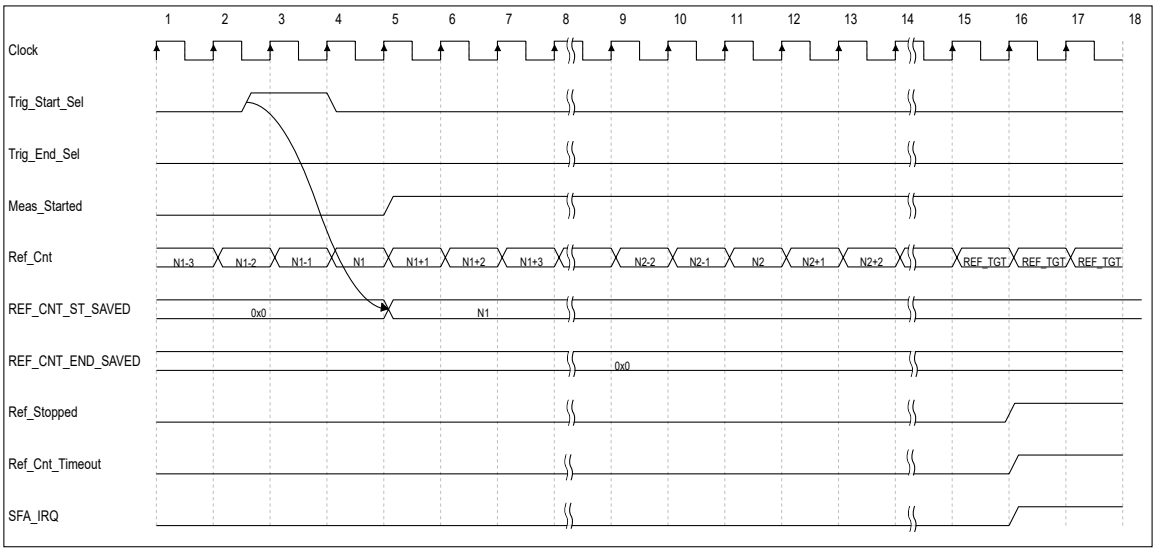

Figure 274. Trigger Based Measurement Timeout

52.4.4.1.3.3.4 Clocking

The SFA has several clock sources, for internal behaviour, register access, and for frequency measurement. Their role during the frequency measurement is covered in the Functional Description chapter. They are listed in the table below:

Table 450. SFA Clocks

Input	Description
ipg_clk	IPS System Bus Clock
ipg_clk_s	IPS System Bus Clock for pmodel
ipt_clk	High Speed TestClock
sfa_clk_inputs	Clocks under Test
sfa_ref_clk_inputs	Clocks for Reference Clock choices

52.4.4.1.3.3.5 Interrupts

This module has single interrupt: ipi_init. This interrupt is asserted when:

- CNT_STAT[4] is set and CTRL [5] is enabled
- CNT_STAT[5] is set and CTRL2[16] is enabled
- CNT_STAT[6] is set and CTRL2[17] is enabled

52.4.4.1.3.4.1.2 Signal Frequency Analyser (SFA) Control (CTRL)

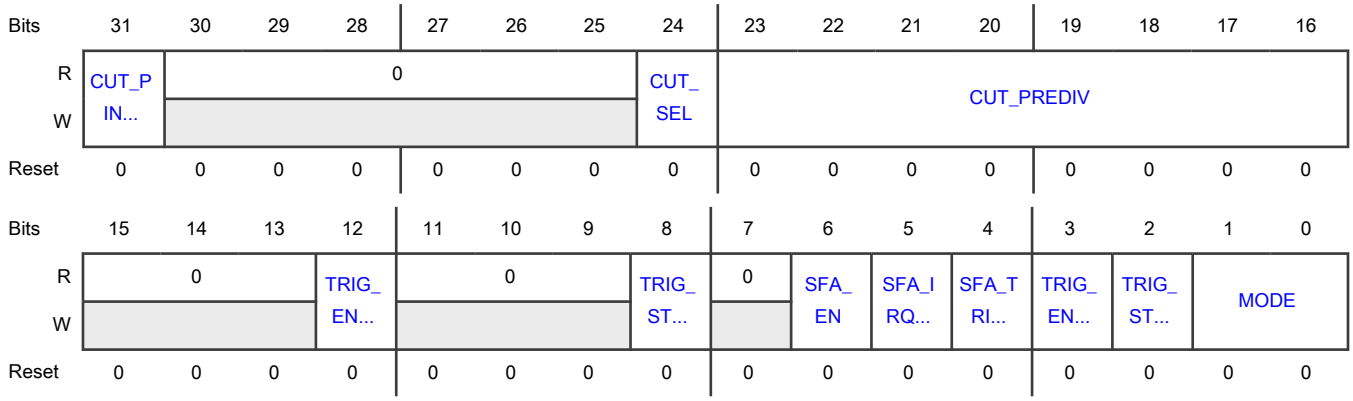
Offset

Register	Offset
CTRL	0h

Function

The SFA Control register contains fields to select both the type of measurement and the signal sources to be measured. The measurement mode will determine whether the SFA performs a frequency, period, or trigger based measurement.

Diagram



Fields

Field	Function
31 CUT_PIN_EN	CUT_PIN_EN This register field controls the connection of the clock under test to an external pin.
30-25 —	Reserved
24 CUT_SEL	CUT_SEL These bits control which SoC clock is connected to the clock under test counter.
23-16 CUT_PREDIV	CUT_PREDIV The CUT_PREDIV 8-bit field provides an integer division of the input CUT signal prior to the CUT counter. Only integer values are implemented and the least significant bit is ignored. 0000_0000b - No Divide 0000_0001b - No Divide 0000_0010b - Divide by 2 0000_0011b - Divide by 2 0000_0100b - Divide by 4 0000_0101b - Divide by 4 0000_0110b - Divide by 6 0000_0111b - Divide by 6 0000_1000b - Divide by 8 0000_1001b - Divide by 8 0000_1010b-1111_1101b - Divide by CUT_PREDIV - CUT_PREDIV%2 1111_1110b - Divide by 254 1111_1111b - Divide by 254

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-13 —	Reserved
12 TRIG_END_SEL	Signal MUX For Trigger Based Measurement End This bit selects which signal will be used to commence a trigger based measurement. An edge of this signal will act as a trigger to end the measurement sequence. Either rising edge or falling edge can be selected by programming TRIG_END_POL.
11-9 —	Reserved
8 TRIG_START_SEL	Signal MUX For Trigger Based Measurement Start This bit selects which signal will be used to start an edge to edge measurement. An edge of this signal will act as a trigger to begin the measurement sequence. Either rising edge or falling edge can be selected by programming EDGE_START_POL.
7 —	Reserved
6 SFA_EN	SFA Enable This bit is the general SFA Enable signal. To run any measurement, this signal must be set to 0b1. This signal must be set to 0b0 when modifying any clock inputs, clock divider values, or trigger selects. For example, prior to writing TRIG_END_POL, TRIG_START_POL, TRIG_START_SEL, TRIG_END_SEL, CUT_PREDIV, or CUT_SEL make sure that this bit is set to 0b0. 0b - The SFA is disabled. 1b - The SFA is enabled.
5 SFA_IRQ_EN	SFA Interrupt Enable This signal determines if interrupts are enabled for the SFA. When enabled, an interrupt will be issued upon completion of a measurement. 0b - Interrupts are disabled. 1b - Interrupts are enabled.
4 SFA_TRIG_MEAS_EN	SFA Triggered Measurement Enable The SFA can be triggered to start a new frequency measurement when operating with either MODE = 0x0 or MODE = 0x1. This register field will be inactive if MODE > 0x1. The start trigger will be selected with TRIG_START_SEL and the measurement will begin when the first edge is received with polarity TRIG_START_POL. Note, SFA_EN bit must be set prior to beginning any measurements. The startup process requires a dummy write to the REF_CNT register to enable trigger detection followed by a trigger from the selected source. Refer to section Frequency Measurements for more information. 0b - The measurement will start by default with a dummy write to the REF and CUT counters. 1b - The measurement will start after receiving a dummy write to the REF_CNT followed by receiving the trigger edge selected by TRIG_START_SEL and TRIG_START_POL.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 TRIG_END_POL	Trigger End Polarity This signal determines the polarity of the trigger signal which will end a trigger based measurement. 0b - Rising edge of TRIGER[TRIG_END_SEL] will end the measurement sequence. 1b - Falling edge of TRIGGER[TRIG_END_SEL] will end the measurement sequence.
2 TRIG_START_POL	Trigger Start Polarity This signal determines the polarity of the start signal when measuring in trigger mode. 0b - Rising edge of TRIGGER[TRIG_START_SEL] will begin the measurement sequence. 1b - Falling edge of TRIGGER[TRIG_START_SEL] will begin the measurement sequence.
1-0 MODE	MEASUREMENT MODE Measurement mode determines which type of timing measurement is performed. 00b - Frequency measurement performed with REF frequency > CUT Frequency. 01b - Frequency measurement performed with REF frequency < CUT Frequency. 10b - CUT period measurement performed. 11b - Trigger based measurement performed. Note, each trigger pulse must be held for at least 2 ref_clk cycles.

52.4.4.1.3.4.1.3 Signal Frequency Analyser Count Status Register (CNT_STAT)

Offset

Register	Offset
CNT_STAT	8h

Function

This register returns status flags to indicate the current state of the REF and CUT counters

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0									FREQ_LT...	FREQ_GT...	SFA_IRQ	REF_CNT...	MEAS_ST...	CUT_STO...	REF_STO...
W										W1C	W1C	W1C				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-7 —	Reserved
6 FREQ_LT_MIN_IRQ	FREQ_LT_MIN interrupt flag FREQ_LT_MIN interrupt flag, it means the cut clk frequency is lower than minimum setting,or trigger measurement period is greater than maximum setting
5 FREQ_GT_MAX_IRQ	FREQ_GT_MAX interrupt flag FREQ_GT_MAX interrupt flag, it means the cut clk frequency is greater than maximum setting,or trigger measurement period is less than minimum setting
4 SFA_IRQ	SFA Interrupt Request This flag indicates that REF_CNT has reached REF_TARGET. More generally, this flag indicates that a measurement has been completed and an interrupt has been issued. Writing a 0x1 to this bit position will clear the interrupt request.
3 REF_CNT_TIMEOUT	Reference Counter Time Out This flag indicates the REF counter reached REF_TARGET before the desired measurement was completed. Every test will commence when REF_CNT == REF_TARGET. For measurement accuracy, this bit should be equal to 0b0 when REF_STOPPED == 0b1. This bit will be cleared on any write to REF_CNT when not performing a measurement.
2 MEAS_STARTED	Measurement Started Flag In frequency measurement mode, this flag indicates when the CUT counter has started counting. Set when CUT counter increments to 1. In period measurement mode, this flag indicates that the first edge of the CUT has been received for period measurement. In edge to edge signal measurement mode, this flag will indicate when TRIGGER[TRIG_START_SEL] has been received for measurement. This event will also push the REF_CNT to the REF_CNT_ST_SAVED register. This flag is only active during CTRL[MODE] == 0x0, 0x2 or 0x3. Cleared on any write to REF_CNT when not performing a measurement.
1 CUT_STOPPED	CUT_STOPPED This flag indicates the CUT counter has stopped counting. Set when either REF or CUT counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement.
0 REF_STOPPED	REF_STOPPED This flag indicates the REF counter has stopped counting. Set when REF counter has reached its target. Cleared on any write to REF_CNT when not performing a measurement. This bit can be polled to indicate when a measurement is complete.

52.4.4.1.3.4.1.4 Signal Frequency Analyser Clock Under Test Counter (CUT_CNT)

Offset

Register	Offset
CUT_CNT	Ch

Function

This register contains the current count of the clock under test. Writes to this register will start the clock under test and reference counters. Counting will stop when either the count matches the contents of the clock under test target count register or when reference counter matches the reference target count register. Note, attempts to read this register before the CUT_STOPPED flag has set will return 0x0000_0000

Diagram

52.4.4.1.4 Basic Radio Integrated Crypto (BRIC)

52.4.4.1.4.1 BRIC

52.4.4.1.4.1.1 Overview

The Basic Radio Integrated Crypto (BRIC) module is a wrapper, with control logic around the Low Tier Crypto (LTC) block and PKB (Private Key Bus) Slave that interfaces with EdgeLock Secure Enclave. This module provides the legacy interface (IPS + DMA) to the LTC module, contains additional logic to enable direct hardware interfacing for simple AES functions and a PKB interface with the EdgeLock Secure Enclave to receive KEYS securely over the PKB interface. Essentially, the logic takes control of the IPS interface so that another HW entity can easily interface.

The BRIC module allows for legacy behavior of the LTC. The IPS bus and relevant DMA signals are brought out to be used by the system. When in isolated mode, the control of these signals comes from the internal logic using a dedicated hardware interface. For example, RPA checking can be performed by a direct hardware connection as opposed to using a bus master to interface with the LTC.

52.4.4.1.4.1.1.1 Block Diagram

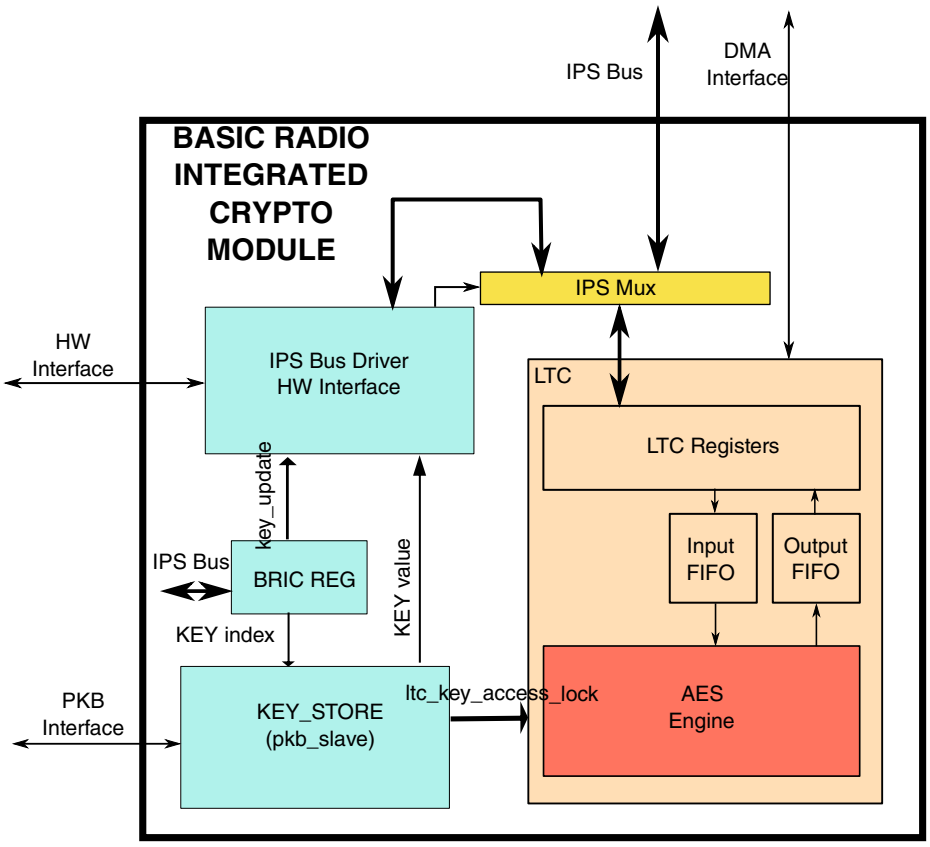

Figure 275. BRIC Block Diagram

52.4.4.1.4.1.1.2 Features

- Supports all LTC functions (See LTC block guide)
- IPS and DMA interface for use by the system as needed
- Dedicated HW interface that overrides the IPS interface
- HW interface simplified for easy integration
- PKB Slave that interfaces directly with EdgeLock Secure Enclave for secure KEY Transfer
- No RAM footprint

52.4.4.1.4.1.2 Functional Description

The BRIC module provides following functionalities:

- Legacy LTC mode
- Hardware Interface mode
- Secure key transfer

52.4.4.1.4.1.2.1 Legacy LTC mode

If the HW interface mode is not selected. The BRIC module simply passes through the IPS and DMA signals. Is this configuration the core, or any bus master for that matter, can access the LTC in the traditional manner and use its capabilities as described in the LTC block guide.

52.4.4.1.4.1.2.2 Hardware interface mode

If the HW interface is selected, the BRIC module will take over control of the LTC.

The first part of this is to check that no process is pending by checking the AB bit in LTC_STA. If this bit is clear, the IPS module enable is then checked to confirm that no accesses are in progress on the IPS bus. When the module enable is low, the xfr_wait will be asserted until the HW interface is disabled. This will effectively block any bus master from accessing the LTC until the HW interface has completed its activity. **NOTE: There is a possibility that SW could be interrupted while configuring the LTC. The BRIC module will not maintain such configuration and SW should take care to resolve this situation if it happens by re-configuring.**

In addition to blocking the system IPS bus, the DMA signals will also be blocked to avoid any spurious requests during HW interface operation. This completes the interface isolation and hi_ready will be asserted. Once the external interfaces have been isolated as per above, the HW interface will begin operation according to the following sequence (HWM indicates HW master below):

1. HWM waits for hi_ready = 0
2. HWM asserts lock_bric for continuous BRIC access for multiple key resolution
3. HWM sets key_in[127:0] and prand[23:0] to desired values
4. HWM asserts hi_mode
5. BRIC uses key_in[127:0] and prand[23:0] to configure and execute ah(key_in,prand) using the LTC as per the Bluetooth Low Energy privacy specification.
6. BRIC sets resultant hash value on hash[23:0] when the LTC is complete, then asserts hash_comp.
7. HWM waits until hash_comp is asserted
8. HWM captures the hash
9. HWM repeats steps **3-8** as needed
10. HWM de-asserts lock_bric

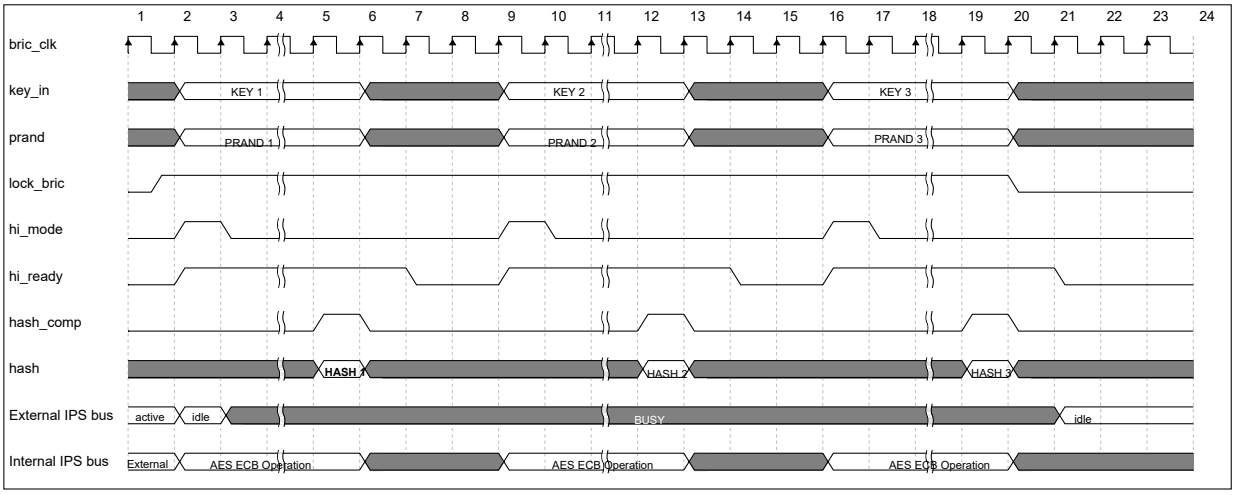

Figure 276. Multiple RPA hash generation

52.4.4.1.4.1.2.3 Software Access during HW mode

To avoid any unexpected results due to software access through IPS bus during HW mode the following response methods are implemented.

IPS_XFR_WAIT is asserted through out the HW mode to inform that SW that BRIC is busy. Hence any SW access will have to wait till the HW access is over.

IPS_XFR_ERR is asserted whenever there is a SW access during ongoing HW mode. This is to avoid SW waiting for longer time till the end of HW operation.

Both the above signal behavior can be controlled individually through register bits in BRIC_CONFIG register.

A few SW-HW access scenarios are listed in below timing diagrams.

1. HW request is asserted while SW access is ongoing - HW waits for SW access to be over
2. SW access start and HW request at the same clock - HW waits for SW access to be over
3. SW access during HW mode - respond with WAIT/ERROR/WAIT & ERROR based on the configuration

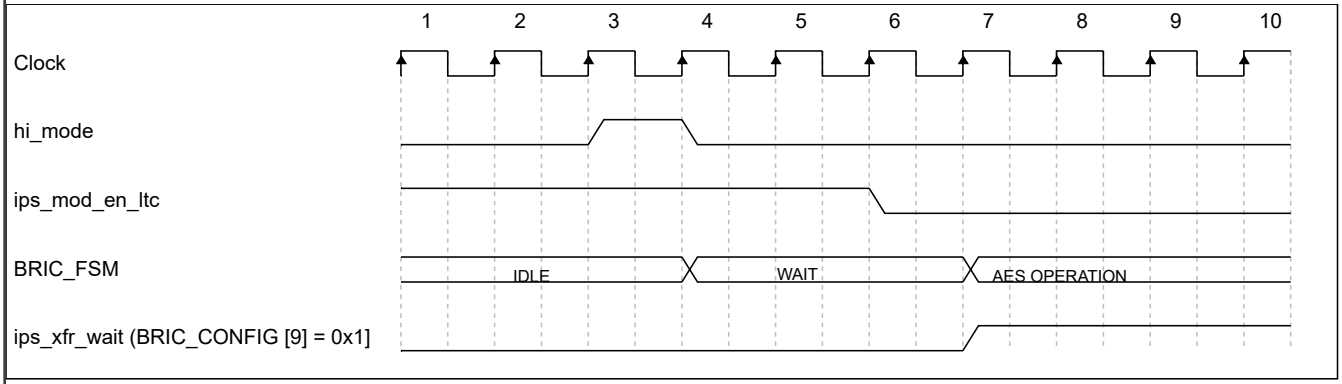

Figure 277. HW request asserted during SW access

Figure 278. SW access and HW request at same clock

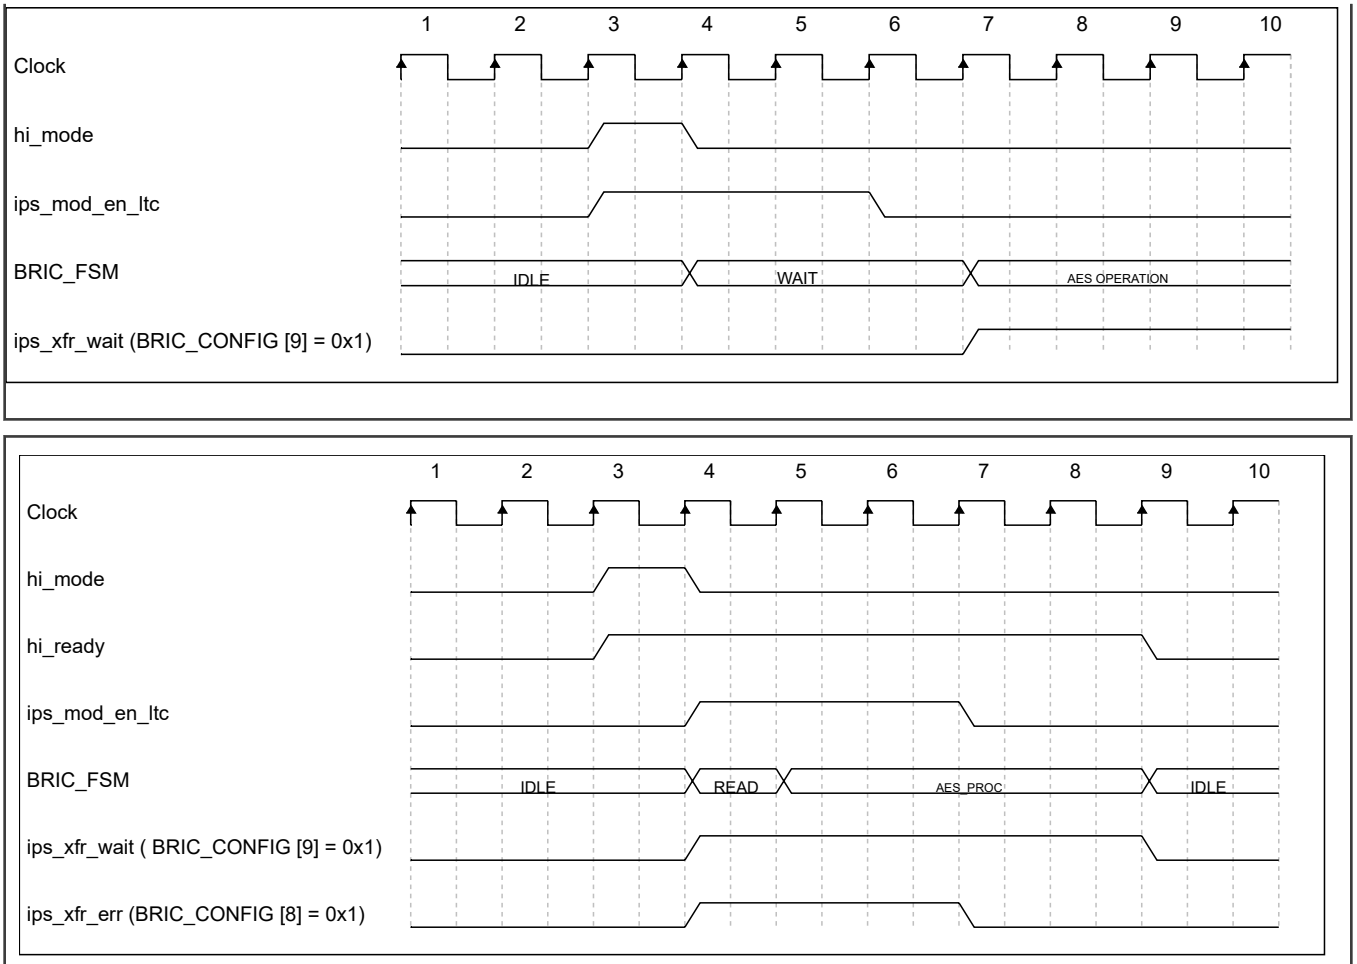

Figure 279. SW access during HW mode

52.4.4.1.4.1.2.4 Secure KEY transfer

The PKB master (EdgeLock Secure Enclave) can write the KEY securely over a PKB interface to any of the two KEY registers present in the BRIC. Any one of these KEYs (transferred over PKB interface) can be selectively transferred to the LTC by writing the index 0/1 to the KEY_INDEX_REGISTER.

The BRIC key_store module can accept and store two 128 bit keys from security module over the secure PKB interface. The written KEYs are no more readable from BRIC.

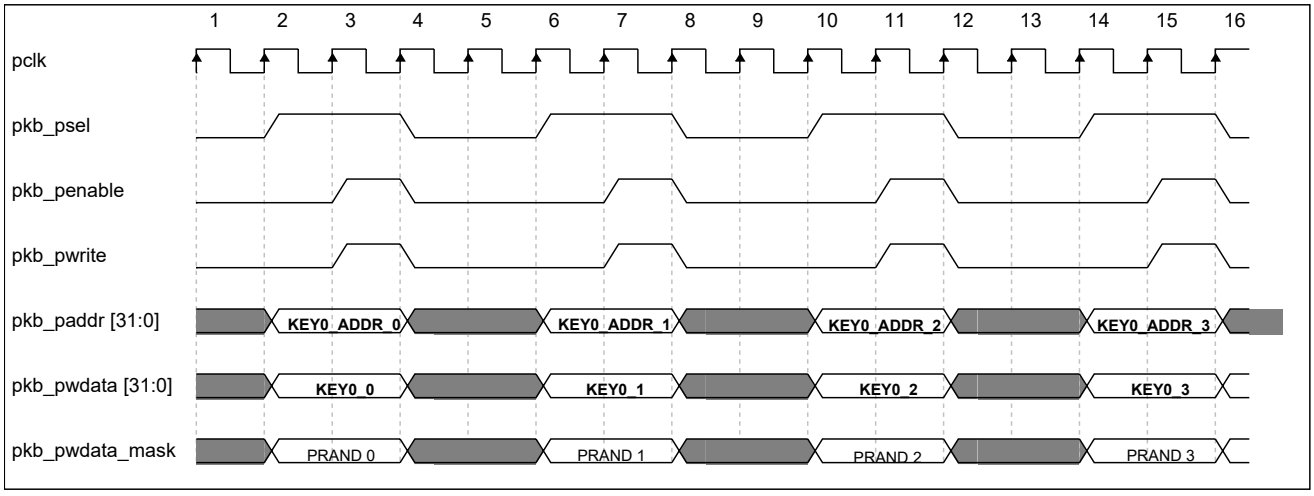

Figure 280. KEY write through PKB

Once KEYs are written by the security IP t to the BRIC the processor can initiate a KEY transfer by writing a valid value to the BRIC KEY_INDEX register. The below transactions indicate the steps involved in transferring a KEY from PKB master (security IP) to LTC module.

1. Write KEY value to BRIC key_store module through PKB interface securely. PKB bus is write only.
2. To transfer the KEY from BRIC key_store to LTC update the KEY_INDEX register with intended value
3. KEY_INDEX register update triggers KEY value write to LTC through the HW IPS interface

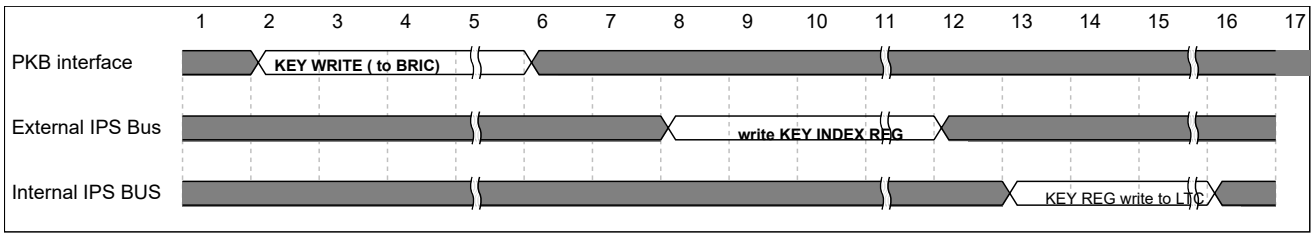

Figure 281. PKB KEY transfer to LTC

52.4.4.1.4.1.2.5 LTC KEY read access

LTC legacy module has a provision to disable the KEY read access by asserting the input signal "ltc_key_access_lock". In the BRIC this input signal has to be tied to "high" (KEY read is locked/disabled) always. To ensure a read path for the LTC KEY for special requirements like debug a different method is implemented and available for the debug software. This is by writing a key value of all 1's to KEY0 REGISTER or KEY1 REGISTER in the BRIC key store through the PKB interface. The KEY register in LTC will be readable as long as the value is retained in any of the KEYx Registers.

52.4.4.1.4.1.2.6 Clocking

The BRIC has two clock sources, for internal logic, register access and peripheral PKB interface. They are listed in the table below:

Table 451. BRIC Clocks

Input	Description
ipg_clk	IPS System Bus Clock - for internal logic and register access
pclk	Peripheral Clock - to access PKB Interface

52.4.4.1.4.1.2.7 Interrupts

The LTC interrupt is passed through to the BRIC output in all modes of operation except HW interface mode.

During HW interface mode the LTC module generates a done_interrupt once encryption is complete. BRIC state machine clears this interrupt internally and hence this interrupt is masked from the output during HW interface mode.

52.4.4.1.4.1.3 Initialization

There is no particular sequence to initialize the BRIC.

52.4.4.1.4.1.4 External Signal Descriptions

Signal	Width	I/O	Function
ipg_clk	1	I	IP Bus Clock, Free-running
ipg_hard_async_reset_b	1	I	asynchronous HW reset
ipt_se_gatedclk	1	I	Scan enable for gated clocks
ipg_soft_reset	1	I	synchrounous soft reset
ipg_stop	1	I	IPG stop mode
ipg_sop_ack	1	O	IPG stop acknowledge
bric_busy	1	O	BRIC/LTC busy
IPS Bus Interface			
ips_module_en	1	I	IPS module enable
ips_rwb	1	I	IPS read/write
ips_addr [15:0]	16	I	IPS address
ips_wdata [31:0]	32	I	IPS write data
ips_byte_en [3:0]	4	I	IPS byte enable
ips_rdata [31:0]	32	O	IPS read data
ips_xfr_wait	1	O	IPS transfer wait
ips_xfr_err	1	O	IPS transfer error
DMA/Interrupt			
ipd_done_idata	1	I	IPD done in data
ipd_done_odata	1	I	IPD done out data
ipd_req_idata	1	O	IPD request in data
ipd_req_odata	1	O	IPD request out data
ipi_bric_int	1	O	Interrupt
Direct HW Interface			
key_in [127:0]	128	I	Key input
prand [23:0]	24	I	PRAND input for creating hash
hash [23:0]	24	O	Hash output from AES

Table continues on the next page...

Table continued from the previous page...

Signal	Width	I/O	Function
lock_bric	1	I	Lock LTC IPS interface for direct Hardware access (Multiple RPA resolution) • **0 :** Legacy IP interface can be used to access LTC • **1 :** Legacy IPS bus disabled, direct HW Interface is active
hi_mode	1	I	Request hash operation (high pulse of one clock cycle) through Hardware interface. key_in and prand inputs has to be valid at the time of assertion hi_mode. hi_ready will be 1 while a hash operation is performed. • **0 :** Legacy IPS interface is available, HW Interface is not • **1 :** IPS bus disabled, direct HW Interface to be used
hi_ready	1	O	HW interface ready • **0 :** HW Interface ready to accept command, safe to change hi_mode • **1 :** HW Interface busy, no inputs should be changed
hash_req	1	I	Not used
hash_comp	1	O	Hash operation complete. Asserts for one clock cycle when 'hash' is valid and can be read.
Private Key Bus (PKB) Interface			
pkb_psel	1	I	PKB APB select
pkb_penable	1	I	PKB APB Enable
pkb_paddr	32	I	PKB APB address
pkb_pwrite	1	I	PKB APB write enable (1= write, read not supported)
pkb_pwdata	32	I	PKB APB write data
pkb_pwdata_mask	32	I	PKB APB write data mask
pkb_pready	1	O	PKB APB ready
pkb_pslverr	1	O	PKB APB slave error

52.4.4.1.4.1.5 Memory Map and register definition

The BRIC memory map and register description is included in the following section.

52.4.4.1.4.1.5.1 BRIC register descriptions

52.4.4.1.4.1.5.1.1 BRIC Base Address memory map

RADIO.BRIC base address: 48A0_6700h

Offset	Register	Width (In bits)	Access	Reset value
0h - Ch	KEY0 Registers (PKB) (KEY0_0 - KEY0_3)	32	W	0000_0000h
10h - 1Ch	KEY1 Registers (PKB) (KEY1_0 - KEY1_3)	32	W	0000_0000h
20h	BRIC CONFIG register (BRIC_CONFIG)	32	RW	0000_0200h

52.4.4.1.4.1.5.1.2 KEY0 Registers (PKB) (KEY0_0 - KEY0_3)

Offset

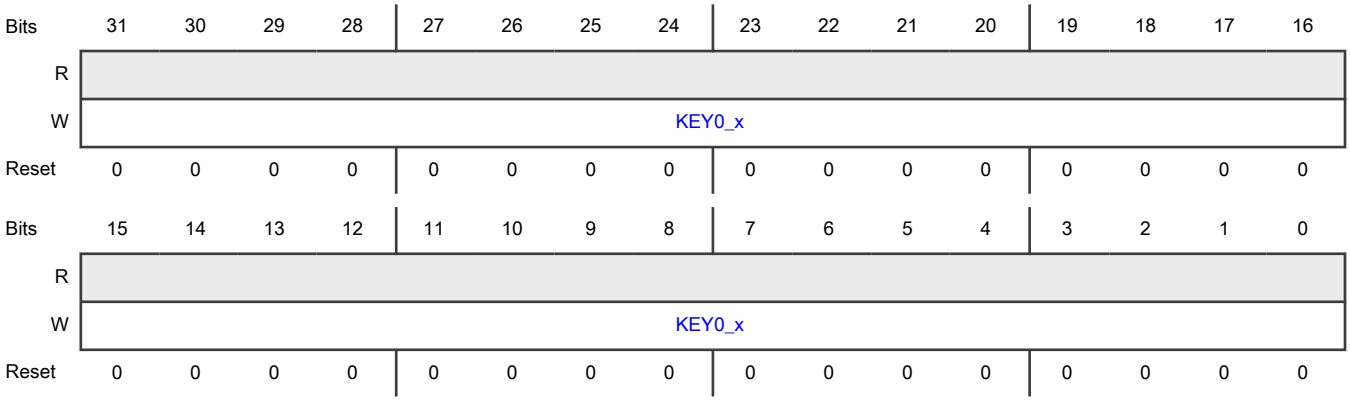
Register	Offset
KEY0_0	0h
KEY0_1	4h
KEY0_2	8h
KEY0_3	Ch

Function

The KEY0 Register normally holds the left-aligned key for the internal crypto engine written by the EdgeLock Secure Enclave. The MSB "KEY0_3" is in offset 0Ch. The Key is 128 bits in length and is written as four PKB masked write access.

The value in the Key0 Register can be transferred to the crypto engine by writing the KEY_INDEX_CONFIG register with value 00h.

Diagram



Fields

Field	Function

52.4.4.1.4.1.5.1.3 KEY1 Registers (PKB) (KEY1_0 - KEY1_3)

Offset

Register	Offset
KEY1_0	10h
KEY1_1	14h
KEY1_2	18h
KEY1_3	1Ch

Function

The KEY1 Register normally holds the left-aligned key for the internal crypto engine written by the EdgeLock Secure Enclave. The MSB "KEY1_3" is in offset 1Ch. The Key is 128 bits in length and is written as four PKB masked write access.

The value in the "KEY1" Register can be transferred to the crypto engine by writing the KEY_INDEX register with value 01h.

Diagram

52.4.4.1.4.1.5.1.4 BRIC CONFIG register (BRIC_CONFIG)

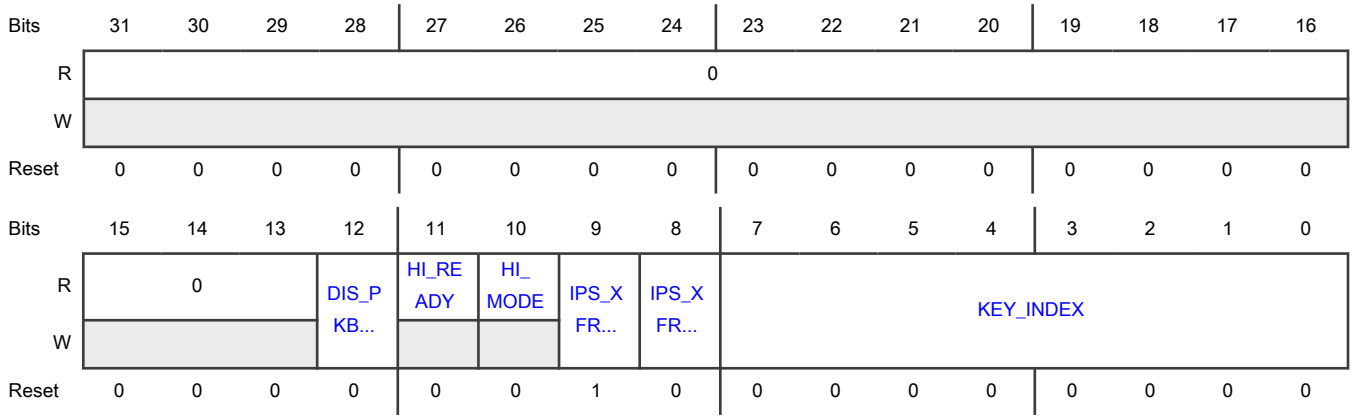
Offset

Register	Offset
BRIC_CONFIG	20h

Function

Configuration and Status register in BRIC

Diagram



Fields

Field	Function
31-13 —	This bit is reserved and should not be set.
12 DIS_PKB_ERR_RESP	Disable (0x1) PKB error response (Error response will be forced to zero)
11 HI_READY	Indicates HW mode is in progress and any SW access during this time is responded with an IPS_ERROR or IPS_WAIT depending on the configuration
10 HI_MODE	Indicates HW mode request to BRIC is active. BRIC may be in HW mode or waiting for a SW access to be over to start the HW mode when this bit is 0x1
9 IPS_XFR_WAIT_EN	Enable (0x1) ips_xfr_wait generation on IPS access during HW mode
8 IPS_XFR_ERR_EN	Enable (0x1) ips_xfr_err generation on IPS access during HW mode
7-0 KEY_INDEX	KEY INDEX KEY INDEX value for selecting the KEY from the PKB slave key array to be transferred to LTC. Writing this field with a valid value (0x0 or 0x1) triggers the KEY transfer from the PKB Slave KEY array to the LTC. To initiate KEY transfer to LTC a write has to be done to this register even if there is no change in KEY value

52.4.4.1.4.2 LTC

52.4.4.1.4.2.1 LP Trusted Cryptography Block Diagram

LP Trusted Cryptography is an architecture that allows multiple cryptographic hardware accelerator engines to be instantiated and share common registers. This version of LTC only supports AES. The following figure presents a top-level diagram of the LP Trusted Cryptography module with an AES engine.

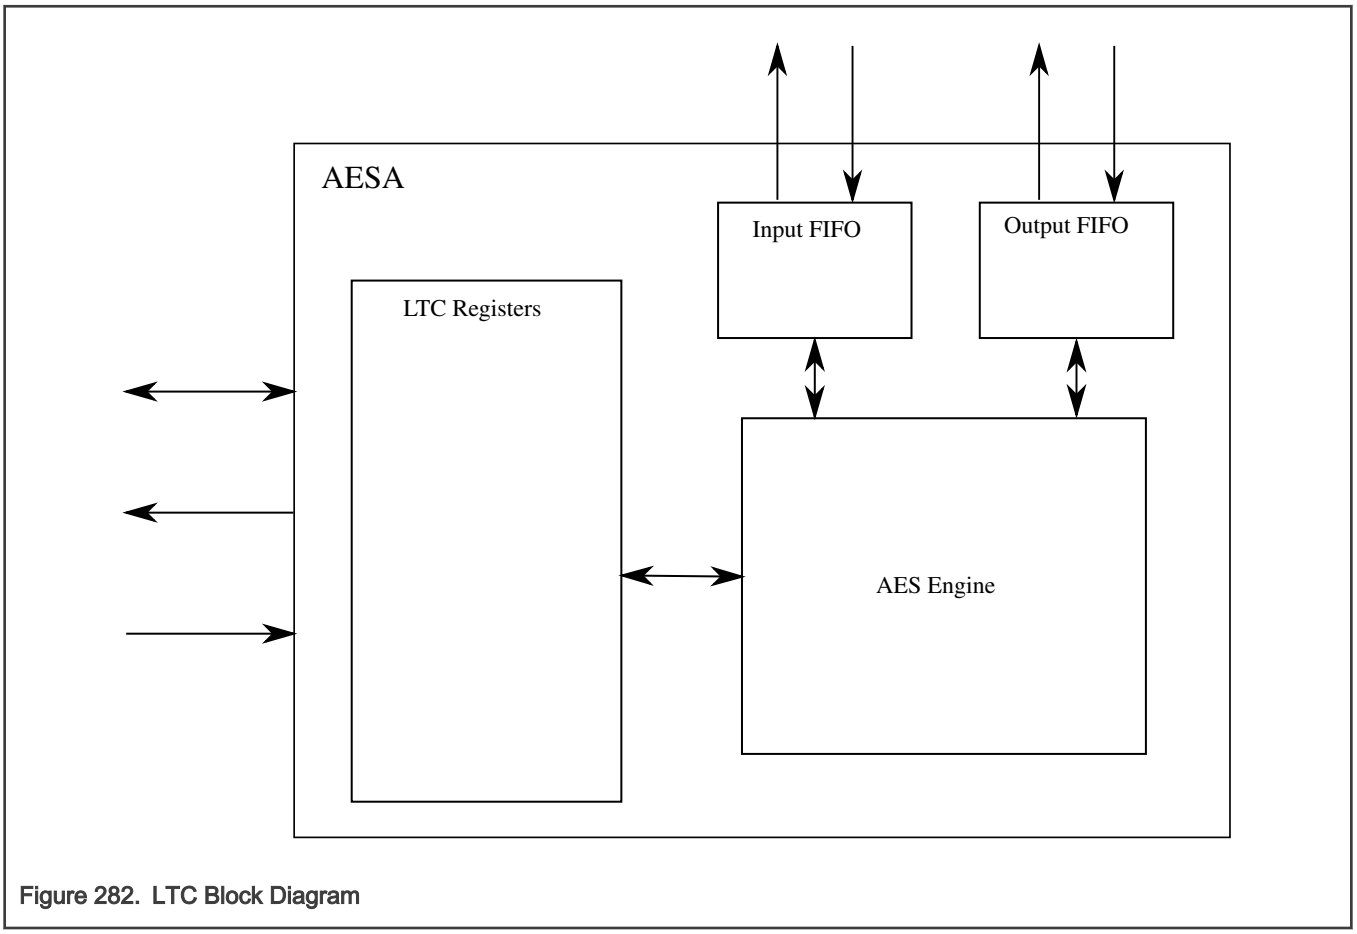


Figure 282. LTC Block Diagram

52.4.4.1.4.2.2 Feature summary

LTC includes the following:

- Cryptographic authentication
  - Message authentication codes (MAC)
    - AES-CMAC
    - AES-XCBC-MAC
  - ICV checking
- Authenticated encryption algorithms
  - AES-CCM (counter with CBC-MAC)
- Symmetric key block ciphers
  - AES (128-bit keys)
  - Cipher modes
    - ECB, CBC, CTR, OFB, CFB128 for AES

52.4.4.1.4.2.3 functionality

52.4.4.1.4.2.3.1 Differences between the AES encrypt and decrypt keys

The decrypt form of the key is different from the encrypt form of the key, because AES successively modifies the cryptographic key during the steps of the cryptographic operation. The decryption operation yields the correct result only if the modified form of the key (the decrypt key) is used at the beginning of the decryption operation. Unless told otherwise (via the DK bit in the Mode Register), AES assumes that a key loaded from memory is the encrypt key, that is, the form appropriate for encryption. If a decryption operation is specified and DK = 0, AES first goes through the steps required to derive the decrypt key from the encrypt key, and then performs the decryption operation. If a decryption operation is specified and DK = 1, the steps required to derive the decrypt key are skipped and the decryption operation is performed immediately, significantly improving performance for small data blocks.

Note that the difference between the encrypt key and the decrypt key must be taken into account when sharing keys between jobs. When an AES decryption job loads a key from memory, it is probably an encrypt key, so the DK bit in the Mode Register should be set to 0 so that AES derives the decrypt key from the encrypt key before beginning the decryption operation. But when a subsequent AES decryption job shares the key from a previous decryption job, the key that is shared is a decrypt key. In that case, the DK bit should be set to 1, which tells AES to skip the key derivation steps. If DK were set to 0 in this case, the decrypt key would be modified as if it were an encrypt key, and consequently, the wrong key value would be used in the decryption operation.

52.4.4.1.4.2.3.2 AESA modes of operation

The following modes are supported by AESA:

- Electronic codebook (ECB)
- Cipher block chaining (CBC)
- Output feedback (OFB)
- 128-bit cipher feedback (CFB128)
- Counter (CTR)
- Extended cipher block chaining message authentication code (XCBC-MAC)
- Cipher-based MAC (CMAC)
- CTR and CBC-MAC (CCM)

AES modes can be classified into these categories:

- Confidentiality (ECB, CBC, CTR, OFB, CFB128)
- Authenticated Confidentiality (CCM)
- Authentication (XCBC-MAC, CMAC)

CBC mode can also be viewed as an authentication mode when used to encrypt data, because it provides CBC-MAC in the context registers.

52.4.4.1.4.2.3.3 AESA use of registers

Note the following regarding the AESA's use of registers:

- For all modes, if AESA is selected and the mode code written to the Mode Register does not correspond to any of the implemented AES modes, the illegal-mode error is generated.
- If ICV-only jobs are created (no data or no additional data to be processed, only ICV to be checked) in modes that support ICV check, the ICV_TEST mode bit should be set, and the AS mode field should be programmed to Update.

52.4.4.1.4.2.3.4 AES ECB mode

The electronic codebook (ECB) mode is a confidentiality mode that features, for a given key, the assignment of a fixed, ciphertext block to each plaintext block, analogous to the assignment of code words in a codebook. In ECB encryption, the forward cipher

function is applied directly and independently to each block of the plaintext. The resulting sequence of output blocks is the ciphertext. In ECB decryption, the inverse cipher function is applied directly and independently to each block of the ciphertext. The resulting sequence of output blocks is the plaintext.

52.4.4.1.4.2.3.4.1 AES ECB mode use of the Mode Register

AES ECB mode uses the Mode Register as follows:

- The Encrypt (ENC) field should be 1 for ECB encryption and 0 for ECB decryption.
- The Algorithm State (AS) field is not used in ECB mode.
- The Additional Algorithm Information (AAI) field must be set with value 20h that activates ECB mode. Setting the MSB in the AAI field (interpreted as the Decrypt Key or DK bit for AES operations) specifies that the key loaded to the Key Register is the decryption form of the key, rather than the encryption form of the key. If DK = 0, when a decryption operation is requested LTC processes the content of the Key Register to yield the decryption form of the key. If DK = 1, LTC skips this processing. The illegal-mode error is generated if DK = 1 and ENC=1.
- The Algorithm (ALG) field is used to activate AES by setting it to 10h .

52.4.4.1.4.2.3.4.2 AES ECB mode use of the Context Register

The AES ECB mode does not use Context Registers.

52.4.4.1.4.2.3.4.3 AES ECB Mode use of the Data Size Register

The length of the message to be processed in bytes must be written to the Data Size register. If this value is not divisible by 16, the Data Size error is generated.

52.4.4.1.4.2.3.4.4 AES ECB Mode use of the Key Register

ECB keys must be written to the Key Register and can have 16 bytes.

52.4.4.1.4.2.3.4.5 AES ECB Mode use of the Key Size Register

The number of bytes in the ECB key must be written to the Key Size register by the time that MODE and DATA SIZE have been written.

52.4.4.1.4.2.3.5 AES CBC, OFB, CFB128 modes

The CBC, OFB, CFB128 modes are considered together because of their similarities and are described in this table.

Table 452. AES CBC, OFB, CFB128 modes

Name	Abbreviation	Function
Cipher-Block Chaining mode	CBC	Confidentiality mode whose encryption process features the combining ("chaining") of the plaintext blocks with the previous ciphertext blocks. The CBC mode requires an IV (Initialization Vector) to combine with the first plaintext block **NOTE** CBC mode uses both forward and inverse AES cipher. OFB and CFB use only forward AES cipher.
Cipher FeedBack mode (128-bit)	CFB128	Confidentiality mode that features the feedback of successive ciphertext segments into the input blocks of the forward cipher to generate output blocks that are exclusive-ORed with the plaintext to produce the ciphertext,

Table continues on the next page...

Table 452. AES CBC, OFB, CFB128 modes (continued)

Name	Abbreviation	Function
		and vice versa. The CFB mode requires an IV as the initial input block. AESA implements 128-bit CFB mode where every ciphertext/plaintext block must have 128 bits.
Output FeedBack mode	OFB	Confidentiality mode that features the iteration of the forward cipher on an IV to generate a sequence of output blocks that are exclusive-ORed with the plaintext to produce the ciphertext, and vice versa. The OFB mode requires IV. The last block of OFB input data can have fewer than 16 bytes.

52.4.4.1.4.2.3.5.1 AES CBC, OFB, and CFB128 modes use of the Mode Register

The AES CBC, OFB, and CFB128 modes use the Mode Register as follows:

- The Encrypt (ENC) field should be 1 for encryption and 0 for decryption, except for OFB mode in which this bit is not used.
- The ICV/TEST bit is not used in these modes.
- The Algorithm State (AS) field is used only in CBC mode to prevent IV update in the context for the last data block when set to "Finalize" (2h).
- The Additional Algorithm Information (AAI) field defines which mode is used for processing. For CBC, OFB, and CFB128, these values are 10h, 40h, and 30h, respectively.
- The Algorithm (ALG) field is used to activate AES by setting it to .

52.4.4.1.4.2.3.5.2 AES CBC, OFB, and CFB128 modes use of the Context Register

The AES CBC, OFB, and CFB128 modes use the Context Register as follows:

- AES CBC, OFB, and CFB all use the Context Registers to provide IV, which is updated with every processed block of a message. When a message is split into chunks and processed in multiple sessions, the IV must be saved and later restored for the next chunk to be processed correctly. At the end of CBC processing, IV is also the MAC of the message.
- If the AS field of the Mode Register is set to Finalize (2h) or Initialize/Finalize (3h) in the CBC mode, the last IV update is not written to the context. This enables CBC encryption to effectively perform ECB encryption transformation of a single-block message located in the context in place of IV, and with an all-zero block provided as input data through the FIFO without overwriting the context.

Table 453. Context usage in CBC, OFB, CFB mode

Context Word	Definition
0	IV [127:96]
1	IV [95:64]
2	IV [63:32]
3	IV [31:0]

52.4.4.1.4.2.3.5.3 AES CBC, OFB, and CFB128 modes use of the Data Size Register

The AES CBC, OFB, and CFB128 modes use the Data Size Register as follows:

- The byte length of the message to be processed must be written to the Data Size Register.

- The first write to this register initiates processing. This register can also be written during processing, in which case the value written is accumulated to the current state of the register.
- After the Data Size Register is written for the last time, its value must be divisible by 16 in CBC and CFB128 modes, otherwise the data-size error is generated.
- Only OFB decrements the value in this register with every processed block.

52.4.4.1.4.2.3.5.4 AES CBC, OFB, and CFB128 mode use of the Key Register

The AES CBC, OFB, and CFB128 modes uses the Key Register as follows:

- A CBC, OFB, or CFB key must be written to the Key Register.
- Keys can have 16 bytes.

52.4.4.1.4.2.3.5.5 AES CBC, OFB, and CFB128 modes use of the Key Size Register

The AES CBC, OFB, and CFB128 modes use the Key Size Register as follows:

- The number of bytes in a key must be written to the Key Size register.
- Any value other than 16 causes a key-size error to be generated.

52.4.4.1.4.2.3.6 AES CTR mode

The counter (CTR) mode is a confidentiality mode that features the application of the forward cipher to a set of input blocks, called counters, to produce a sequence of output blocks that are exclusive-ORed with the plaintext to produce the ciphertext, and vice versa. Note that the counter value must be unique for each data block that is encrypted with the same key. LTC uses a 128-bit counter to ensure that the counter value will not overflow and wrap around.

NOTE

It is the user's responsibility to ensure that the same key value is not used again following a reset.

52.4.4.1.4.2.3.6.1 AES CTR mode use of the Mode Register

The AES CTR mode uses the Mode Register as follows:

- The Additional Algorithm Information (AAI) field should be set to 00h to activate CTR mode.
- The Algorithm State (AS) field when set to "Finalize" (2h) prevents counter update in the context for the last data block.
- The Algorithm (ALG) field is used to activate AES by setting it to .

52.4.4.1.4.2.3.6.2 AES CTR mode use of the Context Register

The AES CTR mode uses the Context Register as follows:

- CTR uses context words 4, 5, 6 and 7 to provide initial counter value (CTR0). This value is incremented with the modulo specified in the Mode Register with every processed block of a message. When a message is split into chunks and processed in multiple sessions, the CTR0 field of context has to be saved and later restored for the next chunk to be processed correctly.
- If the AS field of the Mode Register is set to Finalize (2h) or Initialize/Finalize (3h) in the CTR mode, the last counter update is not written to the context. This enables CTR encryption to effectively perform ECB encryption transformation of a single-block message located in the context words 4, 5, 6 and 7 in place of CTR0 and with all-zero block provided as input data through the FIFO without overwriting the context.

Table 454. Context usage in CTR mode

Context Word	Initial-input definition	Context-switching definition
0	-	-
1	-	-
2	-	-
3	-	-
4	CTR0 [127:96]	CTRi [127:96]
5	CTR0 [95:64]	CTRi [95:64]
6	CTR0 [63:32]	CTRi [63:32]
7	CTR0 [31:0]	CTRi [31:0]

52.4.4.1.4.2.3.6.3 AES CTR mode use of the Data Size Register

The byte-length of the message to be processed must be written to the Data Size register. CTR decrements the value in this register with every processed block.

52.4.4.1.4.2.3.6.4 AES CTR mode use of the Key Register

- CTR key must be written to the Key Register.
- The Key Register can have 16 bytes.

52.4.4.1.4.2.3.6.5 AES CTR mode use of the Key Size Register

The number of bytes in a key must be written to the Key Size register. Any value other than 16 will cause Key Size error to be generated.

52.4.4.1.4.2.3.7 AES XCBC-MAC and CMAC modes

The AES XCBC-MAC and CMAC modes are described together because of their similarities. They are extensions of the AES CBC mode that produces a key-dependent, one--way hash (or message authentication code (MAC)) in a secure fashion across messages of varying lengths. They also provide data-integrity and data-origin authentication regarding the original message source.

52.4.4.1.4.2.3.7.1 AES XCBC-MAC and CMAC modes use of the Mode Register

The AES XCBC-MAC and CMAC modes use the Mode Register as follows:

- The Encrypt (ENC) bit is ignored.
- The ICV_TEST bit must be set for computed MAC to be compared with the received MAC. The received MAC must be written to the Input Data FIFO after message data. If this bit is not set, XCBC-MAC and CMAC do not expect received ICV to be supplied after message data.
- The Algorithm State (AS) field is defined for XCBC-MAC as shown in this table.

Table 455. Mode Register[AS] operation selections in AES XCBC-MAC

Operation	Description
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, derived keys K3 and K2 that are XOR-ed with the last message block are computed and stored in the context to be used in the last processing session. The derived key K1 used as an AES key is computed and written back to the Key Register over the original key
INITIALIZE/FINALIZE	Message is processed in a single XCBC session and the final MAC is computed
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. Derived keys K2 and K3 are provided in the context and the derived key K1 is provided in the Key Register. If decryption is requested, and data size is not written or is set to 0, and ICV_TEST bit is 1 - AS = UPDATE means that Check ICV (CICV) job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, and compares it to the computed MAC that is restored with the rest of the context from the previous session.
FINALIZE	Message is processed in multiple sessions and the current session is the last one. Derived keys K2 and K3 are provided in the context and the derived key K1 is provided in the Key Register. The final MAC is computed

- The Algorithm State (AS) field is defined for CMAC as shown in this table.

Table 456. Mode Register[AS] operation selections in CMAC

Operation	Function
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, the constant L = E(K, 0) is computed as encrypted block of zeros using key K and stored in the context to be used in the last processing session for derivation of keys K1 and K2. One of these keys will be XOR-ed with the last message block.
INITIALIZE/ FINALIZE	Message is processed in a single session and the final MAC is computed
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. The constant L used for key derivation is provided in the context. If decryption is requested, and data size is not written or is set to 0, and ICV_TEST:w bit is 1 - AS = UPDATE means that Check ICV (CICV) job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, and compares it to the computed MAC that is restored with the rest of the context from the previous session
FINALIZE	Message is processed in multiple sessions and the current session is the last one. The constant L used for key derivation is provided in the context. The final MAC is computed

- If the AS field is not set to either "Initialize/Finalize" or "Finalize" and the ICV_TEST bit is set to 1, the illegal-mode error is generated, except for CICV-only jobs.
- The Additional Algorithm Information (AAI) field must be set to 70h for XCBC and 60h for CMAC to be activated.
- The Algorithm (ALG) field is used to activate AES by setting it to .

52.4.4.1.4.2.3.7.2 AES XCBC-MAC and CMAC Modes use of the Context Register

The AES XCBC-MAC and CMAC modes use the Context Register as follows:

- No data needs to be provided in the context when starting a new XCBC or CMAC session.
- The computed MAC and the derived keys K2 and K3 are written back to the context by XCBC.
- The computed MAC and the constant L = E(K,0), computed as encrypted block of zeros using key K, are written back to the context by CMAC.
- When a message is split into chunks and processed in multiple sessions, these values need to be saved before context switch and restored before the next chunk of a message is to be processed. At the end of message processing the first 4 words of the context contain the MAC value.

Table 457. Context usage in XCBC-MAC and CMAC modes

Mode	Context Word	Context-switching definition	Final-result definition
XCBC-MAC	0	MAC[127:96]	MAC[127:96]
	1	MAC[95:64]	MAC[95:64]
	2	MAC[63:32]	MAC[63:32]
	3	MAC[31:0]	MAC[31:0]
	4	K3[127:96]	-
	5	K3[95:64]	-
	6	K3[63:32]	-
	7	K3[31:0]	-
	8	K2[127:96]	-
	9	K2[95:64]	-
	10	K2[63:32]	-
	11	K2[31:0]	-
CMAC	0	MAC[127:96]	MAC[127:96]
	1	MAC[95:64]	MAC[95:64]
	2	MAC[63:32]	MAC[63:32]
	3	MAC[31:0]	MAC[31:0]
	4	L[127:96]	-
	5	L[95:64]	-
	6	L[63:32]	-
	7	L[31:0]	-

52.4.4.1.4.2.3.7.3 AES XCBC-MAC and CMAC modes use of the ICV Size Register

The AES XCBC-MAC and CMAC modes use the ICV Size Register as follows:

- This register is used to provide received ICV/MAC byte-size.
- The computed ICV/MAC written to the context in the XCBC mode is always 16 bytes.
- In CMAC mode, this register determines also the computed MAC size-the remaining bytes are cleared.
- Supported values for ICV size are 4 to 16 bytes. If this register is 0, the size of ICV is 16 bytes.

52.4.4.1.4.2.3.7.4 AES XCBC-MAC and CMAC modes use of the Data Size Register

The AES XCBC-MAC and CMAC modes use the Data Size Register as follows:

- The byte-length of the message to be processed must be written to the Data Size register.
- XCBC-MAC and CMAC decrement the value in this register with every processed block.

52.4.4.1.4.2.3.7.5 AES XCBC-MAC and CMAC modes use of the Key Register

The AES XCBC-MAC and CMAC modes use the Key Register as follows:

- The key must be written to this register.
- For XCBC-MAC, if the AS mode field is set to either "Initialize" or "Initialize/Finalize", it is the original XCBC key (K) that must be written here. Otherwise, the derived key (K1) must be restored to this register. CMAC only uses original key K as an AES key.

52.4.4.1.4.2.3.7.6 AES XCBC-MAC and CMAC modes use of the Key Size Register

The AES XCBC-MAC and CMAC modes use the Key Size Register as follows:

- The total number of key bytes must be written to the Key Size register.
- For XCBC-MAC, any value other than 16 causes a key-size error to be generated. For CMAC, this error is generated only if any value other than 16 is written.

52.4.4.1.4.2.3.7.7 ICV checking in AES XCBC-MAC and CMAC modes

Automatic ICV checking is enabled by setting the ICV bit of the Mode Register to 1. When ICV is set to 1, the AS mode field must be set to either "Finalize" or "Initialize/Finalize"; otherwise the illegal-mode error is generated, except for CICV-only (Check-ICV-only) jobs.

The received ICV must be provided on the FIFO after the message data. The FIFO data type must be set to ICV when it is put on the FIFO. The size of the received and computed ICV is provided in the ICV Size register.

If the ICV check detects a mismatch between the decrypted received ICV and the computed ICV, the ICV error is generated.

52.4.4.1.4.2.3.8 AESA CCM and CCM* mode

CCM and CCM* consists of two related processes: generation encryption and decryption verification, which combine two cryptographic primitives: counter mode encryption (CTR) and cipher-block chaining based authentication (CBC-MAC). Only the forward cipher function of the block cipher algorithm is used within these primitives. Note that the counter value must be unique for each data block that is encrypted with the same key. LTC uses a 128-bit counter to ensure that the counter value does not overflow and wrap around.

NOTE

It is the user's responsibility to ensure that the same key value is not used again following a reset.

52.4.4.1.4.2.3.8.1 Generation encryption

A cipher-block chaining is applied to the payload, the associated data (AAD), and the nonce to generate a message authentication code (MAC); then counter mode encryption is applied to the MAC and the payload to transform them into an unreadable form, called the ciphertext. Thus, CCM generation encryption expands the size of the payload by the size of the MAC.

52.4.4.1.4.2.3.8.2 Decryption verification

Counter-mode decryption is applied to the purported ciphertext to recover the MAC and the corresponding payload; then cipher block chaining is applied to the payload, the received associated data, and the received nonce to verify the correctness of the MAC.

52.4.4.1.4.2.3.8.3 AES CCM and CCM* mode use of the Mode Register

The AES CCM and CCM* mode uses the Mode Register as follows:

- The Encrypt (ENC) bit must be set to 1 for encryption and 0 for decryption.
- The ICV_TEST bit must be set for CCM and CCM* to compare computed MAC with the received MAC when decryption is requested.
- The received MAC must be written to the input-data FIFO after message data.
- Setting the ICV_TEST bit causes the received MAC to be decrypted and compared with the computed MAC.
- The number of MSBs to be compared is defined by the MAC size in the CCM IV (B_0) as described in the CCM and CCM* specification.
- If the AS field is set to FINALIZE, but ICV = 0, AESA does not expect received ICV to be put on the input-data FIFO. In that case, MAC is computed and truncated to the specified size for decryption.
- For encryption, the computed MAC is encrypted and truncated to size. The illegal-mode error is generated if ICV = 1 and ENC = 1.
- If ICV = 1 and the decrypted received MAC do not match computed MAC, the ICV error is generated.
- The Algorithm State (AS) field is defined for CCM as follows:

Table 458. Mode Register[AS] operation selections in AES CCM

Operation	Description
INITIALIZE	Message is processed in multiple sessions and the current session is the first one. During initialization, the initial counter CTR0 is encrypted in the CTR mode and the B0 is processed with the CBC-MAC mode. The resulting values are stored in the context. Also, the size of MAC is decoded from B0 and written to the context. This AS setting must be used whenever the first part (or whole) AAD is being processed
INITIALIZE/ FINALIZE	Message is processed in a single CCM session and the final MAC is computed and encrypted. The initial counter CTR0 and B0 must be provided in the context
UPDATE	Message is processed in multiple sessions and the current session is neither the first nor the last. All context data is restored from the previous session and the key is written to the Key Register. If decryption is requested, and data size is not written or is set to 0, and ICV_TEST bit is 1 - AS=UPDATE means that a CICV-only job is requested. The CICV-only job does not process any data, it just pops received ICV/MAC from the Input Data FIFO, decrypts it and compares it to the computed MAC that is restored with the rest of the context from the previous session
FINALIZE	Message is processed in multiple sessions and the current session is the last one. All context data is restored from the previous session and the key is written to the Key Register. The final MAC is computed and encrypted

- Whenever AS is set to Initialize or Initialize/Finalize, context registers must be zero.
- If the AS field is not set to either Initialize/Finalize or Finalize and the ICV_TEST bit is set to 1, the illegal-mode error is generated. This does not apply in case when only ICV check is requested as described for AS = UPDATE.
- The Additional Algorithm Information (AAI) field must be set to 80h for CCM or CCM* to be activated.
- The Algorithm (ALG) field is used to activate AES by setting it to .

52.4.4.1.4.2.3.8.4 AES CCM and CCM* mode use of the Context Register

The AES CCM and CCM* mode uses the Context Register as follows:

- B0 and the initial counter CTR0 must be provided in the context before the first chunk of the message is to be processed. During initialization, the initial counter CTR0 is encrypted in the CTR mode and B0 (which functions like a CBC-MAC IV in CCM) is processed with the CBC-MAC mode. The resulting values are stored in the context. Also, the size of MAC is decoded from B0 and written to context word 13.
- If there is AAD, the first block of it defines its size, and that value is decoded and written to context word 12. All of the context data must be restored before the next chunk of the message is to be processed in multi-session processing.
- For CCM encryption, the ICV (encrypted final MAC) is written to context words 8, 9, 10 and 11. For CCM decryption, the ICV (received MAC), which is always encrypted, is decrypted to words 8, 9, 10 and 11. The final computed MAC is written (in clear) to words 0, 1, 2 and 3.

Table 459. Context usage in CCM and CCM* mode encryption

Context Word	Initial-input definition	Intermediate definition	Final-output definition
0	B0[127:96]	intermediate MAC state	MAC[127:96]
1	B0[95:64]	intermediate MAC state	MAC[95:64]
2	B0[63:32]	intermediate MAC state	MAC[63:32]
3	B0[31:0]	intermediate MAC state	MAC[31:0]
4	CTR0[127:96]	CTR[127:96]	-
5	CTR0[95:64]	CTR[95:64]	-
6	CTR0[63:32]	CTR[63:32]	-
7	CTR0[31:0]	CTR[31:0]	-
8	-	E(CTR0)[127:96][1]	E(MAC)[127:96]
9	-	E(CTR0)[95:64][1]	E(MAC)[95:64]
10	-	E(CTR0)[63:32][1]	E(MAC)[63:32]
11	-	E(CTR0)[31:0][1]	E(MAC)[31:0]
12	-	AAD Presence Flag[31], Zero[30:16], AAD size[15:0]	-
13	-	Zero[31:3], Encoded MAC size[2:0]	-

1. E(x) means encrypted x

Table 460. Context usage in CCM and CCM* mode decryption

Context Word	Initial-input definition	Context-switching Definition	Final-result definition
0	B0[127:96]	intermediate MAC state	MAC[127:96]

Table continues on the next page...

Table 460. Context usage in CCM and CCM* mode decryption (continued)

Context Word	Initial-input definition	Context-switching Definition	Final-result definition
1	B0[95:64]	intermediate MAC state	MAC[95:64]
2	B0[63:32]	intermediate MAC state	MAC[63:32]
3	B0[31:0]	intermediate MAC state	MAC[31:0]
4	CTR0[127:96]	CTR[127:96]	-
5	CTR0[95:64]	CTR[95:64]	-
6	CTR0[63:32]	CTR[63:32]	-
7	CTR0[31:0]	CTR[31:0]	-
8	-	E(CTR0)[127:96]	Decrypted Received MAC[127:96]
9	-	E(CTR0)[95:64]	Decrypted Received MAC[95:64]
10	-	E(CTR0)[63:32]	Decrypted Received MAC[63:32]
11	-	E(CTR0)[31:0]	Decrypted Received MAC[31:0]
12	-	AAD Presence Flag[31], Zero[30:16], AAD size[15:0]	-
13	-	Zero[31:3], Encoded MAC size[2:0]	-

52.4.4.1.4.2.3.8.5 AES CCM and CCM* mode use of the Data Size Register

The AES CCM and CCM* mode uses the Data Size Register as follows:

- The byte-length of the message to be processed must be written to the Data Size register.
- CCM decrements the value in this register with every processed block.
- The content of the Data Size register must be divisible by 16 after the last write to it if the AS mode field is set to either "Update" or "Initialize". Otherwise, the data-size error is generated. In other words, message splitting can be done only on a 16-byte boundary.

52.4.4.1.4.2.3.8.6 AES CCM and CCM* mode use of the Key Register

CCM and CCM* key must be written to this register; it is always an encryption key.

52.4.4.1.4.2.3.8.7 AES CCM and CCM* mode use of the Key Size Register

The AES CCM and CCM* mode uses the Key Size Register as follows:

- The total number of key bytes must be written to the Key Size register.
- Any value other than 16 causes a key-size error to be generated.

52.4.4.1.4.2.3.8.8 AES CCM and CCM* mode use of the ICV check

The AES CCM and CCM* mode uses ICV checking as follows:

- Automatic ICV checking is enabled by setting the ICV_TEST bit of the Mode Register to 1. When ICV is set to 1, the AS mode field must be set to either "Finalize" or "Initialize/Finalize"-otherwise the illegal-mode error is generated, unless data size is 0 indicating ICV check is only requested. Also, if ICV = 1, the ENC bit must be 0.
- The received ICV must be provided on the input data FIFO after the message data. In CCM, received ICV is always encrypted. The size of the received and computed ICV is for CCM encoded in the B0.
- If the ICV check detects mismatch between the decrypted received ICV and the computed ICV, the ICV error is generated.

52.4.4.1.4.2.4 Standalone AES Examples

Example AES ECB Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write Mode to Primary Mode Register. (0010020Dh)
4. Write Size of data to encrypt/decrypt to Data Size Register.
5. Write data into the Input FIFO.
6. Read data from the Output FIFO.
7. Interrupt is generated after final word is pushed to output FIFO.

Example AES CTR Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write initial counter value to Context Words 4-7 in the Context Register.
4. Write Mode to Primary Mode Register. (0010020Dh)
5. Write Size of data to encrypt/decrypt to Data Size Register.
6. Write data into the Input FIFO.
7. Read data from the Output FIFO.
8. Interrupt is generated after final word is pushed to output FIFO.

Example AES CCM or CCM* Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh) CCM and CCM* both use the same mode value.
    - CCM and CCM* both use the same mode value.
6. Write Size of Authentication Only Data to the AAD Size Register.
7. Write Authentication Only data to the Input FIFO.
    - Authentication data needs to be padded to a 16 byte boundary with zeros.
    - For example if there is 8 bytes of AAD then (00000008h) should be written to AAD Size register and 8 bytes of AAD data followed by 8 bytes of Zero should be written into the Input FIFO.
8. Write Size of data to encrypt/decrypt and authenticate to Data Size Register.

9. Write data into the Input FIFO.
10. Read data from the Output FIFO.
11. Interrupt is generated after final word is pushed to output FIFO.
12. Read MAC from Context Registers
    - MAC is read from Context Registers 0-3.
    - Encrypted MAC is read from Context Registers 8-11.

Example AES CCM or CCM* Authentication Only Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh).
    - CCM and CCM* both use the same mode value.
6. Write Size of Authentication Only Data to the AAD Size Register.
    - The AL bit needs to be set in the AAD Size Register. This tells the AES core engine that it will recieve only Authentication Data. Note for encryption only the mechanism is handled automatically.
7. Write Authentication Only data to the Input FIFO.
    - Authentication data needs to be padded to a 16 byte boundary with zeros.
    - For example if there is 8 bytes of AAD then (00000008h) should be written to AAD Size register and 8 bytes of AAD data followed by 8 bytes of Zero should be written into the Input FIFO.
8. Write data into the Input FIFO.
9. Interrupt is generated after final word is processed from input FIFO.
10. Read MAC from Context Registers
    - MAC is read from Context Registers 0-3.
    - Encrypted MAC is read from Context Registers 8-11.

Example AES CCM or CCM* Encryption Only Operation:

1. Write key to Primary Key Register.
2. Write key size to Primary Key Size Register. (00000010h)
3. Write B0 value to Context Words 0-3 in the Context Register.
4. Write initial counter value to Context Words 4-7 in the Context Register.
5. Write Mode to Primary Mode Register. (0010080Dh).
    - CCM and CCM* both use the same mode value.
6. Write Size of data to encrypt/decrypt to Data Size Register.
7. Write data into the Input FIFO.
8. Read data from the Output FIFO.
9. Interrupt is generated after final word is pushed into the output FIFO.

Writing and Reading Data from the FIFOs:

1. Writing and reading by polling operations.

- The FIFO Status Register(LTCFIFOSTA) shows the number of entries in both the input and output FIFOs. It also shows when the FIFOs are full.
- The input FIFO supports 0x32bit entries.
- The output FIFO supports 4x32bit entries.
- Whenever there is space in the input FIFO the user can write a word into the Input FIFO.
- Whenever there is a word in the output FIFO then the user can read a word from the Output FIFO.

2. Writing and reading FIFOs by DMA operations.
   - The on chip DMA will handle all reads and writes of the FIFOs.
   - The IDE and ODE bits in the Control Register must be written to enable the DMA handshake.
     - IDE will enable dma transfers to the input FIFO when there is space available.
     - ODE will enable dma transfers from the output FIFO when there are words in the FIFO.
   - The on chip DMA should then be programmed to write data to the input FIFO and read data from the output FIFO.

52.4.4.1.4.2.5 LTC register descriptions

All reads of write-only addresses always return zero. Writes to read-only addresses are ignored. LTC will generate a transfer error whenever an undefined address is read or written to on the register bus. Although many of the LTC registers hold more than 32 bits, the register addresses shown in the Memory Map below represent how these registers are accessed over the register bus as 32-bit words.

NOTE

The reset value of some registers differs between different versions of LTC. To ensure driver compatibility across different versions of LTC, when updating fields within registers, the registers should first be read, the required fields updated, and then the register should be written. This will avoid inadvertently changing the settings of other fields in the same register.

52.4.4.1.4.2.5.1 LTC memory map

RADIO.LTC base address: 48A0_6800h

Offset	Register	Width (In bits)	Access	Reset value
0h	Mode Register (MD)	32	RW	0000_0000h

52.4.4.1.4.2.5.2 Mode Register (MD)

Offset

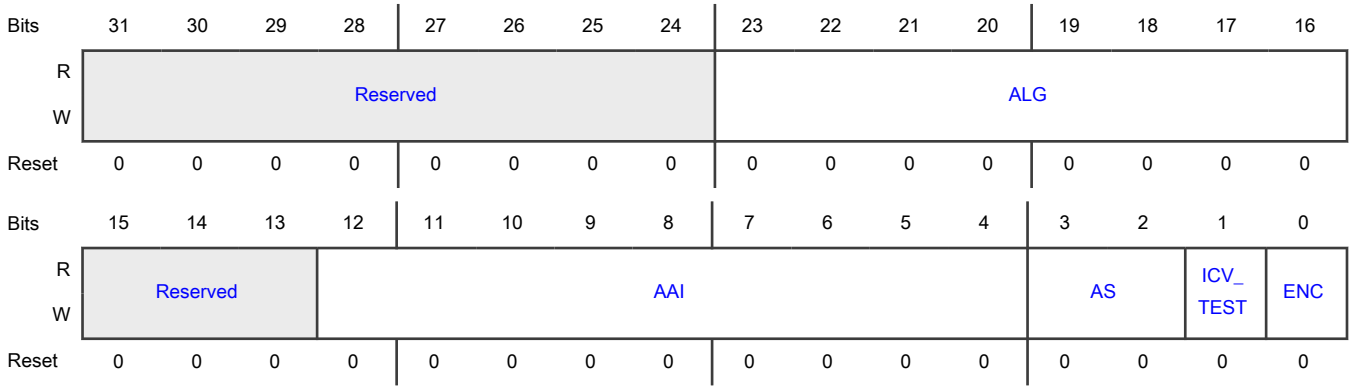
Register	Offset
MD	0h

Function

The Mode Register is used to tell the cryptographic engines which operation is being requested. The interpretation of this register will be unique for each CHA.

This section defines the format of the Mode Register when used with non-public-key algorithms and non-RNG operations.

Diagram



Fields

Field	Function
31-24 —	Reserved Must be 0.
23-16 ALG	Algorithm This field specifies which algorithm is being selected. 0001_0000b - AES
15-13 —	Reserved Must be 0.
12-4 AAI	Additional Algorithm information This field contains additional mode information that is associated with the algorithm that is being executed. See also the section describing the appropriate CHA. **NOTE** Some algorithms do not require additional algorithm information and in those cases this field should be all 0s.

Table 461. AAI Interpretation for AES Modes

[For AES the MSB of AAI is the DK (Decrypt Key) bit.]				
Code [1]	Interpretation		Code[1]	Interpretation
00h	CTR (mod 2^{128})		80h	CCM, CCM*
10h	CBC		90h	Reserved
20h	ECB		A0h	Reserved
30h	CFB		B0h	Reserved
40h	OFB		C0h	Reserved
50h	Reserved		D0h	Reserved
60h	CMAC		E0h	Reserved
70h	XCBC-MAC		F0h	Reserved
			12h	CBC-CS2
Setting the DK bit (i.e. ORing 100h with any AES code above) causes Key Register to be loaded with the AES Decrypt key, rather than the AES Encrypt key.				

1. The codes are mutually exclusive (i.e. they cannot be ORed with each other).

Field	Function
3-2 AS	Algorithm State This field defines the state of the algorithm that is being executed. This may not be used by every algorithm. 00b - Update 01b - Initialize 10b - Finalize 11b - Initialize/Finalize
1 ICV_TEST	ICV Checking This bit selects whether the current algorithm should compare the known ICV versus the calculated ICV. This bit should only be used in modes that support ICV checking. Setting bit with non supported algorithms could cause the hardware to hang. 0 - Don't compare 1 - Compare
0 ENC	Encrypt/Decrypt. This bit selects encryption or decryption. 0b - Decrypt. 1b - Encrypt.

52.4.4.1.4.2.5.3 Key Size Register (KS)

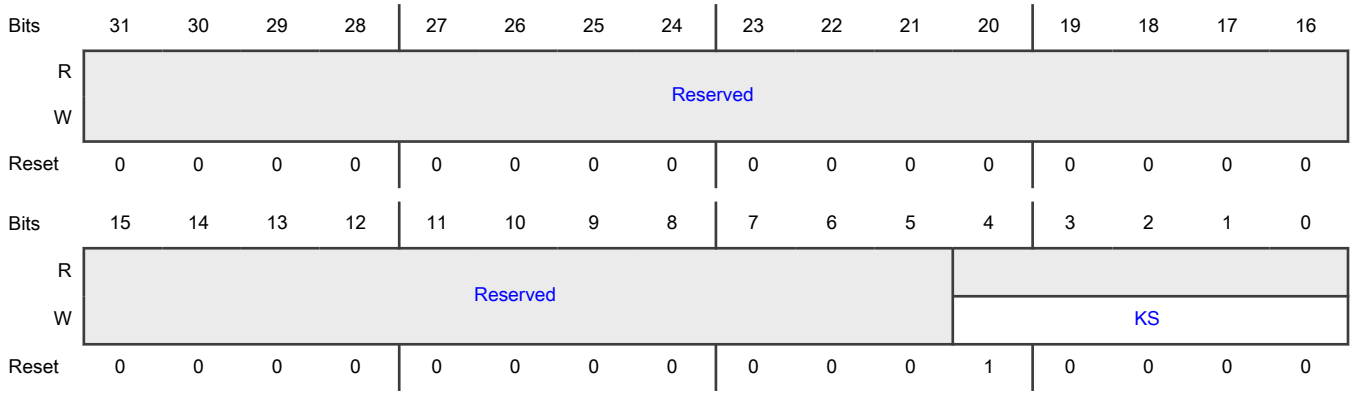
Offset

Register	Offset
KS	8h

Function

The Key Size Register is used to tell the crypto engine(AES) the size of the key that was loaded into the Key Register. The Key Size Register must be written after the key is written into the Key Register. Writing to the Key Size Register will prevent the user from modifying the Key Register. Only 16 byte keys are supported so this register will always read 16 bytes. This register is still required to be written to indicate to the AES engine that the key was loaded.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 KS	Key Size This is the size of a Key measured in bytes

52.4.4.1.4.2.5.4 Data Size Register (DS)

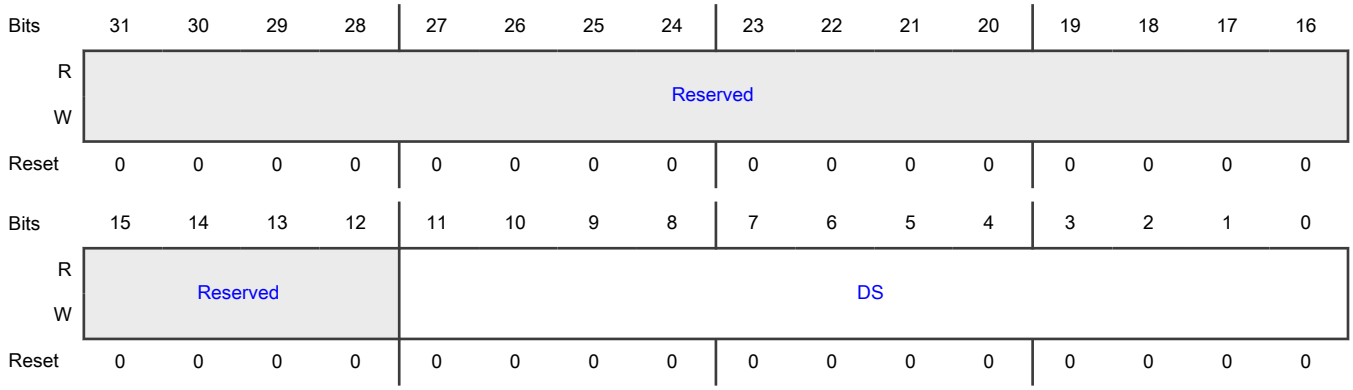
Offset

Register	Offset
DS	10h

Function

The Data Size Register is used to tell a crypto engine the amount of data in bytes that will be loaded into the Input Data FIFO. Note that writing to the AAD Size Register (AADSZ) , will cause this register to also update. This register is additive and any write to this register will be added to the current value in the register. For example, if the DS field currently has the value 16, writing 2 to the least-significant half of the Data Size register (i.e. the DS field) will result in a value of 18 in the DS field. Care should be taken to not overflow the register. Overflowing the register can result in a hang condition. Note that AES decrements this register, so reading the register may return a value less than sum of the values that were written into it. This register is cleared whenever a key is decrypted or encrypted.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 DS	Data Size This is the number of whole bytes of data that will be consumed by the CHA. Note that writing the AAD Size Register will result in this register also being written to.

52.4.4.1.4.2.5.5 ICV Size Register (ICVS)

Offset

Register	Offset
ICVS	18h

Function

The ICV Size Register indicates how much of the last block of ICV is valid when performing AES integrity check modes (e.g. AES-CMAC, AES-XCBC-MAC). This register must be written prior to the corresponding word of data being consumed by AES. In practical terms, this means the register must be written prior to the corresponding data being written to the Input Data FIFO.

Others reserved. 0001b - Mode Error 0010b - Data Size Error 0011b - Key Size Error 0110b - Data Arrived out of Sequence Error 1010b - ICV Check Failed 1011b - Internal Hardware Failure 1100b - CCM AAD Size Error (either 1. AAD flag in B0 =1 and no AAD type provided, 2. AAD flag in B0 = 0 and AAD povided, or 3. AAD flag in B0 =1 and not enough AAD provided - expecting more based on AAD size.) 1111b - Invalid Crypto Engine Selected

52.4.4.1.4.2.5.11 AAD Size Register (AADSZ)

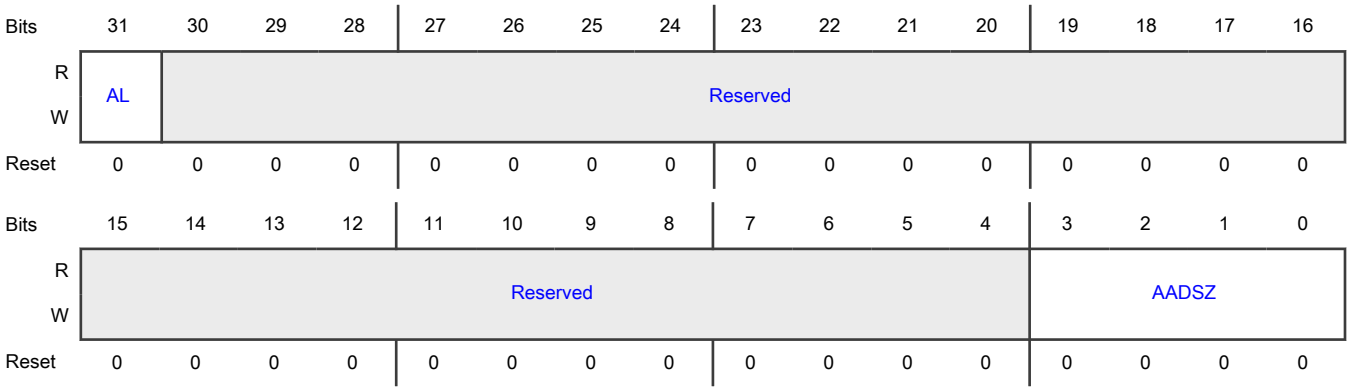
Offset

Register	Offset
AADSZ	58h

Function

The AAD Size Register is used by AESA to determine how much of the last block of AAD is valid. The write to this register should be the entire size of the AAD as it is also added directly to the Data Size Register. The size added to the Data Size Register is the AAD size rounded up to the next 16 byte boundary. For instance, a size of 20 bytes written to the AAD size register will cause 32 bytes to be added to the Data Size Register. The size stored in the AADSZ field represents the number of bytes valid in the final block of AAD. However, the entire size of AAD should be written to the AAD Size Register (AADSZ) Register address location. When authentication only is being done then the AL bit needs to be written to tell the AES engine that this is the last of the data.

Diagram



Fields

Field	Function
31 AL	AAD Last Only AAD data will be written into the Input FIFO.
30-4 —	Reserved
3-0 AADSZ	AAD size in Bytes, mod 16

52.4.4.1.4.2.5.12 Context Register (CTX_0 - CTX_13)

Offset

For a = 0 to 13:

Register	Offset
CTX_a	100h + (a × 4h)

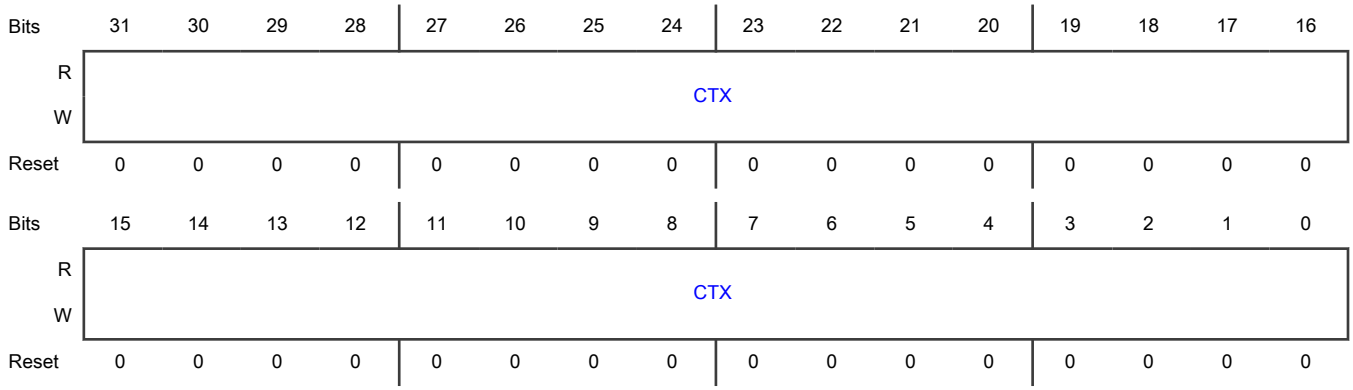
Function

The Context Register holds the context for the internal crypto engine. This register is 448 bits in length. The IP bus write to the Context Register is accessible only as full-word reads or writes to fourteen 32-bit registers. The MSB is located at offset 0100h with respect to the register page.

The bit assignments of this register are dependent on the algorithm, and in some cases the mode of that algorithm. See the appropriate section for the Context Register format used for that algorithm:

- AES ECB: Section AES ECB mode use of the Context Register
- AES CBC: Section AES CBC, OFB, and CFB128 modes use of the Context Register
- AES CTR: Section AES CTR mode use of the Context Register
- AES CCM: Section AES CCM and CCM* mode use of the Context Register

Diagram



Fields

Field	Function
31-0 CTX	CTX

52.4.4.1.4.2.5.13 Key Registers (KEY_0 - KEY_3)

Offset

Register	Offset
KEY_0	200h
KEY_1	204h
KEY_2	208h
KEY_3	20Ch

Function

The Key Register normally holds the left-aligned key for the internal crypto engine. The MSB is in offset 200h. The Key Register is 128 bits in length. The IP bus write to the Key Register is accessible only as full-word reads or writes to four 32-bit registers.

Before the value in the Key Register can be used in a cryptographic operation, the size of the key must be written into the Key Size Register. Once the Key Size Register has been written, the Key Register cannot be written again until the Key Size Register has been cleared.

Diagram

22-16 OFL	Output FIFO Level These bits indicate the current number of entries in the Output FIFO.
15 IFF	Input FIFO Full The Input FIFO is full and should not be written to.
14-7 —	Reserved
6-0 IFL	Input FIFO Level These bits indicate the current number of entries in the Input FIFO. An Entry is 4 bytes.

52.4.4.1.4.2.5.18 Input Data FIFO (IFIFO)

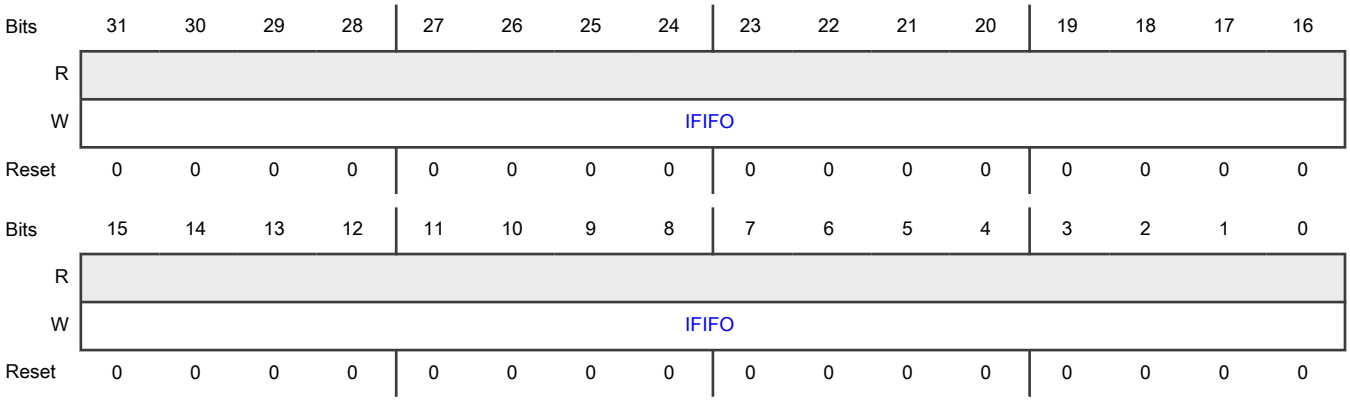
Offset

Register	Offset
IFIFO	7E0h

Function

Data to be processed by the various crypto engines is first pushed into the Input Data FIFO. The Input Data FIFO does not support byte enables. All data should be word aligned. The IFIFO is 0 entries deep, and each entry is four bytes. Care must be used to not overflow the Input Data FIFO. A Write to the Input Data FIFO when FIFOSTA[IFF] is set will cause a bus error. Reads from this address will always return 0x0.

Diagram



Fields

Field	Function
31-0 IFIFO	IFIFO

52.4.4.1.4.2.5.19 Output Data FIFO (OFIFO)

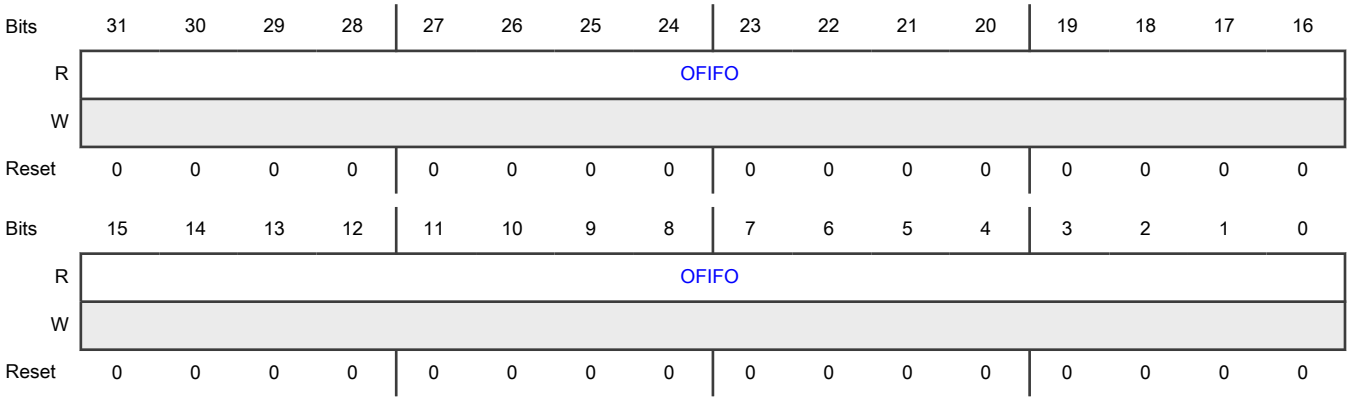
Offset

Register	Offset
OFIFO	7F0h

Function

Data that is output from the AES is pushed into the Output Data FIFO. The OFIFO is 4 entries deep, and each entry is four bytes. During normal operation, the AES will never overflow the Output Data FIFO. Writes to this register are ignored.

Diagram



Fields

Field	Function
31-0 OFIFO	Output FIFO

52.4.4.1.5 WiFi Coexistence Interface

The 2.4GHz radio architecture supports a flexible coexistence interface that enables the narrowband (NB) radio (e.g., Bluetooth, IEEE 802.15.4 and proprietary protocols) to coexist in the same space as a WiFi radio, which shares the same frequency band, or a different IC, with which active synchronization may be required to reduce either power consumption from battery or reduce electro-magnetic interference (EMI). As a simplification, this section primarily showcases the coexistence capabilities of the NB 2.4GHz radio in the context of WiFi radio coexistence. Note that an inter-processor communication (IPC) channel using a serial bus may also be used to augment the capabilities of the HW coexistence interface.

Typical coexistence schemes between a Bluetooth and WiFi designate the WiFi transceiver as the master, and the 2.4GHz transceiver as the slave. However in some cases, an application profile may dictate the opposite. The coexistence strategy is to prevent both the NB 2.4GHz radio and the WiFi radio from transmitting simultaneously; a configuration option exists to prevent the NB 2.4GHz radio from reception when the WiFi radio owns the RF channel. Yet another implementation choice is for the two radios to indicate the nature of their RF activity allowing the coexistence scheme to allow for simultaneous reception on both radios as well as other options when NB and WiFi channels have adequate separation.

52.4.4.1.5.1 Coexistence Pin Definition

The WiFi coexistence pins are described in the following table.

WiFi Coexist Function	Pin Direction	Pin Description
RF_ACTIVE (REQUEST)	O	An output which is asserted prior to any Radio event and remains asserted for the duration of the event.
RF_STATUS (DIRECTION)	O	An output which indicates when the Radio is in an RX or TX event, software can also control this signal directly.
RF_PRIORITY	O	An output which indicates to the external WiFi device that the Radio event is a high priority and it needs access to the 2.4 GHz antenna.
RF_NOT_ALLOWED (!GRANT)	I	External signal which causes the internal Radio to cease radio activity.
RF_TX_CONF	I	Signal from an external Radio which indicates the availability of the 2.4 GHz antenna to the internal Radio. Note that this signal is not connected to the Radio hardware. Radio software can use any interrupt-capable GPIO which the application assigns for this function.

Behavioral control information for the radio pins is provided below. Refer also to Radio Coexistence/FEM/LANT Connections which illustrates how the signals are connected and muxed in the radio.

52.4.4.1.5.1.1 RF_NOT_ALLOWED Behavioral Control

The WiFi IC generates a signal, RF_NOT_ALLOWED. If this signal is asserted, then 2.4GHz radio does not perform any communication. When this signal is de-asserted, then 2.4GHz radio is free to perform communications. In case when the signal RF_NOT_ALLOWED is asserted when 2.4GHz radio has already initiated the transmission/reception of a packet then the 2.4GHz radio must stop its activity immediately. Note that a software override of the RF_NOT_ALLOWED signal is also supported by the radio, which can be used for debug as well as enabling the capability to abort radio activity under software control (based on application layer arbitration between a multi-radio system).

The table below describes register bits in the RFMC and RADIO_MISC to enable, control and provide status for RF_NOT_ALLOWED

Field	Type	Description
RFNA_IBE[2:0]	RW	RFMC bitfield to select which (among several) SOC pin to use for RF_NOT_ALLOWED function
RF_NOT_ALLOWED_EN[3:0]	RW	RADIO_MISC (COEX_CTRL register) bitfield to choose which link layers will receive RF_NOT_ALLOWED signal
RF_NOT_ALLOWED_ASSERTED	W1C	RADIO_MISC (COEX_CTRL register) bitfield sets on assertion of RF_NOT_ALLOWED, cleared only by software.
RF_NOT_ALLOWED	R	RADIO_MISC (COEX_CTRL register) bitfield reflects the raw state of the selected RF_NOT_ALLOWED SOC pin

Table continues on the next page...

Table continued from the previous page...

RF_NOT_ALLOWED_OVRD_EN	RW	RADIO_MISC (COEX_CTRL register) bitfield. If set, allows software to control the RF_NOT_ALLOWED signal to the link layers via the RF_NOT_ALLOWED_OVRD bitfield
RF_NOT_ALLOWED_OVRD	RW	RADIO_MISC (COEX_CTRL register) bitfield. If RF_NOT_ALLOWED_OVRD_EN is set, the RF_NOT_ALLOWED signal to the link layers is driven with the value of the RF_NOT_ALLOWED_OVRD bitfield
RF_NOT_ALLOWED_INV	RW	RADIO_MISC (COEX_CTRL register) bitfield. If set, the selected RF_NOT_ALLOWED pin is inverted before being used as the RF_NOT_ALLOWED signal to the link layers

52.4.4.1.5.1.2 RF_ACTIVE Behavioral Control

The NB radio provides the RF_ACTIVE (REQUEST) output to request coexistence access. This signal can be generated by either the TSM, one of the link layers, or the RFMC.

The table below describes register bits in the TSM, RFMC and RADIO_MISC to enable, control, and provide status for RF_ACTIVE. Refer to the link layer chapters for information on their REQUEST output.

Field	Type	Description
RF_ACTIVE_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE asserts in the RX sequence
RF_ACTIVE_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE de-asserts in the RX sequence
RF_ACTIVE_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE asserts in the TX sequence
RF_ACTIVE_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_ACTIVE de-asserts in the TX sequence
TSM_RF_ACTIVE_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_ACTIVE output
TSM_RF_ACTIVE_OVRD	RW	TSM bitfield to provide override value for TSM RF_ACTIVE output
TSM_SPARE1_EXTEND[7:0]	RW	TSM bitfield to control when how long TSM RF_ACTIVE remains asserted after end of RX or TX sequence. This is intended to close any gaps which may occur between consecutive RX/TX or TX/RX operations
COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.
RFACT_SRC[1:0]	RW	RFMC bitfield to select whether RF_ACTIVE radio output is driven by RFMC (2'b00), TSM/LL output from the COEX_SEL mux (2'b01), or Bluetooth LE bt_clk_req signal (2'b10)
RFACT_WKUP_DLY[5:0]	RW	RFMC bitfield. If RFACT_SRC=2'b00, this configures number of 32kHz reference clocks following enable of the XO to assert the RF_ACTIVE pin for a MAN/WOR/Bluetooth LE wakeup event.
RFACT_IDIS	RW	RFMC bitfield. If RFACT_SRC=2'b00, this selects whether the RF_ACTIVE radio output de-asserts when the TSM becomes idle
RFACT_EN	RW	RFMC bitfield. If RFACT_SRC=2'b00, the RF_ACTIVE radio output is asserted while this bit is set

Table continues on the next page...

Table continued from the previous page...

RFACT_FLAG	W1C	RFMC bitfield. Sets when the RF_ACTIVE radio output asserts
RFACT_IE	RW	RFMC bitfield. If set, the RFMC will generate an interrupt to CM33 when the RF_ACTIVE radio output asserts

52.4.4.1.5.1.3 RF_STATUS Behavioral Control

The NB radio provides the RF_STATUS (DIRECTION) output to indicate when the radio is in an RX or TX event. This signal can be generated by either the TSM or the active link layers.

The table below describes register bits in the TSM and RADIO_MISC to enable and control RF_STATUS. Refer to the link layer chapters for information on their DIRECTION output.

Field	Type	Description
RF_STATUS_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_STATUS asserts in the RX sequence
RF_STATUS_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_STATUS de-asserts in the RX sequence
RF_STATUS_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_STATUS asserts in the TX sequence
RF_STATUS_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_STATUS de-asserts in the TX sequence
TSM_RF_STATUS_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_STATUS output
TSM_RF_STATUS_OVRD	RW	TSM bitfield to provide override value for TSM RF_STATUS output
COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.

52.4.4.1.5.1.4 RF_PRIORITY Behavioral Control

The NB radio provides the RF_PRIORITY[1:0] outputs to indicate the radio access priority. This signal can be generated by either the TSM or the active link layers. Note that if the TSM is chosen, then RF_PRIORITY[1] is always 0.

The table below describes register bits in the TSM and RADIO_MISC to enable and control RF_PRIORITY. Refer to the link layer chapters for information on their PRIORITY output.

Field	Type	Description
RF_PRIORITY_RX_HI[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY asserts in the RX sequence
RF_PRIORITY_RX_LO[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY de-asserts in the RX sequence
RF_PRIORITY_TX_HI[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY asserts in the TX sequence
RF_PRIORITY_TX_LO[7:0]	RW	TSM bitfield to control when TSM RF_PRIORITY de-asserts in the TX sequence
TSM_RF_PRIORITY_OVRD_EN	RW	TSM bitfield to provide override enable for TSM RF_PRIORITY output
TSM_RF_PRIORITY_OVRD	RW	TSM bitfield to provide override value for TSM RF_PRIORITY output

Table continues on the next page...

Table continued from the previous page...

COEX_SEL	RW	RADIO_MISC (COEX_CTRL register) bitfield to select whether the TSM outputs (RF_ACTIVE, RF_STATUS, RF_PRIORITY) or the active Link Layer's outputs are input to the RFMC.

52.4.4.1.5.2 Coexistence Signaling Options

The figure below illustrates a number of Bluetooth & WiFi coexistence signaling (adapted from WiFi alliance documentation). The interface definition between the two radio has evolved over time targeting improved spectral and antenna control efficiency. Most modern BT & WiFi interfaces utilize 3 or more signals.

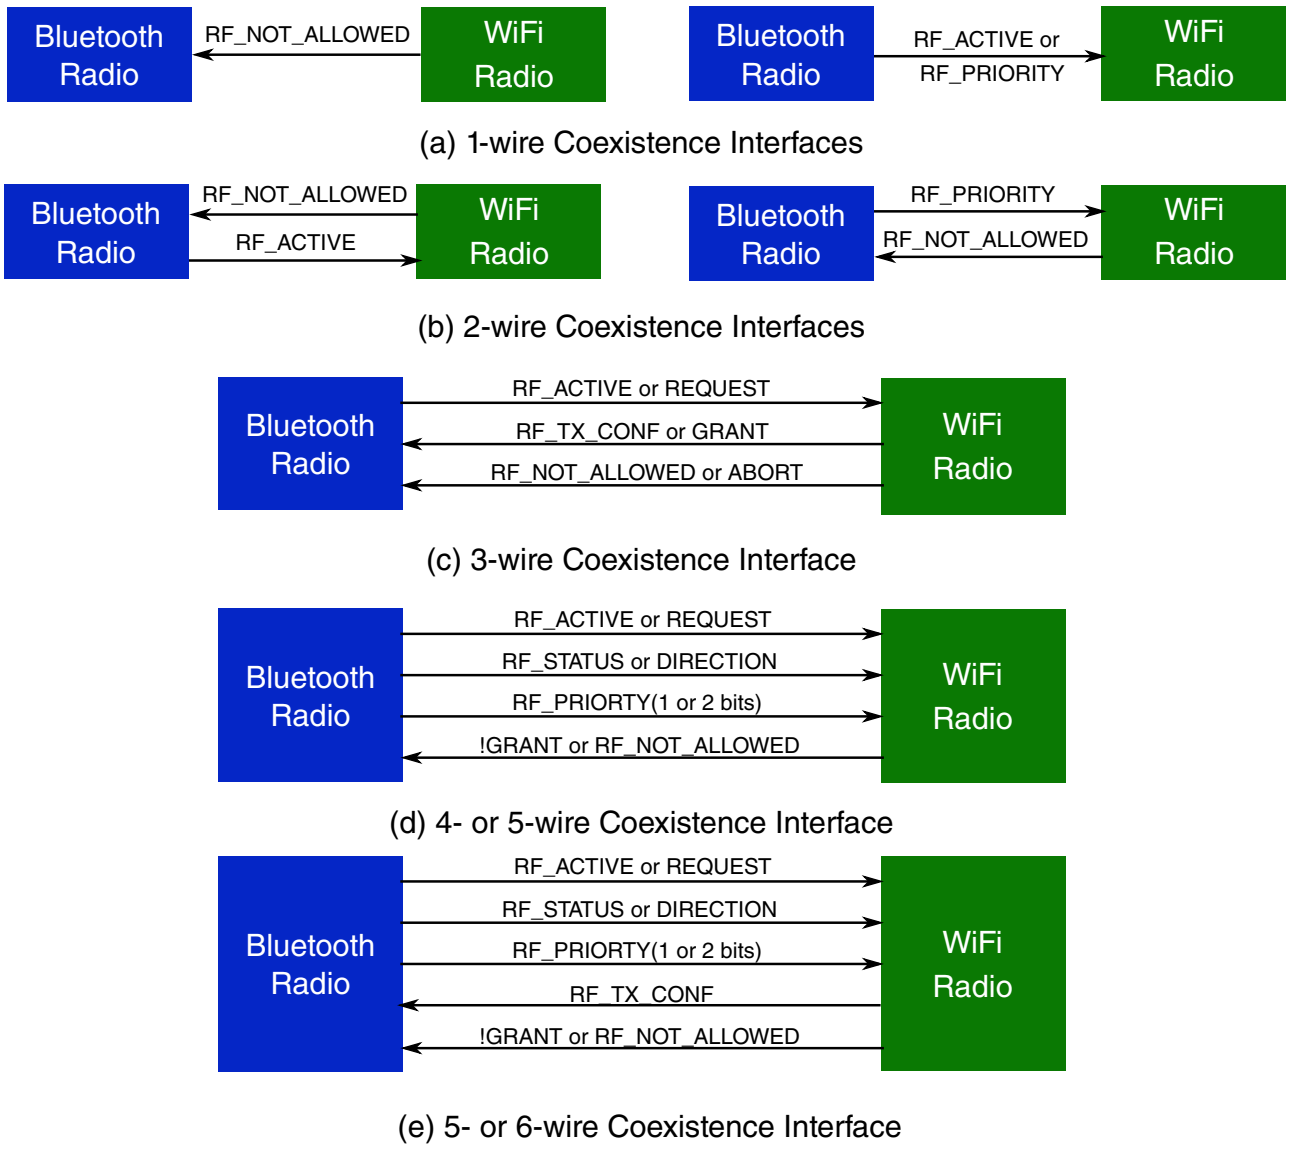


Figure 283. Coexistence signaling options between Bluetooth-LE and WiFi Radios

52.4.4.1.5.3 Example Coexistence Pin Mapping

The table below shows example mapping of legacy coexistence signals supported by the NB 2.4GHz radio for a few WiFi radios available in the market.

WiFi Co-existence Use Case	RF_ACTIVE	RF_STATUS	RF Priority	RF_NOT_ALLOWED	RF_TX_CONF	WiFi SoC
Direction	Output	Output	Output	Input	Input	
Functionality	Indicates a Radio Event; Needs to stay asserted during a radio event; Deasserted if RF_NOT_ALLOW ED==1	Indicates RX/TX event. Optionally RF_Priority signal can be mixed on it	Specifies RF_ACTIVE priority to an external traffic arbiter	Indicates an external command for the NB radio to cease radio activity	Indicates grant of antenna to TX; Need to sample if RF_priority requested; can be any GPIO	
1-Wire Interface, WLAN is Master				X		
1-Wire Interface, BT is Master	X					
2-Wire Interface, Cross Signaling between BT and WLAN	X			X

4-wire: Phillips Interface	X	X		X	X	

52.4.4.1.6 Radio Coexistence/FEM/LANT Connections

The Radio provides flexible mux configuration for 4 coexistence outputs, 4 FEM control outputs and 4 Localization outputs. The detailed connections are shown in below diagram.

NOTE

For the Bluetooth LE use case using the NBU: once asserted the bt_grant_n input should remain asserted until 10us after the bt_request has been de-asserted.

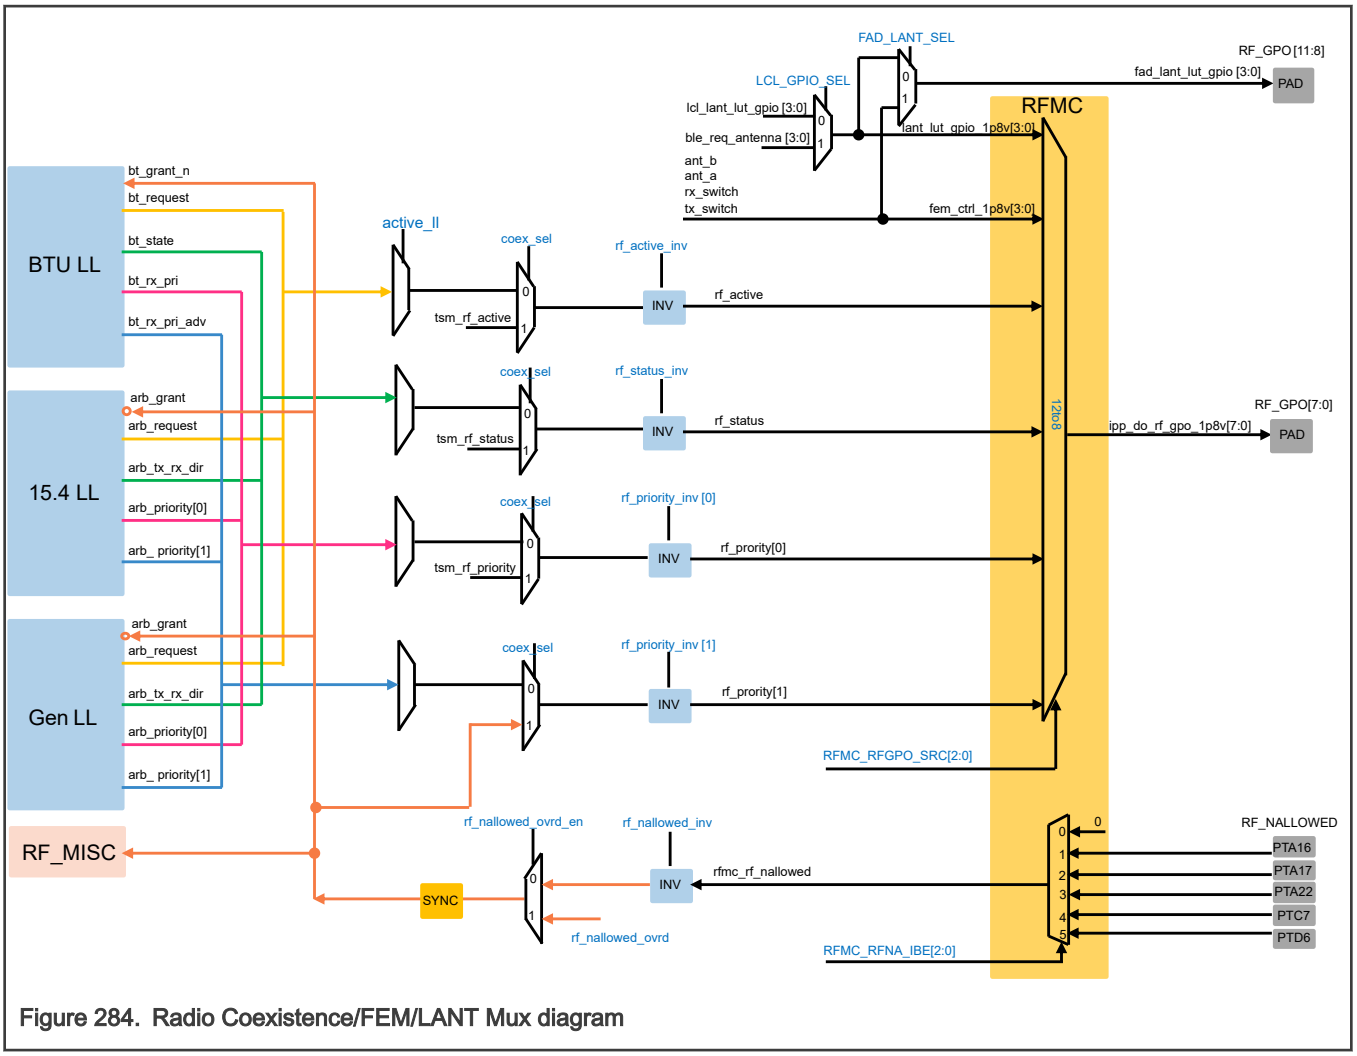

Figure 284. Radio Coexistence/FEM/LANT Mux diagram

52.4.4.2 Transceiver

52.4.4.2.1 Overview

The transceiver is built to support concurrent transmit and receive operations in the 2.4Ghz bands. The PHY layer supports the following protocols :

- Bluetooth Low Energy (BLE) and Channel Sounding
- IEEE 802.15.4 (Zigbee, Thread …)
- Generic FSK

The arbitration between protocols is managed by software through Link Layers.

52.4.4.2.1.1 Block diagram

The transceiver uses a constant envelope direct launch transmitter and a low IF quadrature receiver. A high level figure illustrating the digital and analog components and their hierarchy is shown below.

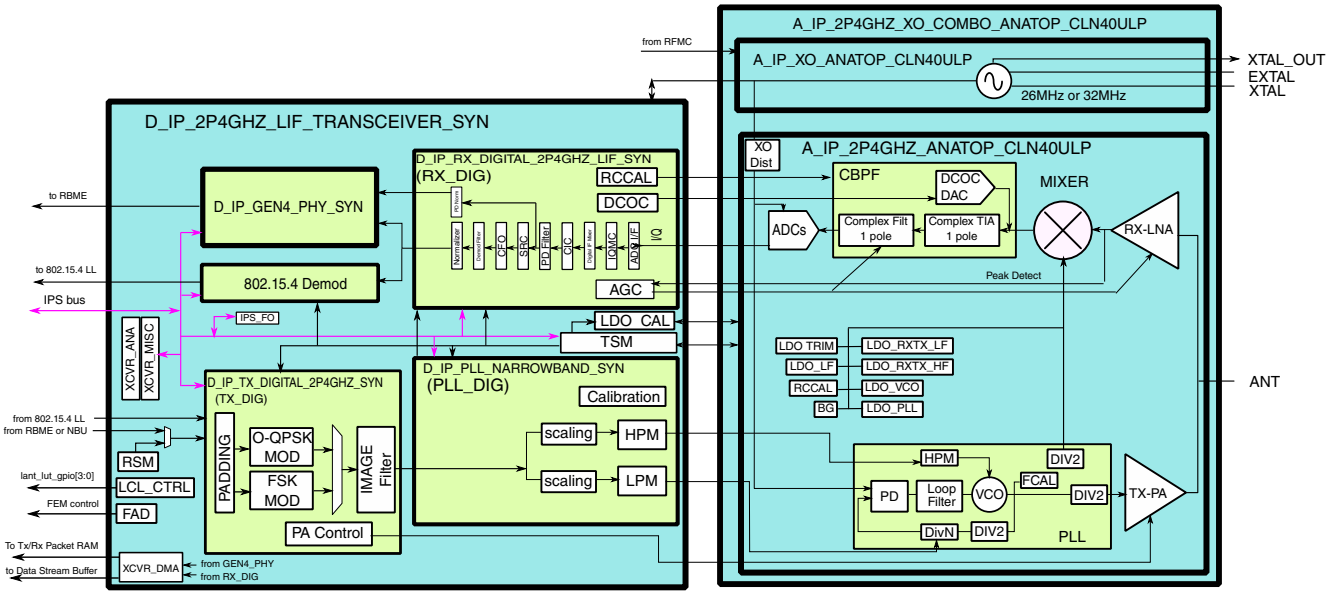

Figure 285. Transceiver Hierarchy

52.4.4.2.1.2 Features

The digital part of the transceiver is split in several sub-modules:

- Transmitter digital module
- Receiver digital module
- PLL digital module
- Zigbee PHY
- 2.4GHz FSK PHY
- Transceiver sequence manager (TSM)
- DMA
- Localization control module (LCL)
- Ranging sequence manager (RSM)
- LDO calibration

52.4.4.2.2 Functional description

52.4.4.2.2.1 Transmitter Digital Module (TX_DIG)

52.4.4.2.2.1.1 Overview

The Transmitter Digital (TX_DIG) processes the Transmission Data from the RF Protocol Link Layers and presents the processed data to the PLL Frequency Synthesizer as the Baseband Frequency Word.

PFC_en (Phase to Frequency Conversion) is set when zigbee symbols are to be transmitted.

52.4.4.2.2.1.1.1 Block diagram

1. Modulation Type is set using TXDIG:MODULATION_TYPE.
2. Data Rate is set using XCVR_CTRL:DATA_RATE[2:0].
3. Bandwidth Time Product is changed by reprogramming the GFSK Gaussian Filter coefficients.

52.4.4.2.2.1.1.2.2 Data Rates

For other Radio protocols, the Transit Data Rate is set by the DATA_RATE bits in the XCVR_CTRL register.

The supported data rates are shown in the table below.

Table 462. Transmitter Data Rates

XCVR_CTRL: DATA_RATE[2:0] Identifies the data rate at the output of the PHY	TX Data Rate
000	2Mbps
001	1Mbps
010	500Kbps
011	250Kbps
100-111	Reserved

52.4.4.2.2.1.1.2.3 Over-Sampling

The TX Digital uses an Oversample Clock to process the transmission data.

The GFSK, GMSK, and MSK Oversample Ratios are summarized below.

Table 463. Oversample Ratios for GFSK, GMSK, and MSK Modulations

TX Data Rate (kb/s)	Ref Clk Freq (MHz)	OSR Ref Clk Divider	OSR Clk Rate (MHz)	Data Oversample Rate
2000	32	2	16	8
1000	32	4	8	8
500	32	8	4	8
250	32	16	2	8
2000	26	1	26	13
1000	26	2	13	13
500	26	4	6.5	13
250	26	8	3.25	13

52.4.4.2.2.1.1.2.4 Frequency Word Adjust

The Transmitter has a frequency adjustment register, FREQ_WORD_ADJ, which is used as a signed 9-bit number that is added to the TX Digital output before it is presented to the PLL as the baseband frequency word. This allows the baseband frequency word to be adjusted, or skewed, by a range of -512 to +511.

This frequency adjustment is applied to the final modulation word from any source (GFSK, FSK, DFT) and there is no protection from a math overflow. So the baseband frequency word range of -4096 to 4095 must be considered when adding this frequency word adjustment.

52.4.4.2.2.1.2 Functional description

52.4.4.2.2.1.2.1 Data Pre-Processing

Before the Transmission Data is processed by the GFSK or FSK Modulators, it can be inverted, and it can also have additional preamble-like data pre-pended.

52.4.4.2.2.1.2.1.1 Data Polarity

The Transmission Data that is received by the TX Digital module is mapped to a positive frequency deviation if the data is a 1, and is mapped to a negative frequency deviation if the data is a 0

This mapping can be reversed by setting the TX_CAPTURE_POL register bit.

52.4.4.2.2.1.2.1.2 Data Padding

Transmission Data Padding is done to avoid abrupt steps in On-Air frequency modulation and thereby minimize spectral transients during the transition from a low Power Amplifier setting to a high Power Amplifier setting prior to protocol data packet transmission.

The abrupt step in modulation is avoided by pre-pending frequency words onto the front end of the actual preamble transmission. The Power Amplifier ramp-up is done while modulating these additional frequency words, and then the modulating power ramp-up smoothly transitions into the packet transmission at the Target Power level.

The data-padding starts right after TxDig_en and is applied to the Tx modulator before and during PA ramp-up as well as PA settling time(PAD_DLY plus PA_PUP_ADJ).

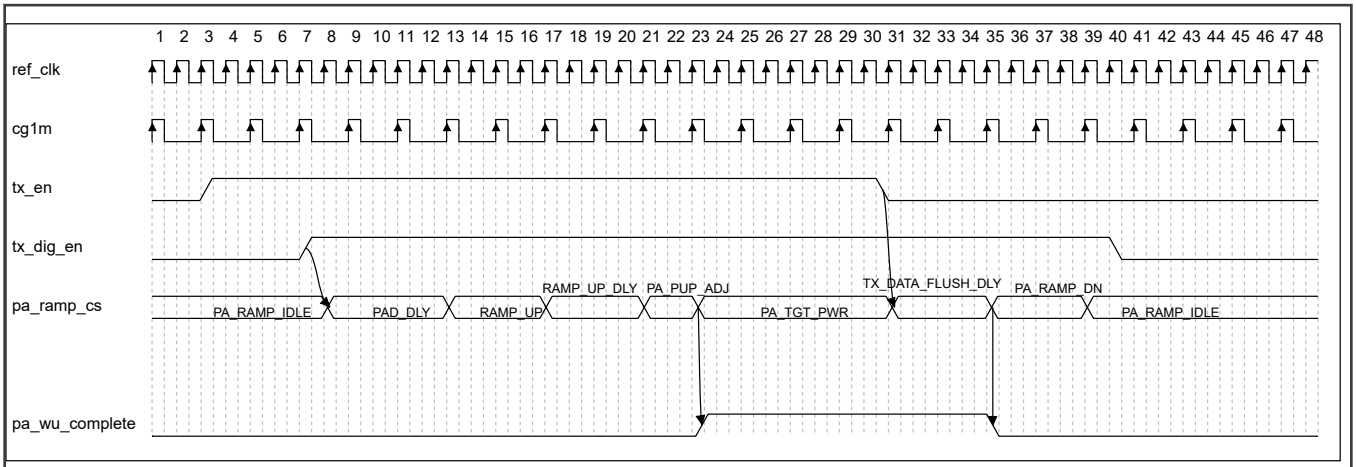

Figure 287. TX padding

There are basically three data padding steps:

- PAD_DLY, if enabled, it adds symbols before rampup.
- RAMP_UP_DLY, smooth transitions to the target power level.
- PA_PUP_ADJ, additional settling time, 2 times ref_clk cycles.
- TX_DATA_FLUSH_DLY, if enabled, it adds symbols before it starts ramping down.

DATA_PADDING_CTRL[PAD_DLY_EN],

- 1'b0, Pad delay is disabled.
- 1'b1:, Pad delay is enabled, and will insert 0-0-0-0... or 1-1-1-1..., based on data_padding_en settings.

DATA_PADDING_CTRL_1[RAMP_UP_DLY]

- It adds the number of cycles after PA ramp-up is completed, up to 31 cg1m cycles.

Table 464. Data Padding Selection

DATA_PADDING_EN[1:0]	Frequency word to PLL
00	13'h000
01	data_pad_pfdev
10	data_pad_mfdev
11	Reserved

52.4.4.2.2.1.2.1.3 Power Amplifier Ramping

PA ramping is included in the 2p4, to prevent abrupt transitions in PA (power amplifier) power, that could cause unwanted spectral transients. During a TX sequence, PA ramping gradually ramps up PA power, between a programmable minimum, and the TX target power. The trajectory of the ramp is programmable, and ramping takes place over the course of 1, 2, or 4us (programmable).

During ramp-down of the Power Amplifier the TX Digital holds the TX Modulation Data at the final value until power reaches the minimum level.

Please refer to the section Power Amplifier Ramping in the Transceiver Sequence Manager chapter for more details.

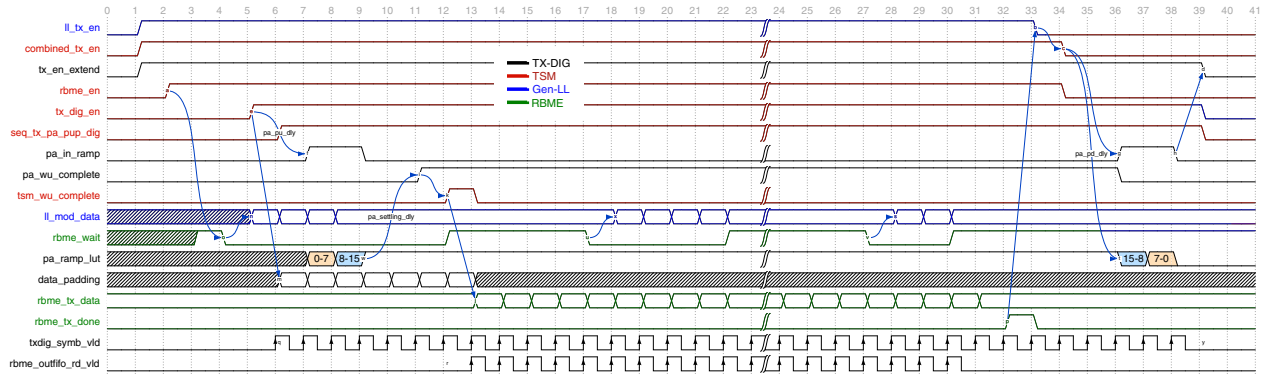

Figure 288. Power Amplifier Ramping

52.4.4.2.2.1.2.2 TX Warmup

When a Link Layer asserts *source*_tx_en (or software sets the FORCE_TX_EN bit) to start a TX burst, the TSM TX warmup sequence will begin. Near the end of the TSM TX warmup sequence, a TSM timing signal (tx_dig_en) will signal to the TXDIG to ramp-up the PA and start sending TX data.

The TXDIG warmup time is the time from tx_dig_en TSM signal assertion to when the TX is ready to send bits on air, which is the assertion of pa_wu_complete by the TXDIG.

The TXDIG warmup time depends on the following:

- pa_ramp_pad
- pa_ramp_up
- pa_ramp_settle (ramp_up_dly+pa_pup_adj)

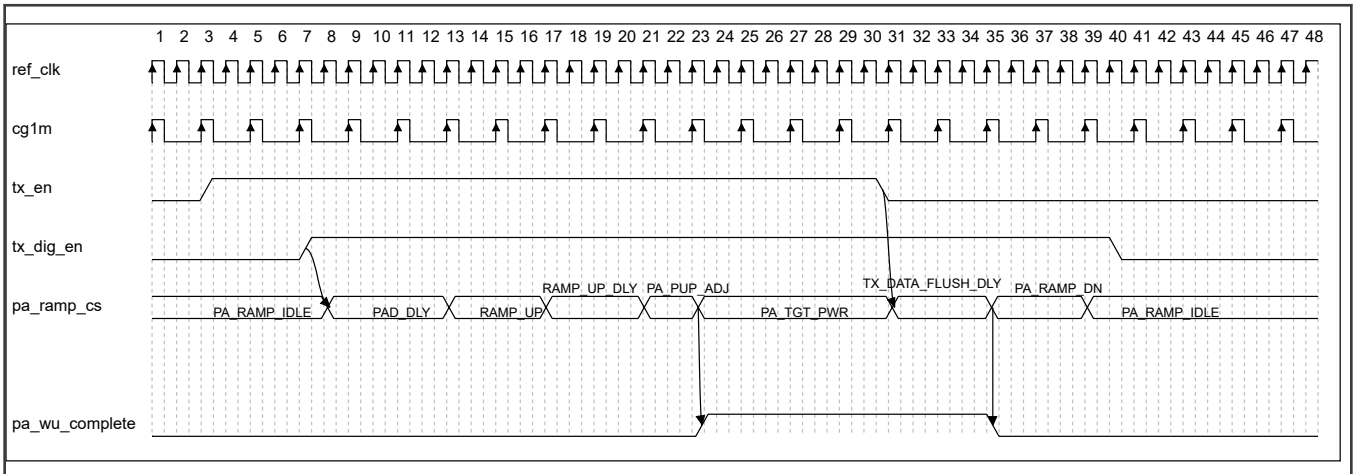

Figure 289. TX warmup delay

So the total TX warmup delay is composed of the following:

- pa_ramp_pad: DATA_PADDING_CTRL[PAD_DLY], in cg1m cycles ,padding before ramp-up (0 if PAD_DLY_EN=0)
- pa_ramp_up: PA_CTRL[PA_RAMP_SEL], 0us, 1us, 2us, or 4us.
- pa_ramp_settle:
  - ramp_up_dly : DATA_PADDING_CTRL_1[RAMP_UP_DLY], number of cg1m cycles plus
  - pa_pup_adj : DATA_PADDING_CTRL[PA_PUP_ADJ], 2 times the number of ref_clk cycles.

52.4.4.2.2.1.2.3 PA Ramping

PA ramping is included in the TXDig, to prevent abrupt transitions in PA (power amplifier) power that could cause unwanted spectral transients. During a TX sequence, PA ramping gradually ramps up PA power, between a programmable minimum, and the TX target power. The trajectory of the ramp is programmable, and ramping takes place over the course of 16 steps, 16 times the bit rate.

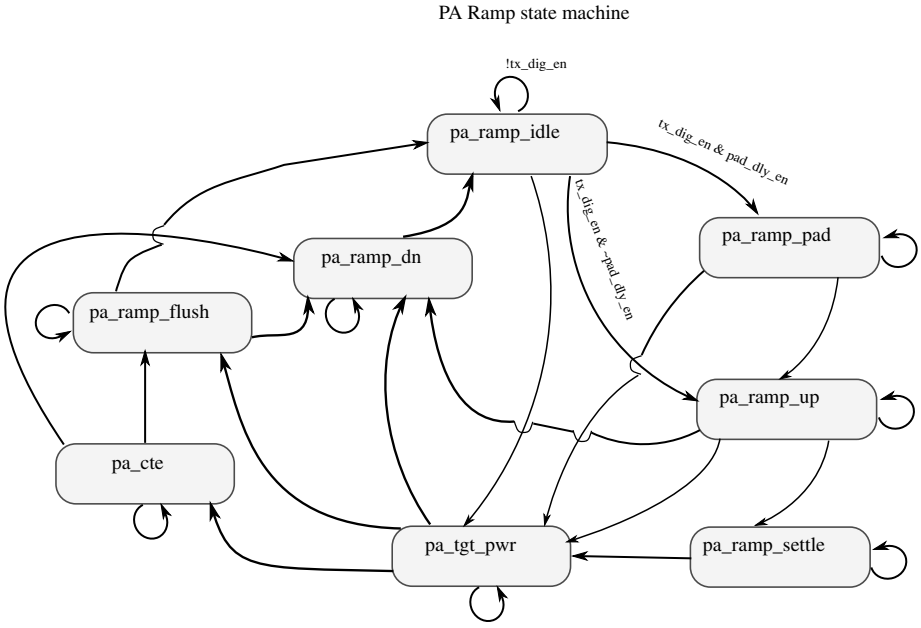

Figure 290. PA Ramp state machine

All fields used below for PA Ramping are contained in PA_CTRL register.

During a TX sequence, PA ramping is triggered by a low-to-high transition of tx_dig_en. At assertion of tx_dig_en the TX Dig will enable the PA, with a minimum power level determined by the lowest power level which is 0 according to a 16-deep pre-programmed register table (PA_RAMP_TBL table). After that, power level will increment according to the table. Incrementing will occur at 16 times the bit rate. At each ramp step, PA power level will be taken from the next entry in the PA_RAMP Table, from 0-15.

After the 16th and final ramp step, PA power level will be the selected target power in PA_TGT_POWER[5:0]. The target power will remain in effect for the duration of the packet transmission.

The overall time for ramping is determined by PA_RAMP_SEL[1:0] (no ramping/1us/2us/4us). For further explanations of PA Ramping , v_ramp_dur will be used to indicate the duration of ramping.

PA_RAMP_SEL[1:0]	v_ramp_dur
0x0	No ramping

Table continues on the next page...

Table continued from the previous page...

PA_RAMP_SEL[1:0]	v_ramp_dur
0x1	1us
0x2	2us
0x3	4us

3 Functional modes can be identified below (they depend on PA_RAMP_SEL) :

- Ramping LUT mode : classical digital ramping, default mode
- Ramping with Linear Interpolation : PA_RAMP_DIG_INTERP_EN bit to enable .
- Ramping with Analog Control :
  - PA_RAMP_ANA_EN bit to enable.
  - PA_RAMP_ANA_IDX[3:0] to select the index from which Analog control will jump over to target power.
  - PA_RAMP_ANA_IDX_TYPE to enable invert mechanism during ramp down.
  - PA_RAMP_HOLD[2:0] to add extra delay before cutting PA after ramp down (1us granularity).

Linear interpolation mode and analog mode will control more accurately the PA ramping and limit RF transmission transients.

Next sections below will describe these 3 modes :

52.4.4.2.2.1.2.3.1 Digital Ramping without Interpolation

PA_RAMP_DIG_INTERP_EN = 0 & PA_RAMP_ANA_EN = 0

This is the default modefor PA Ramping.

It ramps by crossing PA power levels (PA_RAMP table) until reaching target-power level.

52.4.4.2.2.1.2.3.2 Digital Ramping with Interpolation

PA_RAMP_DIG_INTERP_EN = 1 & PA_RAMP_ANA_EN = 0

This is a new mode that adds linear interpolation to existing PA_ramp table. It will bring some improvement to manage spurious in RF emission.

Linear Interpolation is a Mathematical Technique to estimate intermediate values between PA power levels (until reaching target-power level) in a straight-line method. It helps to smoothly adjust ramping and achieves a gradual ramp (up or down) to ensure optimal performance.

The intermediate values given by interpolation introduce a v_ramp_interp, which is a factor that depends on PA_RAMP_SEL.

The number of levels of power becomes : 16*v_ramp_interp , with :

PA_RAMP_SEL[1:0]	v_ramp_interp
0x0	No ramping
0x1	2
0x2	4
0x3	4

52.4.4.2.2.1.2.3.3 Analog Ramping

To enable this feature in the analog block, it is necessary to program the TX_DAC_PA[PA_SMOOTHER_EN] register to one, and then play with different current levels with TX_DAC_PA[PA_SMOOTHER_CUR], which will vary the speed (settling time) of the analog ramp.

To enable the feature in the digital block, program the following values:

PA_RAMP_DIG_INTERP_EN = 0 & PA_RAMP_ANA_EN = 1

This will disable Digital Interpolation when analog ramping is in use.

52.4.4.2.2.1.2.4 GFSK Modulator
52.4.4.2.2.1.2.4.1 Gaussian Filter

GFSK Modulation is implemented using a Gaussian filter and a lookup table to implement the various reference frequencies, data rates, and modulation index values.

The Gaussian filter is a symmetric 16-tap FIR filter with 9-bit quantized coefficients and supports reference frequencies of 32 and 26 MHz at oversampling ratios of 8 and 13 respectively. There are 2 sets of pre-programmed filter coefficients available as shown in the table below.

Table 465. Gaussian Filter Coefficients BT=0.5

Tap Number(s)	32 MHz Ref	26 MHz Ref
0	9'h001	9'h017
1	9'h004	9'h029
2	9'h00d	9'h044
3	9'h029	9'h067
4	9'h063	9'h090
5	9'h0c0	9'h0ba
6	9'h12c	9'h0dc
7	9'h176	9'h0ef
8	9'h176	9'h0ef
9	9'h12c	9'h0dc
10	9'h0c0	9'h0ba
11	9'h063	9'h090
12	9'h029	9'h067
13	9'h00d	9'h044
14	9'h004	9'h029
15	9'h001	9'h017

The pre-programmed filter coefficients can be manually overridden using the gfsk_coeff_man bit to disable the GFSK Filter Lookup Table. In this case the filter coefficients will be taken from the TX GFSK Filter Coefficients register.

The following tables show the coefficients for BT=0.7 and BT=0.3

52.4.4.2.2.1.2.4.2 On-Air Frequency Deviation

By default, the GFSK Modulator presents the modulation word to the PLL starting with the Negative Frequency Deviation, this results in the PLL going On-Air at the Carrier Frequency minus the frequency deviation.

The GFSK Modulator can instead be configured to begin modulating at Zero Frequency Deviation, allowing the PLL to go On-Air at the Carrier Frequency. This configuration is used if the ZERO_FDEV bit in the TX Digital Control register is set.

52.4.4.2.2.1.2.5 FSK Modulator

52.4.4.2.2.1.2.5.1 FSK Modulation Word

The default FSK Modulation mapping translates the chips/bits to a frequency modulation of +Frequency Deviation/PLL Minimum Modulation Step for a data 1, and -Frequency Deviation/PLL Minimum Modulation Step for a data 0.

For a 32 MHz reference clock with a PLL Minimum Modulation Step Size of 244.14 Hz, the default FSK Modulation mapping translates to a +/- 500 kHz peak Frequency Deviation, which is a PLL Baseband Frequency Word of +2047/-2047.

52.4.4.2.2.1.2.5.2 802.15.4 Modes, DFT only.

In Gen4p5, the 802.15.4 mode is only implemented for DFT. No Symbol to chip is implemented, only Phase to Frequency Conversion takes place.

To enable 802.15.4 DFT mode the following settings are needed:

- data_stream_sel = 1'b0.
- radio_dft_mode = 4'b0010: for DFT pattern register.

  or radio_dft_mode = 4'b0011: for DFT LFSR register.
- pfc_en = 1'b1.
- modulator_sel = 1'b1.

52.4.4.2.2.1.2.5.3 FSK Modulator

The FSK Modulation is implemented by mapping directly to a frequency modulation.

For most cases, mFdev is equal to minus Fdev.

Fdev = mod_index * Symbol_Rate/2 * TX_Scale.

TX_Scale = LO_DIV/PLL_Scale

PLL_Scale = 2^PLL_Scale_exp

PLL_Scale_exp = floor(log2(LO_Div))

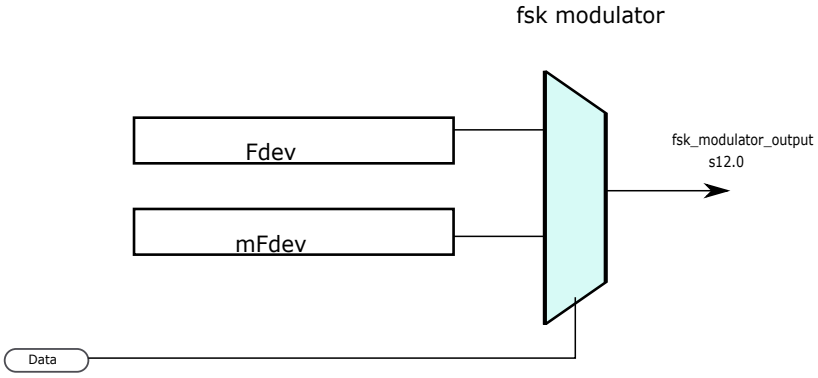

Figure 291. FSK Transmit Modulator

52.4.4.2.2.1.2.6 Data Post-Processing

After the Transmission Data is processed by the GFSK or FSK Modulators, it can be post-processed to remove TX modulation images.

52.4.4.2.2.1.2.6.1 Sample/Hold Images

Power efficient constant envelope transmit modulation is done at a multiple of the symbol clock (Over-Sample Rate), which is chosen as a fraction of the RF Osc reference clock frequency. The transmit modulation signal is then converted to the reference clock rate, at which it is presented to the PLL as the modulation word. This sample/hold (or zero-order hold, ZOH) operation results in TX modulation images that repeat at the fractional reference clock rate at used.

These modulation images are automatically filtered by the sinc ZOH transfer function and the integration (i.e., 1/s) operation of the VCO. These inherent filtering operations result in these modulation images not violating any of the transmit modulation frequency mask. However, to provide additional spectral margin to support using an external power amplifier to boost the transmit power, an image suppression set of FIR filters has been included in the transmit path to suppress the transmit sample/hold images by at least an additional 20 dB.

The transmit image filters are enabled by default in GFSK and GMSK modes and not enabled in IEEE 802.15.4 and MSK modulation modes, but their usage can be overridden using the TX_IMAGE_FILTER_OVRD_EN bit.

52.4.4.2.2.1.2.6.2 Image Filters

The Transmitter uses up to three image filters, by default they are enabled based upon the modulation type and data rate as shown below. There is an option to override the individual filters by programming: sync0_filter_en, sync1_filter_en, and image_fir_filter_en.

Table 469. Default Transmit Image Filter Usage

Ref Clk Freq (MHz)	ModulationType; Data Rate	TX Image Sync0	TX Image Sync1	TX Image FIR

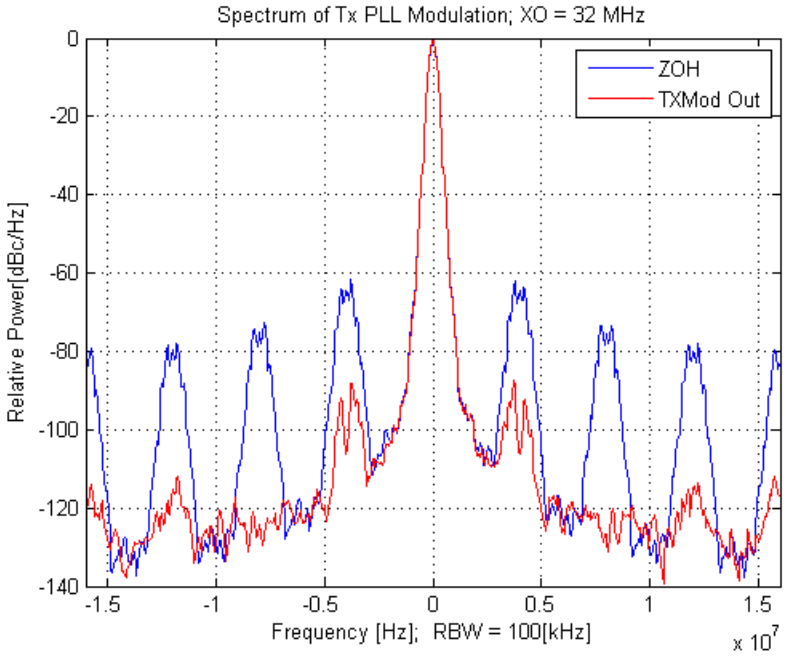

Figure 295. Comparison of Transmit Modulation Images at the PLL Output for 500 kbps GMSK

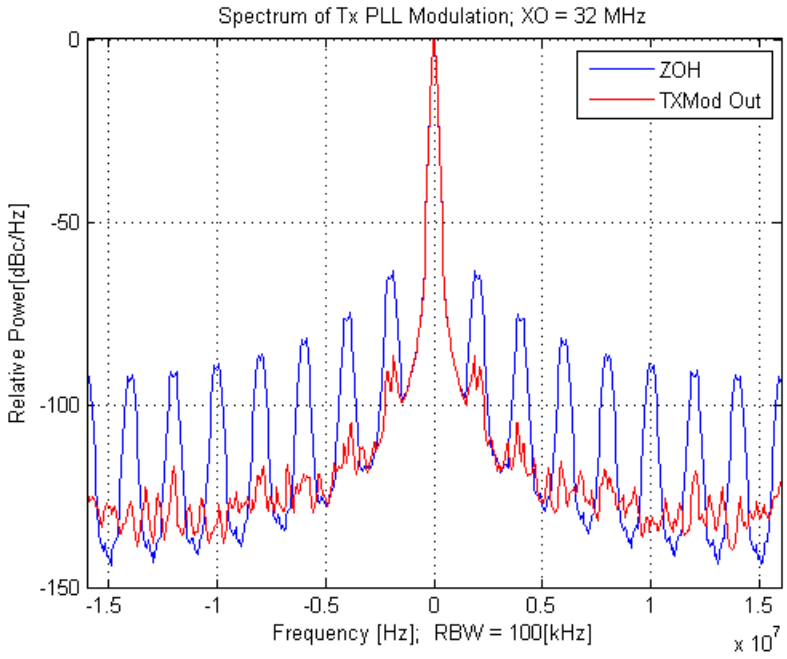

Figure 296. Comparison of Transmit Modulation Images at the PLL Output for 250 kbps GMSK

52.4.4.2.2.1.2.7 CTE (Continuous Tone Extension)

In Bluetooth LE 5.1, Constant Tone Extension (CTE) consists of a constantly modulated series of unwhitened 1 symbols (however TX_DIG 2p4 has the option to transmit 0 symbols as well). The Constant Tone Extension is not included in CRC or MIC calculations and it follows the CRC transmission in the packet. The Constant Tone Extension has a variable length with a minimum duration of 16us.

For direction finding applications, CTE is transmitted during various phases of the programmed antenna switching pattern that compromises of the guard period, the reference period and the switching/sampling slots.

- The Localization Control Module (lcl_ctrl) asserts tx_cte_on (based on cte_dur).
- When tx_en deasserts, TX_DIG looks at the state of tx_cte_on.

  If deasserted, the pa_ramp_cs behaves normally, it will go through the data flush state if a value other than zero is programmed, then it will ramp down.

  If tx_cte_on is asserted, then the pa_ramp_cs state machine keeps the state at target power, then it transmits 0 if CTE_DATA = 1'b0 or 1 if CTE_DATA = 1'b1 (DATA_PADDING_CTRL[4]).

  When tx_cte_on is deasserted, then the state machine behaves as normal: it will go through data flush if a value other than zero is programmed and then it will enter ramp down.

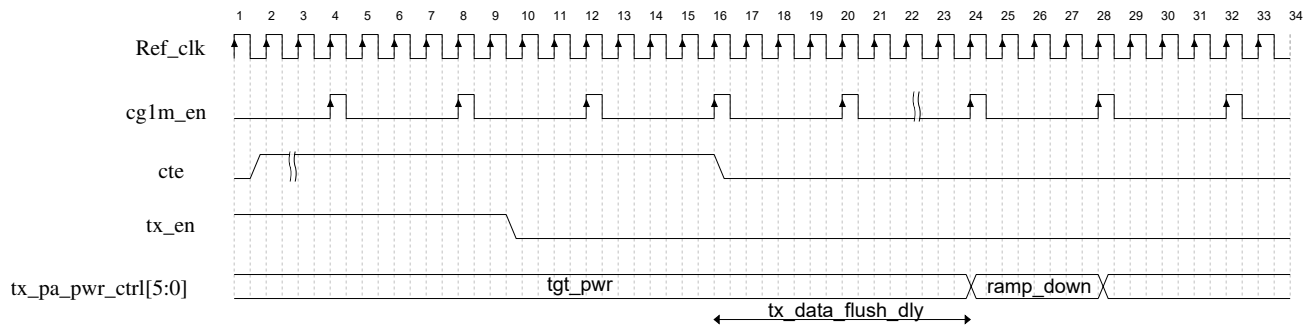

Figure 297. CTE

52.4.4.2.2.1.2.8 Clocking

The TX_DIG uses two clocks, the 26 or 32MHz RF reference clock (ref_clk), and the IPS gated clock (ips_clk) that has been synchronized to the RF reference clock. All programming model registers are clocked by the IPS clock. All other registers are clocked by the RF reference clock.

52.4.4.2.2.1.2.9 Reset

All TX_DIG registers that require a reset are reset by a global asynchronous reset. In addition, a software reset from 2P4Ghz XCVR can reset all TX_DIG modules except TX_DIG control register module.

52.4.4.2.2.1.2.10 Interrupts

This module has no interrupts.

52.4.4.2.2.1.2.11 DMA

There is no DMA associated with this TX_DIG module.

52.4.4.2.2.1.3 External signals

Table 470. Signal description

Signal Name	Direction	Description
ipg_hard_async_reset_b	Input	Hardware asynchronous reset
soft_reset	Input	Software reset
ref_clk	Input	Reference clock
ips_clk	Input	IPS clock
tx_data_out	Input	BLE stream input
tx_symbol_out[3:0]	Input	Zigbee stream input
tx_modulator_output[12:0]	Output	Baseband frequency word for PLL modulation
tx_pa_pwr_ctrl[5:0]	Output	Power amplifier command

52.4.4.2.2.1.4 Initialization

1. Choose correct signal path for TX modulation:
    a. TXDIG_CTRL[MODULATOR_SEL] set to 0 for GFSK or set to 1 for FSK.
    b. TXDIG_CTRL[PFC_EN] set to 1 for phase to frequency conversion or set to 0 if not required.

c. TXDIG_CTRL[DATA_STREAM_SEL] set to 0 for tx_data_padding path or set to 1 for symbol_to_chip path.

2. Enter frequency deviation values:
   a. For FSK:
      i. For 1 Mb/s case: FSK_CTRL[FSK_FDEV_0] and FSK_CTRL[FSK_FDEV_1].
      ii. For 2 Mb/s case: DATARATE_CONFIG_FSK_CTRL[DATARATE_CONFIG_FSK_FDEV0] and DATARATE_CONFIG_FSK_CTRL[DATARATE_CONFIG_FSK_FDEV1].
   b. For GFSK:
      i. For 1 Mb/s case: GFSK_CTRL[GFSK_FDEV].
      ii. For 2 Mb/s case: DATARATE_CONFIG_GFSK_CTRL[DATARATE_CONFIG_GFSK_FDEV].
3. Choose power amplifier (PA) target source:
   a. If PA value is set by link layer, set PA_CTRL[TGT_PWR_SRC] to 1. Please note that whatever is the Link Layer (BLE, Zigbee or GenericFSK), only the 6 LSB of its PA target power related register will be used to program the target power at the PA controller.
   b. If PA value is not set by link layer, set PA_CTRL[TGT_PWR_SRC] to 0 and choose target value with PA_CTRL[PA_TGT_POWER].

52.4.4.2.2.1.5 Application information

The procedures to use this TX_DIG module are described in the sub_chapters and register definition.

52.4.4.2.2.1.6 Register descriptions

The Transmitter Digital memory map and detailed descriptions of all its registers are as follows.

52.4.4.2.2.1.6.1 XCVR_TX_DIG register descriptions

31 TX_PA_PUP_OVRD_EN	TX_PA_PUP_OVRD_EN This bit enables the TX PA_PUP Control bit.
30 TX_PA_PUP_OVRD	TX_PA_PUP_OVRD If the TX_PA_PUP_OVRD_EN bit is set, then this bit turns on (=1) and off (=0) the Transmit TX_PA_PUP bit.
29-28 —	Reserved
27-25	PA_RAMP_HOLD

Table continues on the next page...

Table continued from the previous page...

Field	Function
PA_RAMP_HOLD	Indicates the hold duration after ramp down before switching of pa_pup in us (Only in Analog ramping).
24 PA_RAMP_ANA_IDX_TYPE	PA_RAMP_ANA_IDX_TYPE When set to 1, the jump in LUT will be done at pa_ramp_idx value during ramp up and 15-pa_ramp_idx during ramp_down , to speed up power transition for analog mode ramping.
23-20 PA_RAMP_ANA_IDX	PA_RAMP_ANA_IDX Index used for analog mode set by PA_RAMP_ANA_EN. Once reached, internal ramp counter completes current phase (ramp up or ramp down) in minimum delay. . If PA_RAMP_ANA_IDX_TYPE is 0, the jump in LUT will be done at pa_ramp_idx value during ramp up and ramp down. If PA_RAMP_ANA_IDX_TYPE is set to 1, the jump in LUT will be done at PA_RAMP_ANA_IDX value during ramp up and 15-PA_RAMP_ANA_IDX during ramp down. PA_RAMP0..15 fields in PA_RAMP_TBLx registers must be set accordingly.
19 PA_RAMP_ANA_EN	PA_RAMP_ANA When set, digital ramping is shortened to handover control to analog after a given threshold. Digital ramping starts as in normal mode but as soon as internal counter selects PA_RAMPn with n=PA_RAMP_ANA_THR, next PA_RAMPp steps with p>n are skipped, and PA_TGT_POWER is applied. Ramping done starts from PA_TGT_POWER then jumps directly to PA_RAMPn then goes on decreasing as in normal mode.
18 PA_RAMP_DIG_INTERP_EN	PA_RAMP_DIG_INTERP Select interpolation mode between 2 outputs of the LUT. 0 is no interpolation, 1 is linear interpolation. When bit is set to 1 , the number of levels of power becomes : 16*v_ramp_interp. V_ramp_iterp = 2 with pa_ramp_sel = 1, 4 with pa_ramp_sel > 1. The total duration will still be the same (1/2/4 us acording to pa_ramp_sel).
17-16 PA_RAMP_SEL	PA_RAMP_SEL Indicates the ramp duration or no ramp. 2'b00: Ramp disabled. 2'b01: Ramp = 1us. 2'b10: Ramp = 2us. 2'b11: Ramp = 4us.
15-13 RAMP_CS	RAMP_CS PA Ramp Current State.
12 EARLY_WU_COMPLETE	EARLY_WU_COMPLETE When set, TXDIG 2p4 will assert pa_wu_complete after ramp-up without waiting for the settling time to expire (DATA_PADDING_CTRL_1[RAMP_UP_DLY]). If not set, the assertion of pa_wu_complete takes place normally, that is to say, after ramp-up the assertion of pa_wu_complete will happen after the number of cg1m cycles programmed in RAMP_UP_DLY have happened.
11-9	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
8 TGT_PWR_SRC	TGT_PWR_SRC Indicated the source of the target power value. 1'b0: Target power specified in PA_TGT_POWER field. 1'b1: Target power specified by the link layer. Please note that whatever is the Link Layer (BLE, Zigbee or GenericFSK), only the 6 LSB of its PA target power related register will be used to program the target power at the PA controller.
7-6 —	Reserved
5-0 PA_TGT_POWER	PA_TGT_POWER The contents of this register are used as PA target power when TGT_PWR_SRC=0.

52.4.4.2.2.2 Receiver Digital Module (RX_DIG)

52.4.4.2.2.2.1 Overview

The 2.4GHz Receive Digital Module(RX_DIG) implements the receive digital signal processing functions common to Bluetooth LE, 802.15.4, and Generic Link Layer modes. Generally this includes conditioning the input samples from the ADC and produces a data output for the PHY and an RSSI/LQI for the Link Layers.

52.4.4.2.2.2.1.1 Block Diagram

52.4.4.2.2.2.1.1.1 Data Path

RX_DIG data path is shown below.

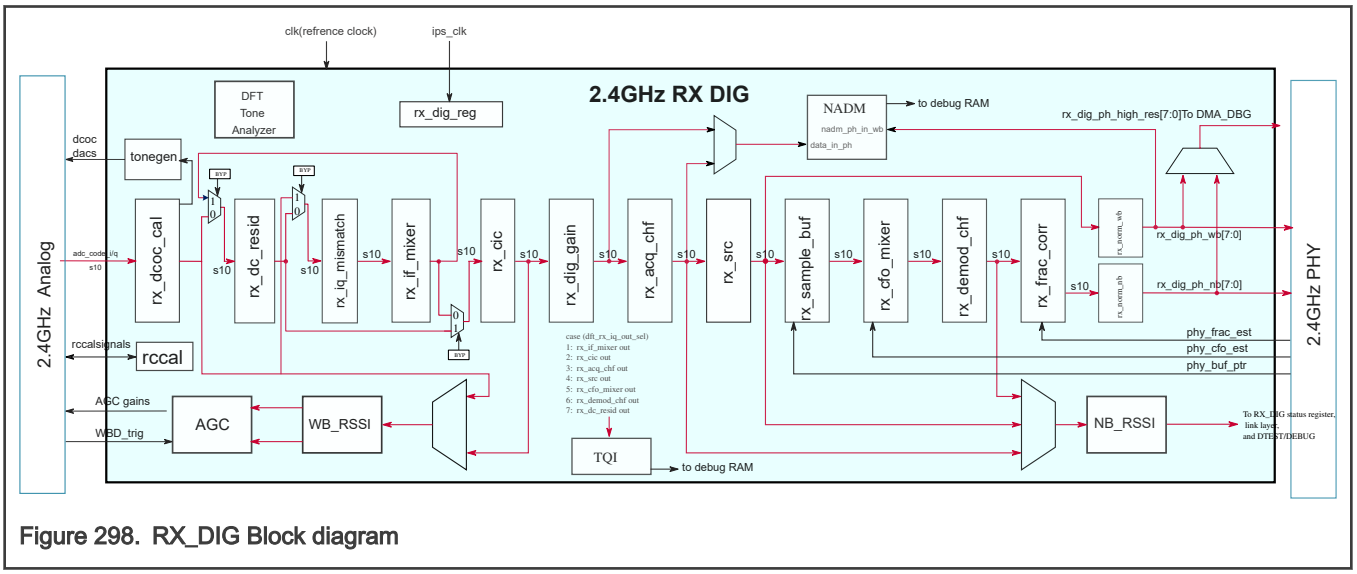

Figure 298. RX_DIG Block diagram

52.4.4.2.2.2.1.1.2 Auxiliary Output

RX_DIG has different kinds of auxiliary output for localization applications, test, or debug purposes. The following figure illustrates the structure of RX_DIG auxiliary outputs. The IQ, phase, and magnitude output support window average function, which

controlled by the DFT_RX_IQ_OUT_SEL field, and the average window size can be chosen from 1(disabled), 4, 8, 16, 32, 64, 128, and 256. An additional smaller complementary average window can be selected from 1(disabled), 4, 8, and 16 for IQ to supply an unique PCT (Phase Correction Term) value to packet RAM via tone_pct. The rx_iq_8b_out is sent to NBU, while other signals mapped to DTEST and/or DMA_DEBUG pages.

NOTE

Check RSSI Estimator section to get the detail information of RSSI and magnitude signals

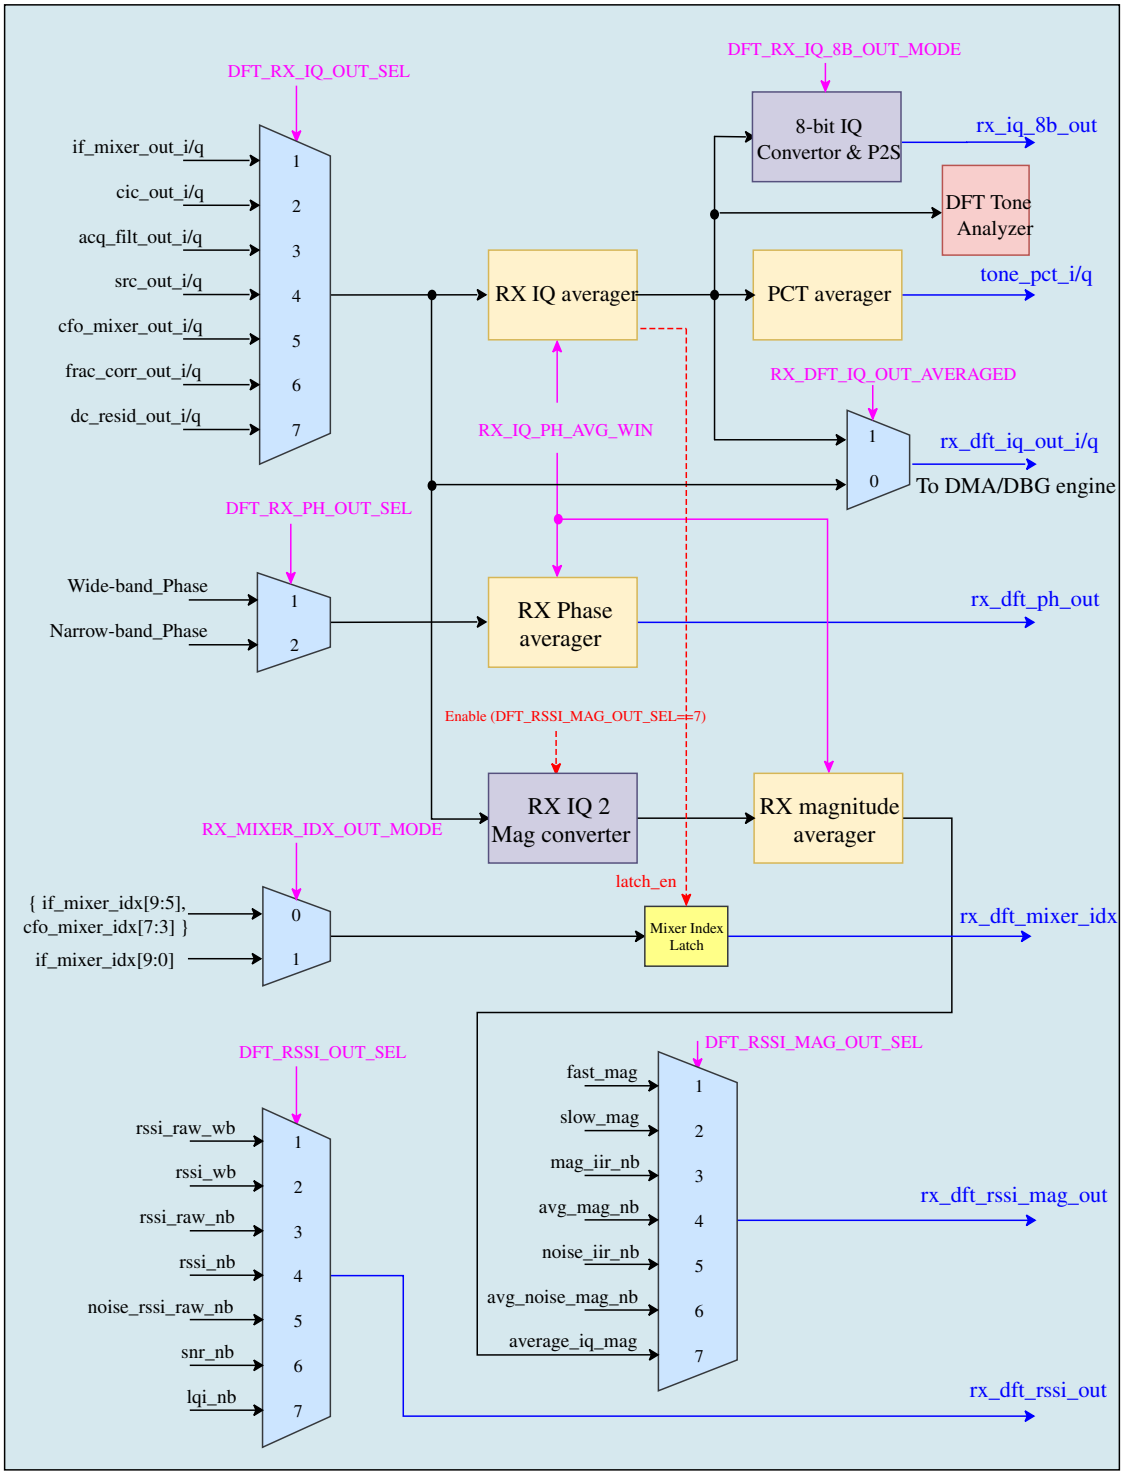

Figure 299. RX_DIG outputs selection diagram

52.4.4.2.2.2.1.2 Features

The 2.4GHz RX_DIG module includes the following features:

- Automatic Gain Control (AGC)
- CIC Decimation Filtering
- Digital IF mixer
- CFO correction
- IQ Mismatch Correction
- Fractional Correction
- Acquisition Channel Filter(16, 24-tap configurable)
- Demod Channel Filter
- Sample Rate Converter
- DC Offset Calibration and Correction
- DC Residual Correction
- Wide-Band and Narrow-Band RSSI estimator module
- Two instances of Normalizer(Wide-Band, Narrow-Band)
- RC Calibration
- Tone Quality Indicator (TQI)
- Normalised Attack Detection Metric (NADM)
- Tone Analyzer
- Multiple Auxiliary Output

52.4.4.2.2.2.1.3 Data Format

The 2.4GHz Radio contains fixed-point data path. In this document, there're two kinds of format to represent the fixed-point data, one is Simulink format [u/s]fix[Nb]_En[Nx], e.g. sfix8_En5, ufix8. And another is the customary format [u/s][N].[M], e.g. s2.5, u8(or u8.0). The below tables show how to parse the fixed point values to real.

Simulink format	
ufix or sfix	Denotes the number is unsigned or singed
Nb	Denotes the total number of bits, including the sign bit if signed
Nx	Denotes the number of bits for fractional

Customary format	
u or s	Denotes the number is unsigned or singed
N	Denotes the number of bits for integer
M	Denotes the number of bits for fractional

Examples	Note: signed values stored as 2's complement.			
Bin	Simulink	Customary	Total bits	Real value
00001111	ufix8	u8 or u8.0	8	15
10000011	ufix8	u8 or u8.0	8	131
0_0011001	sfix8	s7 or s7.0	8	25
1_1111110	sfix8	s7 or s7.0	8	-2
01_011000	ufix8_En6	u2.6	8	1.375
11_000001	ufix8_En6	u2.6	8	3.015625
0_10_11000	sfix8_En5	s2.5	8	2.75
1_11_11100	sfix8_En5	s2.5	8	-0.125

52.4.4.2.2.2.2 Functional Description

52.4.4.2.2.2.2.1 Datarate Selection

The Gen4 Radio has a hardware feature, called datarate selection, to change TX and RX datarate automatically. When RX_DIG.datarate_config_sel = 0, RX_DIG will use primary configuration values. When RX_DIG.datarate_config_sel = 1, RX_DIG will switch to use another set of configuration values for the secondary datarate. All config registers or register fields with "_DRS" postfix indicate registers which will be used for the secondary datarate.

52.4.4.2.2.2.2.2 DC Offset Calibration and Correction

The DCOC block supports the DC offset calibration during RX warmup, and DC correction after RX warmup.

52.4.4.2.2.2.2.2.1 DC Calibration

DC calibration is expected to be performed during each RX warmup. A figure illustrating DCOC during DC calibration is shown below.

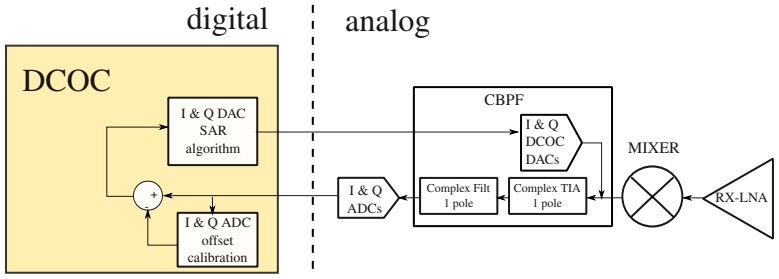

Figure 300. DC Calibration

During DC calibration the following steps are performed

1. The ADC is isolated by putting the CBPF output in a HiZ state, and the ADC inputs are shorted
2. The I and Q ADC outputs are averaged over 4 samples to estimate the DC offset related to the ADCs. These DC offsets are then subtracted from the ADC outputs which are used in steps #4-X below
3. The LNA output is put in HiZ, and the CBPF is put in high gain configuration
4. A SAR algorithm is used to determine the best values for the I DAC. If DCOC_CTRL[DCOC_DAC_ORDER]=1, the Q DAC is used instead in this step.

5. A SAR algorithm is used to determine the best value for the Q DAC. If DCOC_CTRL[DCOC_DAC_ORDER]=1, the I DAC is used instead in this step.
6. Measure the digital correction value on I and Q channel and send the result to the RO register DCOC_DIG_CORR_RESULT. If DCOC_CTRL0.DCOC_DIG_CORR_EN=1(default value), during RX_DIG enabled, the DCOC will compensate the digital correction values on both I and Q channel.

During the SAR for the I DAC, the SAR algorithm evaluates a 4-sample average of the following expression:

SAR_IN = SFIQ * QADC2 + (SFIIP)*(SFII/16) *IADC2

where SFIQ is programmable to be either 0 or 1, SFIIP is programmable to be +1 or -1, SFII is programmable from 0 to 15, IADC2 and QADC2 are the ADC samples corrected by the offsets found in step #2 above.

During the SAR for the I DAC, the SAR algorithm evaluates a 4-sample average of the following expression:

SAR_IN = SFQI * IADC2 + (SFQQP)*(SFQQ/16) *QADC2

where SFQI is programmable to be either 0 or 1, SFQQP is programmable to be +1 or -1, SFQQ is programmable from 0 to 15, and IADC2 and QADC2 are the ADC samples corrected by the offsets found in step #2 above.

After calibration, the ADC offsets and DAC codes determined during calibration can be read in the DCOC_STAT register.

The DCOC has the following additional programmable settings which affect the calibration:

- DCOC_I_CAL_POL. Polarity of the DCOC I DAC
- DCOC_Q_CAL_POL. Polarity of the DCOC Q DAC
- DCOC_CBPF_STL_TIME[3:0]. Settle time in microseconds after estimating the ADC offsets but prior to running the SAR algorithm. This is for the CBPF to be switched from HiZ to high gain.
- DCOC_SAR_STL_TIME[3:0]. Settle time in microseconds during the SAR algorithm, after changing the DAC value
- PULSE_CAPCODE. If this bit is set, then as part of the DCOC calibration sequence, the DCOC calibration logic will direct the RC calibration logic to set its seq_cbpf_ccode output to the maximum value for 3us in order to precharge cap array HiZ nodes.

The programmable values described above are determined through device characterization for the four different CBPF use cases. Preliminary guidance on settings is shown in the table below.

Table 471. DCOC Calibration Settings for 2.4GHz

Programmable Variable	
SFIQ	1
SFQI	1
SFIIP	1
SFQQP	0
SFII	13
SFQQ	9
I_CAL_POL	0
Q_CAL_POL	1
DAC_ORDER	0
CBPF_STL_TIME	3
SAR_STL_TIME	3
PULSE_CAPCODE	0

The total DC calibration duration is a function of the ref clock frequency and some DCOC configs. The reference clock cycle count during DCOC calibration can be calculated as follows:

dcoc_cycle_count = 34 + (CBPF_STL_TIME + SAR_STL_TIME * 12) * count_in_1us + 14 * AVG_WIN_SIZE

Where, count_in_1us = 32 for 32MHz ref clock, and 26 for 26MHz ref clk. CBPF_STL_TIME and SAR_STL_TIME comes from DCOC_CTRL0. AVG_WIN_SIZE = DCOC_CTRL0.DCOC_AVG_WIN ? 8 : 4.

By default config(CBPF_STL_TIME=SAR_STL_TIME=3, AVG_WIN_SIZE=4), dcoc_cycle_count = (ref clock == 32MHz) ? 1338 : 1104. Thus the DC calibration duration is about 42us for 32MHz ref clock and 43us for 26MHz ref clock.

NOTE: DCOC TSM related timing should be updated if the DCOC calibration configs use non-default value.

For a fast RX warmup, the DC calibration is either mostly or entirely skipped, depending on PULSE_CAPCODE. If PULSE_CAPCODE bit is clear, then the TSM fast RX warmup can be programmed such that the TSM enable for the DCOC calibration remains de-asserted during the RX warmup. If PULSE_CAPCODE bit is set, then the TSM fast RX warmup can be programmed such that the TSM enable for the DCOC calibration should assert for only 3us (precharge time)+ CBPF_STL_TIME (settle time). In either case, for a fast RX warmup none of the DCOC offsets will be updated from those calculated in the previous DCOC calibration.

52.4.4.2.2.2.2.2.2 DC Correction

After the RX warmup is complete, the DCOC block handles DC correction. A figure illustrating DCOC operation after RX warmup is shown below.

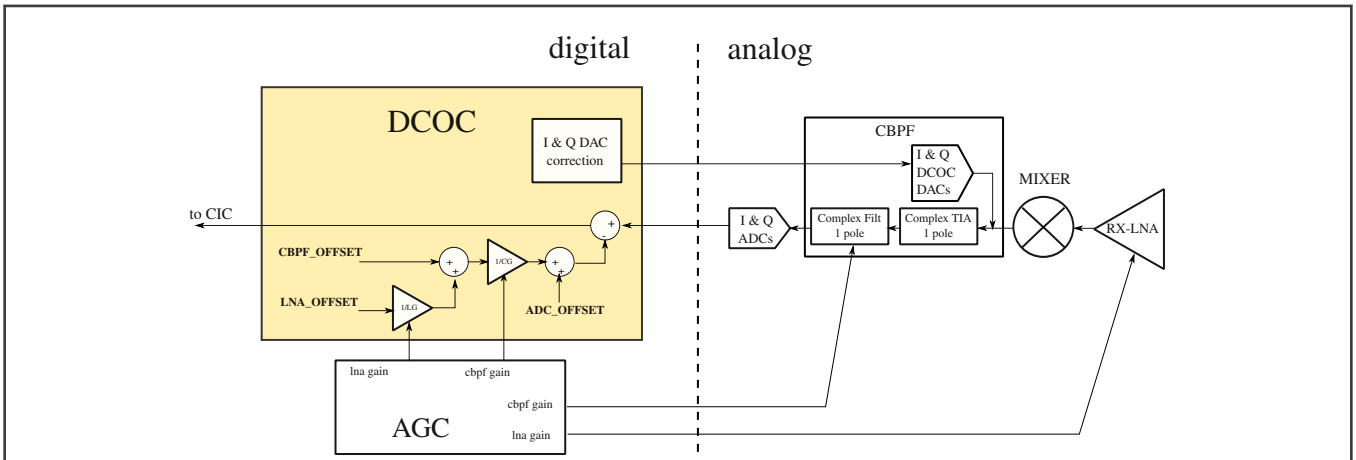

Figure 301. DC Correction

The DAC values and ADC_OFFSETs found during calibration are applied to correct the DC in the receiver. Alternately, the user can override the DAC values by programming DCOC_CTRL2[DCOC_DAC_OVRD_I] and DCOC_CTRL2[DCOC_DAC_OVRD_Q] and setting the DCOC_CTRL0[DCOC_DAC_OVRD_EN] bit. The user can also override the ADC offsets by programming the DCOC_CTRL2[DCOC_ADC_OFFSET_OVRD_I] and DCOC_CTRL2[DCOC_ADC_OFFSET_OVRD_Q] and setting the DCOC_CTRL0[DCOC_ADC_OFFSET_OVRD_EN] bit.

Additionally, the DCOC is capable of correcting for DC offsets which are dependent on the LNA and CBPF gains. These offsets are not determined during the RX warmup calibration. They have to be programmed by the user in the DCOC_CTRL1 register bitfields DCOC_ILNA_OFFSET, DCOC_QLNA_OFFSET, DCOC_ICBPF_OFFSET, and DCOC_QCBPF_OFFSET. These offsets are then scaled based on the AGC gains. In the case of the AGC's LNA gain, the scale factor 1/LG is as follows:

- highest lna gain: 1/LG = 1
- next highest lna gain: 1/LG = 1/4
- next highest lna gain: 1/LG = 1/16
- all other lna gains: 1/LG = 0

In the case of the AGC's CBPF gain, the scale factor 1/CG is as follows:

- high cbpf gain: 1/CG = 1
- low cpbf gain: 1/CG = 1/2

Note that the I & Q DAC correction value is not dependent on the CBPF gain.

52.4.4.2.2.2.2.3 DC Residual Correction

This block is used to compensate for the DC offset which is still present after AGC and DCOC calibration/tracking has completed. It estimates the DC offset by measuring the minimum and maximum value and then applies an additive correction factor to the I and Q channels. This block does not change the value of the DCOC DACs.

The DC Residual Correction block position in the RX chain is controlled by the DC_RES_AFTER_IF_MIXER bitfield of RXDIG_CTRL1 register.

If DC_RES_AFTER_IF_MIXER = 0, the DC REsidual correction is applied just after the DCOC block. If DC_RES_AFTER_IF_MIXER =1 the DC residual correction is done after the IF MIXER block and just before the CIC.

The DC offset is compensated independently on I and Q channels. The correction loop determines the minimum and maximum values over a specified window of samples (*Nwin*) which are then averaged and used (with an update parameter *Alpha*) to create the DC estimate. This DC estimate is then subtracted from the input samples. The applied DC estimate continues to be updated every *NWIN* samples until *IT_FREEZE* of these windows have elapsed, at which time the DC estimate is frozen.

Some addition capabilities are not reflected in figure above:

- the 2^{-Alpha} term can assume values of 1, 1/2, 1/4+1/8, 1/4, 1/8+1/16, 1/8, 1/16+1/32, and 1/16
- the 2^{-Alpha} term can be gearshifted using the DC_RESID_GS_EN and DC_RESID_GEARSHIFT bits.
- Further capabilities related to Long Range support. These are described at the end of this DC Residual Correction section.

Multiple modes of operations can be identified for residual DC offset compensation block. They are presented in table below.

Table 472. Residual DC offset compensation operational modes

Mode	Description	DC_RESID_EN	EXT_DC_EN	IT_FREEZE	DLY	NWIN, ALPHA
Bypass	The DC residual is disabled. The input I and Q samples to the DC Residual block are passed directly to the DC Redisdual output without any modifications. .	0	-	-	-	-
Mode 1	In this mode, DC residual has the role of calculating and applying a DC offset without use of an initial estimate from the DCOC. The DC residual processing is restarted at every AGC gain change This mode is suitable for use when an AGC gain change occurs which is not followed by DCOC tracking.	1	0	>1	>0	program as needed

Table continues on the next page...

Table 472. Residual DC offset compensation operational modes (continued)

Mode 2	In this mode, DC residual has the role of refining the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update. The DC residual processing is restarted whenever DCOC's tracking hold timer expires. This mode is suitable after AGC gain change followed by DCOC tracking.	1	1	>1	-	program as needed
Mode 3	In this mode, DC residual has the role of applying a correction based on the DC offset estimate provided by the DCOC at the end of the DCOC tracking after the last DCOC DAC update. The DC residual processing is restarted whenever DCOC's tracking hold timer expires. This mode is suitable after AGC gain change and DCOC tracking when no further refining is desired.	1	1	1	-	-

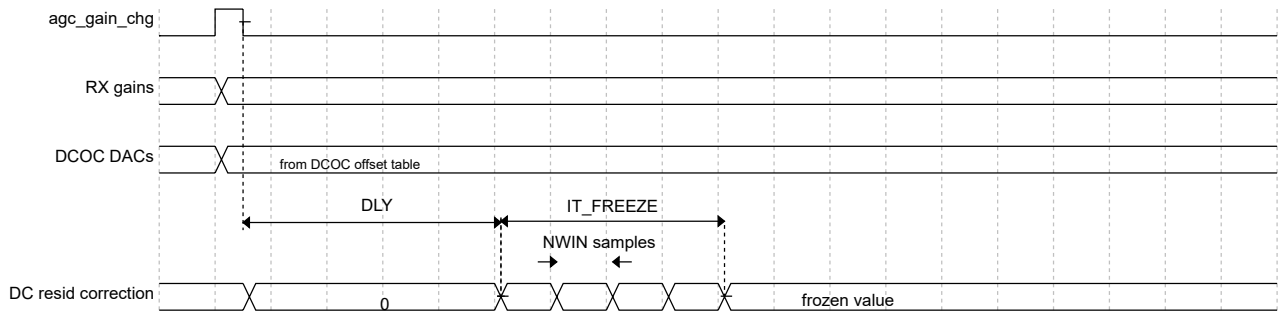

Figure 302. DC residual mode 1 timing

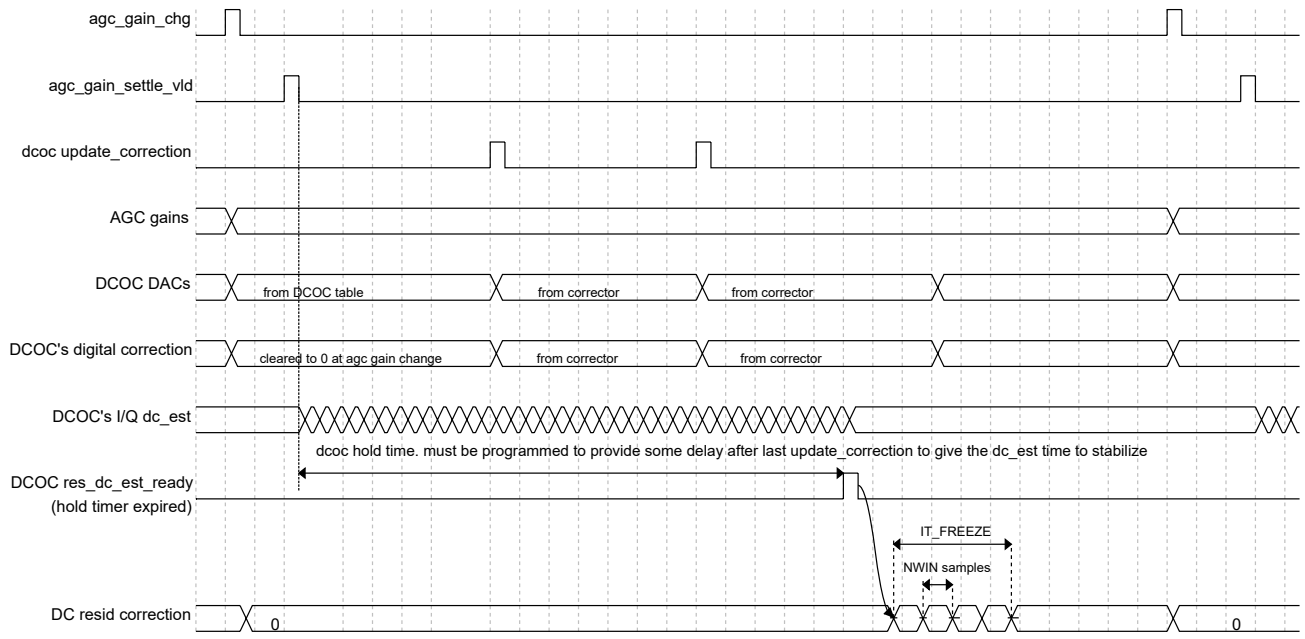

Figure 303. DC residual mode 2 timing

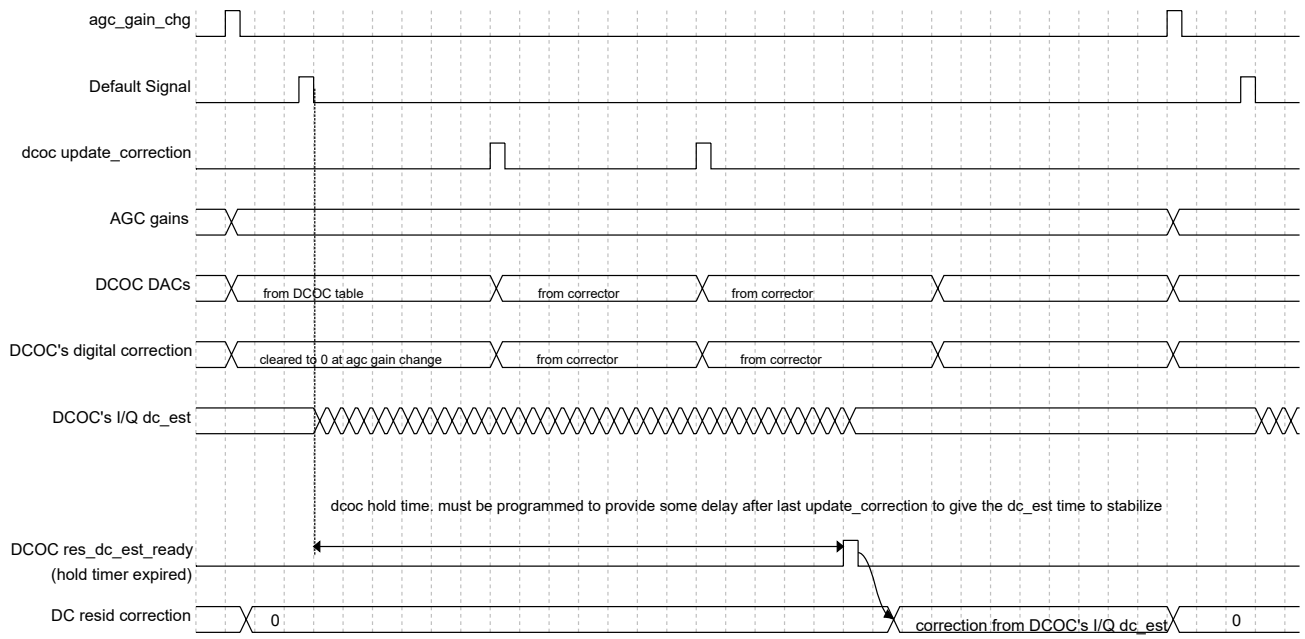

Figure 304. DC residual mode 3 timing

The behavior of the Residual DC block is also dependent on the AGC index and the values programmed for DC_RESID's MIN_AGC_IDX and the DCOC's DCOC_CTRL_1[DCOC_TRK_MIN_AGC_IDX]. This behavior is defined in the table below, which assumes DC_RESID_EN=1.

Table 473. Residual DC offset compensation operation dependency on AGC table index

EXT_DC_EN	MIN_AGC_IDX	DCOC_TRK_MIN_AGC_IDX	Behavior
-	AGC_IDX < MIN_AGC_IDX	-	DC residual is disabled
0	AGC_IDX >= MIN_AGC_IDX	-	DC residual operates in Mode 1 (it does not use an initial estimate from the DCOC)
1		AGC_IDX >= DCOC_TRK_MIN_AGC_IDX	DC residual operates in Mode 2 or 3 (It uses the estimate from the DCOC)
		AGC_IDX < DCOC_TRK_MIN_AGC_IDX	DC residual operates in Mode 1. it does not use the estimate from the DCOC, since the DCOC's tracker is disabled for this AGC gain index

For Long Range, the normal operation of the Residual DC block (as described above) may not reduce the DC level enough to support operation at very low signal levels. The Residual DC block includes an additional feature to handled such cases. If DC_RESID_SECOND_RUN_EN bit is set, then when the AGC index is greater than or equal to DC_RESID_MIN_AGC_IDX2 and the Residual DC block's normal operation has completed, additional DC compensation within the Residual DC block will activate. This "Second Run" DC compensation, when engaged, uses its own set of configuration parameters: DC_RESID_NWIN2, DC_RESID_ALPHA2, DC_RESID_ITER_FREEZE2, DC_RESID_GS2_EN, DC_RESID_GEARSHIFT2. The operation is otherwise similar to the "Mode 2" described above except that the initial DC estimate is the DC offset found at end of Residual DC block's normal operation instead of the estimate from the DCOC module. The following additional features are also supported for "Second Run"

- Slew Rate Control to limit the DC corrections. refer to DC_RESID_SR2_EN and DC_RESID_SLEWRATE2 register descriptions
- Continuous Correction. If DC_RESID_CC_EN bit is set, the DC_RESID_ITER_FREEZ2 is ignored and corrections are applied continuously until the next gain change pulse or initialization
- Operation can be stopped by the PHY. If DC_RESID_PHY_STOP_EN=1, then when the PHY signals that AA found for uncoded has been found, the "Second Run" DC compensation operation is halted (regardless of DC_RESID_ITER_FREEZE2 or DC_RESID_CC_EN bit settings) until the next gain change pulse or initialization.

52.4.4.2.2.2.2.4 I/Q Mismatch Correction

The I/Q mismatch block corrects for I/Q gain and phase mismatch. It can correct up to +/- 9 degrees of phase mismatch and +/- 4 dB of gain mismatch. After correction, phase mismatch is reduced to less than 0.5 degree and gain mismatch less than 0.3 dB.

During end product device calibration, the I/Q phase adjustment coefficient (iqmc_phase_adj) and the I/Q gain adjustment coefficient (iqmc_gain_adj) are determined. Calibration is enabled by setting the CTRL0[RX_IQMC_EN] and IQMC_CTRL0[IQMC_CAL_EN] bit. The following value should be used for calibration: IQMC_CTRL0[IQMC_NUM_ITER]=0x80. The IQMC_CTRL1 register, which also stores the calibration result, should be set to its default value 0x0000_0400. A CW input with a 250 kHz (+/-75 kHz) offset and -2 dBm (+/- 6 dBm) level at the ADC I channel input is required for calibration, though the calibration should also work with lower signal levels down to -18 dBm.

When datarate_config_sel =1, the RX_DIG will use the values stored in the IQMC_CTRL1_DRS register.

NOTE

DCOC calibration should be done before doing I/Q mismatch calibration. Also, during the calibration, the AGC should be disabled.

The IQMC_CTRL0[IQMC_CAL_FREQ_SEL] controls the sample clock frequency of the IQMC module. By default IQMC uses 1/2 reference clock(16MHz or 13MHz). Setting the IQMC_CTRL0[IQMC_CAL_FREQ_SEL] bit let IQMC use 1/4 reference clock(8MHz or 6.5MHz). With the standard number of iterations (IQMC_NUM_ITER=0x80), calibration needs 128 * 64(fixed value

for each iteration) samples. Thus takes 512 us or 1024 us, based on the IQMC_CAL_FREQ_SEL setting, when using 32MHz ref clock.

After calibration is completed the IQMC_CTRL1 register is updated and the IQMC_CAL_EN bit is cleared automatically. The gain calibration and phase calibration loops are shown in the figures below.

NOTE

For each iteration, the 64 samples(fixed value) should cover at least one full cycle of the CW. That means, suppose using 32MHz ref clock, the MINIMUM CW input freq should be 250KHz(period = 4 us) when IQMC_CAL_FREQ_SEL=0, or 125KHz(period = 8 us) when IQMC_CAL_FREQ_SEL=1.

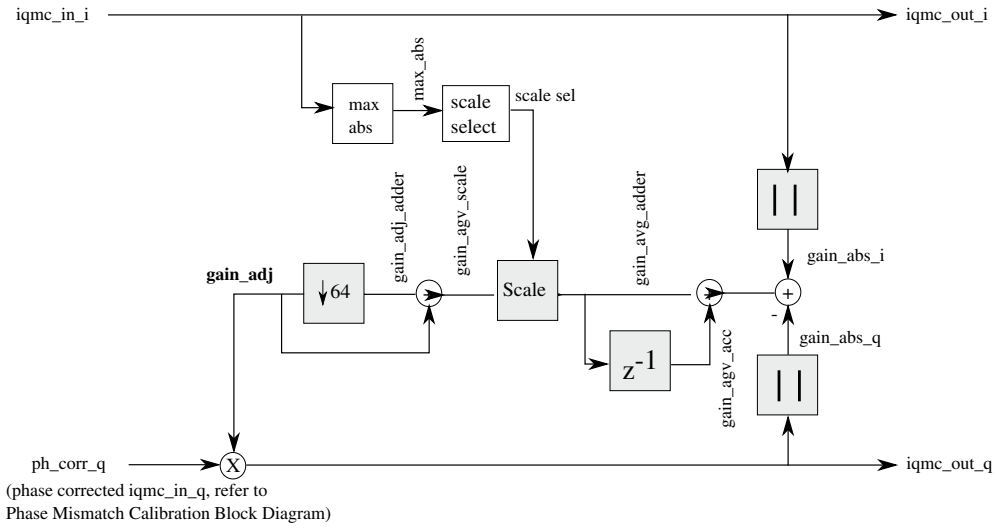

Figure 305. I/Q Gain Mismatch Calibration Block Diagram

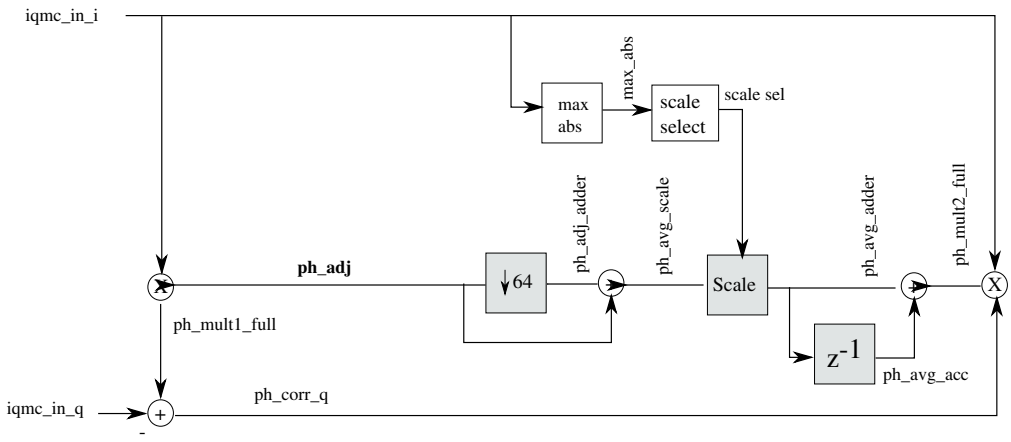

Figure 306. I/Q Phase Mismatch Calibration Block Diagram

Here is the detailed procedures to do I/Q mismatch calibration:

- Do DCOC calibration and apply the result to the input CW signal later
- Disable AGC by clear the CTRL0[AGC_EN]
- Set 0x00000400 for IQMC_CTRL1 register(Default value)

- Set proper values for IQMC_NUM_ITER and IQMC_CAL_FREQ_SEL
- Enter into RX mode and drive the CW tone to the antenna
- Set CTRL0[RX_IQMC_EN]
- Set IQMC_CTRL0[IQMC_CAL_EN]
- Poll IQMC_CTRL0[IQMC_CAL_EN] until it cleared
- Read the calibrated result from IQMC_CTRL2 register

When the receiver is enabled for packet reception, the calibration loops are disabled and the corrections are static. For gain correction, the Q channel is scaled by the gain adjustment coefficient. For phase correction, the I channel is scaled by the phase adjustment coefficient and subtracted from the Q channel. The gain and phase correction values are stored in programming model registers and may be stored in flash to eliminate the need to run I/Q mismatch calibration after each reset.

The gain and phase corrections are illustrated in the figure below.

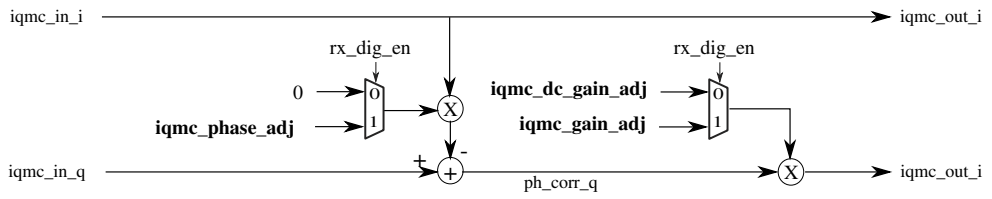

Figure 307. I/Q Mismatch Correction Block Diagram

52.4.4.2.2.2.2.5 Digital IF Mixer

The digital IF mixer performs complex mixing from low IF to DC. The mixer operates on samples at the output of the I/Q mismatch correction module. The mixer is implemented with an effective look-up table size of 1024 entries. The programmable mixer frequency is computed as follows:

DIG_MIXER_FREQ = round[1024*desired_mixer_freq/mixer_sample_frequency]

Where supported ratios of desired_mixer_freq/mixer_sample_frequency are within (-0.25, +0.25).

The table below shows the typical DIG_MIXER_FREQ configuration

Table 474. DIG_MIXER_FREQ configuration based on IF and reference clock frequency

	26MHz	32MHz
IF = 1MHz	39	32
IF = 1.5MHz	59	48

52.4.4.2.2.2.2.6 CIC Decimation Filter

RX_DIG has an Cascaded Integrator Comb (CIC) decimation filters. The CIC operates on output samples from the Digital IF Mixer at the RF reference clock rate. The order of CIC is 3 or 4 configurable and also the decimation rate can be programmed as needed by the application.

A block diagram of the CIC filter is shown below.

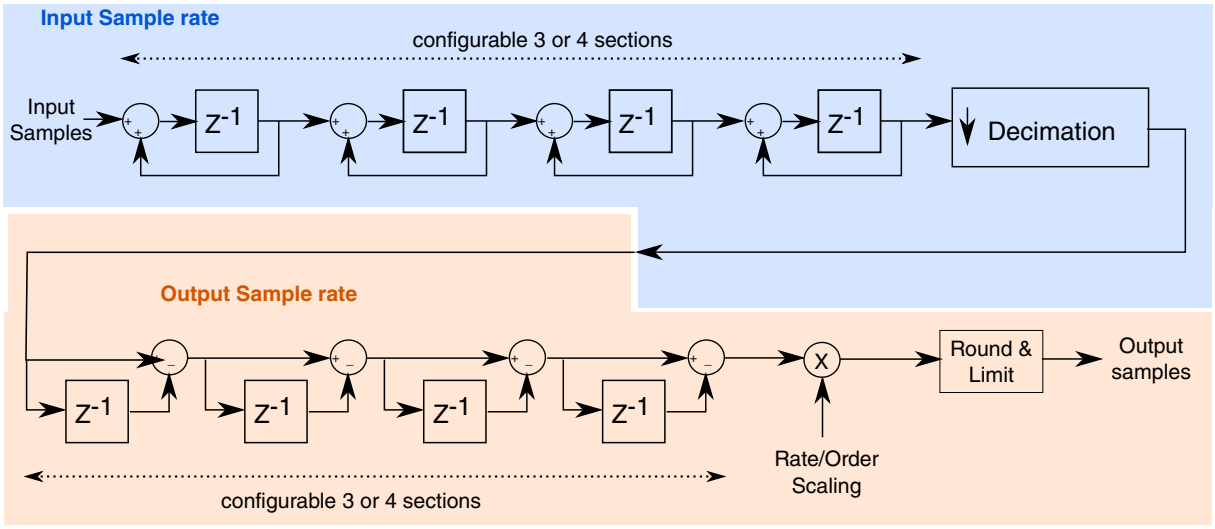

Figure 308. CIC Filter Block Diagram

The table below shows the typical CIC rate configuration.

Table 475. CIC rate configuration base on bitrate and reference clock frequency

	26MHz	32MHz
250Kbps	4	5(Only support 3-order)
500Kbps	3	4
1Mbps	2	3
2Mbps	1	2

52.4.4.2.2.2.7 Digital Gain

This block is a simple configurable multiplier applied at the output of CIC. The output of this module is computed as follows:

dig_gain_out_i/q = cic_out_i/q * (1 + RX_DIG_GAIN * 1 / 8)

Here the "RX_DIG_GAIN" can be choose from 0 ~ 7, therefore the actual gain value can be 1, 1.125,1.25, 1.375, 1.5, 1.625, 1.75, 1.875.

52.4.4.2.2.2.8 Acquisition Channel Filter

The acquisition channel filter is a 16/24-tap configurable symmetric FIR filter with real 6-bit to 10-bit coefficients. It operates at the CIC output rate on the output from Digital Gain module.

For 24-tap configuration:

$H(z) = h_0 + h_1z^{-1} + h_2z^{-2} + ... + h_{11}z^{-11} + h_{11}z^{-12} + ... + h_1z^{-22} + h_0z^{-23}$

For 16-tap configuration:

$H(z) = h_3 + h_4z^{-1} + h_5z^{-2} + ... + h_{11}z^{-7} + h_{11}z^{-8} + ... + h_4z^{-14} + h_3z^{-15}$

The filter output is scaled by 1/512, therefore the sum of the 12 or 8(depends on the CTRL0[RX_ACQ_FILT_LEN]) coefficients programmed in register ACQ_FILT_0_3 ~ ACQ_FILT_10_11 is expected to be <=256 in order to avoid saturation.

52.4.4.2.2.2.9 Sample Rate Conversion (SRC) Filter

The sample rate conversion block is used for a fractional clock rate conversion of the sampled decimated signal, when 26MHz reference clock is used. For the 2.4GHz targeted modulations, the PHY data rate is always 4x the symbol rate (of 2Mbps, 1Mbps, 500kbps or 250kbps) for (G)FSK modes and 4x the 2Mchips/sec rate for IEEE 802.15.4. These desired frequencies are not related to the ADC clock rate by an integer factor, which necessitates the need for a fractional sample rate conversion that is performed by SRC. For a complete list of the fractional conversion modes refer to . The SRC is enabled by setting RX_DIG_CTRL[RX_SRC_EN] to 1, and the conversion factor is selected by RX_DIG_CTRL[RX_SRC_RATE] as described below.

52.4.4.2.2.2.2.10 IQ Sample Buffer

This block is a 1~32 depth buffer for storing IQ values output from RX SRC. The sample buffer depth is controlled by Gen4 PHY, but can be bypassed by setting RX_SAMPLE_BUF_BYPASS in CTRL1 register.

NOTE:

1. If RX CFO MIXER bypassed, should plus 1 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

2. If RX Fractional Correction bypassed, should plus 1 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

3. If both RX CFO MIXER and RX Fractional Correction bypassed, should plus 2 to the original IQ sample buffer pointer config value in PHY(PREPHY_MISC_BUFF_PTR_LR and PREPHY_MISC_BUFF_PTR_GFSK)

52.4.4.2.2.2.2.11 CFO Mixer

The CFO mixer performs complex mixing to eliminate carrier frequency offset which operates at SRC out clock domain. The mixer is implemented with an effective look-up table size of 256 entries. Typically the CFO correction coefficient(cfo_est[9:0]) comes from PHY, but can be overridden by RX_CFO_EST_OVRD_EN and RX_CFO_EST_OVRD fields in CTRL1 register. The target CFO mixer frequency computed as follows:

cfo_frequency = round[cic_out_freq*cfo_est/2048]

The supported CFO correction range is +/-0.25 datarate. e.g. for 1Mbps, +/-250KHz CFO can be eliminated

52.4.4.2.2.2.2.12 Demodulation Channel Filter

The demodulation channel filter is a 9-tap symmetric FIR filter with real 9-bit to 10-bit coefficients. It operates at the SRC output rate on the output from CFO Mixer module.

$H(z) = h_0 + h_1z^{-1} + h_2z^{-2} + h_3z^{-3} + h_4z^{-4} + h_3z^{-5} + h_2z^{-6} + h_1z^{-7} + h_0z^{-8}$

The filter output is scaled by 1/512, therefore the 5 coefficients programmed in register DEMOD_FILT_0_1 and DEMOD_FILT_2_4 should be meet below formula:

$(h_0 + h_1 + h_2 + h_3) * 2 + h_4 <= 512$

52.4.4.2.2.2.2.13 Fractional Correction

This block is responsible with the timing error compensation. The correction factor comes from Gen4 PHY, but can be override by RX_DIG register.

The timing error compensation is realized via linear interpolation using past, current and future samples:

IQOut[k] = IQIn[k] + (IQIn[k+1]-IQIn[k])*abs(FracDly[k]), if FracDly[k]>=0

IQOut[k] = IQIn[k] + (IQIn[k-1]-IQIn[k])*abs(FracDly[k]), if FracDly[k]<0

52.4.4.2.2.2.2.14 Normalizer

The normalizer block converts the 11-bit I/Q input signal into phase output as shown in the block diagrams below. The RX_DIG has two instances of normalizer, wide-band and narrow-band, both of them have the same structure. The difference is the wide-band normalizer connects to the output of RX_SRC, while the narrow-band normalizer uses RX_FRAC_CORR output. In addition, a rounded version, PH_ZB[4:0], of PH_WB[7:0] is sent to ZB_DEMOD.

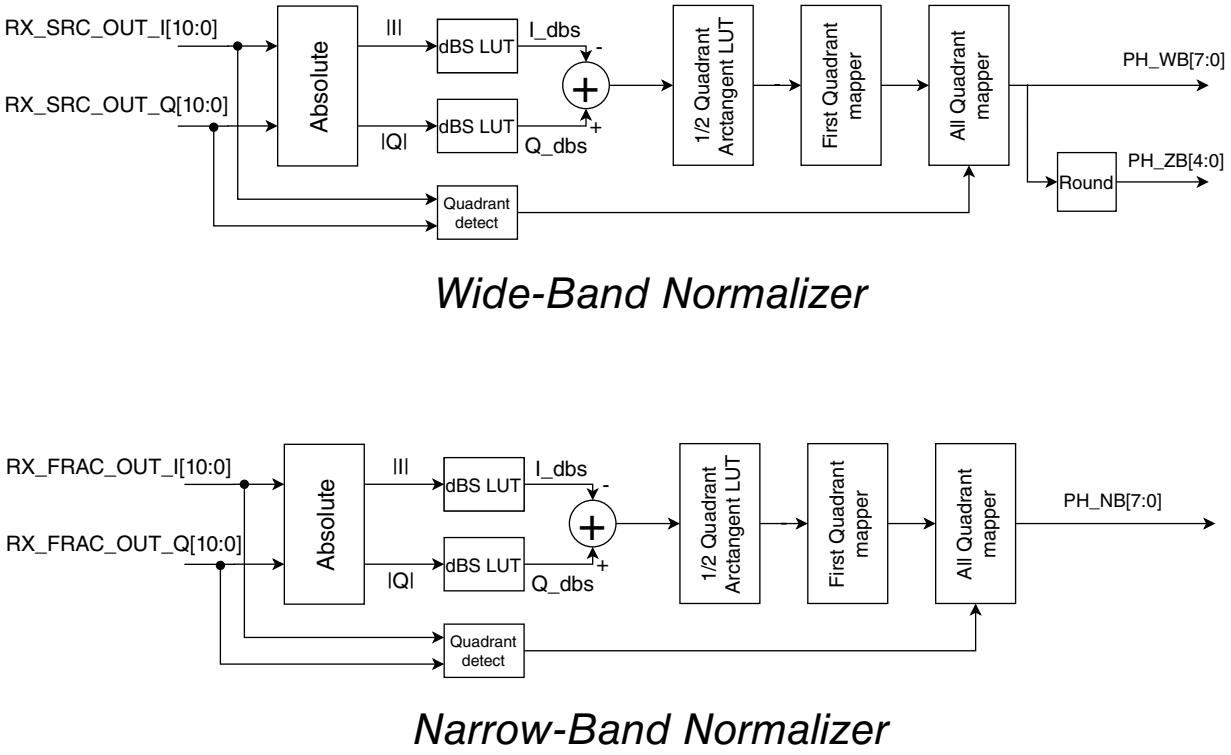

Figure 309. RX_DIG Normalizer Structure

52.4.4.2.2.2.2.15 RSSI Estimator

The role of the RSSI (Received Signal Strength Indication) estimator is to measure the energy of an incoming signal. RX_DIG has two RSSI estimator instances called Wide-Band RSSI estimator(WB_RSSI) and Narrow-Band RSSI estimator(NB_RSSI).

WB_RSSI measures the magnitude of ADC(default) or CIC output and provides the results to feed AGC. The input of NB_RSSI can be chosen from SRC(default), Acquisition Channel Filter, Demodulation Channel Filter, or Fractional Correction output and the results used by link layer controller or software.

52.4.4.2.2.2.2.15.1 Wide-band RSSI

Wide-Band RSSI(WB-RSSI) mainly for generating fast_mag and slow_mag for AGC. When AGC in magnitude mode, the AGC gain index is determined by fast_mag and slow_mag.

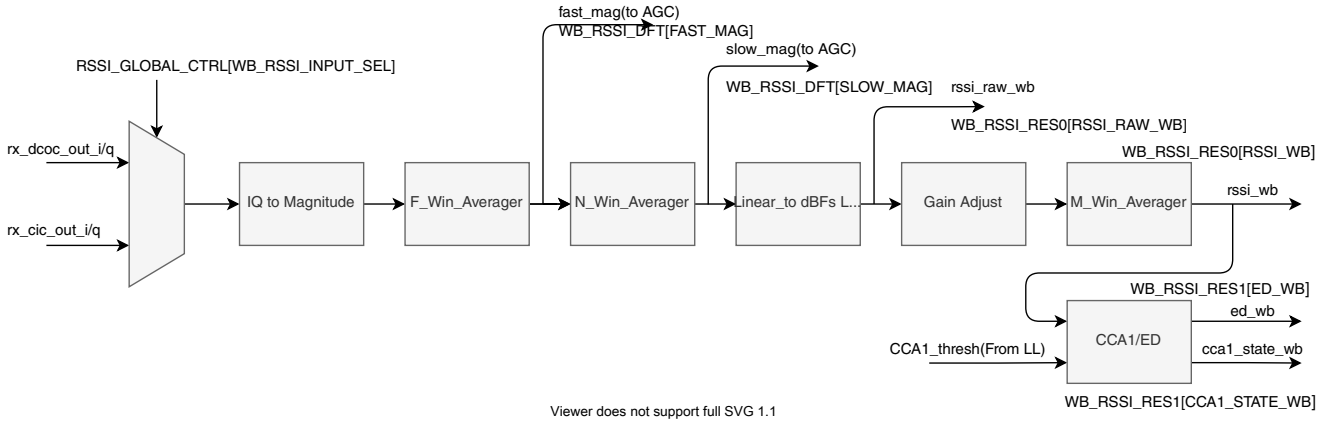

Figure 310. WB-RSSI block diagram

RSSI_WB Calculation:

rssi_wb = rssi_raw_wb - agc_log_gain + rssi_adj_wb + 13

Where:

1. rssi_raw_wb represent the dBFs result of I/Q signal magnitude. rssi_raw_wb = 20*log10((adc_i^2 + adc_q^2)^0.5/1024) ≈ max(adc_i, adc_q) + 0.375*min(adc_i, adc_q)

2. agc_log_gain indicate current analog gain values, which store in AGC_IDX*_GAIN_VAL[LOG_GAIN_*] and selected by AGC based on current AGC gain index

3. rssi_adj_wb is set by WB_RSSI_CTRL[RSSI_ADJ_WB]

52.4.4.2.2.2.2.15.1.1 WB-RSSI Freerun Mode

By default, WB-RSSI working in continuous mode(freerun), until AGC enter into FREEZE state. For debug purpose, by setting WB_CONT_MEAS_OVRD_EN=1 and WB_CONT_MEAS_OVRD=0, the WB-RSSI will stop working once the first rssi_wb calculation done. See RSSI_RDY_WB bit description to get the information about how to get WB-RSSI results continuously.

52.4.4.2.2.2.2.15.2 Narrow-Band RSSI

The role of the Narrow-Band RSSI(NB-RSSI) is to estimate and report: narrow band received signal strength, SNR and LQI result to link layer controller. It also can be chosen for CCA1/ED calculation.

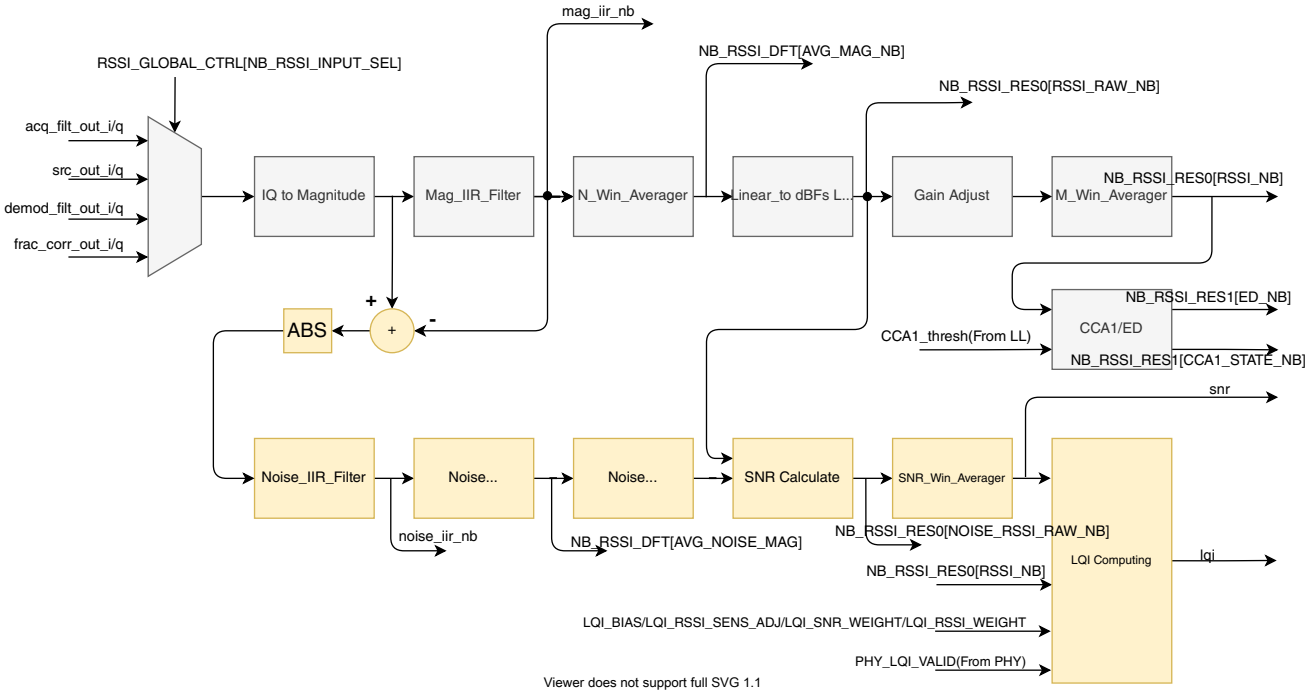

Figure 311. NB-RSSI block diagram

RSSI_NB Calculation:

rssi_nb = rssi_raw_nb - agc_log_gain + rssi_adj_nb + 13

Where:

1. rssi_raw_nb represent the dBFs result of I/Q signal magnitude. rssi_raw_nb = 20*log10((i^2 + q^2)^0.5/1024) ≈ max(i, q) + 0.375*min(i, q)

2. agc_log_gain indicate current analog gain values, which store in AGC_IDX*_GAIN_VAL[LOG_GAIN_*] and selected by AGC based on current AGC gain index

3. rssi_adj_nb is set by NB_RSSI_CTRL[RSSI_ADJ_NB]. **NOTE**: If CTRL0[RX_DIG_GAIN] set a non-zero value. Should add a negative offset value to NB_RSSI_CTRL[RSSI_ADJ_NB]

52.4.4.2.2.2.2.15.2.1 NB-RSSI Freerun Mode

By default, NB-RSSI working in one-time mode. By setting NB_CONT_MEAS_OVRD_EN=1 and NB_CONT_MEAS_OVRD=1 bit, the NB-RSSI will calculate RSSI/LQI/SNR continuously. See RSSI_RDY_NB bit description to get the information about how to get NB-RSSI results continuously.

52.4.4.2.2.2.2.15.2.2 NB-RSSI Manually Enable Mode

By default, NB-RSSI starts when PHY AA found. To manually trigger the NB-RSSI(e.g. for software CCA), follow the below steps:

- Make sure XCVR in idle mode
- Clear RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD]
- Set RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD_EN]
- Set RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD_EN] and RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD]
- Start RX sequence
- Wait RX warmup done
- Set RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD], when software get ready

- Poll NB_RSSI_RES0[RSSI_RDY_NB] until 1, which means the NB-RSSI results(

  RSSI_NB/SNR_NB/LQI_NB/ED_NB

) are ready. Check RSSI_RDY_NB bit description for more information
- When measurement done, clear RSSI_GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD], GLOBAL_CTRL[NB_RSSI_AA_MATCH_OVRD_EN], RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD_EN], RSSI_GLOBAL_CTRL[NB_CONT_MEAS_OVRD]
- Write 1 to RSSI_RDY_NB to clear this status bit
- Exit RX mode

52.4.4.2.2.2.2.15.3 CCA1 and ED Measurement

Both WB and NB RSSI can do CCA1 and ED measurement. The following steps show how to enable the CCA1 and ED function.

- Config CCA1_ED_FROM_NB bit to select use which RSSI instance to do CCA1 and ED measurement
- Set either WB_CCA1_ED_EN or NB_CCA1_ED_EN bit based on the value of CCA1_ED_FROM_NB
- Set CCA1 threshold. Note, this config is located in GEN-LL or 15p4-LL
- Launch CCA1 sequence from GEN-LL or 15p4-LL

> **NOTE**
>
> If 15p4-LL is active, set 15p4_PHY->CCA_LQI_SRC[CCA1_FROM_RX_DIG], or the CCA1 will be measured by 15p4_PHY

52.4.4.2.2.2.2.16 Automatic Gain Control (AGC)

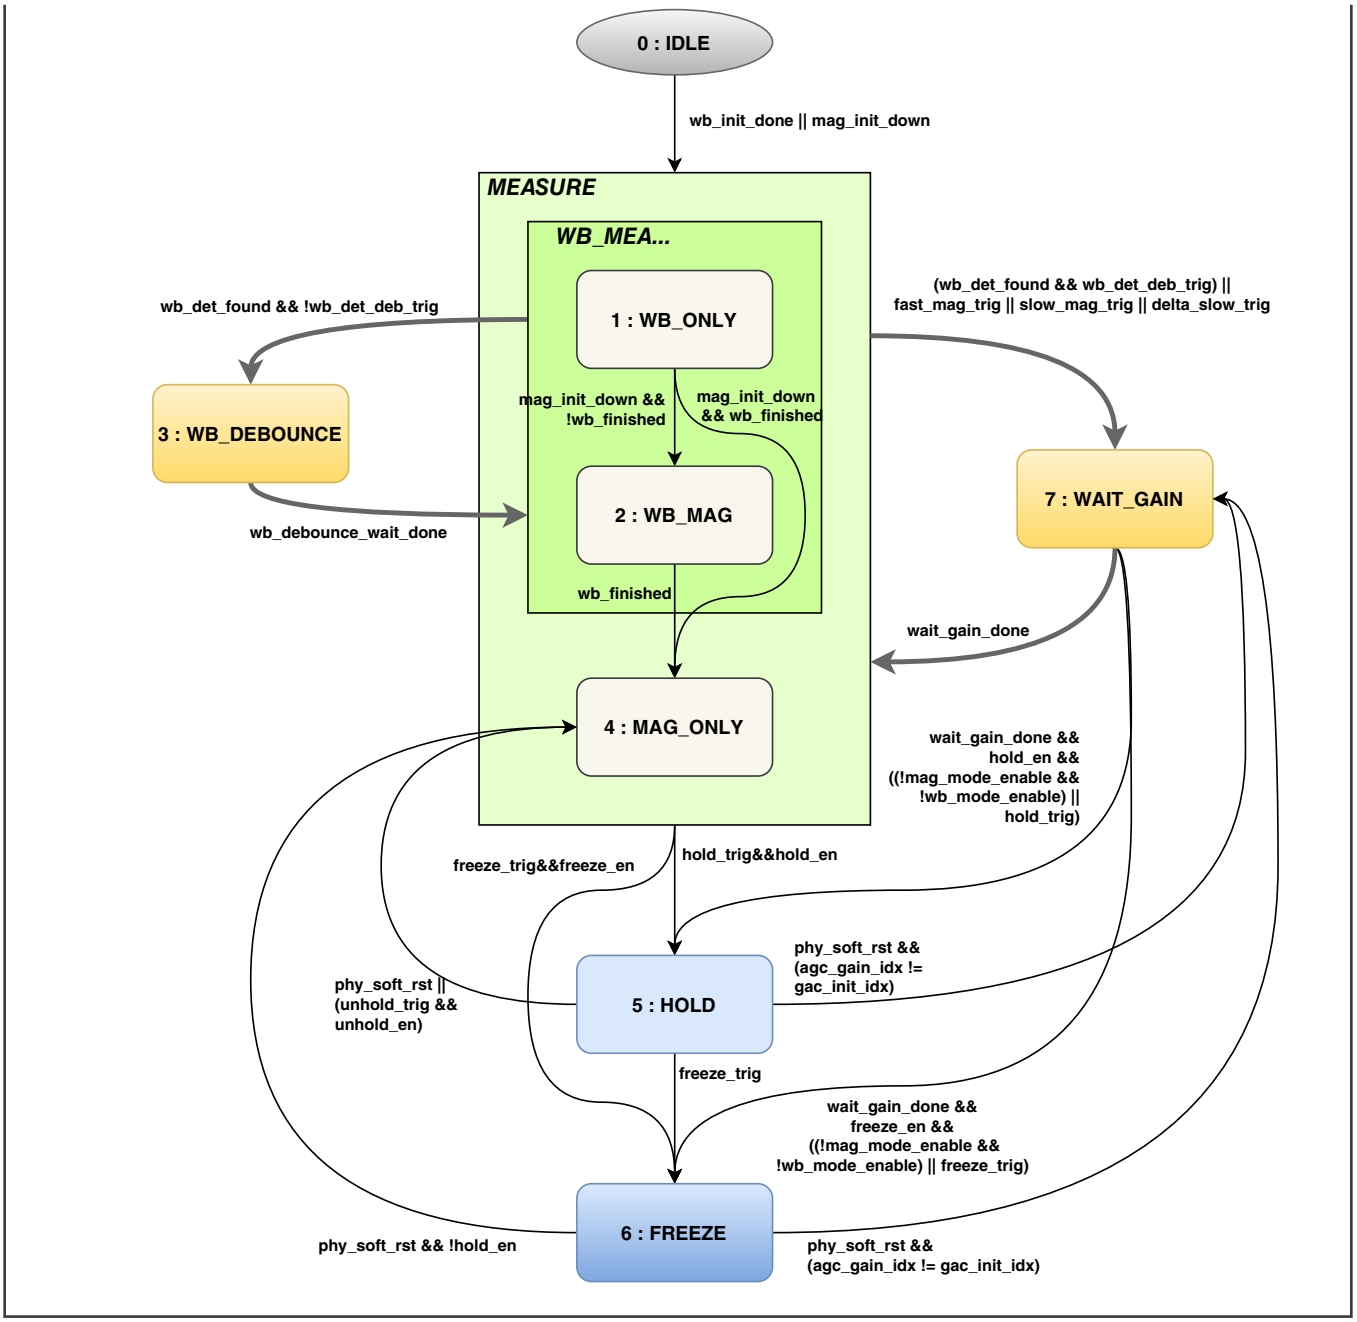
The Automatic Gain Control (AGC) system is designed to ensure that the received signal does not become distorted because of clipping in the analog receive chain, while attempting to maintain an optimal signal level for demodulation. There are two locations where gain may be adjusted: analog LNA, and analog CBPF. The AGC system manipulates these gains to maintain a targeted ADC input signal level. The targeted ADC signal level is chosen as a compromise between receiver linearity, blocker headroom requirements and the goal to maximize the digital signal SNR that is provided to the protocol-specific PHY demodulators.

The AGC system operated with a state machine that is depicted in below figure and has the following significant states:

- **IDLE(000b)**: No actions are taken. The system waits for RX_DIG enable and than AGC initial wait done
- **WB_ONLY(001b)**: AGC is working with Wide-Band detector enabled
- **WB_MAG(010b)**: AGC is working with Wide-Band detector and magnitude mode enabled
- **WB_DEBOUNCE(011b)**: AGC is in WB trigger debounce waiting state
- **MAG_ONLY(100b)**: AGC is working with magnitude mode enabled
- **HOLD(101b)**: AGC hold mode
- **FREEZE(110b)**: AGC is freeze
- **WAIT_GAIN(111b)**: Wait analog gain settle state.

52.4.4.2.2.2.2.16.1 AGC FSM

Figure 312. AGC FSM state diagram



52.4.4.2.2.2.2.16.2 AGC Gain Step Triggers

Gen4 AGC has two kinds of gain step trigger sources. One is from the analog comparator output called wideband detector(WBD) or peak detector, which can only make AGC gain step down. The other is the magnitude output from WB-RSSI, which can make AGC gain step down or up. When WBD enabled, the AGC works in WB_ONLY mode. When magnitude mode enabled, AGC works in MAG_MODE mode. In addition, if both WBD and magnitude mode enabled, AGC works in WB_MAG mode.

In one RX sequence, WBD can trigger once or twice(called WBD step1 and step2), based on the settings of AGC_CTRL[AGC_WBD_EN]. Each step has its own threshold and gain index step down config. In addition, to avoid the WBD triggered by noise or glitch on the antenna, users can enable the WBD dual clip function. When this function enabled, only continually twice trigger occurs can be considered as one WBD trigger. The cooldown(or debounce wait) time can be set by AGC_WBD_STEP1_DUAL_CLIP_WAIT and AGC_WBD_STEP2_DUAL_CLIP_WAIT.

For magnitude mode, AGC compares the FAST_MAG and/or SLOW_MAG value from WB_RSSI with the AGC_THR_FAST and/or AGC_IDX*_THR values to determine gain index step up or step down.

There's a special magnitude trigger called delta slow trigger. To enable delta slow detection, slow magnitude mode also need to be enabled. When the previous Nth(Defined by DELTA_SLOW_WAIT) slow mag value minus the latest slow mag value exceed the value set in DELTA_SLOW_THR, the AGC will issue a big gain index step up, defined by AGC_DELTA_SLOW_STEP.

52.4.4.2.2.2.2.16.3 AGC Gains

Gen4 AGC supports up to 12-gear of gain index and enables 11-gear(10~0) by default. Each gain index has its own analog gain control settings and stored in AGC_IDX*_GAIN_CFG register.

The AGC_IDX*_GAIN_VAL registers store the analog gain values for each gain index. The LOG_GAIN is referenced by WB-RSSI and NB-RSSI module to estimate the input power level of RF signal, while LINEAR_GAIN used by Gen4 PHY to determine whether there is RF signal on the antenna.

52.4.4.2.2.2.2.16.4 AGC State

52.4.4.2.2.2.2.16.4.1 IDLE

This is the default state of AGC. AGC will keep in this state until initialize done. The AGC internal counter will start counting(use reference clock) when RX_DIG enabled. When the AGC counter matches the value of AGC_WBD_INIT_WAIT or AGC_MAG_INIT_WAIT, the AGC will trans to measurement state(WB_ONLY, WB_MAG or MAG_ONLY). Typically, if both WBD and magnitude mode enabled, the programed AGC_WBD_INIT_WAIT should no less than AGC_MAG_INIT_WAIT.

52.4.4.2.2.2.2.16.4.2 WB_ONLY

After the AGC initialization done, if AGC_WBD_EN!=0 and AGC_WBD_INIT_WAIT<AGC_MAG_INIT_WAIT, AGC will trans to this mode. In WB_ONLY mode, the AGC only accepts WBD trigger.

If AGC_WBD_AUTO_DIS_CFG != 00, AGC will disable WBD automatically when condition matches. See description of AGC_WBD_AUTO_DIS_CFG for more info. After WBD disabled, AGC will trans to next mode, typically the MAG_ONLY.

If AGC_WBD_STEP*_DUAL_CLI P_EN set, two consecutive WBD triggers treat as one effective AGC gain change trigger. That means the first WBD trigger will make AGC trans to WB_DEBOUNCE mode and wait a moment. After AGC back to WB_ONLY mode, if the WBD trigged again in time, typically less than 5 reference clock cycles, AGC will step down the gain index.

AGC supports WBD gain limit function. If agc_wbd1_gain_limit_en set, after wbd_step1 trig occurs, the AGC max gain will be set as "agc_init_gain – wbd_step1”, that means even if mag value is too small, AGC will not increase gain_idx larger than “agc_max_gain – wb_step1”(NOTE: Typically, agc_max_gain = agc_init_gain). Similar function for agc_wb2_gain_limit_en.

52.4.4.2.2.2.2.16.4.3 MAG_ONLY

In this state, AGC will compare the magnitude from WB-RSSI with the threshold to determine the AGC gain index. There are two kinks of magnitude called fast_mag and slow_mag and which are using for driven the fast mag trigger(called fast mag mode) and slow mag trigger(called slow mag mode). The difference between fast mode and slow mode is response time and adjustment accuracy. Both fast and slow mag mode can be enabled individually, however, delta slow mode can only work with slow mag mode enabled.

52.4.4.2.2.2.2.16.4.4 WB_MAG

This state can be considered as a combination of WB_ONLY and MAG_ONLY. In this state, AGC accepts both WBD and magnitude triggers.

52.4.4.2.2.2.2.16.4.5 WAIT_GAIN

After AGC gain index changed, AGC will enter into WAIT_GAIN state and keep a while. At the same time, reset the WBD and WB-RSSI.

52.4.4.2.2.2.2.16.4.6 WB_DEBOUNCE

If WBD dual clip(debounce) function enabled, AGC will enter into this state when the first WBD trigger occurs without gain index change and reset the WBD at the same time. After a while(defined by AGC_WBD_DUAL_CLIP_TIMEOUT), AGC will back to WB_ONLY or WB_MAG state.

52.4.4.2.2.2.2.16.4.7 HOLD

There are two ways to enter into HOLD state, hold mode timeout(defined by AGC_HOLD_TIMEOUT) matches or hold mode trigger(selected by AGC_PHY_HOLD_TRIG_SEL) occurs.

Note, the hold mode timeout counter will start work when AGC enter into WB_ONLY, WB_MAG or MAG_ONLY and reset when AGC gain index changed.

In HOLD state, AGC will disable WBD and fast mag comparison. However, if AGC_UNHOLD_FEAT_EN[0] and AGC_SLOW_EN set, AGC will be continuing to monitor the slow magnitude values to determine whether exit HOLD and back to MAG_ONLY state.

When AGC_UNHOLD_FEAT_EN[1] set, AGC will exit HOLD mode after N(defined by AGC_UNHOLD _FEAT_TIMEOUT) micro second and back to MAG_ONLY mode.

52.4.4.2.2.2.2.16.4.8 FREEZE

In this state, AGC will disable both WBD and mag comparison. Freeze mode timeout(defined by AGC_FREEZE_TIMEOUT) matches or freeze mode trigger(selected by AGC_PHY_FREEZE_TRIG_SEL) occurs can make AGC enter into FREEZE state.

If both HOLD and FREEZE state triggered by timeout, the AGC will enter into HOLD state first, then wait for freeze timeout and finally enter into FREEZE state. However, AGC can trans to FREEZE state immediately when PHY freeze trigger occurs.

When AGC_UNFREEZE_FEAT_EN set, if RX sequence not be finished in N(defined by AGC_UNFREEZE_FEAT_TIMEOUT) micro second, AGC will exit FREEZE mode and back to MAG_ONLY mode.

52.4.4.2.2.2.2.16.5 AGC PHY Magnitude Threshold

The 2.4GHz PHY acquisition module needs 2 threshold values, mag_thr and mag_thr_hi, to determine if the current input signal is valid.

When the magnitude of the input signal exceeds the mag_thr(pt_sig_pres=01b), the 2.4GHz PHY acquisition module starts working and use GEN4_PHY->FSK_CFG0[HAMMING_AA_LOW_PWR] to find access address. In addition, if the magnitude exceeds both mag_thr and mag_thr_hi(pt_sig_pres=11b), the acquisition module will use another hamming value (GEN_LL->NTW_ADR_CTRL[NTW_ADR_THR] or GEN4_PHY->FSK_CFG0[BLE_NTW_ADR_THR], depends on which LL is active)to do access address searching.

The mag_thr and mag_thr_hi are AGC gain index dependent, which means for each AGC gain index, there's one pair of mag_thr and mag_thr_hi value. These values are configured by AGC_IDX*_GAIN_VAL[MAG_THR_*] and AGC_IDX*_GAIN_VAL[MAG_THR_HI_*] fields.

Furthermore, when datarate_config_sel = 1, a pair of **signed** offset(AGC_IDX*_GAIN_CFG[MAG_THR_*_DRS_OFS] and AGC_IDX*_GAIN_CFG[MAG_THR_HI_*_DRS_OFS]) values will be added to the AGC_IDX*_GAIN_VAL[MAG_THR_(HI_)*] to calculate the final threshold value.

The below example shows how to determine the mag_thr and mag_thr_hi value when the AGC gain index is 11.

When datarate_config_sel = 0 :

mag_thr = AGC_IDX11_GAIN_VAL[MAG_THR_11]

mag_thr_hi = AGC_IDX11_GAIN_VAL[MAG_THR_HI_11]

When datarate_config_sel = 1 :

mag_thr = AGC_IDX11_GAIN_VAL[MAG_THR_11] + AGC_IDX11_GAIN_CFG[MAG_THR_11_DRS_OFS]

mag_thr_hi = AGC_IDX11_GAIN_VAL[MAG_THR_HI_11] + AGC_IDX11_GAIN_CFG[MAG_THR_11_HI_DRS_OFS]

NOTE: for each AGC gain index, the programmed AGC_IDX*_GAIN_VAL[MAG_THR_*] , AGC_IDX*_GAIN_VAL[MAG_THR_HI*],

AGC_IDX*_GAIN_CFG[MAG_THR_*_DRS_OFS], and AGC_IDX*_GAIN_CFG[MAG_THR_HI*_DRS_OFS] values should let mag_thr and mag_thr_hi meet the following equation:

0 <= mag_thr <= mag_thr_hi <= 2047

52.4.4.2.2.2.2.17 RC Calibration

The RX RC Calibration module uses a binary search to find the best 5bit calibration code (rccal_code[4:0]) for the RC calibration circuit in the analog. It is expected that the RC calibration will be performed on each RX warmup. The entire RCCAL sequence requires no more than 8us for all XO reference frequencies supported.

The rccal_code code is then used to calculate a 7bit code for the CBPF circuit, which is dependent on a programmable bandwidth setting (bw_code)and IF setting (sc_code). Also, programmable offsets are provided to allow additional adjustments to the rccal_code or to the computed CBPF code:

cbpf_ccode = round[9 + 2*bw_code)*(2 + sc_code)*(48 + rccal_code + rccal_code_offset)/32] + cpbf_ccode_offset

The figure below illustrates the RC calibration timing. The calibration sequence is initiated by a TSM control signal (seq_rccal_pup). After the seq_rccal_pup asserts, there is a 1.0us settling time followed by a few clock cycles where rccal_code[4:0] = 5'h1_F. Then, 5 calibration stages are performed, each of which requires 1us + 10clks.

Near the end of each calibration stage, the rccal_cmpout signal from the analog is used to determine whether the appropriate bit of rccal_code[4:0] will be set or cleared. By default, the rccal_cmpout is sampled 2 clk cycles after rccal_sample de-asserts, but there are also programmable options for 1clk and 3clk cycles. Also, there is a programmable option to invert the rccal_cmpout signal if needed.

The total calibration time is 1.0us + 5 clks + 5*(1us + 10clks), which is less than 9us for 26MHz and less than 8us for all other XO reference frequencies supported.

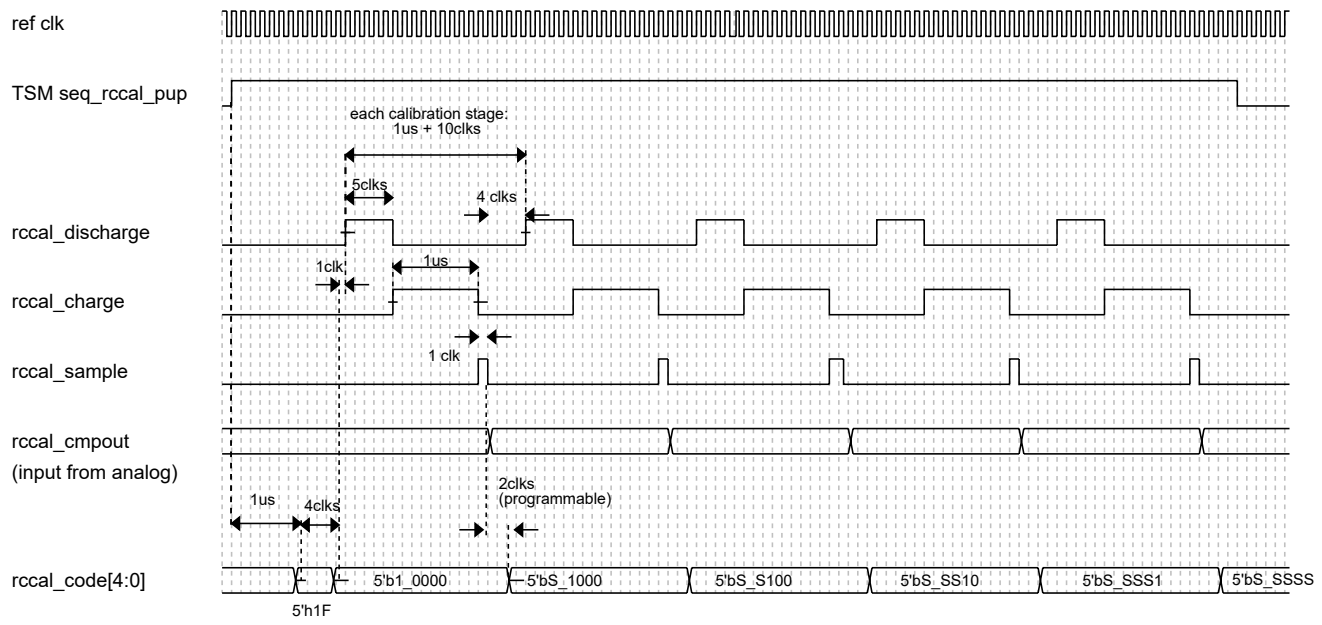


Figure 313. RCCAL timing

52.4.4.2.2.2.2.18 TQI

The Tone Quality Indicator (TQI) is a quality measurement of the received tone. Its value (good, medium or bad) is based on the comparison of the received signal quality factor(a kind of standard deviation measurement) versus programmable thresholds.

52.4.4.2.2.2.2.19 NADM

Normalized Attack Detection Metric (NADM) is aimed at detecting Early Commit Late Detect/ Early Detect Late Commit (ECLD/EDLC) attacks. It yields two results per packet:

- FM correlator measures how close the received GFSK signal is from an expected GFSK reference.
- FM symbol path provides the ability of detecting one or more bit errors in the payload.

52.4.4.2.2.2.20 Clocking

The RX_DIG uses two clocks, the 26 or 32MHz RF reference clock (clk), and the IPS gated clock (ips_clk) that has been synchronized to the reference clock. All programming model registers are clocked by the IPS clock. All other registers are clocked by the RF reference clock.

52.4.4.2.2.2.21 Reset

All RX_DIG registers that require a reset are reset by a global asynchronous reset. The rx_init signal also synchronously resets the state of various rxdig sub-modules. In addition, a software reset from 2P4Ghz XCVR can reset all RX_DIG modules except RX_DIG control register module.

52.4.4.2.2.2.22 Interrupts

All interrupts are managed at transceiver level and will be described in the corresponding section.

52.4.4.2.2.2.23 DMA

DMA engine and Packet RAM debug engine located in transceiver will have the possibility to get data from rx_digital datapath at different levels. These data will be sent to Packet RAM or System RAM at host level.

Refer to DMA section in the Transceiver chapter for more information about DMA possibility inside the RX.

52.4.4.2.2.3 Initialization

To enable the Rx digital bloc, the registers must be first programmed in the correct mode, as described in the chapter Functional description for each sub bloc. Then, the rx_dig_en should be set via TSM programming.

52.4.4.2.2.4 Application information

The sub-blocs inside rx_digital will be enabled with the procedures described in the sub_chapters and register definition.

Then, the rx_digital bloc will be enabled from TSM programming , mainly rx_dig_en and rx_init signals.

52.4.4.2.2.5 Memory Map and register definition

The 2p4GHz RX_DIG memory map and register description is included in the following section.

52.4.4.2.2.5.1 2P4GHZ_RX_DIG register descriptions

52.4.4.2.2.5.1.1 RX_DIG_REG memory map

Table continues on the next page...

Table continued from the previous page...

Field	Function
DR_OVRD_IN_CTE	For debugging purpose. Keep 0 for the normal case.
30 RX_AGC_EN	AGC Enable 0b - AGC is disabled 1b - AGC is enabled
29 CIC_CNTR_FREE_RUN_EN	CIC Dec Counter Free Run Enable This bit is for RSM use case. If this bit set, during rsm_active=1, the CIC decimation counter will keep running even rx_dig_en=0. In addition, the rx_init will not reset the CIC decimation counter.
28 —	Reserved
27 RX_FSK_ZB_SEL	PHY/Demodulator selection 0b - 2.4GHz PHY is selected 1b - 15.4 PHY is selected
26 —	Reserved
25-23 RX_IQ_8B_OUT_MODE	RX 8-bit IQ Output Mode The 8-bit I/Q source is selected by DFT_CTRL[DFT_RX_IQ_OUT_SEL] 000b - Disable 8-bit IQ output 001b - {I[10],I[9:3]}, {Q[10],Q[9:3]} 010b - {I[10],I[8:2]}, {Q[10],Q[8:2]} 011b - {I[10],I[7:1]}, {Q[10],Q[7:1]} 100b - Dynamic scaling
22 RX_SRC_EN	RX Sample Rate Converter Enable When use 26MHz reference clock, SRC should be enabled. 0b - SRC is disabled. 1b - SRC is enabled.
21 RX_ACQ_FILT_BYPASS	Acquisition Filter Bypass This bit is for test purpose and should not be set in normal mode. 0b - Acquisition filter is enabled 1b - Acquisition filter is bypassed
20	Acquisition Filter Length When set 1, only ACQ_FILT_H4 - ACQ_FILT_H11 are used.

Table continues on the next page...

Table continued from the previous page...

Field	Function
RX_ACQ_FILT_LEN	0b - Acquisition filter length is 24. 1b - Acquisition filter length is 16.
19 —	Reserved
18-16 RX_DIG_GAIN	RX Digital Gain Value The values listed here below are intended as multipliers 000b - Digital gain value is 1.000. 001b - Digital gain value is 1.125. 010b - Digital gain value is 1.250. 011b - Digital gain value is 1.375. 100b - Digital gain value is 1.500. 101b - Digital gain value is 1.625. 110b - Digital gain value is 1.750. 111b - Digital gain value is 1.875.
15 —	Reserved
14-12 CIC_RATE	CIC Decimation Rate The actual CIC decimation Rate is 2^CIC_RATE. Note: check CIC_ORDER description for more information. 000b - Decimation Rate is 1. 001b - Decimation Rate is 2. 010b - Decimation Rate is 4. 011b - Decimation Rate is 8. 100b - Decimation Rate is 16. 101b - Decimation Rate is 32. 110b - Reserved 111b - Reserved
11 CIC_ORDER	CIC Order(Stage) Selection The programmed value of CIC_ORDER and the CIC decimation rate(dec_rate) should conform to the formula: (4-CIC_ORDER)*log2(dec_rate) <= 16 0b - 4-stage CIC 1b - 3-stage CIC

Table continues on the next page...

Table continued from the previous page...

Field	Function
10-2 DIG_MIXER_FREQ	Digital Mixer Frequency Represents the ratio of the digital mixer frequency to the sample rate frequency at the digital mixer (which is at the CIC output rate). Supported ratios are in the range (-0.25, 0.25). Computed as nearest integer to 1024*desired_mixer_freq/mixer_sample_rate_frequency. Check Digital IF Mixer section for more information.
1 RX_IQMC_EN	IQ Mismatch Compensation Enable NOTE: When IQMC_CTRL0[IQMC_CAL_EN]=1, RX_IQMC_EN should also be set. 0b - IQ mismatch compensation is disabled. 1b - IQ mismatch compensation is enabled.
0 ADC_CLIP_EN	ADC Output Clip Enable When enabled, RXDIG input adc_i and adc_q value will be saturated to +-512. 0b - ADC clip is disabled. 1b - ADC clip is enabled.

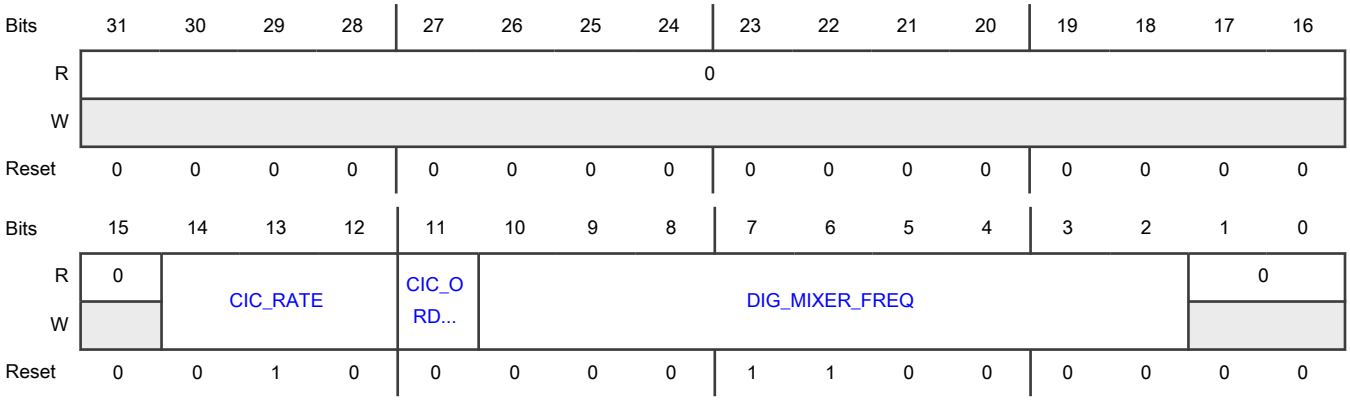
Diagram



Fields

Field	Function
31 RX_IQ_PH_OUTPUT_COND	RX IQ or Phase Output Conditioning This field only has effect when DFT_CTRL[DFT_RX_IQ_OUT_SEL], DFT_CTRL[DFT_RX_PH_OUT_SEL] set a non-zero value or DFT_CTRL[DFT_RSSI_MAG_OUT_SEL]=7. When this bit cleared, the RX_DIG will output the selected IQ and/or Phase, Mag signal to DTEST and/or DMA_DEBUG as soon as RX_DIG starts work. For localization application, set this bit can let RX_DIG send the IQ and/or Phase signal to DTEST and/or DMA_DEBUG only during localization(AoA/AoD/HADM/PDE) sample slot. It will reduce the packet buffer usage and software loading. NOTE: this bit has to be set to 1 in order to generate correct PCT data. 0b - Output IQ and/or Phase all-time 1b - Only output IQ and/or Phase during localization sample slot
30-28 RX_IQ_PH_AVG_WIN	RX IQ Phase Output Average Window Config Programing a non-zero value to this field will apply a window averager on RX_DIG output IQ, Phase signal, or Mag. The actual average window size is 2^(RX_IQ_PH_AVG_WIN+1). NOTE: Programing a non-zero value to this field will reduce the RX IQ and/or Phase output rate to 1/2^(RX_IQ_PH_AVG_WIN+1). 000b - Disable RX IQ and/or Phase output average function 001b - Average window size = 4 010b - Average window size = 8 011b - Average window size = 16 100b - Average window size = 32 101b - Average window size = 64 110b - Average window size = 128 111b - Average window size = 256
27 RX_MIXER_IDX_OUT_MODE	RX_DIG Mixer Index Output Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	RX_DIG has 10-bit mixer(s) index output to DMA_DEBUG. By default, the 10-bit output is composed by rx_if_mixer_idx[9:5] and rx_cfo_mixer[7:3]. By setting RX_MIXER_IDX_OUT_MODE, the RX_DIG will send rx_if_mixer_idx[9:0] to DMA_DEBUG.
26 RX_CFO_EST_OVRD_EN	CFO Estimation Override Enable When this bit set, the CFO mixer will use RX_CFO_EST_OVRD value to do CFO compensation. 0b - CFO override is enabled 1b - CFO override is disabled
25-16 RX_CFO_EST_OVRD	CFO Estimation Override Value This field only valid when RX_CFO_EST_OVRD_EN=1
15 RX_FRAC_CORR_OVRD_EN	Fractional Correction Coefficient Override Enable When this bit set, the Fractional correction module will use RX_FRAC_CORR_OVRD value to do correction.
14-12 RX_FRAC_CORR_OVRD	Fractional Correction Coefficient Override Value This field only valid when RX_FRAC_CORR_OVRD_EN=1
11 RX_DC_RES_AFTER_IF_MIX	When programmed to 1, it moves the DC RESIDUAL block after the IF MIXER When 0, the DC RESIDUAL is between the DCOC and IQMC blocks
10 RX_DEMOD_FILT_BYPASS	Demod Channel Filter Bypass This bit is for test purpose and should not be set in normal mode. 0b - Demod channel filter is enabled. 1b - Demod channel filter is bypassed.
9 RX_HIGH_RES_NORM_SEL	High Resolution Phase Source Select 0b - From RX_NORM_NB 1b - From RX_NORM_WB
8 RX_NB_NORM_EN	Narrow-Band Normalizer Enable 0b - Narrow-Band normalizer is disabled. 1b - Narrow-Band normalizer is enabled.
7 DIS_WB_NORM_AA_FOUND	Disable WB-NORM when AA found When this bit set, RX_DIG will disable the WB-NORM as soon as AA(access address) found by 2.4GHz PHY to save power. NOTE: when using 15p4 PHY, this bit should be cleared.
6	DC_RESID Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
DC_RESID_EN	When set to 1, this field enables the DC Residual block. This bloc is doing DC tracking over the time to compensate it with windows mechanism. When this bit is 0, the DC Residual block is bypassed
5 RX_SAMPLE_BUF_AUTO_GATE	Sample Buffer Automatically Gate Off When enabled, after PHY_AA_MATCH asserted, unused taps of sample buffer will be gated off to save power. Here, unused taps is controlled by 2.4GHz PHY.
4 RX_SAMPLE_BUF_BYPASS_IN_CTE	Bypass Sample Buffer During CTE If enabled, during CTE field receiving, sample buffer will be bypassed to save power and reduce latency.
3-2 RX_IQ_AVG_WIN_PCT	RX IQ Output Average Window Config to generate PCT Programing a non-zero value to this field will apply a window averager on IQ data from first averager to generate PCT data. The actual average window size is 2^(RX_IQ_PH_AVG_WIN_PCT+1). NOTE: Programing a non-zero value to this field will reduce the RX IQ output rate to 1/2^(RX_IQ_AVG_WIN_PCT+1). 00b - Disable RX IQ output average function 01b - Average window size = 4 10b - Average window size = 8 11b - Average window size = 16
1 RX_DFT_IQ_OUT_AVERAGED	I/Q output as raw or averaged data If set to 1, RX_DIG outputs I/Q averaging else it outputs raw data. 0b - Raw data at rx_dft_iq_out 1b - Averaged data at rx_dft_iq_out
0 RX_SAMPLE_BUF_BYPASS	Bypass Sample Buffer This bit is for test or debug purpose, should not be set in normal mode.

52.4.4.2.2.2.5.1.5 RXDIG DFT Control (DFT_CTRL)

25 AGC_WBD_STEP2_DUAL_CLIP_EN	AGC WBD Step2 Dual Clip Enable When this bit set. AGC need two consecutive WB trigger occurs then issue WB step 2 gain step down. The cool-down duration is specified by AGC_WBD_STEP2_DUAL_CLIP_WAIT
24-21 AGC_WBD_THR1	AGC WBD Step1 threshold Threshold value(unit: mV) for AGC WBD step1. 0000b - 49.31 0001b - 67.56 0010b - 90.98 0011b - 117.42 0100b - 150.66 0101b - 180.98 0110b - 211.87 0111b - 245.2 1000b - 288.31 1001b - 336.02 1010b - 394.34 1011b - 462.71 1100b - 548.04 1101b - 650.13 1110b - 771.65 1111b - 918.12
20-17 AGC_WBD_THR2	AGC WBD Step2 threshold Threshold value(unit: mV) for AGC WBD step2. The actual threshold voltage is as same as the description in AGC_WBD_THR1.
16-14 AGC_WBD_STEP1_SZ	AGC WBD Step1 Gain Decrease Value Specify the gain index decrease value when AGC WBD step1 triggered. Actual gain step is: AGC_WBD_STEP1_SZ + 1
13-11 AGC_WBD_STEP2_SZ	AGC WBD Step2 Gain Decrease Value Specify the gain index decrease value when AGC WBD step2 triggered. Actual gain step is: AGC_WBD_STEP2_SZ + 1
10 AGC_FAST_EN	AGC Fast Magnitude Mode Enable 0b - Disable fast magnitude mode 1b - Enable fast magnitude mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 AGC_FAST_STEP_UP_EN	AGC Fast Magnitude Mode Step Up Enable AGC step up enable in fast magnitude mode. This bit only take effect with AGC_FAST_EN=1. If this bit cleared, the fast magnitude mode can only make AGC gain index step down. 0b - Fast magnitude mode can only make AGC gain index step down 1b - Fast magnitude mode can make AGC gain index step down or step up
8 AGC_SLOW_EN	AGC Slow Magnitude Mode Enable 0b - Disable AGC slow magnitude mode 1b - Enable AGC slow magnitude mode
7 AGC_DELTA_SLOW_EN	AGC Delta Slow Magnitude Mode Enable AGC delta slow magnitude mode enable. Note: The AGC delta slow magnitude mode can only work with AGC slow magnitude mode enabled(AGC_SLOW_EN=1). 0b - Disable AGC delta slow magnitude mode 1b - Enable AGC delta slow magnitude mode
6-4 AGC_DELTA_SLOW_STEP	AGC Delta Slow Mode Gain Step Up Value Gain index change for a big step up when delta slow mode triggered
3-2 AGC_HOLD_EN	AGC Hold Mode Enable AGC hold mode enable and control 00b - Disable AGC hold mode 01b - AGC hold when preamble found 10b - AGC hold when AGC hold timeout matched 11b - AGC hold when preamble found or hold timeout matched
1-0 AGC_UNHOLD_FEAT_EN	AGC Unhold Enable AGC unhold feature enable and config. AGC_UNHOLD_FEAT_EN[0]: When AGC in HOLD mode and the selected mag values exceed the range of "agc_hold_mag +/- ipr_hold_mag_margin", AGC will exit from HOLD mode. NOTE: See AGC_TIMING2[AGC_UNHOLD_MAG_SRC_SEL] and AGC_TIMING2[AGC_UNHOLD_MAG_CNT_SEL] for more info AGC_UNHOLD_FEAT_EN[1]: If AGC does not enter into FREEZE mode or receive done in time, AGC will exit HOLD mode. The unhold timeout value is set by AGC_UNHOLD_TMEOUT NOTE: AGC_UNHOLD_FEAT_EN=3 is a valid configuration

52.4.4.2.2.2.5.1.39 AGC Control Status (AGC_CTRL_STAT)

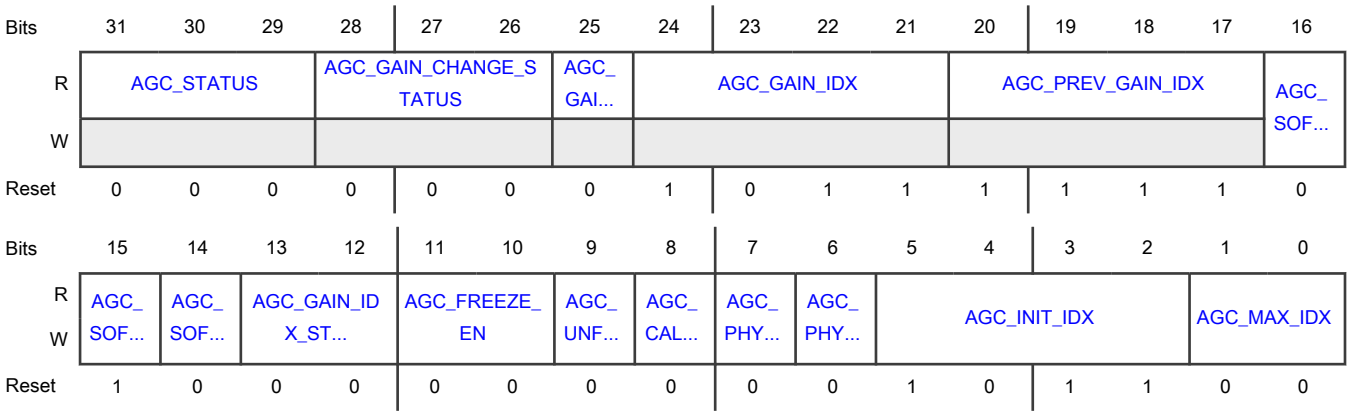
Offset

Register	Offset
AGC_CTRL_STAT	94h

Function

AGC control and status register

Diagram



Fields

Field	Function
31-29 AGC_STATUS	AGC FSM Status Indicate the current state of AGC state machine. This field will be 0 when RX_DIG or AGC are not enabled. 000b - AGC_IDLE 001b - AGC_WB_ONLY 010b - AGC_WB_MAG 011b - AGC_WB_DEBOUNCE 100b - AGC_MAG_ONLY 101b - AGC_HOLD 110b - AGC_FREEZE 111b - AGC_WAIT_GAIN_SETTLE
28-26 AGC_GAIN_CHANGE_STATUS	AGC Gain Change Status Indicate the latest AGC gain index change reason. This field will be 0 when RX_DIG or AGC not be enabled. 000b - No gain change 001b - Gain decreased by WBD step1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - Gain decreased by WBD step2 011b - Gain decreased by fast mode 100b - Gain increased by fast mode 101b - Gain decreased by slow mode 110b - Gain increased by slow mode 111b - Gain increased by delta slow mode
25 AGC_GAIN_CHANGE	AGC Gain Change Indicate the AGC gain is changing. NOTE: This is a pulse signal, software may not read it correctly.
24-21 AGC_GAIN_IDX	AGC Gain Index Indicate current AGC gain index. This field will be reset to AGC_INIT_IDX when AGC or RX_DIG disabled(rx_dig_en deassert) . To get the AGC gain index value using for previous packet receiving, enable the AGC gain index store function(set a non-zero value for AGC_GAIN_STORE field) and read the AGC_PREV_GAIN_IDX field.
20-17 AGC_PREV_GAIN_IDX	AGC Previous Gain Index Indicate previous AGC stable gain index. To use this status field, user should set a non-zero value for AGC_GAIN_IDX_STORE. The value of this field will be kept until next AGC gain store trigger occurs. That means RX_DIG disable or RX_DIG initial will not reset this field. See AGC_GAIN_IDX and AGC_GAIN_IDX_STOR for more info.
16-15 AGC_SOFT_RST_SRC_SEL	PHY AGC Soft Reset Sel 00b - Disable PHY AGC soft reset function 01b - Use posedge phy_soft_rst to reset AGC 10b - Use negedge phy_soft_rst to reset AGC 11b - Use negedge phy_agc_freeze_trig to reset AGC
14 AGC_SOFT_RST_GAIN_SEL	PHY AGC Soft Reset Gain Sel 0b - AGC keep current gain index when PHY AGC soft reset trigged, 1b - AGC return to AGC_INIT_IDX when PHY AGC soft reset trigged,
13-12 AGC_GAIN_IDX_STORE	Enable and config AGC gain index store function. The stored AGC gain index can be read from AGC_PREV_GAIN_IDX field 00b - AGC gain index store function is disabled 01b - Store AGC gain index when AGC enter into HOLD mode 10b - Store AGC gain index when AGC enter into FREEZE mode 11b - Store AGC gain index when AA matched
11-10	AGC Freeze Mode Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AGC_FREEZE_EN	AGC Freeze mode enable and configure 00b - Disable AGC freeze mode 01b - AGC freeze when AA/SFD matched 10b - AGC freeze when AGC freeze timeout matched 11b - AGC freeze when AA/SFD matched or freeze timeout matched
9 AGC_UNFREEZE_FEAT_EN	AGC Unfreeze Feature Enable 0b - AGC unfreeze function is disabled 1b - AGC will exit FREEZE mode when AGC_UNFREEZE_TMEOUT matched and aa_found not be asserted
8 AGC_CALC_MAG_IN_FRZ	AGC Calculate Magnitude In Freeze Mode RXDIG continues to calculate the magnitude value after AGC freezed. NOTE: If NB_RSSI module is expected to start measurement by the assertion of aa_match, pd_found, or sdf_detect, and one of those signal set as AGC Freeze mode trigger, setting this bit is required or the NB-RSSI module cannot work when AGC freezed.
7 AGC_PHY_FREEZE_TRIG_SEL	AGC PHY Freeze Trigger Select 0b - PHY_AGC_FREEZE_TRIG is select as AGC freeze trig. 1b - PHY_AGC_HOLD_TRIG is select as AGC freeze trig.
6 AGC_PHY_HOLD_TRIG_SEL	AGC PHY Hold Trigger Select 0b - PHY_AGC_HOLD_TRIG is select as AGC hold trig. 1b - PHY_AGC_FREEZE_TRIG is select as AGC hold trig.
5-2 AGC_INIT_IDX	AGC Initial Gain Index Initial AGC gain index value. Note: the AGC_INIT_IDX should not greater than 11. Also see AGC_MAX_IDX for more information.
1-0 AGC_MAX_IDX	AGC Max Gain Index Actual AGC max gain index is: 12 - AGC_MAX_IDX. When reaches the max gain index AGC will not perform gain index step up. Value 0 for AGC_MAX_IDX is forbidden.

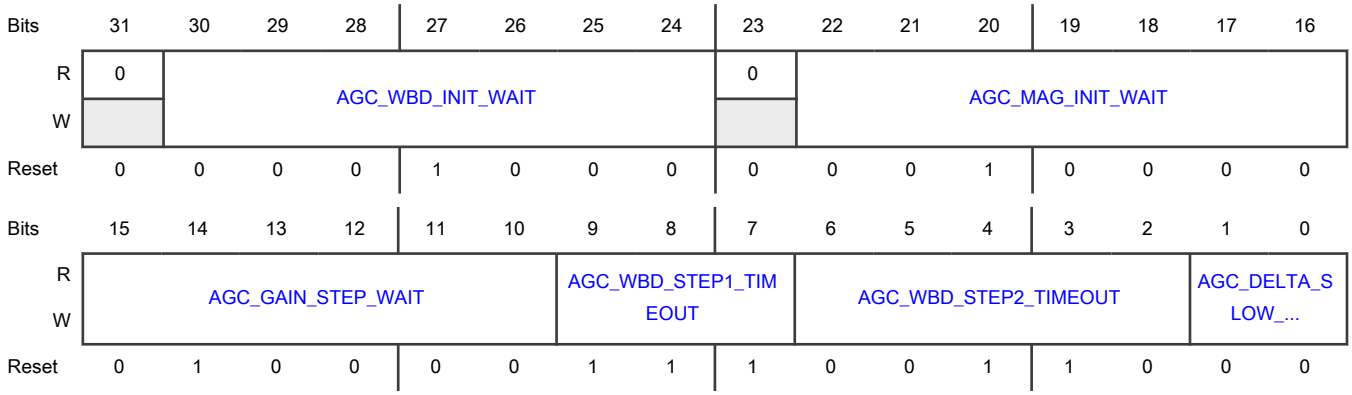
52.4.4.2.2.2.5.1.40 AGC Timing Control 0 (AGC_TIMING0)

Offset

Register	Offset
AGC_TIMING0	98h

Function
AGC timing control 0

Diagram



Fields

Field	Function
31 —	Reserved
30-24 AGC_WBD_INIT_WAIT	AGC WBD Mode Initial Wait Time When RXDIG enabled, the AGC will wait AGC_WBD_INIT_WAIT reference clock cycles than enable WB detect function. NOTE: The programmed value should not be less than 2 and not larger than AGC_MAG_INIT_WAIT
23 —	Reserved
22-16 AGC_MAG_INIT_WAIT	AGC Magnitude Mode Initial Wait Time When RXDIG enabled, the AGC will wait AGC_MAG_INIT_WAIT reference clock cycles than enable FAST and/or SLOW mode. NOTE: The programmed value should not less than 2 and not largen than AGC_WBD_INIT_WAIT
15-10 AGC_GAIN_STEP_WAIT	AGC Gain Change Wait Time Determine the duration of AGC WAIT_GAIN_STEL state. That means the number of reference clock cycles to wait for analog stable after AGC gain index changed.
9-7 AGC_WBD_STEP1_TIMEOUT	AGC WBD Timeout WBD step1 timeout value. This timeout counter will start work at the point of AGC WBD initialization done. If AGC_WBD_AUTO_DIS[1]=1 and no WB trigger occurs, AGC will disable WB detect function. The actual timeout duration(Unit is microsecond) is: AGC_WBD_STEP1_TIMEOUT + 1
6-2 AGC_WBD_STEP2_TIMEOUT	AGC WBD Step2 Timeout Indicating the WBD step2 enable duration, counted by reference clock cycles. If no WBD step2 trigger occurs, the AGC will disable WBD function. NOTE: The programmed value should be no less than 2.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1-0 AGC_DELTA_SLOW_WAIT	AGC Delta Slow Mode Timing In delta slow mode, AGC will compare current slow_mag(slow_mag[N]) to the previous Kth(Here K = AGC_DELTA_SLOW_WAIT+1)slow mag(slow_mag[N-k]) and check whether the delta slow mag(slow_mag[N-K] - slow_mag[N]) exceed DELTA_SLOW_THR. If yes, the AGC will issue a delta slow trig and increase the gain index by AGC_DELATA_SLOW_STEP.

Fields

Field	Function
31-30 —	Reserved
29-26 AGC_WBD_DUAL_CLIP_TIMEOUT	Indicate the max duration, count by reference clk, for WBD debounce. If WBD not be triggered again in this time, debounce failed. If AGC_WBD_EN=2, the programmed AGC_WBD_DUAL_CLIP_TIMEOUT value should be no large than AGC_WBD_STEP2_TIMEOUT. This field has no effect when AGC_WBD_STEP1_DUAL_CLIP_EN || AGC_WBD_STEP2_DUAL_CLIP_EN=0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
25-20 AGC_WBD_STEP2_WAIT	AGC Gain Change Wait For WBD step2 Gain stable wait duration, count by reference clock, for AGC WBD step2.
19-17 AGC_WBD_STEP1_DUAL_CLIP_WAIT	AGC WBD step1 Debounce Wait Time Cooldown duration, count by reference clock, for WBD step1.
16-14 AGC_WBD_STEP2_DUAL_CLIP_WAIT	AGC WBD step2 Debounce Wait Time Cooldown duration, count by reference clock, for WBD step2.
13-7 AGC_HOLD_TIMEOUT	AGC HOLD Mode Wait Time If AGC_HOLD_EN[1] = 1, AGC will trans to hold state when hold timeout matched. The actual hold timeout duration can be calculated as: hold_timeout_duration(microsecond) = AGC_HOLD_TIMEOUT + 1 The hold_timeout counter will start work at the point of AGC initialization done, and which will be reset when every gain index changed.
6-0 AGC_FREEZE_TIMEOUT	AGC FREEZE Mode Wait Time If AGC_FREEZE_EN[1] = 1, AGC will trans to FREEZE state when freeze timeout matched. The actual freeze timeout duration can be calculated as: freeze_timeout_duration(microsecond) = AGC_FREEZE_TIMEOUT + 1 If HOLD function enabled, the freeze_timeout counter will start work when AGC entered into HOLD mode,or it will start counting at the point of AGC initialization done. Similar to the hold_timeout counter, the freeze_timeout counter will be reset when every gain index changes.

24-16 STEP_DOWN_THR_2	STEP_DOWN_THR_2 When current AGC_GAIN_IDX=n, if slow_mag > STEP_DOWN_THR_n, AGC will decrease the gain index.
15-9 —	Reserved
8-0 STEP_UP_THR_2	STEP_UP_THR_2 When current AGC_GAIN_IDX=n, if slow_mag < STEP_UP_THR_n, AGC will increase the gain index.

52.4.4.2.2.2.5.1.83 AGC IDX1 Slow Mode Threshold (AGC_IDX1_THR)

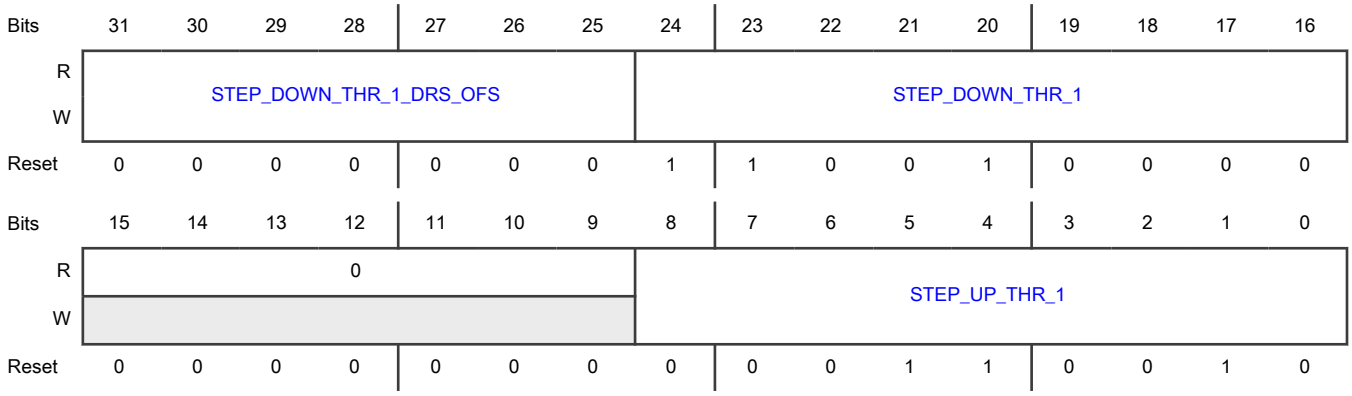
Offset

Register	Offset
AGC_IDX1_THR	144h

Function

AGC_IDXn_THR registers store the threshold values for AGC slow mode. Each AGC gain index has it's own step down and step up threshold. NOTE: There's no STEP_UP_THR for gain index 11 and no STEP_DOWN_THR for gain index 0.

Diagram



Fields

Field	Function
31-25 STEP_DOWN_THR_1_DRS_OFS	STEP_DOWN_THR_1 DRS Offset When datarate_sel=1, the actual slow mode step down threshold in gain idx 1 is "STEP_DOWN_THR_1 + STEP_DOWN_THR_1_DRS_OFS" NOTE: 1. "STEP_DOWN_THR_*_DRS_OFS" is a signed value. 2. the "STEP_DOWN_THR_* + STEP_DOWN_THR_*_DRS_OFS".should in the range of 0 to 511.
24-16 STEP_DOWN_THR_1	STEP_DOWN_THR_1 When current AGC_GAIN_IDX=n, if slow_mag > STEP_DOWN_THR_n, AGC will decrease the gain index.
15-9 —	Reserved
8-0 STEP_UP_THR_1	STEP_UP_THR_1 When current AGC_GAIN_IDX=n, if slow_mag < STEP_UP_THR_n, AGC will increase the gain index.

52.4.4.2.2.2.5.1.84 AGC IDX0 Slow Mode Threshold (AGC_IDX0_THR)

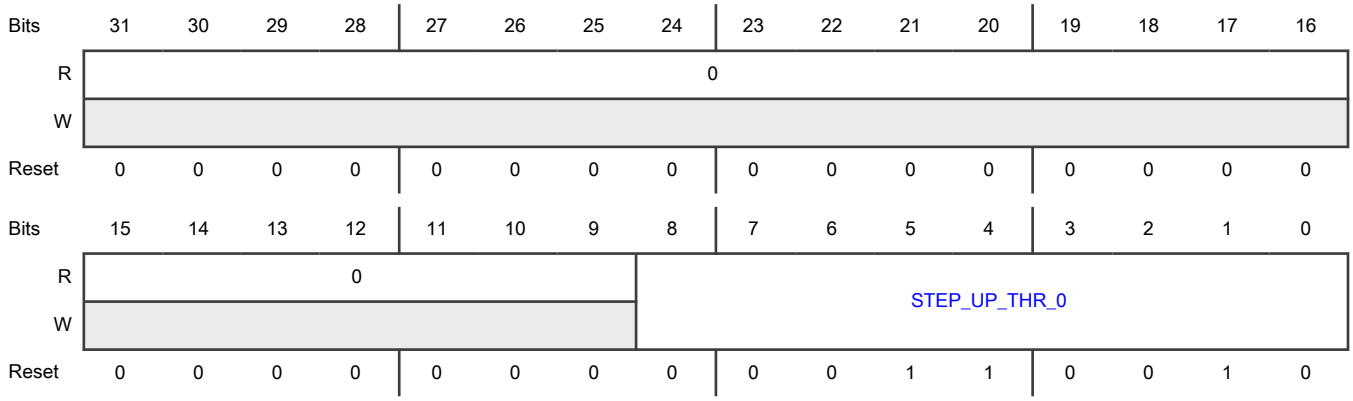
Offset

Register	Offset
AGC_IDX0_THR	148h

Function

AGC_IDXn_THR registers store the threshold values for AGC slow mode. Each AGC gain index has it's own step down and step up threshold. NOTE: There's no STEP_UP_THR for gain index 11 and no STEP_DOWN_THR for gain index 0.

Diagram



Fields

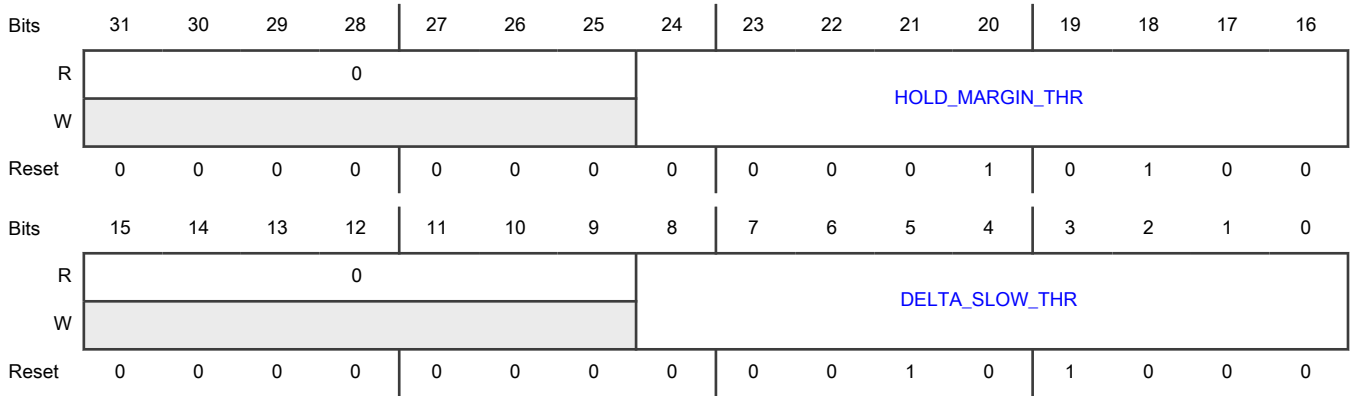
Field	Function
31-9 —	Reserved
8-0 STEP_UP_THR_0	STEP_UP_THR_0 When current AGC_GAIN_IDX=n, if slow_mag < STEP_UP_THR_n, AGC will increase the gain index.

52.4.4.2.2.2.5.1.85 AGC Miscellaneous Thresholds (AGC_THR_MIS)

Offset

Register	Offset
AGC_THR_MIS	14Ch

Diagram



Fields

Field	Function
31-25 —	Reserved
24-16 HOLD_MARGIN_THR	STEP_UP_THR_VLG2large If AGC unhold function enabled, AGC will record the last slow magnitude value(call as hold_mag) before enter into HOLD mode and continue measuring the slow magnitude. If there are two consecutive slow_mag values match the equation "abs(slow_mag-hold_mag) > HOLD_MARGIN_THR", AGC will exit HOLD mode.
15-9 —	Reserved
8-0 DELTA_SLOW_THR	STEP_UP_THR_VLG2 The threshold value for delta slow mode. Check the description of AGC_CTRL[AGC_DELTA_SLOW_EN] and AGC_CTRL[AGC_DELTA_SLOW_STEPS] for more information.

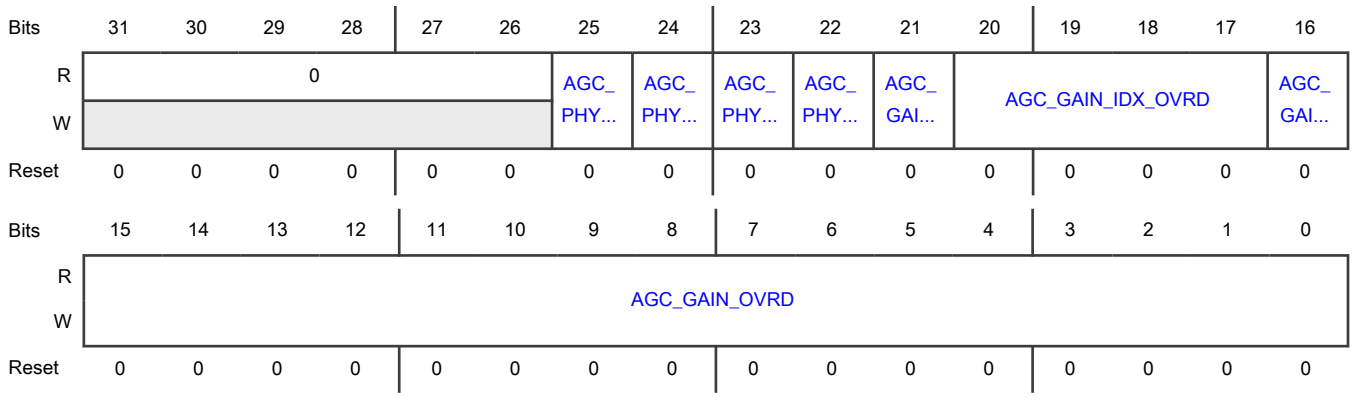
52.4.4.2.2.2.5.1.86 AGC Override Control (AGC_OVRD)

Offset

Register	Offset
AGC_OVRD	150h

Function
AGC override function control.

Diagram



Fields

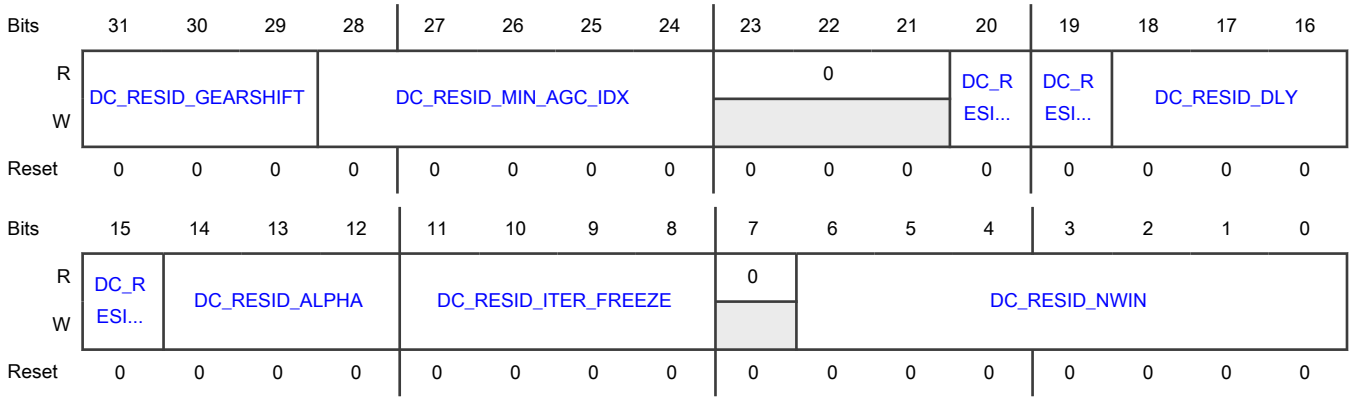
Field	Function
31-26 —	Reserved
25 AGC_PHY_FREEZE_OVRD_EN	PHY_FREEZE_TRIG signal override enable
24 AGC_PHY_FREEZE_OVRD	PHY_FREEZE_TRIG signal override value
23 AGC_PHY_HOLD_OVRD_EN	PHY_HOLD_TRIG signal override enable
22 AGC_PHY_HOLD_OVRD	PHY_HOLD_TRIG signal override value
21 AGC_GAIN_IDX_OVRD_EN	AGC gain index override enable.
20-17 AGC_GAIN_IDX_OVRD	AGC gain index override value.
16 AGC_GAIN_OVRD_EN	AGC gain config override enable
15-0 AGC_GAIN_OVRD	AGC gain config override values. NOTE: AGC Gain Override function has higher priority than AGC Gain Index override function

52.4.4.2.2.2.5.1.87 DC Residual Control (DC_RESID_CTRL)

Offset

Register	Offset
DC_RESID_CTRL	154h

Diagram



Fields

Field	Function
31-29 DC_RESID_GEARSHIFT	DC Residual Gearshift If gearshifting is enabled (DC_RESID_GS_EN = 1), the DC residual will use DC_RESID_ALPHA for DC_RESID_GEARSHIFT windows (DC_RESID_NWIN samples) then will use DC_RESID_ALPHA+1 for the remaining windows.
28-24 DC_RESID_MIN_AGC_IDX	DC Residual Minimum AGC Table Index Specifies the minimum AGC table index value at which DC residual can be enabled. E.g., if this is 5'd0, then the DC residual is enabled for all AGC gain table indexes (assuming RX_DC_RESID_EN is set) if this is 5'd20, then tracking is enabled for AGC gain table indexes 20-26 (assuming RX_DC_RESID_EN is set).
23-21 —	Reserved
20 DC_RESID_EXT_DC_EN	DC Residual External DC Enable 0b - External DC disable. The DC Residual activates at a delay specified by DC_RESID_DLY after an AGC gain change pulse. The DC Residual is initialized with a DC offset of 0. 1b - External DC enable. The DC residual activates after the DCOC's tracking hold timer expires. The DC Residual is initialized with the DC estimate from the DCOC tracking estimator.
19 DC_RESID_SECOND_RUN_EN	DC Residual Second Run Enable This bit enables additional DC residual compensation (primarily intended for Long Range) after the normal DC residual operation has completed. 0b - Second Run disabled 1b - Second Run enabled
18-16 DC_RESID_DLY	DC Residual Delay The delay from activation of the DC residual block to the time when it starts processing. For a 32MHz reference clock, the delay in microseconds matches the value programmed. For other clock frequencies,

Table continues on the next page...

Table continued from the previous page...

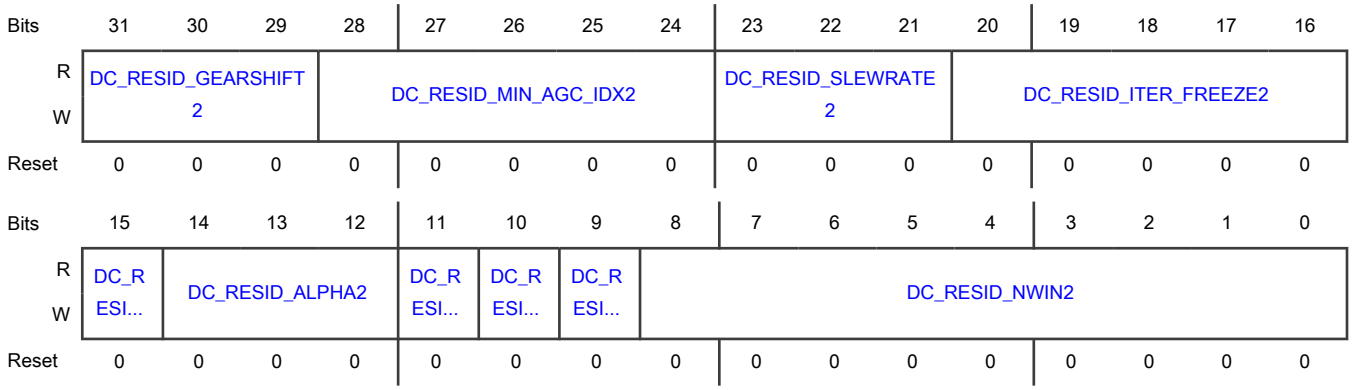
Field	Function
	the delay is scaled based on the clock period. Supported values: 0-7. This delay is only used when EXT_DC_EN=0.
15 DC_RESID_GS_EN	DC Residual Gearshift Enable Controls whether or not gearshifting is enabled. See description of DC_RESID_GEARSHIFT for more information on gearshifting. 0b - Gearshifting disabled 1b - Gearshifting enabled
14-12 DC_RESID_ALPHA	DC Residual Alpha The Alpha parameter controls the rate at which the DC estimate is updated. 000b - Update factor is 1 001b - Update factor is 1/2 010b - Update factor is 1/4 + 1/8 011b - Update factor is 1/4 100b - Update factor is 1/8 + 16 101b - Update factor is 1/8 110b - Update factor is 1/16 + 1/32 111b - Update factor is 1/16
11-8 DC_RESID_ITER_FREEZE	DC Residual Iteration Freeze Number of windows of DC_RESID_NWIN samples before the DC is frozen. Supported values: 1-8
7 —	Reserved
6-0 DC_RESID_NWIN	DC Residual NWIN Number of samples in a window.

52.4.4.2.2.2.5.1.88 DC Residual Control2 (DC_RESID_CTRL2)

Offset

Register	Offset
DC_RESID_CTRL2	158h

Diagram



Fields

Field	Function
31-29 DC_RESID_GEARSHIFT2	DC Residual Gearshift, for Second Run If gearshifting is enabled (DC_RESID_GS2_EN = 1) for Second Run, the DC residual will use DC_RESID_ALPHA2 for DC_RESID_GEARSHIFT2 windows (DC_RESID_NWIN2 samples) then will use DC_RESID_ALPHA2+1 for the remaining windows.
28-24 DC_RESID_MIN_AGC_IDX2	DC Residual Minimum AGC Table Index, for Second Run Specifies the minimum AGC table index value at which DC residual can be enabled while Second Run is active. E.g., if this is 5'd0, then the DC residual is enabled for all AGC gain table indexes (assuming RX_DC_RESID_EN is set) if this is 5'd20, then tracking is enabled for AGC gain table indexes 20-26 (assuming RX_DC_RESID_EN is set).
23-21 DC_RESID_SLEWRATE2	DC Residual Slew rate, for Second Run If Slew rate control is enabled (DC_RESID_SR2_EN = 1), changes in the DC correction will be limited to this maximum absolute value, while Second Run is active.
20-16 DC_RESID_ITER_FREEZE2	DC Residual Iteration Freeze, for Second Run Number of windows of DC_RESID_NWIN samples before the DC is frozen. This is used only when Second Run is active.
15 DC_RESID_GS2_EN	DC Residual Gearshift Enable, for Second Run Controls whether or not gearshifting is enabled for Second Run. See description of DC_RESID_GEARSHIFT2 for more information on gearshifting. 0b - Gearshifting disabled for Second Run 1b - Gearshifting enabled for Second Run
14-12 DC_RESID_ALPHA2	DC Residual Alpha, for Second Run The Alpha parameter controls the rate at which the DC estimate is updated. The update factor is shown below. This is used only when the Second Run is active. 000b - Update factor is 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - Update factor is 1/2 010b - Update factor is 1/4 + 1/8 011b - Update factor is 1/4 100b - Update factor is 1/8 + 16 101b - Update factor is 1/8 110b - Update factor is 1/16 + 1/32 111b - Update factor is 1/16
11 DC_RESID_SR2_EN	DC Residual Slew rate Enable, for Second Run When DC Residual is performing Second Run, if this bit is set, then changes in the DC correction will be limited by DC_RESID_SLEWRATE after Gearshifting.
10 DC_RESID_CC_EN	DC Residual Continuous Correction Enable When DC Residual is performing Second Run, if this bit is set, then the DC_RESID_ITER_FREEZE2 will be ignored and the DC Residual will perform continuous corrections.
9 DC_RESID_PHY_STOP_EN	DC Residual PHY Stop Enable When DC Residual is performing Second Run, if this bit is set, then when the PHY's aa found uncoded signal is asserted, further DC correction updates will be stopped.
8-0 DC_RESID_NWIN2	DC Residual NWIN, for Second Run Number of samples in a window. This is used only when DC_RESID_SECOND_RUN_EN=1.

52.4.4.2.2.2.5.1.89 DC Residual Control DataRate1 (DC_RESID_CTRL_DRS)

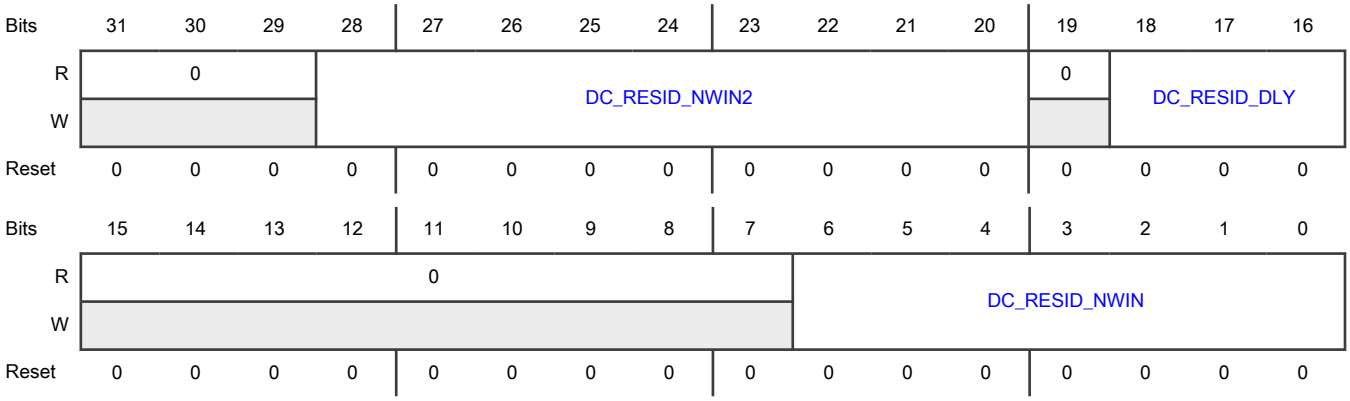
Offset

Register	Offset
DC_RESID_CTRL_DRS	15Ch

Function

The bits in the _DRS registers are only used when the Bluetooth LE signals to request a 2Mbps data rate, or the Generic LL signals using datarate_config_sel to request an alternate data rate.

Diagram



Fields

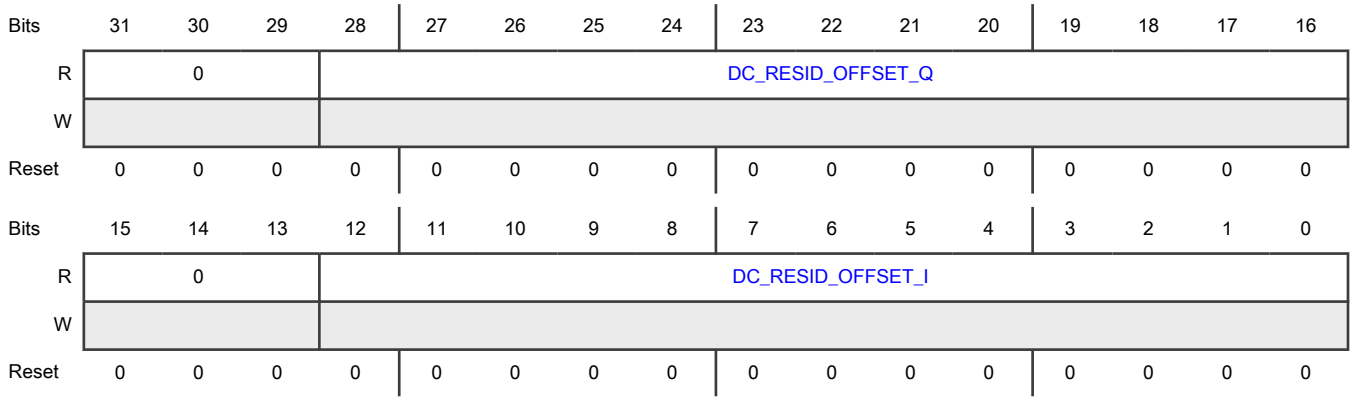
Field	Function
31-29 —	Reserved
28-20 DC_RESID_NWIN2	DC Residual NWIN, for Second Run Number of samples in a window. This is used only when DC_RESID_SECOND_RUN_EN=1.
19 —	Reserved
18-16 DC_RESID_DLY	DC Residual Delay The delay from activation of the DC residual block to the time when it starts processing. For a 32MHz reference clock, the delay in microseconds matches the value programmed. For other clock frequencies, the delay is scaled based on the clock period. Supported values: 0-7. This delay is only used when EXT_DC_EN=0.
15-7 —	Reserved
6-0 DC_RESID_NWIN	DC Residual NWIN Number of samples in a window.

52.4.4.2.2.2.5.1.90 DC Residual Estimate (DC_RESID_EST)

Offset

Register	Offset
DC_RESID_EST	160h

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 DC_RESID_OFFSET_Q	DC Residual Offset Q Reflects the current DC residual offset estimate for Q channel. Format is s11.1. This is provided for debug and characterization purposes only.
15-13 —	Reserved
12-0 DC_RESID_OFFSET_I	DC Residual Offset I Reflects the current DC residual offset estimate for I channel. Format is s11.1. This is provided for debug and characterization purposes only.

52.4.4.2.2.2.5.1.91 DfT tone analyzer (DFT_TONE_ANALYZER0)

Offset

Register	Offset
DFT_TONE_ANALYZER0	164h

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
10-8 RX_SAMPLE_ADJ	RX sample delay line adjustment This register is used mainly for debug purposes. It allows to adjust the timing by modifying the number of samples @ 4/8 Mhz (after acquisition filter) of the delay line.This could help for Channel Sounding RTT demodulation adjustment.
7-4 —	Reserved
3-0 SN_AGC_INIT_IDX2	AGC Initial Gain Index of the second part of CS sub-event in sniffer mode Initial AGC gain index value of the second part of CS sub-event in sniffer mode. Note: the SN_AGC_INIT_IDX2 should not greater than 11. Also see AGC_MAX_IDX for more information.

52.4.4.2.2.2.5.1.100 Controls for the NADM module (NADM_CTRL)

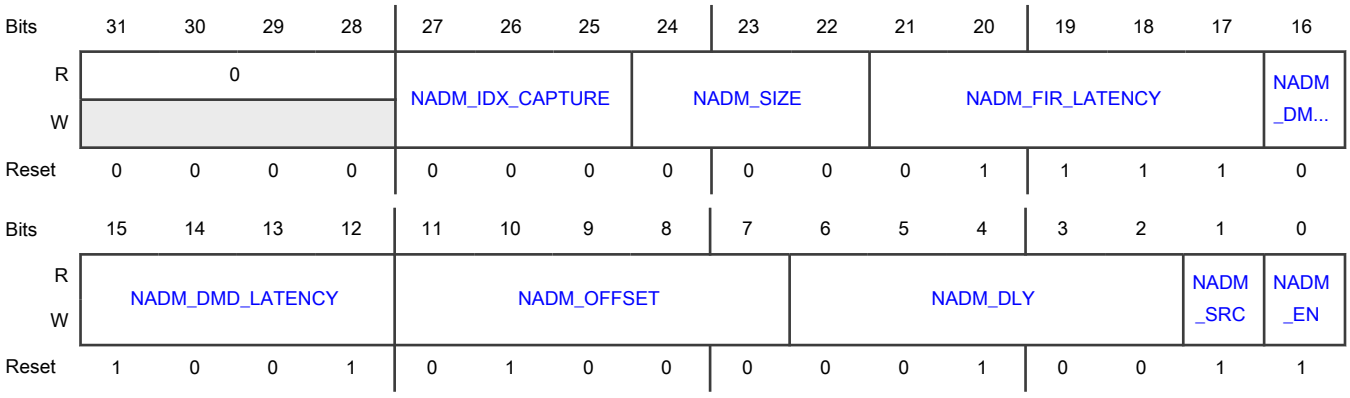
Offset

Register	Offset
NADM_CTRL	188h

Function

Controls for the NADM (Normalized Attack Detection Metric) module.

Diagram



Fields

Field	Function
31-28	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
27-25 NADM_IDX_CAPTURE	Index used to get optimum fm_diff in DMA_DBG Debug feature,Index [0..4] to select best coorelator to get optimum fm_diff in DMA_DBG.
24-22 NADM_SIZE	NADM size aligned on RTT_TYPE standard value Data size for NADM :in nominal mode, it should be set the same as RTT_TYPE. Other setting could be used in case of proprietary mode to add some extra datas.
21-17 NADM_FIR_LATENCY	FM correlator path, delay between reference start and correlator start. Delay in PHY clock cycles between GFSK reference start and phase correlator start. This allows to take into account the propagation time inside the reference GFSK filter.
16-12 NADM_DMD_LATENCY	FM symbol error path, NADM trigger delay after access address reception. Delay in NADM clock cycles after access address reception to trigger NADM symbol error path finite state machine.
11-7 NADM_OFFSET	FM correlator path, offset in the delay array. This selects the delay in PHY clock cycles of the first correlator instance, allowing to align properly center correlator versus reference signal.
6-2 NADM_DLY	FM correlator path, NADM trigger delay after access address reception. Delay in PHY clock cycles after access address reception to trigger NADM finite state machine.
1 NADM_SRC	FM correlator path, select source. Selects the source of the NADM FM correlator path. 0b - CHF in selected. NADM module source is channel filter input signal. 1b - CHF out selected. NADM module source is channel filter output signal.
0 NADM_EN	NADM module enable. Enables NADM module operation. 0b - Nadm operation is disabled. 1b - Nadm operation is enabled.

52.4.4.2.2.2.5.1.101 NADM latest packet results. (NADM_RES)

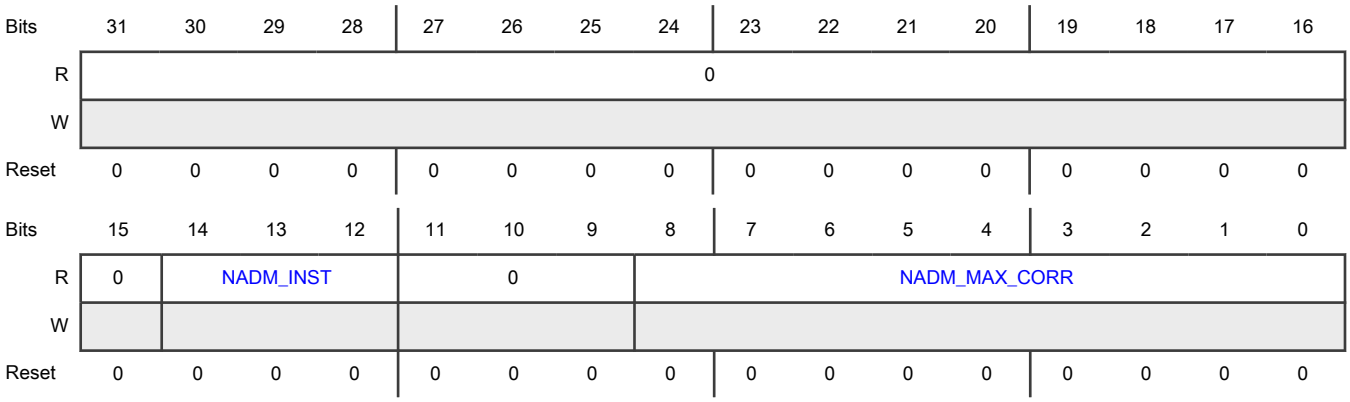
Offset

Register	Offset
NADM_RES	18Ch

Function

Latest packet results for the NADM (Normalized Attack Detection Metric) module. To be used for debug purposes, normal usage of NADM values is done with the packet RAM.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-12 NADM_INST	NADM correlator instance yielding maximum correlation value. Latest packet maximum correlation instance.
11-9 —	Reserved
8-0 NADM_MAX_CORR	NADM maximum correlation value. Latest packet maximum correlation value.This field corresponds to the raw correlation result, before internal truncation. It needs to be divided by two (discard the LSB) to match the nadm value sent to the packet RAM.

52.4.4.2.2.2.5.1.102 Fine CFO module controls. (FCFO_CTRL)

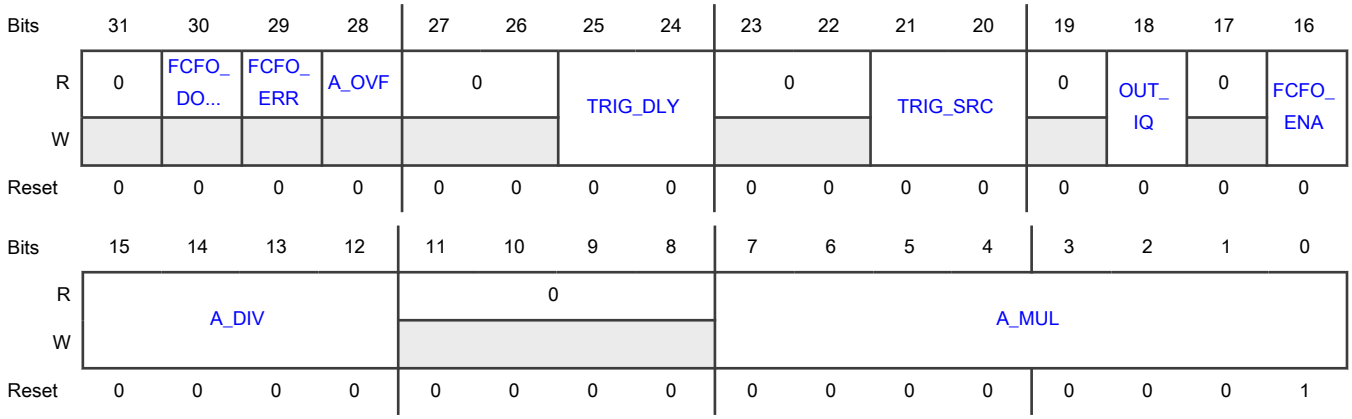
Offset

Register	Offset
FCFO_CTRL	190h

Function

Fine CFO module controls.

Diagram



Fields

Field	Function
31 —	Reserved
30 FCFO_DONE	FCFO done. Fine CFO has run.
29 FCFO_ERR	FCFO value error. FCFO value error occured. Can be caused either by tone analyser overflow (chec ta bits) or alpha multiplier overflow (check fcfo bit).
28 A_OVF	Alpha multiplier overflow. Alpha multiplier overflow occured.
27-26 —	Reserved
25-24 TRIG_DLY	Delay between trigger and fcfo start. Delay between trigger and fcfo start. 00b - Selects 2us trigger delay. 01b - Selects 5us trigger delay. 10b - Selects 10us trigger delay. 11b - Selects 15us trigger delay.
23-22 —	Reserved
21-20 TRIG_SRC	Selects FCFO trigger source. Selects FCFO trigger source.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Selects TPM as trigger source 01b - Selects TFM as trigger source 10b - Selects software as trigger source.
19 —	Reserved
18 OUT_IQ	FCFO output format. Selects FCFO module output format. 0b - Fcfo output are g function values (previous/current). 1b - Fcfo output are IQ values.
17 —	Reserved
16 FCFO_ENA	Enables FCFO module. Enables FCFO module. 0b - Fcfo algorithm disabled. 1b - Fcfo algorithm enabled.
15-12 A_DIV	Alpha linear division coeficient Interpolation linear division coeficient for g function. In powers of two.
11-8 —	Reserved
7-0 A_MUL	Alpha linear multiplication coeficient Interpolation linear coeficient for g function.

52.4.4.2.2.2.5.1.103 Tone parameters. (FCFO_TN)

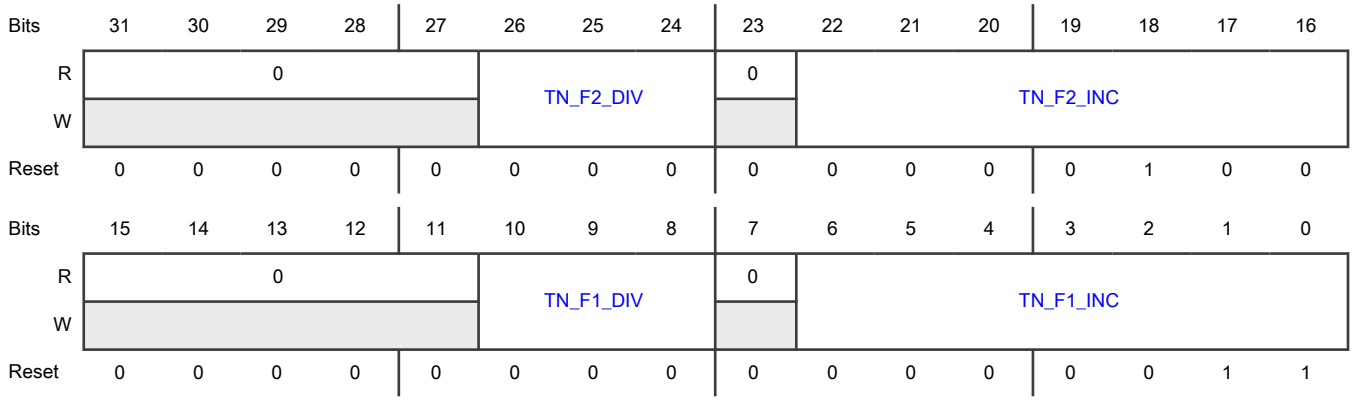
Offset

Register	Offset
FCFO_TN	194h

Function

Tone parameters for FCFO module.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TN_F2_DIV	Tone F2 clock divisor. Tone F2 clock divisor.
23 —	Reserved
22-16 TN_F2_INC	Tone F2 increment. Tone F2 increment.
15-11 —	Reserved
10-8 TN_F1_DIV	Tone F1 clock divisor. Tone F1 clock divisor.
7 —	Reserved
6-0 TN_F1_INC	Tone F1 increment. Tone F1 increment.

52.4.4.2.2.2.5.1.104 F2 carrier iq phases (FCFO_TN_PH)

Offset

Register	Offset
FCFO_TN_PH	198h

Function

Initial phases of the F2 carrier. For F1 settings are in tone analyser register.

15-0 G_CUR	g function, current value. If OUT_IQ set to 0, current g function value. If OUT_IQ set to 1, I value for X1 probe analysis.

52.4.4.2.2.3 PLL Digital Module (PLL_DIG)

52.4.4.2.2.3.1 Overview

The PLL Frequency Synthesizer is a Digital Module that -

1. Selects the Radio Carrier Frequency
2. Coarse Tunes the VCO and Calibrates the High Port DAC
3. Controls the PLL Loop Divider value to lock the VCO at the Carrier Frequency
4. Applies the Baseband Frequency Word as High Port Modulation (HPM) to the VCO High Port DAC
5. Applies the Baseband Frequency Word as Low Port Modulation (LPM) to the PLL Loop Divider
6. Monitors the PLL lock status and flags unlocked conditions
7. Provides DFT features for evaluating the PLL Frequency Synthesizer during factory validation and testing

52.4.4.2.2.3.1.1 Block diagram

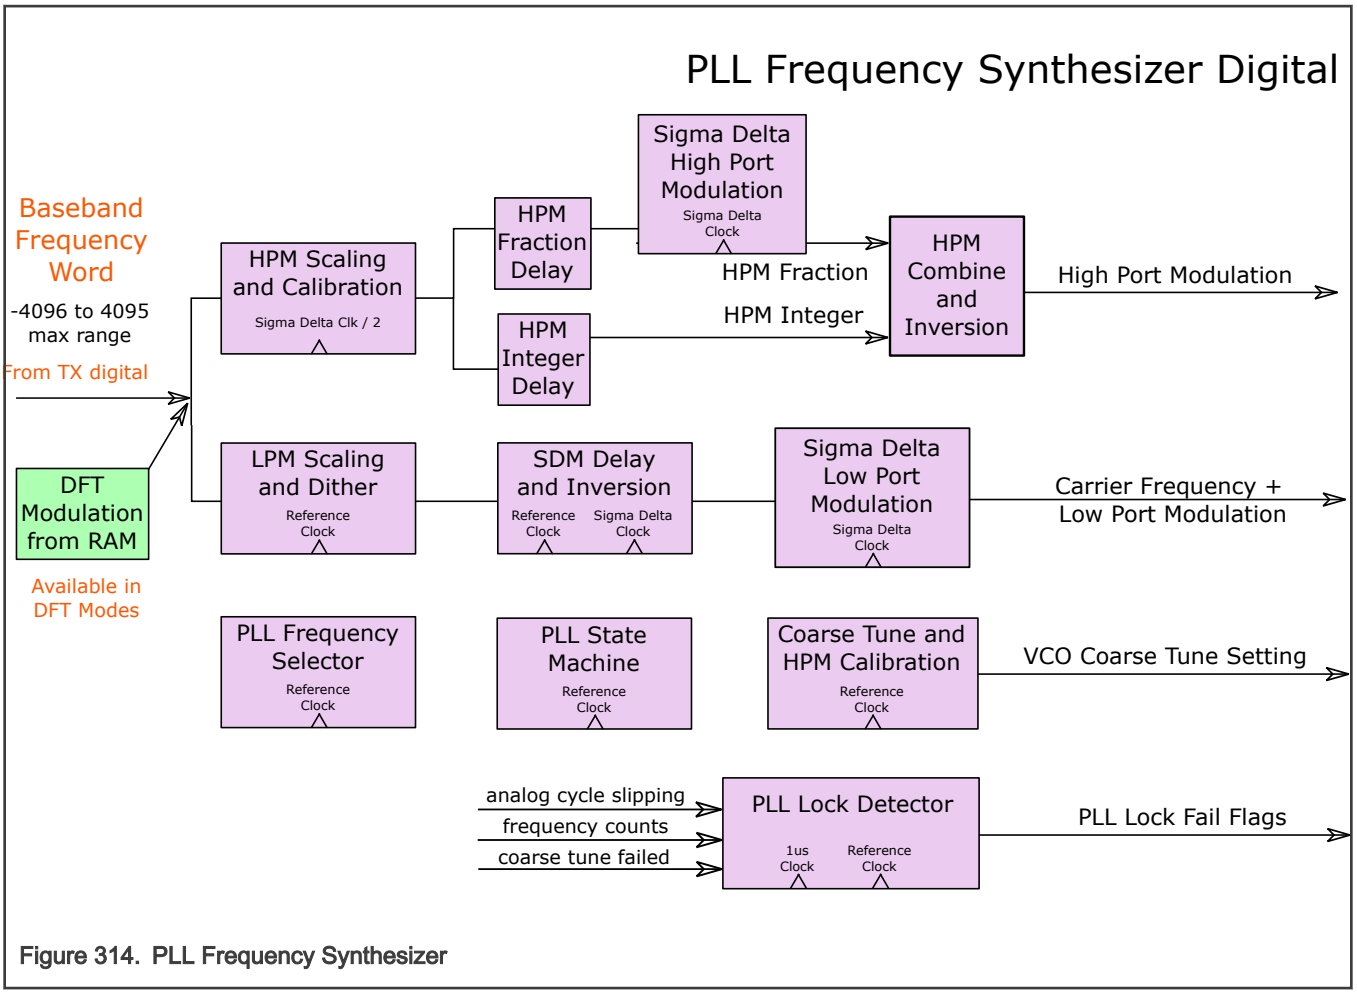

Figure 314. PLL Frequency Synthesizer

52.4.4.2.2.3.1.2 Features

52.4.4.2.2.3.1.2.1 Baseband Frequency Word

52.4.4.2.2.3.1.2.1.1 Range Frequency Word

The Transmitter Digital presents the PLL Frequency Synthesizer with a signed 13-bit Baseband Frequency word to modulate onto the RF Carrier Frequency. The Baseband Frequency Word range is -4096 to 4095, which provides a modulation range of +/- 1000 kHz when using a 32 MHz reference frequency with a PLL Minimum Frequency Step Size of 244.14 Hz. Note, this range can be adjusted using LPM_CTRL[LPM_SCALE] along with LPM_CTRL[HPM_CAL_SCALE] to adjust the PLL Minimum Frequency Step Size.

52.4.4.2.2.3.1.2.1.2 Manual Frequency Word

The Baseband Frequency word can be overridden by software if the MOD_DISABLE bit is set. In this case the PLL Digital will use the MODULATION_WORD_MANUAL register as the source of the modulation.

Note that due to the speeds at which the High Port and Low Port react to changes in the modulation word, and the speed at which software is able to effect such changes, for all practical purposes this can only support low frequency modulation.

52.4.4.2.2.3.2 Functional description

52.4.4.2.2.3.2.1 Carrier Frequency Tuning

52.4.4.2.2.3.2.1.1 Radio Frequency Selection

The PLL Digital has hardware support for 128 RF channels in 1 MHz increments spanning the range from 2.360 GHz to 2.487 GHz.

Each supported carrier frequency is derived by Fractional-N Frequency Synthesis using the Low Port Sigma Delta Modulator. Note, the frequency selection registers should be programmed from the perspective of TX operation. If the PLL is operating in an RX mode then the CHAN_MAP_EXT[NUM_OFFSET] will be utilized to derive the RX channel frequency. The NUM_OFFSET register field represents the IF frequency difference between RX and TX. Also, CFO should be computed during SQTE FCS and the software should program step_cfo[15:0] into packet RAM for each channel, this value is automatically added to the numerator at each step for compensation.

These 128 RF channels are mapped to the various supported RF Protocols through two lookup tables as shown in the figure below.

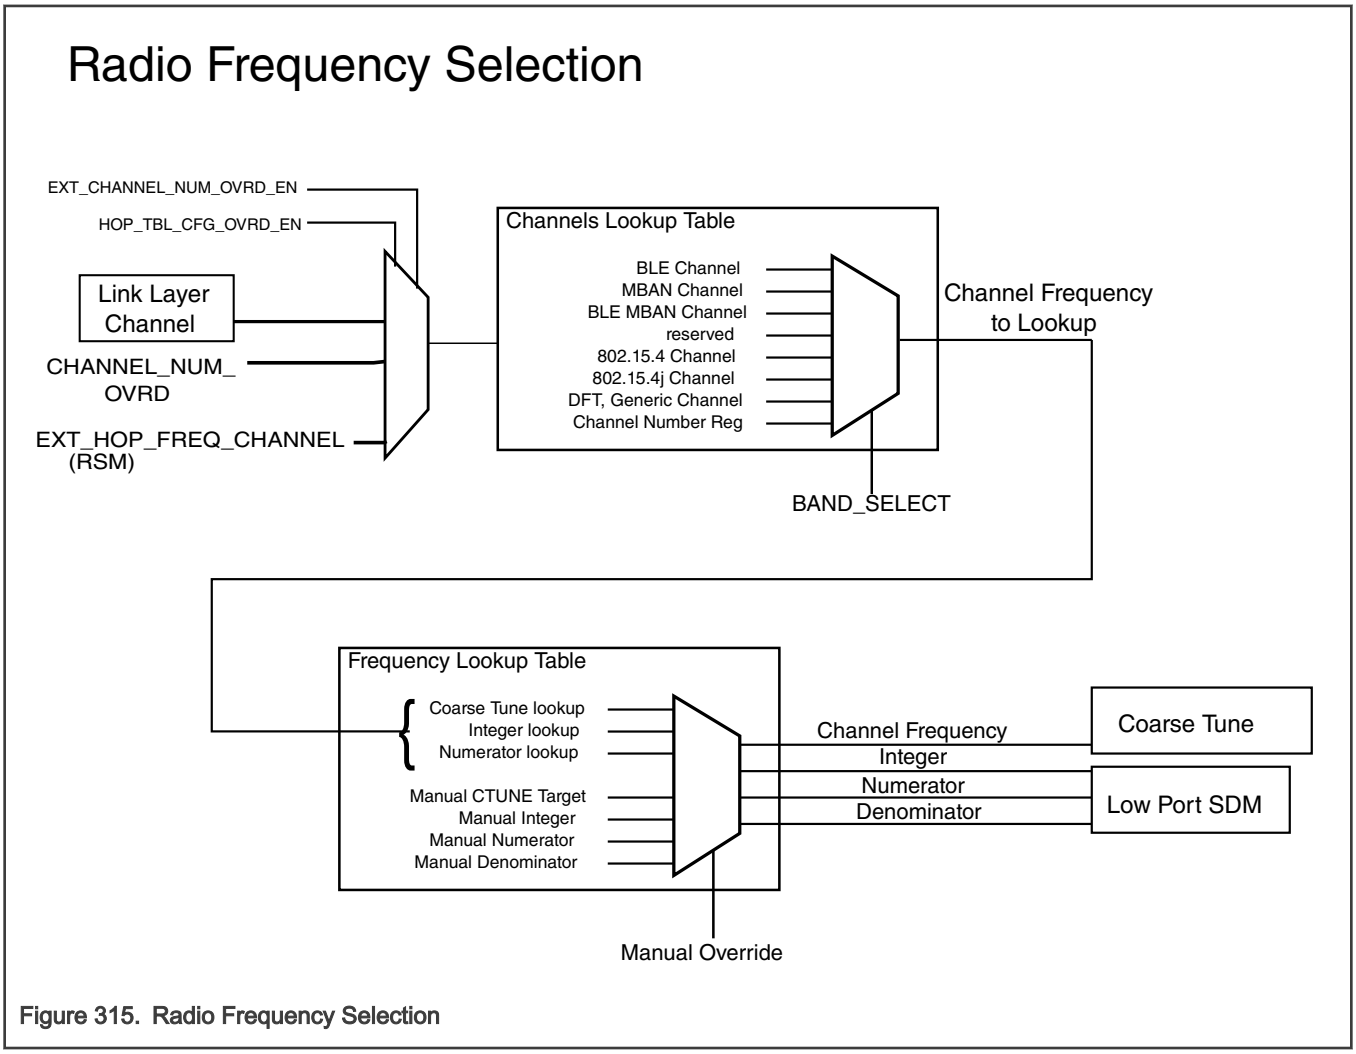

Figure 315. Radio Frequency Selection

52.4.4.2.2.3.2.1.2 RF Channels Supported

The channel frequencies for each protocol are shown in the tables below. The channel mapping is selected based on the register CHAN_MAP[BAND_SELECT].

42	2,402	85	2,445		

52.4.4.2.2.3.2.1.3 Channel Selector

During typical Radio usage, the channel selection is done automatically by the Link Layer.

Channel selection can be overridden using the PLL_CHAN_MAP register bits HOP_TBL_CFG_OVRD_EN and HOP_TBL_CFG_OVRD. If HOP_TBL_CFG_OVRD_EN is set then the CHANNEL_NUM_OVRD register selects the Radio Channel Number instead of the Link Layer. In addition, the HOP_TBL_CFG_OVRD selection will determine how the CHANNEL_NUM_OVRD is interpreted.

52.4.4.2.2.3.2.1.4 Manual Carrier Frequency

The internal frequency mapping can be bypassed and software can directly control the Low Port Sigma Delta inputs to select any channel frequency in the VCO's range (in increments of the Low Port Minimum Frequency Step Size).

The Radio Channel Frequency override is manually selected by setting the SDM_MAP_DISABLE bit along with the LPM_INTG, LPM_NUM, and LPM_DENOM register values.

Any modulation from the TX Digital will be added to this manual frequency selection.

The Manual carrier frequency selected can be calculated using the formula below:

Radio Carrier Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

52.4.4.2.2.3.2.2 VCO Calibration

52.4.4.2.2.3.2.2.1 Coarse Tune

The VCO Coarse Tune is carried out by a Successive Approximation Register method that computes the best coarse tune setting for the VCO in successive steps from MSB to LSB.

This SAR method uses a Frequency Meter count value that is successively compared to expected counts to determine the best coarse tune setting for the VCO.

The coarse tune setting can be overridden for test and validation purposes, and the individual frequency counts used at each successive step for the coarse tune setting are available for viewing in DTEST mode and also as register values in the PLL register space.

52.4.4.2.2.3.2.2.2 High Port DAC Calibration

The objective of the HPM DAC Calibration is to determine the DAC Step Size and estimate the ratio of this DAC unit step to the Low Port Minimum Frequency Step Size.

Once the step size of the High Port DAC is known, a scaling factor is applied to correctly map the baseband frequency word to the High Port modulation.

The length of the calibration time is set using the HPM_CAL_TIME register and the size of the DAC array used is selected using the HPM_CAL_ARRAY_SIZE register.

The register HPM_COUNT_ADJUST[3:0] provides a (-8/+7) range of adjustment to the HPM Calibration Count Difference for the HPM Calibration lookup table to allow for any count error bias that may be present. This adjusted Count Difference is used with a Lookup Table to choose the HPM Calibration Factor

52.4.4.2.2.3.2.2.2.1 HPM CAL Factor

The HPM_CAL_FACTOR read register shows the value that is currently being used by High Port Modulation Multiplier. This value is from the most recent High Port calibration unless it is being overridden using the HP_CAL_DISABLE and HPM_CAL_FACTOR_MANUAL registers.

For localisation purpose, additional options are available to override HPM cal factor value by HPM_CAL_FACTOR_MANUAL register value or packet RAM table value:

1. HPM calibration result (HPM_CAL_FACTOR) comes from a table inside packet RAM if one or both of the following conditions are met:
    a. RSM_HPM_CAL is set to 1.
    b. HPM_DYNAMIC_SEL is set to 1
        i. in TX mode.
        ii. in RX mode during packets if HPM_DYNAMIC_RX_PKT_TABLE is set to 1.
        iii. in RX mode during tones if HPM_DYNAMIC_RX_TONE_TABLE is set to 1.

2. HPM calibration result ((HPM_CAL_FACTOR) comes from HPM_CAL_FACTOR_MANUAL register If one or both of the following conditions are met:
    a. HP_CAL_DISABLE is set to 1.
    b. HPM_DYNAMIC_SEL is set to 1
        i. in RX mode during packets if HPM_DYNAMIC_RX_PKT_TABLE is set to 0.
        ii. in RX mode during tones if HPM_DYNAMIC_RX_TONE_TABLE is set to 0.

NOTE

HPM dynamic mode enabled by HPM_DYNAMIC_SEL register is meant to be used in channel sounding to get dynamically HPM cal factor in RX (tones and packets) mode either from packet RAM table or HPM_CAL_FACTOR_MANUAL register. In TX mode the factor comes from packet RAM table.

52.4.4.2.2.3.2.3 High Port Modulation

The High Port Modulator multiplies the HPM Calibration Factor and the PLL Baseband Frequency Word to get the High Port Modulation Word.

The High Port Modulation Word is represented by both an Integer and a Fractional portion. The Fraction is processed by the High Port Sigma Delta Modulator and the result is combined with the Integer and used to control the VCO High Port DAC.

52.4.4.2.2.3.2.3.1 High Port DAC

The High Port Digital to Analog Converter is designed to take the High Port Modulation Word and convert it to a control voltage that is applied as modulation to the VCO High Port.

52.4.4.2.2.3.2.3.1.1 HPM DAC Settings

The HPM DAC settings during calibration and normal operation are shown in the table below.

Warning : TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the PLL_VCO_TRIM_KVM[2:0] register.

Table 478. Nominal HPM DAC parameters in various modes

Radio TX Mode		DAC max swing (mV)	DAC output common mode (mV)	DAC swing during operation	Vcm (mV) / HPM_VCM	OPAMP gain setting (R2/R1) / HPM_FDB_RES	Common mode at varactor (mV)	Swing at Varactor input (mV)	Kvm (MHz/Kv)	Deviation at VCO (KHz)[1]
802.15.4/ 2000kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	20	+/-3280
	TX operation	+/-82	82	+/-51.2	391 / 3'b000	1/ 2'b00	700	+/51.2	20	+/-1024
Bluetooth Low Energy/ 1000kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2 / 2'b01	700	+/-164	10	+/-1640
	TX operation	+/-82	82	+/-51.2	391 / 3'b000	1/ 2'b00	700	+/51.2	10	+/-512

Table continues on the next page...

Table 478. Nominal HPM DAC parameters in various modes (continued)

500kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	10	+/-1640
	TX operation	+/-82	82	+/-25.6	391 / 3'b000	1/ 2'b00	700	+/25.6	10	+/-256
250kHz	HPM calibration	+/-82	82	+/-82	288 / 3'b001	2/ 2'b01	700	+/-164	10	+/-1640
	TX operation	+/-82	82	+/-12.8	391 / 3'b000	1/ 2'b00	700	+/12.8	10	+/-128

1. On-Air modulation frequency is a divide by 2 of the VCO frequency.

52.4.4.2.2.3.2.3.1.2 HPM DAC Bump

The HPM DAC Calibration is normally done at 2X the On-Air Modulation Range, this is accomplished by writing the PLL HPM Analog Bump Control (PLL_HPM_BUMP) register bits:

- HPM_VCM_CAL, value applied during HPM DAC Calibration
- HPM_FDB_RES_CAL, value applied during HPM DAC Calibration
- HPM_VCM_TX, value applied during Radio Transmissions or only during Radio TX if HPM_BUMP_RX_TX_EN set to 1
- HPM_FDB_RES_TX, value applied during Radio Transmissions or only during Radio TX if HPM_BUMP_RX_TX_EN set to 1
- HPM_VCM_RX, value applied during Radio RX if HPM_BUMP_RX_TX_EN set to 1
- HPM_FDB_RES_RX, value applied during Radio RX if HPM_BUMP_RX_TX_EN set to 1

If the registers are written in such a way that the DAC range is not doubled, then the HPM_CAL_NOT_BUMPED bit must be set to change the math in the HPM Calibration.

52.4.4.2.2.3.2.3.1.3 HPM DAC 1 MHz Range

TX operation with On-Air modulation ranges greater than +/- 250 kHz (+/- 500 kHz at the VCO) require that the VCO Kvm be adjusted using the PLL_VCO_TRIM_KVM[2:0] register.

This VCO Kvm setting should be made prior to HPM DAC calibration.

52.4.4.2.2.3.2.3.2 High Port Sigma Delta

The High Port fractional modulation is implemented using a 2nd-order MASH Sigma Delta Modulator (SDM), which converts the 6-bit fractional portion of the high port modulation word to a 3-state thermometric code {-1,0,+1}. The resulting code is then added to the integer portion of the high port modulation word and the final result is applied to the HPM DAC.

52.4.4.2.2.3.2.3.2.1 HPM SDM Dither

In addition to the nominal SDM functionality, the HPM SDM design includes a zero-mean dithering to mitigate idle tones that can occur when modulating a string of ones or zeros.

The Dither is implemented using a Linear-Feedback Shift Register (LFSR) which provides a 1-bit pseudo-randomization that adds or subtracts 1-bit to the 6-bit fractional portion before it is processed by the Sigma Delta Modulator.

The length of the LFSR can be selected using the HPM_LFSR_SIZE register, and the scale can be changed using the HPM_DTH_SCL bit. The Dither can also be disabled by clearing the HPM_DTH_EN bit.

52.4.4.2.2.3.2.3.3 High Port Delay, Disable, Invert

The HPM Integer and Fraction portions each have an array of programmable delays available to allow the HPM modulations to be matched to each other and to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The HPM delay steps are in increments of the PLL Sigma Delta Clock divided by 2, and the LPM SDM delay steps are in increments of the PLL Sigma Delta Clock. All three delay step settings are in the range of {0 to 15}.

There are several inversion bits that can be used if needed:

- HPM_CAL_INVERT, Invert the High Port Modulator during Calibration
- HPM_MOD_IN_INVERT, Invert the input word to the High Port Modulator
- HPM_INTEGER_INVERT, Invert the High Port Modulation Integer portion
- HPM_SDM_OUT_INVERT, Invert the HPM SDM Fractional Output

High Port Modulation can be disabled by setting the HPM_MOD_DISABLE bit, in this case the HPM_MOD_MANUAL register value is applied to the VCO High Port. Disabling high port modulation can be useful depending on the modulation range required for the desired data rate. For use cases where no high port modulation is required, the TX warm-up time can be reduced by skipping the HPM Calibration. To skip HPM CAL, the register bit HPMCAL_CTRL[HPM_CAL_SKIP] must be set. In this case, the HPM_MOD_MANUAL register should be set to 0x80. Note, the TSM default warm-up sequence must be overridden if HPM_CAL_SKIP is set to recover the HPM CAL warm-up time.

52.4.4.2.2.3.2.4 Low Port Modulation

The Low Port Modulator uses a 3rd order Sigma-Delta to produce a fractional division (Fractional-N Frequency Synthesis) to control the PLL Loop Divider and tune the VCO to the Radio Carrier Frequency.

The Low Port Baseband Frequency Word is added as modulation to the Sigma-Delta input.

52.4.4.2.2.3.2.4.1 Low Port Resolution

The table below shows the PLL Minimum Frequency Step Sizes for Modulation and Carrier Frequency tuning. Note, the PLL Minimum Carrier Frequency Step size is equivalent to the PLL Numerator LSB resolution. This step size is measured at the PLL VCO. This table is calculated using the default numerator value of Numerator = 0x400_0000.

Note that the minimum step size for carrier frequency tuning is a divide by 256 of the modulation step sizes.

Table 479. PLL Minimum Frequency Step Size

Ref Clk Freq (MHz)	32	26
PLL Minimum Modulation Step (Hz)	244.14	198.36
PLL Minimum Carrier Frequency Step (Hz)	0.9536	0.7749

The Integer, Numerator, and Denominator are presented at the input to the Sigma-Delta Modulator.

A 3-level quantized Sigma-Delta output signal {-1, 0, +1} is generated and combined with the Integer divide value to produce the Modulus Divide Ratio for the PLL Loop Divider. The resulting RF Frequency can be calculated using the formula below:

RF Frequency = ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))

WARNING : The fraction (LPM_NUM / LPM_DENOM) must be in the range of -0.55 to +0.55 for valid Sigma Delta Modulator operation.

52.4.4.2.2.3.2.4.2 Low Port SDM Dithering

While in Transmit mode the input to the SDM is naturally dithered by the Low Port modulation, which keeps the SDM from generating a pseudo-periodic output. However, in Receive mode, the SDM can potentially generate idle tones (dominant frequency modes at its output) when the input to the SDM is a constant. And in either Transmit or Receive mode the LPM SDM can generate idle tones if the Fraction is near zero.

To mitigate these impairments, the Numerator input to the SDM is dithered whenever the Numerator is in the near zero range { -64 to 63 }, or whenever the Radio is in Receive Mode.

This dither operation can also be overridden using the LPM_D_OVRD and LPM_D_CTRL bits.

52.4.4.2.2.3.2.4.3 Low Port Delay, Disable, Invert

The Low Port Modulator has an array of programmable delays available to allow the HPM modulation to be matched to the LPM modulation and the delay through the PLL Loop Divider and onto the VCO feedback loop.

The Low Port Modulation can be delayed at the PLL Loop Divider by delaying the input to the LPM SDM (LPM_SDM_DELAY).

There is an option to invert the Numerator (LPM_SDM_INV) before it is applied to the SDM in order to invert the sigma-delta modulation to the PLL.

The Low Port Modulation of the Loop Divider can be disabled by setting the LPM_DISABLE bit. When the modulation is disabled the LPM SDM will continue to tune the VCO to the Radio Carrier Frequency.

52.4.4.2.2.3.2.4.4 Inline Phase Return

Inline Phase Return (INPR) is the ability of the hardware to send back the tone in Channel Sounding ranging on the fly, without needed of BLE ranging service.

We have the possibility to get phase information data on initiator during T_PM coming from reflector. To realize that, we adjust phase on reflector for the Transmitter to take into account phase variation for each transfer.

The IQ measured by the initiator can be directly used by the algorithm, because the phase ambiguity is removed during the process.

The correction will be done by adjusting phase with first antenna phase information received on a multiple antenna context.

Additionally, we can shut down the PA for the steps / antenna paths where the TQI measured is very low.

This method eliminates the need of transferring the IQ data over the air.

All fields used below for Inline Phase Return are contained in LPM_SDM_CTRL2 and LPM_SDM_CTRL3 registers.

The significant fields are :

- EN_INPR : 0=Disable / 1=Enable INPR feature .
- EN_INPR_RX_NORM : Enable the integration of phase shift measured from IQ received.
- INPR_DT [2:0] : Integration period (4/8/16/32 sigma-delta modulation cycles).
- INPR_CORR_INV : Possibility to invert corrected number value for INPR.
- INPR_TX_TQI_DIS : Possibility to disable TQI indicator for INPR loopback.

This feature is only available on the reflector side.

It is important to mention that when INPR is enabled, the TQI measured affects the next TX transmission that will be done by the reflector's side : If the TQI indicator measured is bad , the Reflector will cut the powering of TX and therefore prevents it from transmitting, meaning the importance of setting a good TQI thresholds (TQI_THR[T1] and TQI_THR[T2]),this condition can be disabled by Writing 1 in INPR_TX_TQI_DIS .

The mechanism offers 2 operational modes :

52.4.4.2.2.3.2.4.4.1 Normal Mode (INPR from IQ norm return)

EN_INPR = 1 & EN_INPR_RX_NORM = 1 (Can be offset with Packet Ram phase value if needed, 0 by default) .

Apply a phase shift based on the integration of : value in Packet Ram and norm measured from the received IQ .

52.4.4.2.2.3.2.4.4.2 Test Mode (INPR from Only Packet Ram)

EN_INPR = 1 & EN_INPR_RX_NORM = 0

It is possible to apply a phase shift directly and only from the Packet Ram (by programming it in fstep_ram_rdata_req[87:80], register is signed, see Section Packet Ram Data Structures). This functionality might be helpful while validating product since it gives the ability to pre-program a phase shift while ranging.

52.4.4.2.2.3.2.5 Lock Detector

The PLL Lock Detector has two methods to measure the stability of the PLL and check that it is tuned to the selected Radio Frequency.

The real-time results of the PLL Lock Detect module can be read as register bits, and flags are set and can be cleared to provide software long-term access to any PLL unlock events.

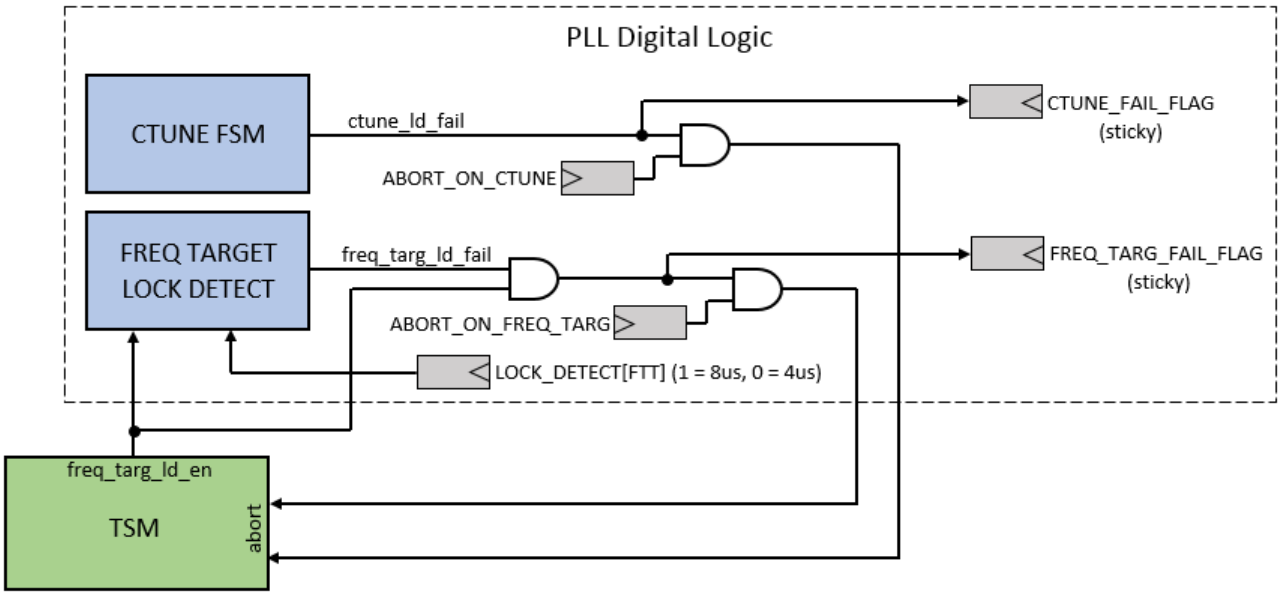

Figure 316. PLL Lock Detect Block Diagram

52.4.4.2.2.3.2.5.1 Coarse Tune Fail

During every Radio start-up sequence the PLL does a Coarse Tune Calibration to select a VCO setting that will allow the PLL to correctly tune and lock the VCO when the PLL/VCO loop is closed.

During the coarse tune calibration a count is maintained that indicates how close the coarse tune is to the targeted Radio Frequency, if this count is outside of the threshold selected by the Coarse Tune Lock Detect Fail Level register (LOCK_DETECT[CTUNE_LDF_LEV]), then the Coarse Tune Failure Flag bit (CTFF) will be set.

The CTFF bit is cleared by writing a 1 to it.

The CT_FAIL bit always shows the real time status of the latest Coarse Tune Calibration. If the absolute count difference was out of the range selected by CTUNE_LDF_LEV, then this bit will be set.

52.4.4.2.2.3.2.5.2 Fine Tune Fail

An additional lock detect method, Fine Tune Lock Detect, can be added to the end of a start-up sequence. The PLL turns on the PLL Frequency Meter for a time that is requested by the Frequency Target Window time select register bits, separately selected for RX (FTW_RX) and TX (FTW_TX).

By default, the pll frequency meter will be turned off after the standard warm-up routine (HPM CAL in TX Mode, CTUNE in RX Mode). The Fine Tune Lock Detect sequence required that the frequency meter remain on after standard warm-up. To override the default behaviour, the LOCK_DETECT[FCAL_HOLD_EN] bit must be set. This will keep the frequency meter on until the Fine Tune Lock Detect sequence has been ran. Note, to trigger the fine tune lock detect sequence, the TSM will also need to be programmed to insert a lock detect at the end of warm-up.

These bits select either a 4us or an 8us count period and if the frequency counter is outside of the threshold selected by the Frequency Target Fail Threshold registers, FTF_RX_THRSH and FTF_TX_THRSH, then the Frequency Target Fail Flag bit (FTFF) will be set.

The FTFF bit is cleared by writing a 1 to it

The FT_FAIL bit always shows the real time status of the latest Fine Tune Frequency Measurement. If the absolute count difference was out of the range selected by Frequency Target Fail Threshold registers, then this bit will be set.

52.4.4.2.2.3.3 Initialization

To enable the digital PLL block, no specific procedure is needed for the clocks or reset. The registers must be programmed in the correct mode, as described in the chapter Functional description.

52.4.4.2.2.3.4 Application information

The procedures to use this module are described in the sub_chapters and register definition.

52.4.4.2.2.3.5 Memory Map and Register Definition

The PLL Digital memory map and detailed descriptions of all its registers are as follows.

30-28 CTUNE_TGT_OFFSET	Coarse Tune Target Frequency Offset In RX Mode, the PLL Coarse Tune Target Frequency will be subtracted from the CTUNE_TGT_OFFSET to form the final CTUNE Target Frequency. Note, if this register field is left as zero, then it will have no effect. A value should only written here if the NUM_OFFSET is large enough to require a CTUNE modification. This value should be written as a 3-bit two's compliment number. Register bit 30 is the CTUNE_TGT_OFFSET sign bit. The unit for CTUNE_TGT_OFFSET is MHz. This register can provide a maximum offset of +3 MHz or -4 MHz from the internally calculated CTUNE Target.
27-0 NUM_OFFSET	Numerator Offset The NUM_OFFSET register field represents the IF frequency difference between RX and TX. To achieve this offset, the NUM_OFFSET value will be subtracted from the internally derived PLL Numerator value. Note that the numerator LSB will change the PLL target frequency according to the table in section Low Port Modulation . This value represents a multiple of the pll minimum frequency step size. In RX Mode, this register holds a signed two's compliment offset which will be subtracted from the PLL Numerator value calculated using the PLL internal channel mapping logic. Warm-up in RX mode will automatically subtract this value from the PLL Numerator. If NUM_OFFSET == 0 then no frequency offset will exist between Tx to Rx. Bit 27 of this register provides the sign bit for RX_NUM_OFSET. The largest positive number supported is 0x3FF_FFFF. The largest negative number supported is 0xC00_0000. Note, manual override mode won't use this register field.

52.4.4.2.2.3.5.1.6 PLL Lock Detect Control (LOCK_DETECT)

Fields

Field	Function
31-30 FREQ_COUNT_TIME	Frequency Meter Count Time This is the length of time that the Frequency Meter will count VCO clocks. 00b - 800 us 01b - 25 us 10b - 50 us 11b - 100 us
29 FREQ_COUNT_FINISHED	Frequency Meter has finished the Count Time This bit is set when the FREQ_COUNT_TIME value is reached, it is cleared when FREQ_COUNT_GO is cleared.
28 FREQ_COUNT_GO	Start the Frequency Meter The Frequency Meter starts when this bit is set and runs until the FREQ_COUNT_TIME value is reached. The bit should not be cleared until after the counting is finished. After the Counting Time finishes, the FREQ_COUNT_FINISHED bit will read as a one. Then the measured frequency can be calculated by reading the frequency counts in the DFT_FREQ_COUNTER register (PLL_DFT_OCR_1[DFT_FREQ_COUNTER]) and dividing by the FREQ_COUNT_TIME. Note that the counting is done at the VCO frequency which is 2X the Carrier Frequency
27-25 FTW_TXRX	TX and RX Frequency Target Window time select In Radio Receive Mode, register field is decoded to select the length of time to count for the estimation of PLL lock frequency, which is compared with the Frequency Target Window, we refer to this decoding as FTW_RX. In Radio Transmit Mode, register field is decoded to select the length of time to count for the estimation of PLL lock frequency, which is compared with the Frequency Target Window, we refer to this decoding as FTW_TX.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - FTW_TX = 4us ; FTW_RX = 4us 001b - FTW_TX = 4us ; FTW_RX = 8us 010b - FTW_TX = 8us ; FTW_RX = 4us 011b - FTW_TX = 8us ; FTW_RX = 8us 100b - FTW_TX = 16us ; FTW_RX = 16us 101b - FTW_TX = 16us ; FTW_RX = 32us 110b - FTW_TX = 32us ; FTW_RX = 16us 111b - FTW_TX = 32us ; FTW_RX = 32us
24 FCAL_HOLD_EN	Frequency Counter Hold Enable This bit controls if the pll ripple counter stays on after the PLL warm-up sequence (TX or RX). By default (FCAL_HOLD_EN==0b0), the ripple counter will be turned off after completing CTUNE in RX mode and HPM CAL in TX mode. If the ripple counter is turned off after the standard warm-up sequence, then a lock detect sequence cannot be inserted during warm-up. To support this lock detect sequence, FCAL_HOLD_EN can be asserted to ensure the PLL ripple counter is maintained in an on state after the default CTUNE or HPM CAL state. In addition, the TSM should be programmed to run the lock detect sequence at the appropriate time during warmup. 0b - The frequency counter is turned off after CTUNE (RX Mode) or HPM CAL (TX Mode) 1b - The frequency counter is held on after CTUNE (RX Mode) or HPM CAL (TX Mode) for an optional lock detect sequence.
23-18 FTF_TX_THRSH	TX Frequency Target Fail Threshold In Radio Transmit Mode, the FT_FAIL and FTFF bits will be set after the Frequency Target Count completes if the absolute value of the count difference from the frequency target count is greater than this register value.
17-12 FTF_RX_THRSH	RX Frequency Target Fail Threshold In Radio Receive Mode, the FT_FAIL and FTFF bits will be set after the Frequency Target Count completes if the absolute value of the count difference from the frequency target count is greater than this register value.
11-8 CTUNE_LDF_LEV	CTUNE Lock Detect Fail Level The CT_FAIL and CTFF bits will be set after Coarse Tune Calibration completes if the absolute value of the Coarse Tune best count difference (CTUNE_BEST_DIFF in the PLL_CTUNE_RESULTS register) is greater than this register value.
7-6 —	Reserved
5 FTFF	Frequency Target Failure Flag This bit is set when FT_FAIL is first set, and this bit is cleared by writing a 1 to it.
4	Real time status of Frequency Target Failure

Table continues on the next page...

Table continued from the previous page...

Field	Function
FT_FAIL	If the Frequency Target Count has completed and the count was out of the range selected by FTW_TX or FTW_RX, then this bit will be set.
3-2 —	Reserved
1 CTFF	CTUNE Failure Flag, held until cleared This bit is set when CT_FAIL is first set, and this bit is cleared by writing a 1 to it.
0 CT_FAIL	Real time status of Coarse Tune Fail signal If the Coarse Tune Calibration has completed and the best count difference is out of the range selected by CTUNE_LDF_LEV, then this bit will be set.

52.4.4.2.2.3.5.1.7 PLL High Port Modulator Control (HPM_CTRL)

Fields

Field	Function
31 HPM_MOD_IN_INVERT	Invert High Port Modulation If this bit is set then the High Port Modulation Word is inverted before it is multiplied and split into Integer and Fractional values.
30-29	High Port Modulation Calibration Time

Table continues on the next page...

Table continued from the previous page...

Field	Function
HPM_CAL_TIME	This bit selects the length of time to count during HPM Calibration and is used by the math implemented in the HPM Calibration Factor lookup table. 00b - 25 us 01b - 50 us 10b - 100 us 11b - N/A
28 HPM_CAL_INVERT	Invert High Port Modulator Calibration If this bit is set then the order of the High Port Calibration is reversed in order to get a positive count difference between the Maximum and Minimum settings of the HPM DAC.
27 HPM_INTEGER_INVERT	Invert High Port Modulation Integer If this bit is set then the High Port Modulation Integer value, after the multiply and split into Integer and Fractional values, will be inverted before it is applied to the VCO High Port DAC Array.
26-24 HPM_SCALE	High Port Modulation Scale This register controls the scaling of the High Port Modulation word. 000b - No Scaling 001b - Divide by 2 010b - Multiply by 2 011b - Multiply by 4 100b - Divide by 4 101b - Multiply by 8 110b - Divide by 8 111b - N/A
23 HPM_DTH_EN	Dither Enable for HPM LFSR If this bit is set, the High Port Fraction will be Dithered by the High Port LFSR before it is applied to the High Port SDM.
22 HPM_DYNAMIC_RX_TONE_TABLE	If HPM_DYNAMIC_SEL is set to 1, RX tone will be applied following HPM calibration factor: 0b - constant value from HPM_CAL_FACTOR_MANUAL register 1b - table value from packet RAM
21 HPM_DYNAMIC_RX_PKT_TABLE	If HPM_DYNAMIC_SEL is set to 1, RX packet will be applied following HPM calibration factor: 0b - constant value from HPM_CAL_FACTOR_MANUAL register 1b - table value from packet RAM
20	HPM Dither Scale

Table continues on the next page...

Table continued from the previous page...

Field	Function
HPM_DTH_SCL	If this bit is set, the LFSR dithering of the High Port Fraction will be multiplied by 2.
19 RX_HPM_CAL_EN	Receive HPM Calibration Enable If this bit is set, HPM Calibration takes place in receive mode.
18-16 HPM_LFSR_SIZE	HPM LFSR Length This register selects the length of the HPM LFSR and the associated LFSR Tap Mask 000b - LFSR 9, tap mask 100010000 001b - LFSR 10, tap mask 1001000000 010b - LFSR 11, tap mask 11101000000 011b - LFSR 13, tap mask 1101100000000 100b - LFSR 15, tap mask 111010000000000 101b - LFSR 17, tap mask 11110000000000000 110b - Reserved 111b - Reserved
15 HPM_SDM_IN_DISABLE	Disable HPM SDM Input If this bit is set, the Fractional portion of the High Port Modulation to the High Port SDM is disabled, and the High Port SDM input comes from the HPM_SDM_IN_MANUAL register.
14 HPM_SDM_OUT_INVERT	Invert HPM SDM Output If this bit is set the High Port SDM result will be Inverted before it is applied to the VCO High Port DAC Array.
13 HPFF	HPM SDM Invalid Flag This bit is set if the High Port Sigma Delta Modulator output is invalid due to an error in the fraction applied, and this bit is cleared by writing a 1 to it.
12 HPM_CLK_CONFIG	HPM Clock Config When this bit is set, the HPM modulation path including the HPM_SDM operate at the CLK_SDM clock (which is the 2x reference clock derived from PLL loop divider). By default they operate at the reference clock.
11 —	Reserved
10 HPM_DYNAMIC_SEL	HPM dynamic calibration factor source selection for channel sounding If set to 1, HPM calibration factor will be automatically applied as following during channel sounding: - for TX mode, factor will be from a table (packet RAM)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	- for packet RX mode, factor will be either from a table (packet RAM) or constant (HPM_CAL_FACTOR_MANUAL) according to HPM_DYNAMIC_RX_PKT_TABLE bit - for tone RX mode, factor will be either from a table (packet RAM) or constant (HPM_CAL_FACTOR_MANUAL) according to HPM_DYNAMIC_RX_TONE_TABLE bit
9-0 HPM_SDM_IN_MANUAL	Manual High Port SDM Fractional value If HPM_SDM_IN_DISABLE is set, this register is the value that is applied as the Fractional value to the input of the High Port SDM.

Fields

Field	Function
31 LPM_SDM_USE_NEG	Use the Negedge of the Sigma Delta clock If this bit is set then the negative edge of the Sigma Delta clock is used to launch the Low Port Modulation word to the VCO Loop Divider.
30	LPM SDM Skip Counter Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
LPM_SKIP_CNT_DELAY	This bit gives possibility to bypass 3 flops delay between sigma_delta output and codes output digital, could be use to speed up transition between 2 domains for SDM codes
29 LPM_CODES_ADJ	LPM SDM Codes Adjustment This bit enable the SDM code adjustment at the clock switching transition between ref_clk and sdm_clk (adjust with FCODES_VAL and LPM_FCODES_CNT fields of LPM_SDM_CTRL1) SDM codes corrections are applied when this field set to 1 or when register lpm_fast_sw=1.
28 LPM_FAST_SW	LPM Fast Switch mode If set to 1, this will send sdm codes just after pll loop is closed and use sigma_delta clock from analog as the sdm codes generator . This will speed up transition after loop is closed. This will also force some codes at the beginning of closed loop (FCODES_VAL and LPM_FCODES_CNT fields of LPM_SDM_CTRL1)
27-24 LPM_SCALE	LPM Scale Factor This register controls the scaling of the Baseband Frequency Word and is used to match the Modulation Frequency Deviation required to the Low Port Sigma Delta Modulator LSB size in Hz. 0000b - No Scaling 0001b - Multiply by 2 0010b - Multiply by 4 0011b - Multiply by 8 0100b - Multiply by 16 0101b - Multiply by 32 0110b - Multiply by 64 0111b - Multiply by 128 1000b - Multiply by 256
23 LPM_D_OVRD	LPM Dither Override Mode Select When this bit is set, the Scaled Baseband Frequency Word applied to the Low Port Sigma Delta Modulator will be dithered if LPM_D_CTRL is set, and not dithered if LPM_D_CTRL is cleared. If this bit is cleared, then the LPM Numerator will be dithered in Radio Receive mode, and also in Radio Transmit mode when the LPM Numerator approaches an Integer value in order to preserve the validity of the Sigma Delta Modulator output.
22 LPM_D_CTRL	LPM Dither Control in Override Mode If LPM_D_OVRD is set, this bit turns LPM Dithering on and off.
21-20 —	Reserved
19-16 LPM_DTH_SCL	LPM Dither Scale

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This register controls the scale of the Dithering added to the Scaled Baseband Frequency Word before it is applied to the Low Port Sigma Delta Modulator as the LPM Numerator. The unit for the ranges shown below is the LP SDM LSB in Hz. 0000b - Reserved 0001b - Reserved 0010b - Reserved 0011b - Reserved 0100b - Reserved 0101b - -128 to 96 0110b - -256 to 192 0111b - -512 to 384 1000b - -1024 to 768 1001b - -2048 to 1536 1010b - -4096 to 3072 1011b - -8192 to 6144 1100b - Reserved 1101b - Reserved 1110b - Reserved 1111b - Reserved
15 LPM_DISABLE	Disable LPM SDM This bit controls the Modulation of the Low Port Sigma Delta. If this bit is set, the Low Port Sigma Delta Modulator will be active and control the PLL to maintain a steady frequency based on the current Integer, Numerator, and Denominator values that are being applied. No Modulation or Dithering will be added to the steady frequency result.
14 LPM_SDM_INV	Invert LPM SDM If this bit is set the Scaled Baseband Frequency Word, including any Dithering, will be Inverted before it is applied to the Low Port Sigma Delta Modulator.
13 LPFF	LPM SDM Invalid Flag This bit is set if the Low Port Sigma Delta Modulator output is invalid due to an error in the fraction applied, and this bit is cleared by writing a 1 to it.
12 PLL_LD_DISABLE	Disable PLL Loop Divider If this bit is set, the Low Port Sigma Delta Modulator output is disabled, and the PLL Loop Divider value applied to the PLL comes from the PLL_LD_MANUAL register.
11-8	High Port Calibration Word Scaling

Table continues on the next page...

Table continued from the previous page...

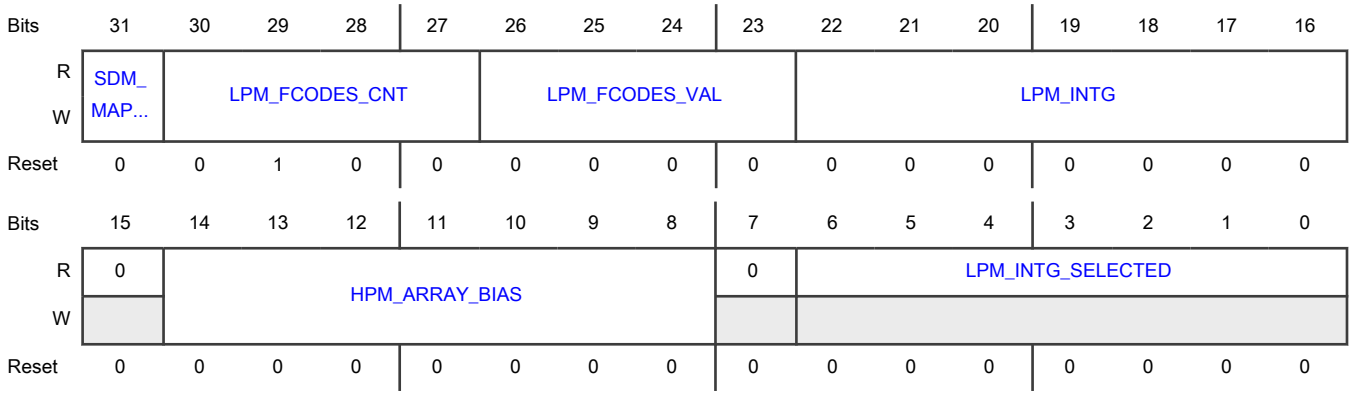
Field	Function
HPM_CAL_SCALE	The calibration factor LPM_LSB/HPM_LSB will be scaled using the following bitfield settings. This bit field should be adjusted in conjunction with LPM_SCALE according to the modulation range. The default setting is no scaling factor applied. 0000b-0010b - No Scaling 0011b - Divide by 32 0100b - Divide by 16 0101b - Divide by 8 0110b - Divide by 4 0111b - Divide by 2 1000b - No Scaling 1001b - Multiply by 2 1010b - Multiply by 4 1011b - Multiply by 8 1011b-1111b - No Scaling
7-5 —	Reserved
4-0 PLL_LD_MANUAL	Manual PLL Loop Divider value If PLL_LD_DISABLE is set, this register is the value that is applied to the PLL Loop Divider.

52.4.4.2.2.3.5.1.10 PLL Low Port Sigma Delta Control 1 (LPM_SDM_CTRL1)

Offset

Register	Offset
LPM_SDM_CTRL1	34h

Diagram



Fields

Field	Function
31 SDM_MAP_DISABLE	Disable SDM Mapping If this bit is set, the Low Port Sigma Delta Modulator internal frequency mapping based on Protocol specific channel numbers is disabled, and the Radio Channel Frequency is selected by setting the LPM_INTG, LPM_NUM, and LPM_DENOM registers to get a frequency that equals : ((Reference Clock Frequency x 2) x (LPM_INTG + (LPM_NUM / LPM_DENOM))
30-27 LPM_FCODES_CNT	LPM SDM Forced Counter When feature LPM_FAST_SW or LPM_CODES_ADJ are activated, we can force the sigma delta output with LPM_FCODES_VAL during this period value. This is in number of clock_switcher_period.
26-23 LPM_FCODES_VAL	LPM SDM Forced Value When feature LPM_FAST_SW or LPM_CODES_ADJ are activated, we can force the sigma delta output with this value. There is an offset of 32, so value 0 represents a code SDM of 32.
22-16 LPM_INTG	Manual Low Port Modulation Integer Value If SDM_MAP_DISABLE is set, this register is the value that is applied to the Low Port Sigma Delta Modulator for the Integer, the nominal range is 36 to 39 in decimal.
15 —	Reserved
14-8 HPM_ARRAY_BIAS	Bias value for High Port DAC Array Midpoint The value of this register represents a signed six bit value that can be used to adjust the midpoint of the High Port Modulator DAC. The range of adjustment is -64 to +63, and the adjustment is made to the High Port Modulation Word before the multiply, and before the split into Integer and Fractional values. The range of adjustment in Hz is approximately +/- 62.5 kHz
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
6-0 LPM_INTG_SELECTED	Low Port Modulation Integer Value Selected This shows the Integer value that is currently being applied to the Low Port Sigma Delta Modulator.

52.4.4.2.2.3.5.1.18 Max and Min Transmit Frequencies For TX Configuration 1 (MAX_MIN_TX_CFG1_FREQ)

Offset

Register	Offset
MAX_MIN_TX_CFG1_FREQ	58h

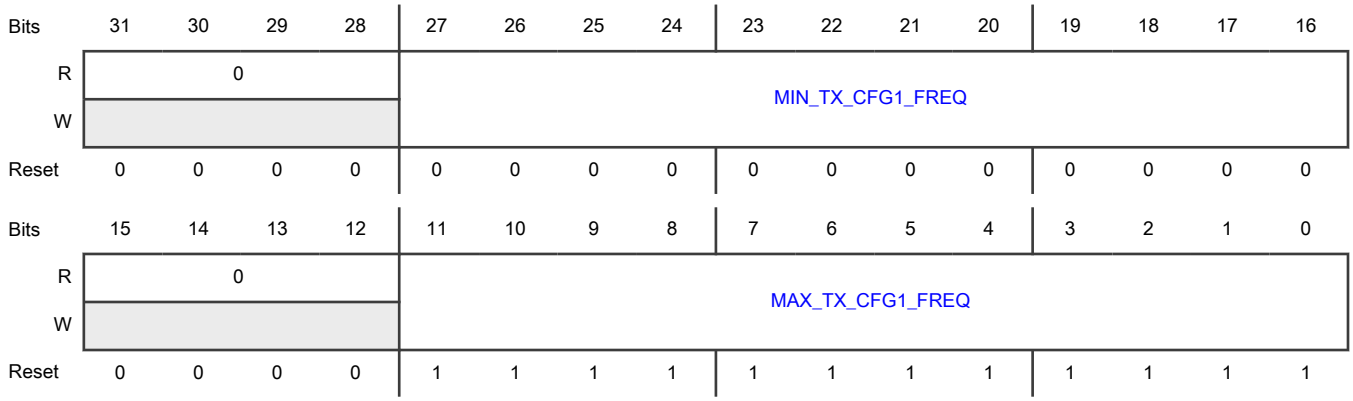
Function

Due to regulatory compliance requirements, more than one set of TX configuration settings may be required to meet out-of-band spectral emission requirements for TX frequencies near either the upper or lower limit of a frequency band. The PLL has a built in capability to detect when the TX carrier frequency is below or above a carrier frequency in MHz.

The MAX_TX_CFG1_FREQ register field should be programmed with a frequency threshold to detect when an alternate TX configuration must be utilized. When the PLL center frequency is selected to be greater than this threshold, a signal will be sent to the TX Digital logic indicating the need to use an alternate configuration. Note, to disable this feature, program the MAX_TX_CFG1_FREQ to 12'hFFF. This will ensure the alternative TX configuration is not selected.

The MIN_TX_CFG1_FREQ register field should be programmed with a frequency threshold to detect when an alternate TX configuration must be utilized. When the PLL center frequency is selected to be lower than this threshold, a signal will be sent to the TX Digital logic indicating the need to use an alternate configuration. Note, to disable this feature, program the MIN_TX_CFG1_FREQ to 12'h000. This will ensure the alternative TX configuration is not selected.

Diagram



Fields

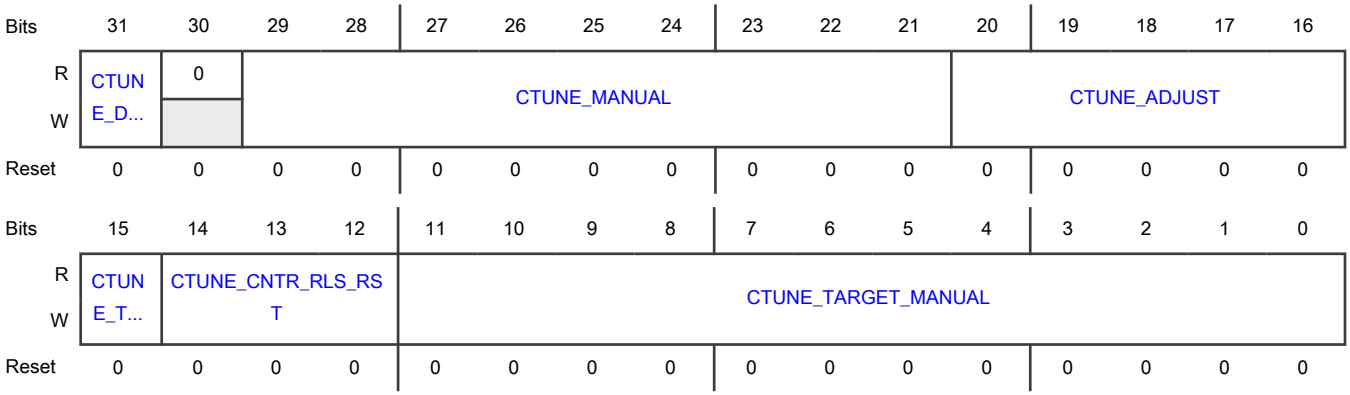
Field	Function
31-28 —	Reserved
27-16 MIN_TX_CFG1_FREQ	Minimum Transmit Frequency for Standard TX Settings This register should be programmed with the frequency threshold (MHz) to be used by PLL Digital to determine when to switch to alternate TX settings. If the PLL center frequency is lower than this programmed value, the TX digital will select an alternate configuration for modulation.
15-12 —	Reserved
11-0 MAX_TX_CFG1_FREQ	Maximum Transmit Frequency for Standard TX Settings This register should be programmed with the frequency threshold (MHz) to be used by PLL Digital to determine when to switch to alternate TX settings. If the PLL center frequency is greater than this programmed value, the TX digital will select an alternate configuration for modulation.

52.4.4.2.2.3.5.1.19 PLL Coarse Tune Control (CTUNE_CTRL)

Offset

Register	Offset
CTUNE_CTRL	5Ch

Diagram



Fields

Field	Function
31 CTUNE_DISABLE	Coarse Tune Disable If this bit is set, the Coarse Tune Setting applied to the VCO comes from the CTUNE_MANUAL register.
30 —	Reserved
29-21 CTUNE_MANUAL	Manual Coarse Tune Setting If CTUNE_DISABLE is set, this register is the value that is applied to the VCO as the Coarse Tune Setting.
20-16 CTUNE_ADJUST	Coarse Tune Count Adjustment This register is a signed four bit value that adjusts the PLL Frequency Meter count used in the Coarse Tune Calibration. The range of adjustment is -16 to +15, and the adjustment is only made to the PLL Frequency count used by the Coarse Tune Calibration sequence.
15 CTUNE_TARGET_DISABLE	Disable Coarse Tune Target If this bit is set, the Frequency Target presented to the Coarse Tune Calibrator comes from the CTUNE_TARGET_MANUAL register.
14-12 CTUNE_CNTR_RLS_RST	Coarse Tune Counter Release Reset This field adds up to 7 ref_clk cycles to ctune_counter_release_rst.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The programmed number of cycles is 2 + CTUNE_CNTR_RLS_RST, thus the maximum programmed value could be 9. Field should be limited to 6 (32MHz ref_clk) and 3 (26MHz ref_clk) to fit PLL state machine timings.
11-0 CTUNE_TARGET_MANUAL	Manual Coarse Tune Target If CTUNE_TARGET_DISABLE or LPM_SDM_CTRL1[SDM_MAP_DISABLE] is set, this register is the value that is presented to the Coarse Tune Calibrator as the Frequency Target in MHz.

52.4.4.2.2.3.5.1.20 PLL Data Rate Override Control (DATA_RATE_OVRD_CTRL1)

Offset

Register	Offset
DATA_RATE_OVRD_CTRL1	60h

Function

The Bluetooth Low Energy LL defines test cases with asymmetric data rates in multiple connection modes. The PLL configuration must be switched by hardware when a new configuration is requested. The DATA_RATE_SWITCH register is intended to provide an override for various control registers in the PLL. The following register fields will be overridden when the Bluetooth Low Energy LL requests the updated data rate:

PLL_LPM_CTRL[LPM_SCALE]

PLL_LPM_CTRL[HPM_CAL_SCALE]

HPM_BUMP[HPM_FDB_RES_CAL]

HPM_BUMP[HPM_FDB_RES_TX]

Note that the alternate datarate can also be requested by the GENFSK, the RSM (for Channel Sounding) and by software, via the RF_CTRL[RIF_SEL_2MBPS_OVRD] register.

52.4.4.2.2.4 Transceiver Sequence Manager (TSM)

52.4.4.2.2.4.1 Introduction

52.4.4.2.2.4.1.1 Overview

The Transceiver Sequence Manager controls the warmup and warmdown processes for all radio sequences. The TSM provides for a TX sequence, and an RX sequence. For both TX and RX, a warmup and a warmdown sequence is supported. The length of each sequence is programmable, from 1 – 254us. The resolution of the TSM is 1us. Controls for all analog and digital transceiver blocks are provided. Each TSM output enables, or otherwise provides control for, a transceiver-related block. Each TSM output has 4 8-bit registers, with which to control the point at which the output asserts during the warmup (1 register for TX, 1 for RX), and the point at which it deasserts (1 register for TX, 1 for RX). Some TSM outputs, which are known in advance to require identical timing, are “ganged together”, to reduce area and required programming. For DFT, and non-mission-mode validation, each TSM output can be placed under direct software control, using register overrides. Any sequence can be temporarily halted, by setting an optional, programmable breakpoint.

52.4.4.2.2.4.1.2 Features

The TSM includes the following features:

- TX warmup and warmdown sequence and RX warmup and warmdown sequence for every controllable output.
- Programmable sequence length from 1 to 254 microseconds for each sequence in 1 microsecond increments.
- Multi-protocol

- Ability to place TSM outputs under software control for test and non-mission mode validation.
- Ability to signal link layers upon PLL unlock or RF_NOT_ALLOWED conditions.
- Fast Warmup Capability for TX and RX
- LPPS Support
- Programmable breakpoint capability to halt any sequence temporarily.

52.4.4.2.2.4.2 Functional Description

52.4.4.2.2.4.2.1 Sequence Counter

The TSM supports 1 TX and 1 RX sequence. Each sequence consists of 3 phases:

1. WARMUP phase
2. ON phase
3. WARMDOWN phase

The central element of the TSM is an 8-bit counter. The counter is held at 0 during the idle state. From idle state, any sequence can be launched, by an initiating event. (See Section “Sequence Initiation”). At an initiating event, the TSM counter counts up from 0 to a programmed stop point during the WARMUP phase, determined by the END_OF_TX_WU or END_OF_RX_WU register, depending on whether the sequence is TX or RX. At the end-of-warmup “stop point”, the TSM counter holds its count, and the TSM sequence enters the ON phase. The TSM counter will remain in the ON phase, and hold its count, until the initiating event deasserts (See Sequence Termination). When either of these conditions occurs during the ON phase, the TSM will resume counting from the point it was holding during the ON phase, and the sequence will enter the WARMDOWN phase. The counter will continue counting until a programmed stop point is reached. This stop point is determined by the END_OF_TX_WD or END_OF_RX_WD register, depending on whether the sequence is TX or RX. Once this point is reached, the sequence returns to idle, and the TSM counter returns to 0.

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

All TSM-controlled outputs are active-high. Any TSM-controlled output can be asserted once during a sequence (either TX or RX sequence), and then deasserted once. Or, the output can be held in a deasserted state for the duration of the sequence. The precise timing for the assertion and deassertion of each TSM-controlled output, for both TX and RX sequences, is determined by 4 8-bit registers assigned to that output (see TSM-Controlled Outputs). The TSM resolution is 1us. This is the update rate for the TSM counter, and sets the granularity with which warmup and warmdown processes can be controlled.

52.4.4.2.2.4.2.2 TSM-Controlled Outputs

The TSM-controlled outputs are shown in the table below. In general, each output signal is assigned a unique TSM_TIMING register to control its timing, but in cases where output signals will always be asserted and deasserted at the same time, the signals can share a TSM_TIMING register (e.g., seq_ldo_gang_pup).

Output Signal Name	TSM_TIMING #	TSM_TIMING Name

1. This signal is inverted with respect to the timing signal
2. This is the pup for the RX peak detector

During the WARMUP and WARMDOWN phases of any sequence, any TSM-controlled output can be programmed to assert once and then deassert once, by programming the timing registers associated with the output. Each output has 4 8-bit timing registers associated with it. The name of the register matches the name of the output:

*OUTPUTNAME*_TX_HI[7:0]

*OUTPUTNAME*_TX_LO[7:0]

*OUTPUTNAME*_RX_HI[7:0]

*OUTPUTNAME*_RX_LO[7:0]

In the case of grouped outputs, the timing registers associated with the signal controlling the group, control timing for the entire group.

During the WARMUP phase of a TX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_TX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the TX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_TX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_TX_HI[7:0], is greater than the length of the TX sequence (set by register END_OF_TX_WD[7:0]), then that signal will never transition high during the TX sequence. A convenient way of ensuring a signal does not assert during a TX sequence, is to set its *OUTPUTNAME*_TX_HI[7:0]=255.

During the WARMUP phase of a RX sequence, as the 8-bit TSM counter increments, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_HI[7:0], but is less than the programmed value of *OUTPUTNAME*_RX_LO[7:0], the corresponding TSM output will transition high. During the WARMUP or WARMDOWN phase of the RX sequence, once the TSM counter equals or exceeds the programmed value of *OUTPUTNAME*_RX_LO[7:0], the TSM output will transition low. If the programmed value of *OUTPUTNAME*_RX_HI[7:0], is greater than the length of the RX sequence (set by register END_OF_RX_WD[7:0]), then that signal will never transition high during the RX sequence. A convenient way of assuring a signal does not assert during a RX sequence, is to set its *OUTPUTNAME*_RX_HI[7:0]=255.

The following diagram depicts the TSM counter, and the control logic used to assert and deassert the TSM-controlled outputs. For clarity, logic for only 2 of the outputs (pll_dig_en, sigma_delta_en) are shown.

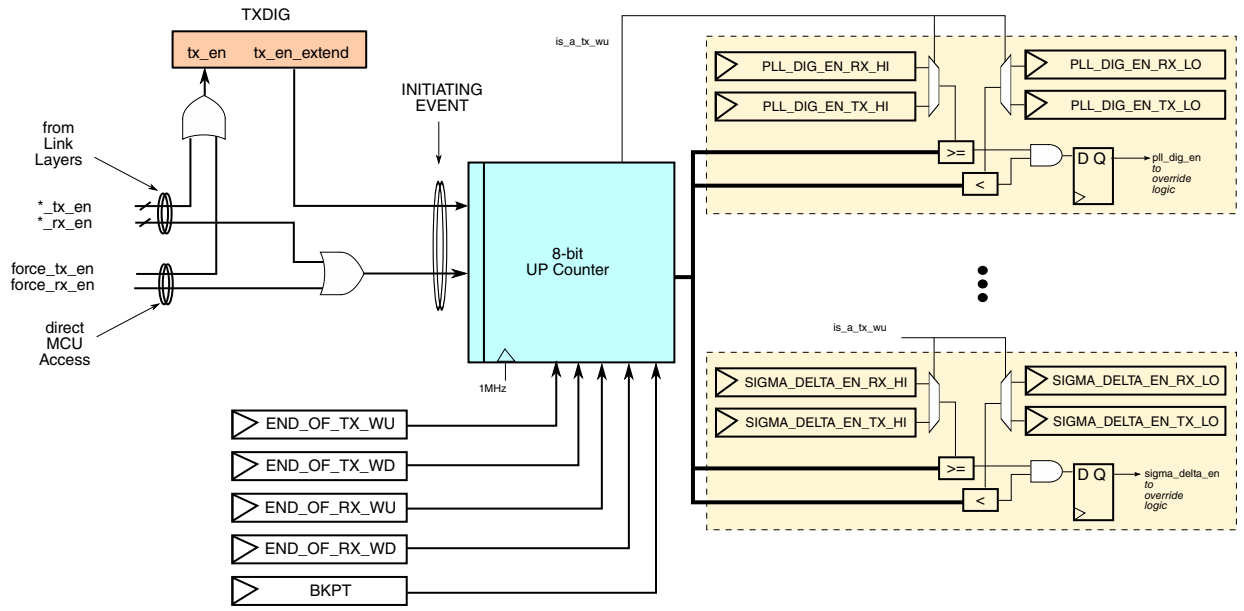

Figure 317. TSM BLOCK DIAGRAM

52.4.4.2.2.4.2.3 Timing Registers

There are a set of timing registers for each TSM-controlled output (or, for the signal controlling the group for the “grouped” outputs). Each register set consists of 4 bitfields: one to control the assertion time of the output for TX sequences, one to control the assertion time for RX sequence, one to control the deassertion time for TX sequences, and one to control the deassertion time for RX sequences. For TSM-controlled outputs that are grouped, one set of timing registers controls the timing for all members of the group. For each of these sets, the following table lists the SoC register name, and 4 timing register names associated with each.

SOC REGISTER NAME	BITS [31:24]	BITS [23:16]	BITS [15:8]	BITS [7:0]
TIMINGxx	RX_LO[7:0]	RX_HI[7:0]	TX_LO[7:0]	TX_HI[7:0]

Some of the TSM outputs have relevance for TX sequences only. For those, timing registers are only provided for TX assertion and deassertion times. The RX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during RX sequences.

Some of the TSM outputs have relevance for RX sequences only. For those, timing registers are only provided for RX assertion and deassertion times. The TX timings for such outputs are essentially hardwired to 255, meaning there will be no signal assertion during TX sequences.

52.4.4.2.2.4.2.4 Sequence Initiation

The SoC will include one or more protocol engines. Any of the protocol engines, can launch a TSM sequence. Each protocol engine will have an initiating signal for a TX sequence, and another for an RX sequence.

For direct software control, the MCU/Host can initiate a TX sequence warmup directly, by setting the FORCE_TX_EN bit, and later initiate a TX sequence warmdown by clearing the bit. The MCU/Host can initiate a RX sequence warmup directly, by setting the FORCE_RX_EN bit, and later initiate a RX sequence warmdown by clearing the bit. These bits reside in the TSM_CTRL register.

From idle state, the asserting of any initiating event (*source*_tx_en or *source*_rx_en), will begin the TSM WARMUP phase and begin incrementing the TSM counter from 0. The initiating source needs to hold the initiating signal asserted (high) through the

course of the WARMUP, and then for the duration of the desired ON phase. Deasserting the initiating signal transitions the TSM to the WARMDOWN phase (see Section “Sequence Termination”).

Needless to say, from idle state, a TX-initiating event (assertion of any TSM *source*_tx_en input) will launch a TX sequence. The TSM output **tx_mode** will go high to indicate a TX sequence is underway. Also, from idle state, an RX-initiating event (assertion of any TSM *source*_rx_en input) will launch an RX sequence. The TSM output **rx_mode** will go high to indicate a RX sequence is underway.

Only 1 initiating source can be allowed to assert at any given time. Under no circumstances should a TX and RX initiating source be asserted simultaneously.

Once a TSM sequence has been launched, the WARMUP phase is entered and TSM counter incrementing will commence. Up-counting will continue until one of the following conditions is met:

1. Deassertion of the initiating event. TSM will transition to WARMDOWN phase
2. tsm_count=END_OF_*SEQ*_WU, where *SEQ*=TX or RX. TSM will transition to ON phase
3. Breakpoint. TSM stay in its current phase and hold its count

A transition from WARMUP to ON phase means TSM will hold its count at END_OF_*SEQ*_WU, where *SEQ*=TX or RX.

A transition from ON to WARMDOWN phase means TSM will cease its hold, and resume counting at END_OF_*SEQ*_WU+1, where *SEQ* = TX or RX. (see Section “Sequence Termination”).

A transition from WARMUP to WARMDOWN phase means the tsm_count will jump to END_OF_*SEQ*_WU+1 (where *SEQ* = TX or RX), and resume counting from there. (see Section “Sequence Termination”).

The 4 8-bit registers which control the duration of the WARMUP phase (END_OF_TX_WU[7:0] and END_OF_RX_WU[7:0]), and the duration of the WARMDOWN phase (END_OF_TX_WD[7:0] and END_OF_RX_WD[7:0]), reside in the END_OF_SEQ register.

52.4.4.2.2.4.2.5 Sequence Termination

A sequence may be terminated during the WARMUP on ON phase by deassertion of the initiating event (*source*_tx_en or *source*_rx_en). This will cause a transition to WARMDOWN phase, at which point the TSM counter will resume counting from END_OF_*SEQ*_WU+1 (where *SEQ*=TX or RX).

NOTE

For TX, deassertion of the initiating tx_en event does not cause an immediate transition to TSM WARMDOWN phase. The tx_en deassertion is first recognized by the TXDIG to ramp-down the PA. After the TXDIG completes the PA ramp-down, its tx_en_extend output to the TSM will de-assert causing the TSM to transition to WARMDOWN. See more on PA ramp timing in the next section.

52.4.4.2.2.4.2.6 PA Ramp Timing

In previous generation of radios, the PA ramp was controlled in the TSM. The PA ramp-up was started near the end of the TSM TX warmup sequence and completed before the end of the TSM TX warmup sequence. The PA ramp-down started at beginning of the TSM TX warmdown sequence and completed before the end of the TSM TX warmdown sequence. In addition to the PA ramp timing, the TSM also output the PA ramp values from a programmable look-up table.

For the current generation of radio, the PA ramp will be controlled in the TXDIG instead of the TSM. The operation is described as follows.

When a Link Layer asserts *source*_tx_en (or software sets the FORCE_TX_EN bit) to start a TX burst, the TSM TX warmup sequence will begin. Near the end of the TSM TX warmup sequence, a TSM timing signal (tx_dig_en) will signal to the TXDIG to ramp-up the PA and start sending TX data. The TXDIG will also control the PA power-up signal (seq_tx_pa_pup in figure below) to the analog to turn on the PA. After the TXDIG completes the PA ramp-up, it outputs pa_wu_complete to the TSM, and the TSM in turn creates 1us-width pulses tsm_wu_almost_complete and tsm_wu_complete. Note that the TSM count may or may not have reached end_of_tx_wu by the time the TXDIG finishes ramping up the PA; in the example below, the PA ramp-up does not complete until after TSM count has reached end_of_tx_wu. Note also that the figure shows the link layer (or force tx_en signal)

is a direct input to the TXDIG, and the TXDIG outputs a tx_en_extend (which asserts at the same time as tx_en) to the TSM; the TXDIG takes no action on assertion of tx_en but the de-assertion is used in ramp-down as described in the next paragraph.

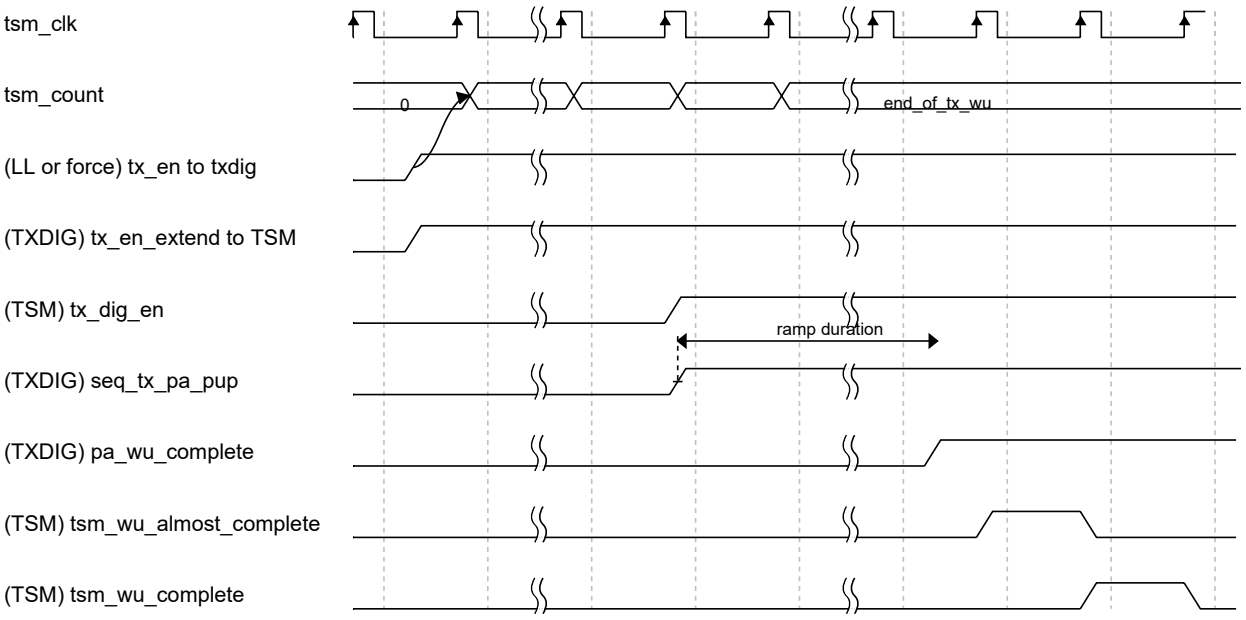

Figure 318. PA Ramp-Up Timing

When the Link Layer deasserts *source*_tx_en (or software clears the FORCE_TX_EN bit) to end a TX burst, the TXDIG will begin to ramp-down the PA. The TSM will not begin its warmdown until after the TXDIG has completed ramp-down of the PA. The TXDIG will provide an output signal (tx_en_extend) to the TSM which asserts at the same time as *source*_tx_en but does not de-assert until after the PA ramp-down has completed by the TXDIG. At that time, the TSM will complete its TX warm-down sequence (deasserting tx_dig_en, and turning off the PLL and other circuits in the analog, etc.) . Since the PA ramp-down is handled in the TXDIG, the TSM TX warm-down timing is expected to be shorter than in previous generation radios.

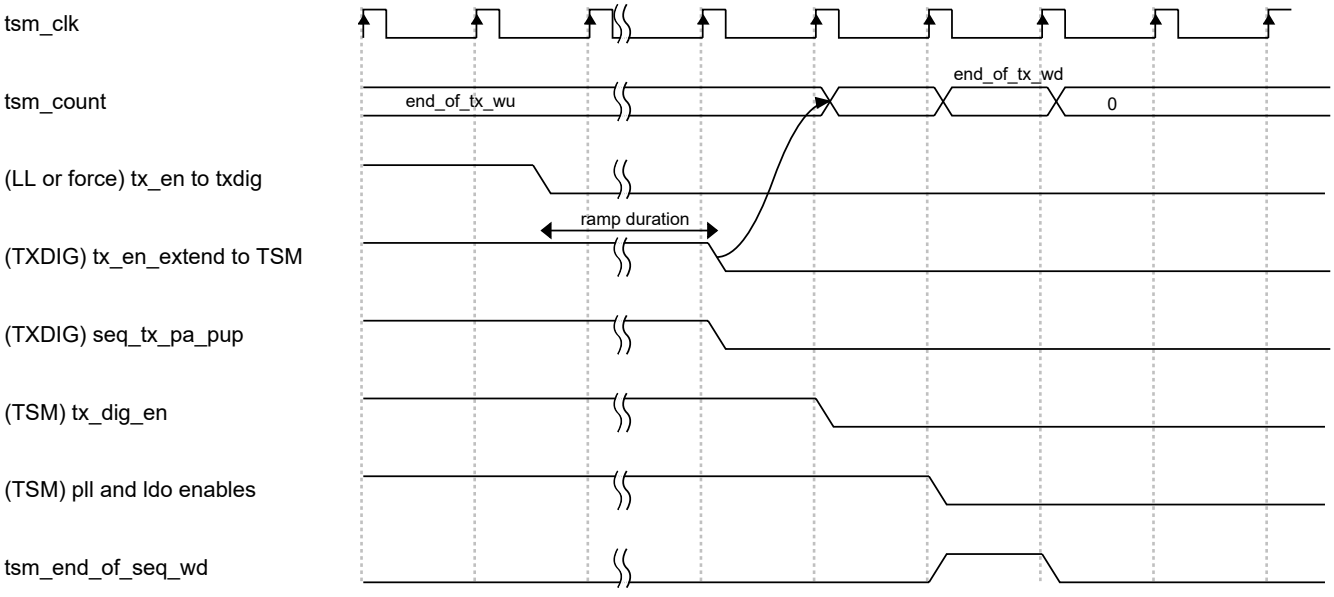

Figure 319. PA Ramp-Down Timing

For all link layers, if a TX PLL unlock or RF_NOT_ALLOWED condition occurs the link layer will need to de-assert the tx_en. Then the PA ramp-down and TSM TX warmdown will proceed as described in the figure above. (See also Abort conditions)

52.4.4.2.2.4.2.7 Overrides

Each of the TSM-controlled outputs has independent override control, except for the 4 GPIO triggers. In addition, two special TSM outputs, tx_mode and rx_mode, also have their own override controls.

Two register bits are assigned to each output, to implement the override function. The bits are named:

*OUTPUTNAME*_OVRD_EN

*OUTPUTNAME*_OVRD

Setting the *OUTPUTNAME*_OVRD_EN=1, allows the *OUTPUTNAME*_OVRD bit to directly control the state of the output. Clearing *OUTPUTNAME*_OVRD_EN=0 returns control of the output to the TSM.

The override bit-pairs reside in the TSM_OVRDyy registers.

Overrides have no effect on TSM operation, TSM counting, sequence initiation, or sequence termination. Overrides may be engaged at any time, during any TSM phase, including during idle state.

52.4.4.2.2.4.2.8 Breakpoint

Breakpoint can be used to temporarily suspend a TSM sequence. A breakpoint can be set during the WARMUP or WARMDOWN phase of any TSM sequence. An 8-bit BKPT[7:0] register field resides in the TSM_CTRL register. During a TSM sequence, when the TSM counter matches the BKPT register value, counting stops and the counter holds in its current state. Deassertion of the initiating event will be ignored during the breakpoint. The breakpoint can be lifted by modifying the BKPT[7:0] register. Once the breakpoint is lifted, the TSM proceeds in the phase it was in prior to the breakpoint match, and the TSM counter begins incrementing again from the point at which the breakpoint occurred. Deassertion of the initiaing event will then be recognized and handled as described in Sequence Termination. The default value for BKPT[7:0] is 255, which is greater than the length of any allowed sequence, so a breakpoint will not trigger during a sequence, unless a lower value is programmed.

52.4.4.2.2.4.2.9 Abort conditions

In some situations, it may be desirable to abort an RX or TX sequence. The TSM can detect these situations and alert the link layers. The link layer can then decide to de-assert its rx_en and tx_en outputs to the TSM which causes the sequence to end.

52.4.4.2.2.4.2.9.1 PLL Unlock

The TSM can be configured to detect and signal the link layer for any of the following PLL unlock conditions:

1. Coarse Tune Unlock
2. Frequency Target Unlock

The TSM is configured to react to PLL unlock condition via the TSM CTRL register's , ABORT_ON_FREQ_TARG, ABORT_ON_CTUNE,RX_ABORT_DIS and TX_ABORT_DIS bits. Additionally, the table below shows the TSM controlling signal for each the mechanism.

Lock Detect Mechanism	TSM Controlling Signal
Coarse Tune	pll_dig_en (indirect)
Freq. Target	freq_targ_ld_en

52.4.4.2.2.4.2.9.2 RF_NOT_ALLOWED

As of the Gen4.5 radio, the RF_NOT_ALLOWED is not qualified by the TSM. The RF_NOT_ALLOWED signal will be used directly by the link layer(s), which will take appropriate action to de-assert their tx_en or rx_en signal as needed.

52.4.4.2.2.4.2.10 TSM RF_ACTIVE Extension

The TSM RF_ACTIVE can be used as the radio's RF_ACTIVE coexistence output. As such, this signal needs to be asserted high a programmable amount of time before a radio event takes place and remains high until either the radio event has been completed or aborted. There should be no glitches/unwanted transitions between successive radio events (e.g., RX->TX or TX->RX). This can be a problem for protocols, such as Bluetooth LE or 802.15.4, which require the transmission of an acknowledge packet shortly after reception and reception of an acknowledge packet shortly after transmission. Bluetooth LE Advertising and Scan states offer other scenarios where closely-spaced (but not adjoining) TX and RX operations are required. The inter-frame spacing between the successive RX and TX operations is long enough such that TSM RF_ACTIVE would normally deassert and reassert between operations, creating the unwanted transitions which must be avoided.

To remedy this, a feature has been added to TSM which allows the TSM RF_ACTIVE output to be optionally extended by a programmable amount, after the nominal TSM sequence completes. The programmable limit is long enough to accommodate the RF_ACTIVE glitch which would otherwise occur using the 802.15.4 192µs turnaround time. The TSM RF_ACTIVE extension will occur for all sequences (TX and RX) for which TSM RF_ACTIVE is programmed to assert, whenever register TSM_SPARE1_EXTEND>0. The hardware mechanism for extending TSM RF_ACTIVE is illustrated in the following diagram:

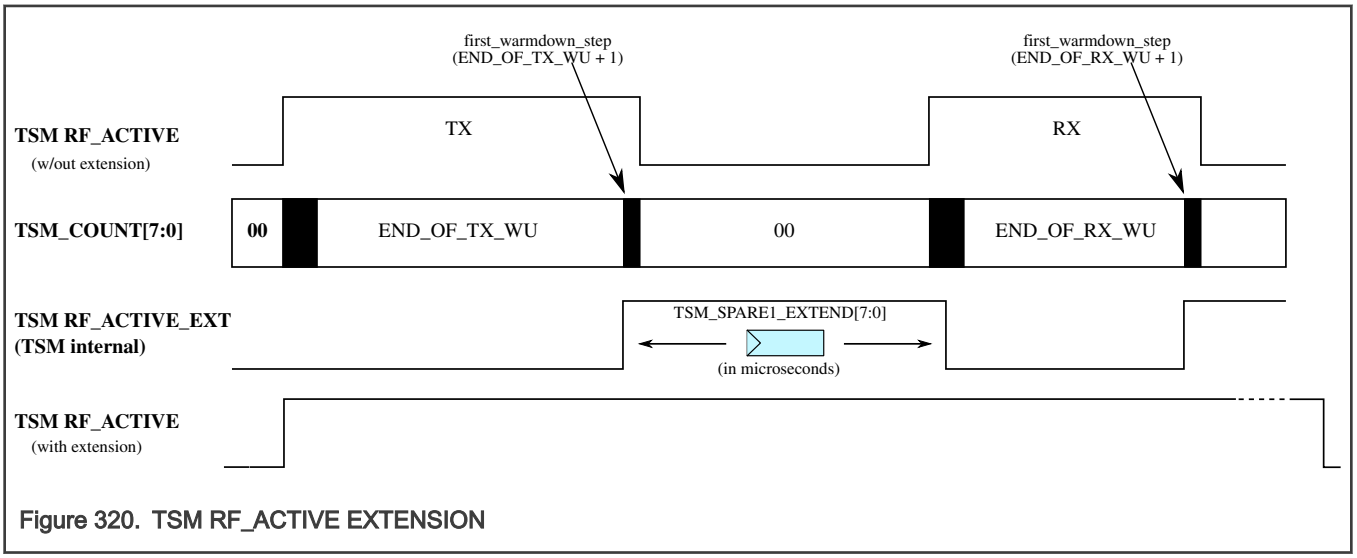

Figure 320. TSM RF_ACTIVE EXTENSION

The trigger for the extension is the TSM's first warmdown step (END_OF_xx_WU + 1), which will be reached whenever the Link Layer deasserts its TX/RX command. If enabled, the extension signal will assert (high) at this point, and will remain high for *TSM_SPARE1_EXTEND* microseconds. The extension signal (TSM RF_ACTIVE_EXT) is logically "OR-ed" with the existing TSM-controlled output TSM RF_ACTIVE, to generate the composite, extended RF_ACTIVE signal. Software can cut short the extension at any time by writing TSM_SPARE1_EXTEND=0. Setting this register to 0 also disables the extension feature from activating on any new TSM sequence. The register TSM_SPARE1_EXTEND[7:0] yields an extension range from 0 to 255µs.

52.4.4.2.2.4.2.11 Low Power Preamble Search (LPPS)

To reduce power consumption during 802.15.4 preamble-search receive state, a low-power-preamble-search (LPPS) mode can be optionally enabled. When engaged, the correlators are disabled approximately 50% of the time during preamble search. The same signal used to dynamically enable/disable the correlators, can be used to enable/disable selected analog and RF blocks in tandem, to further reduce power consumption. The LPPS_CTRL register in XCVR space, has one bit to master-enable LPPS mode (LPPS_ENABLE), and several other bits to allow selected analog and RF blocks to be “duty-cycled” in sync with the correlators. For more details on the LPPS algorithm, see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search* for more details on the LPPS algorithm.

By default, LPPS mode is not enabled.

During LPPS mode, correlators and RF blocks are duty-cycled with timing controlled by the LPPS signal **lpps_lp_en**, which is a single-wire output from the 802.15.4 demodulator. In general, eligible blocks will be powered off when **lpps_lp_en** is high, and perform normal operation when **lpps_lp_en** is low. Transitions on **lpps_lp_en** will be handled by the TSM in the following ways:

lpps_lp_en 1 → 0:

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be reasserted at this point.
2. TSM shall recycle to a programmable point in the RX warmup. The TSM RECYCLE_COUNT2[7:0] register selects the TSM_COUNT to recycle to.
3. After jumping to the TSM_COUNT indicated in RECYCLE_COUNT2, TSM shall from this point forward execute a Fast RX Warmup (see Section FAST TSM Fast Warmups later in this chapter). For the Fast RX Warmup, the registers LPPS_START_RX[7:0] and LPPS_DEST_RX[7:0] shall be used to program the TSM "jump" start and end points, as defined in the Fast RX Warmup section. The LPPS_START_RX and LPPS_DEST_RX registers reside in the LPPS_CTRL register. These registers are specific to LPPS fast warmups, and do not apply to non-LPPS fast warmups.

lpps_lp_en 0 → 1:

1. TSM outputs which are programmed to be eligible for LPPS duty-cycling (e.g, those associated with TZA, BBA, ADC) shall be deasserted at this point.
2. TSM outputs which are not eligible for LPPS duty-cycling shall remain asserted.

Note that several LPPS timing parameters are configurable (see Chapter Multi-standard PHY, Section *IEEE Low-power Preamble Search*), and LPPS_FILL_COUNT[6:0] is based on the LPPS fast warmup time. Software configuring LPPS parameters, such as LPPS_FILL_COUNT, must calculate the LPPS fast warmup time, in µs, based on the register programming described in the section above. Here is the equation:

LPPS_FAST_WARMUP_DURATION = END_OF_RX_WU - RECYCLE_COUNT2 + 1 - (LPPS_DEST_RX - LPPS_START_RX - 1)

for example,

LPPS_FAST_WARMUP_DURATION = 104 - 28 + 1 - (102 - 40 - 1)

LPPS_FAST_WARMUP_DURATION = 16µs

Note that the penalty for the reduced power consumption in LPPS mode during preamble search, is a slight degradation in receiver sensitivity. Note also that the TSM override bits, also override LPPS functionality. The override bits provide ultimate control over all TSM outputs.

Programming control for LPPS, includes a master-enable register bit for the LPPS state-machine, as well as individual control bits to enable selected analog and digital blocks to be turned on-and-off during LPPS operation. The following table lists the LPPS register bits, and the TSM outputs controlled by each.

Table 480. LPPS Register Controls

LPPS Register Bit	Description
LPPS_ENABLE	Master enable for LPPS mode. Allows correlators to be duty-cycled during Preamble Search, and selected analog and digital blocks to be duty-cycled simultaneously.
LPPS_LNA_MIX_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_rx_lna_pup, seq_rx_mix_pup , seq_spare1 for peak detector
LPPS_CBPF_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_cbpf_pup, seq_cbpf_en_dcoc
LPPS_ADC_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_adc_pup
LPPS_LO_RX_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_lo_pup_vlo_rx
LPPS_LO_RXDRV_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_lo_pup_vlo_rxdrv

Table continues on the next page...

Table 480. LPPS Register Controls (continued)

LPPS Register Bit	Description
LPPS_RX_DIG_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_dig_en
LPPS_RX_PHY_ALLOW	When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_phy_en

52.4.4.2.2.4.2.12 Powersave warmup and fast rx2tx transition

The previous sections illustrate the detailed control and timing generated by the TSM, operating in nominal-timing mode. There are situations that allow for the possibility to streamline and shorten the TSM warmup sequences. These situations arise when the transceiver is operating on the same RF channel for many consecutive transmit and/or receive operations. Multiple closely-spaced TX operations on the same channel allow the HPM calibration to be skipped, after such a calibration is performed once on a given RF channel; similarly, multiple closely spaced RX operations on the same channel allow DC offset calibration to be skipped, after such a calibration is performed once on a given RF channel.

Fast and Power-saving TSM warmups have been devised to accomplish this streamlining. Once engaged, during a fast or power-saving warmup, a portion of the nominal, programmed warmup is bypassed, or skipped over, by instructing the TSM counter to jump, once it reaches a certain count, to a new count that is not just an increment-by-one. The starting point for the “jump” as well as the destination count, or end point for the “jump”, are TSM programmable registers. There are one pair of start/destination registers for TX, and another for RX, allowing one such jump per sequence.

Power-saving warmups can be used in conjuction with any of the link layers. In a power-saving warmup, the PLL sends a pwrsave_tx_wu_ok (or pwrsave_rx_wu_ok) signal to the TSM to let the TSM known that that the PLL is on the same channel as the previous tx (or rx) channel. For a power-saving warmup, the TSM will insert some idle time after the link layer asserts tx_en (or rx_en) so that the overall time from the link layer asserting tx_en (or rx_en) to when the radio is on-air remains constant. The link layer is therefore unaware that a power-saving warmup has occurred. The power savings benefit is that the analog and calibration circuits are on for a shorter during during warmup.

Fast TSM warmup is required by the link layer. Currently, only the Generic LL supports fast TSM warmups. A fast warmup is similar to a power-saving warmup, except that the TSM does not insert any idle time after the link layers tx_en (or rx_en). So the time from the link layer asserting tx_en (or rx_en) to when the radio is on-air is shorter for a fast warmup. A fast warmup request from the link layer has higher priority than a power-saving warmup ok from the PLL. In fact, the TSM does not qualify a fast warmup request with the pwrsave_tx_wu_ok (or pwrsave_rx_wu_ok) signal from the PLL; the Generic LL programmer must ensure that previous warmup calibrations can be skipped before requesting a fast warmup.

Enables bits provide software with fine control over precisely when fast and power-saving warmups are allowed, versus nominal warmups.

In addition, TSM sequences have in the past been discrete TX or RX operations, with a required software command to initiate the sequence, and a return-to-idle after the sequence is complete, before a new sequence-start command can be issued. For some link layers, it is highly desirable to be able to jump directly from the end of a CCA measurement (CCA = Clear Channel Assessment), which is essentially an RX operation, to a packet transmit operation, without returning the TSM to IDLE in between, if CCA deems the channel to be free. A new TSM transition called “Fast RX2TX” accomplishes this. The Generic or 802.15.4 Link Layer will signal to TSM when to perform such a transition, and TSM will respond by jumping from the RX “ON” phase, to a programmable point within the TX warmup. At the very least, this will allow the re-warmup of the required analog regulators to be skipped, since they can stay on during the transition. Also, since the PLL is staying on the same channel, there is no need to cycle the VCO off, and then on again, so the VCO-related TSM controls can be programmed to maintain their states during the transition. Enable bits provide software with fine control over precisely when a “Fast RX2TX” is allowed, versus a nominal RX-to-IDLE-to-TX ordering of events.

Fast RX2TX can also be combined with a Fast TX Warmup to yield an ultrafast TX warmup sequence, if, as is likely, the RF channel has not changed since the previous TX warmup. In this case, the Fast TX warmup is conditioned by the PLL's pwrsave_tx_wu_ok.

Interaction with other blocks is required to support TSM fast warmup capability. The PLL digital block is responsible for selecting the correct frequency for RF operations, and will keep track of whether consecutive warmup operations utilize the same channel or

not; it will signal this information to the TSM. The PLL digital block will maintain such tracking separately for TX and RX warmups. The TSM will then signal back to the PLL digital block when a TX warmup is actually “fast” or not; the PLL digital block will use this information to instruct its state machine to skip HPM calibration. For RX warmups, the TSM will signal to the RX digital block, when to skip DC calibration, and instead use stored values.

The new inter-block signaling to support fast TSM warmups is illustrated in the following diagram, followed by a table which describes the new signaling.

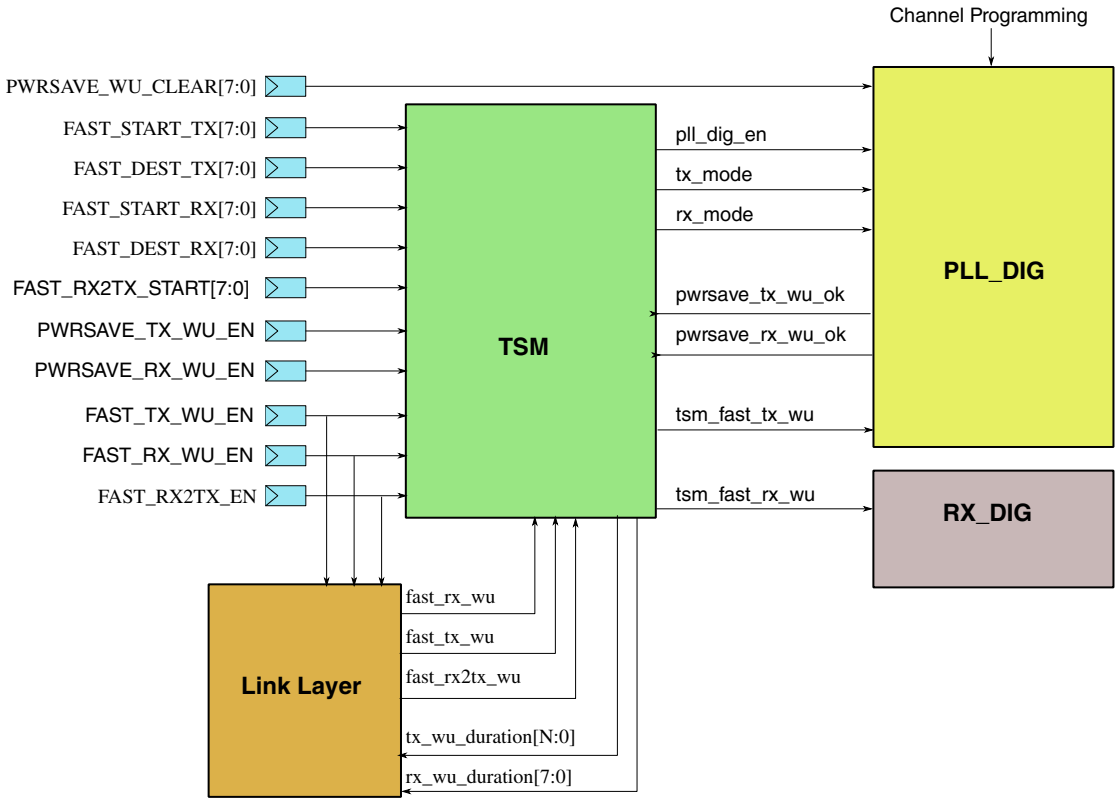

Figure 321. XCVR SIGNALLING TO SUPPORT TSM FAST WARMUPS

“Fast Warmup” Signal	Source	Destination	Description
pll_dig_en	TSM	PLL Digital	Rising edge of this signal used by PLL_DIG to capture the Channel Programming for the current warmup
tx_mode	TSM	PLL Digital	Used in conjunction with pll_dig_en to capture the Channel Programming for TX sequences
rx_mode	TSM	PLL Digital	Used in conjunction with pll_dig_en to capture the Channel Programming for RX sequences

Table continues on the next page...

Table continued from the previous page...

"Fast Warmup" Signal	Source	Destination	Description
fast_rx_wu	Generic LL	TSM	Link layer requests a Fast RX warmup
fast_tx_wu	Generic LL	TSM	Link layer requests a Fast TX warmup
fast_rx2tx_wu	ZSM (802.15.4) or Generic LL	TSM	The RF channel is free to transmit immediately after an RX burst. TSM should jump directly from RX "ON" phase to TX "WARMUP" phase, entering at the FAST_RX2TX_START point.
pwrsave_rx_wu_ok	PLL Digital	TSM	Indicates that the Channel Programming on the *current* RX warmup has not changed since the *last* RX warmup
pwrsave_tx_wu_ok	PLL Digital	TSM	Indicates that the Channel Programming on the *current* TX warmup has not changed since the *last* TX warmup
tsm_fast_tx_wu	TSM	PLL Digital	This is a fast or power-saving TX warmup. PLL_DIG should skip calibration.
tsm_fast_rx_wu	TSM	RX Digital	This is a fast or power-saving RX warmup. RX Dig should skip DCOC Cal.
rx_warmup_duration[7:0]	TSM	Link Layer	Indicates the RX warmup time.
tx_warmup_duration[7:0]	TSM	Link Layer	Indicates the TX warmup time, including PA ramp time

TSM Registers to support Fast TSM Warmups and Fast RX2TX are described in the following table.

Field	R/W	Description
PWRSAVE_TX_WU_EN	rw	1: Enable Power-Saving TX Warmup (if pwrsave_tx_wu_ok asserted by PLL_DIG) 0: Disable Power-Saving TX Warmups
PWRSAVE_RX_WU_EN	rw	1: Enable Power-Saving RX Warmup (if pwrsave_rx_wu_ok asserted by PLL_DIG)

Table continues on the next page...

Table continued from the previous page...

Field	R/W	Description
		0: Disable Power-Saving RX Warmups
PWRSAVE_WU_CLR	rw	This is not used directly by the TSM. It creates a signal to the PLL to clear its wu_ok. It should be set and then cleared by software. 1: Direct the PLL to clear the *wu_ok signals 0: Do nothing
FAST_TX_WU_EN	rw	1: Enable Fast TX Warmup (if fast_tx_wu_ok asserted by PLL_DIG) 0: Disable Fast TX Warmups
FAST_RX_WU_EN	rw	1: Enable Fast RX Warmup (if fast_rx_wu_ok asserted by PLL_DIG) 0: Disable Fast RX Warmups
FAST_RX2TX_EN	rw	1: Enable Fast RX-to-TX transitions (if fast_rx2tx_wu is asserted by ZSM) 0: Disable Fast RX-to-TX transitions
FAST_START_TX[7:0]	rw	During a Fast or Power-Saving TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump.
FAST_DEST_TX[7:0]	rw	During a Fast or Power-Saving TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be

Table continues on the next page...

Table continued from the previous page...

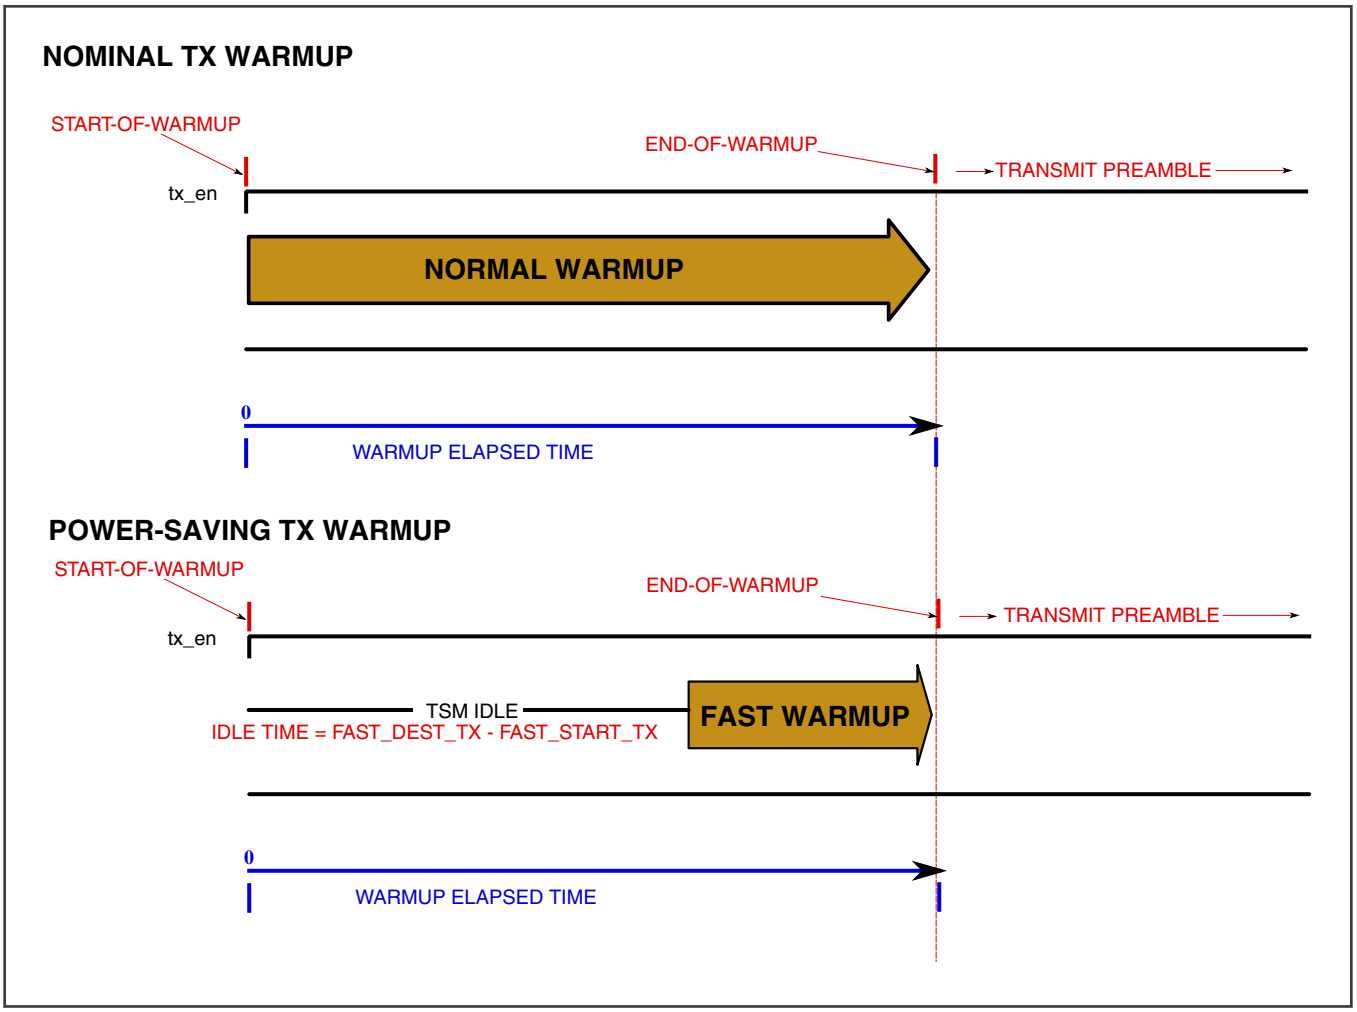
Field	R/W	Description
		replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
FAST_START_RX[7:0]	rw	During a Fast or Power-Saving RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump.
FAST_DEST_RX[7:0]	rw	During a Fast or Power-Saving RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast or Power-Saving RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
FAST_RX2TX_START[7:0]	rw	During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when Link Layer asserts fast_rx2tx_wu. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.

Software running on the various protocol engines which utilize the TSM to provide access to the channel, need not be aware that the total warmup time has been reduced, when the TSM executes a power-saving warmup, as opposed to a nominal warmup. (With the exception of the Generic LL), Link Layer software expects TSM warmup times to be a fixed constant, actually 2 fixed

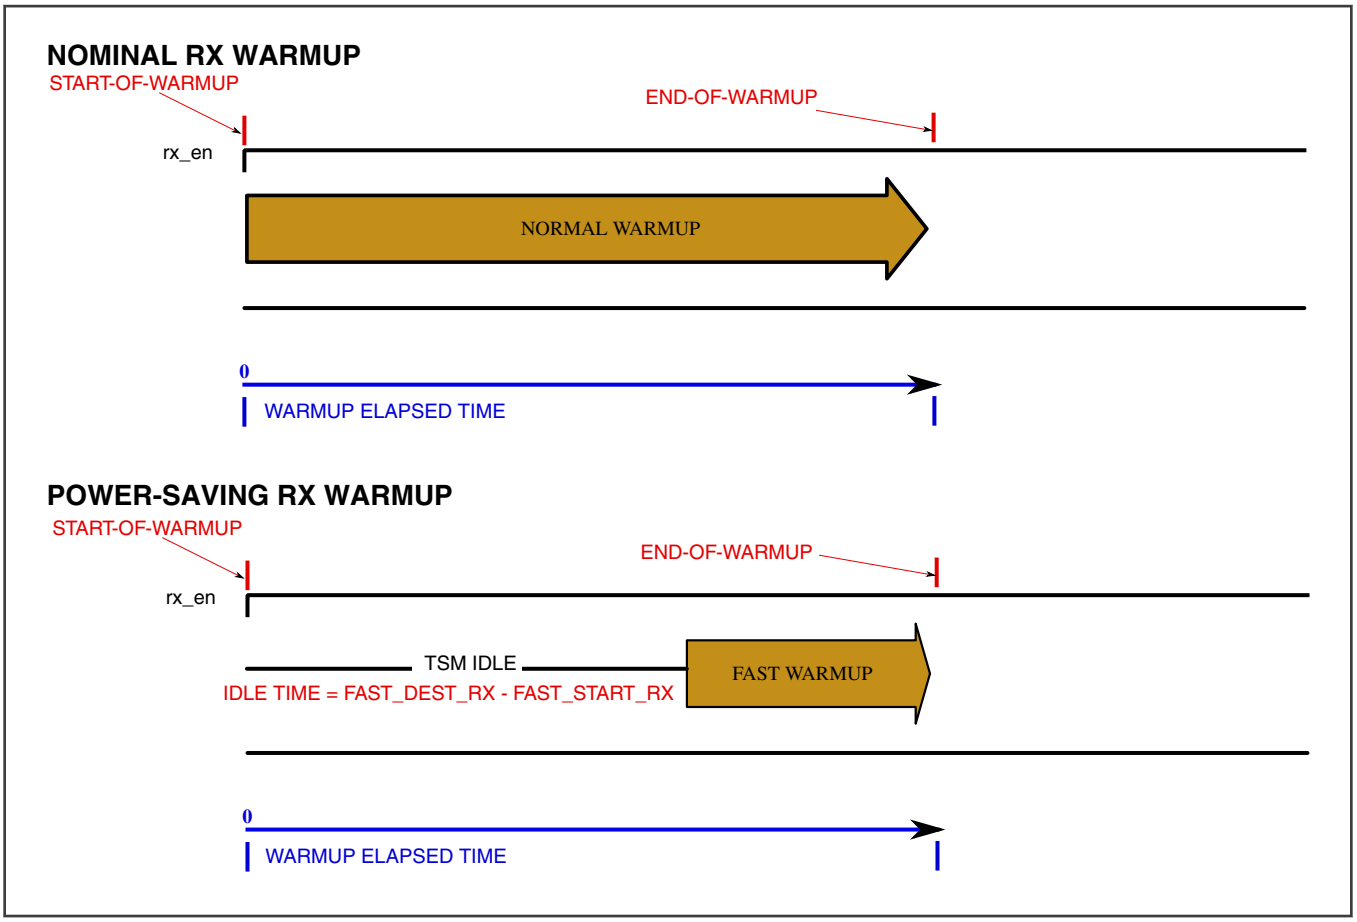
constants, one for TX warmups and one for RX warmups. Software must account for these TX and RX warmup times when they are scheduling transceiver operations, so that the first symbol of preamble is transmitted at the correct instant for transmit operations, and that the receiver is ready to receive the first symbol of preamble at the correct instant for receive operations. Software views these warmup times as fixed lead times that must be accounted for in advance of a transceiver operation.

In order to make the power-saving warmup time reduction transparent to software, when a power-saving TSM warmup is executed, the TSM will delay the start of the warmup, by the amount of time skipped by the jump. That keeps the total elapsed time, from the instant the software launches the TSM sequence, to the point at which the warmup completes, identical for power-saving and nominal warmups.

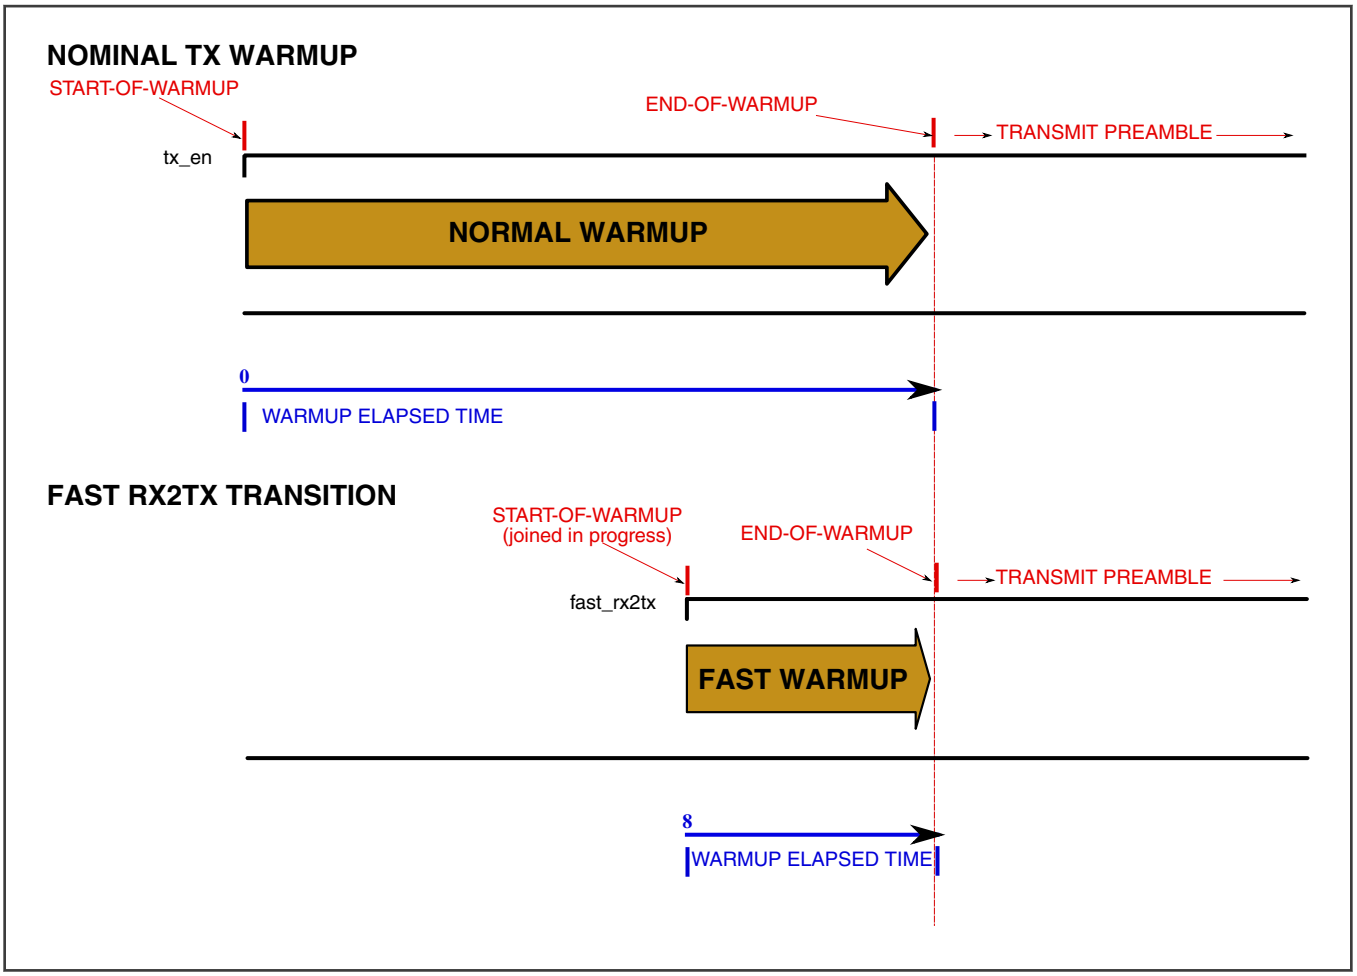
The following diagram illustrates how the TSM delays the start of the Power-saving TX sequence, relative to the nominal TX sequence, so that the delta time between tx_en (TSM launch signal), and the transmission of the first bit of preamble, is the same in either case.



The following diagram illustrates how the TSM delays the start of the Power-saving RX sequence, relative to the nominal RX sequence, so that the delta time between rx_en (TSM launch signal), and the ability to receive first bit of preamble, is the same in either case.



The FAST RX2TX transition is handled differently. The objective in such a transition is to get to the point of transmitting the first bit of preamble ASAP. There is no warmup time that software needs to account for in this case, since the RX-to-TX transition is handled completely by hardware. The following diagram compares a nominal TX warmup, with a foreshortened “Fast RX2TX” warmup.



52.4.4.2.2.4.2.13 FAST Transition Support for Ranging Sequence Manager

For the Ranging Sequence Manager (RSM), the TSM supports the following additional features:

- Ability for the RSM to request Fast RX-to-TX transition described in previous section. The RSM outputs a fast_rx2tx_wu signal to the TSM to request this transition
- Fast TX-to-RX feature, analogous to the Fast RX-to-TX feature. The RSM outputs a fast_tx2rx_wu signal to the TSM to request this transition.
- An alternate set of START times for the Fast RX-to-TX and Fast TX-to-RX features. This allows the RSM to use the primary set of START times for its IP (Interlude Period) transitions and the alternate set for its FC (Frequency Change) transitions. The RSM outputs a signal fast_fc_wu to the TSM to select which set to use.
- Ability for the RSM to request FAST RX in conjunction with Fast TX-to-RX transiiton. These use the FAST_START_RX[7:0] and FAST_DEST_RX[7:0] as described in the previous section. The RSM outputs a fast_rx_wu signal to request FAST RX.
- Ability for the RSM to request FAST TX in conjunction with Fast RX-to-TX transiiton. These use the FAST_START_TX[7:0] and FAST_DEST_TX[7:0] as described in the previous section. The RSM outputs a fast_tx_wu signal to request FAST TX.

Refer to Role Swap and Frequency Change Transitions section in the Ranging Sequence Manager topic for more information about RSM use of these TSM features.

The TSM Registers added to support these additional features for the RSM are described in the following table.

Field	R/W	Description
FAST_TX2RX_EN	rw	1: Enable Fast TX-to-RX transitions (if fast_tx2rx_wu is asserted by RSM) 0: Disable Fast TX-to-RX transitions
FAST_TX2RX_START[7:0]	rw	During a Fast TX-to-RX transition (FAST_TX2RX_EN=1) the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when RSM asserts fast_tx2rx_wu with fast_fc_wu=0. The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.
FAST_RX2TX_START_FC[7:0]	rw	During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when RSM asserts fast_rx2tx_wu with fast_fc_wu=1. (If fast_fc_wu=0, the TSM will use FAST_RX2TX_START[7:0]) The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
FAST_TX2RX_START_FC[7:0]	rw	During a Fast TX-to-RX transition (FAST_TX2RX_EN=1) the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when RSM asserts fast_tx2rx_wu with fast_fc_wu=1. (If fast_fc_wu=0, the TSM will use FAST_TX2RX_START[7:0]) The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.

52.4.4.2.2.4.2.14 Programming Restrictions

The following restrictions are imposed on TSM programming. Violating the restrictions may result in unpredictable behavior.

1. The maximum value for END_OF_TX_WU[7:0] is 253
2. The maximum value for END_OF_RX_WU[7:0] is 253
3. The maximum value for END_OF_TX_WD[7:0] is 254
4. The maximum value for END_OF_RX_WD[7:0] is 254
5. END_OF_TX_WD[7:0] – END_OF_TX_WU[7:0] >= 1

6. END_OF_RX_WD[7:0] – END_OF_RX_WU[7:0] >= 1
7. BKPT[7:0] != END_OF_TX_WD[7:0]
8. BKPT[7:0] != END_OF_RX_WD[7:0]
9. For any TSM output: OUTPUTNAME_TX_HI[7:0] <= OUTPUTNAME_TX_LO[7:0]
10. For any TSM output: OUTPUTNAME_RX_HI[7:0] <= OUTPUTNAME_RX_LO[7:0]

Restrictions 9 and 10 above, if violated, will result in the TSM-controlled output held in a deasserted state throughout the sequence.

To guarantee non-assertion of a particular TSM-controlled output throughout the course of a sequence, simply program its OUTPUTNAME_SEQ_HI = OUTPUTNAME_SEQ_LO = 255 (where SEQ = TX or RX).

52.4.4.2.2.4.2.15 Interrupts

For debug purposes, TSM has two timing control outputs (tsm_irq0_start_trigger_en and tsm_irq1_stop_trigger_en) which can be used to either generate interrupts to the host processor. Like all other TSM-controlled outputs, the point during the TX or RX warmup at which the interrupt is triggered, is fully programmable.

To use either tsm_irq0_start_trigger_en or tsm_irq1_stop_trigger_en as an interrupt, set the TSM_IRQ0_EN or TSM_IRQ1_EN bit, respectively, in the TSM_CTRL registers. Because the TSM is part of XCVR space, and XCVR space does not have its own interrupt vector, the TSM interrupt is "assigned" to the Link Layer currently in possession of the radio. Each Link Layer controller has in its address space, a TSM_IRQ status bit, as well as a enable bit to allow/disallow the TSM interrupt to assert the Link Layer's interrupt line to the MCU. The TSM_IRQ status bit, as it appears in each Link Layer's address space, is a logical "OR" of the TSM's TSM0_IRQ and TSM1_IRQ. The Link Layer TSM_IRQ is read-only. It can be cleared by clearing both TSM0_IRQ and TSM1_IRQ in the XCVR's XCVR_STATUS register. In the XCVR_STATUS register, TSM0_IRQ and TSM1_IRQ are both write-1-to-clear bits. See the Register Description for each individual Link Layer, for a description of the TSM_IRQ read-only interrupt status bit, and its bit positioning within the Link Layer's address space.

The tsm_irq0_start_trigger_en can also be used as a start trigger source for the Transceiver DMA or Packet RAM Debug mode. The tsm_irq1_stop_trigger_en can also be used as a stop trigger source for the Packet RAM Debug mode.

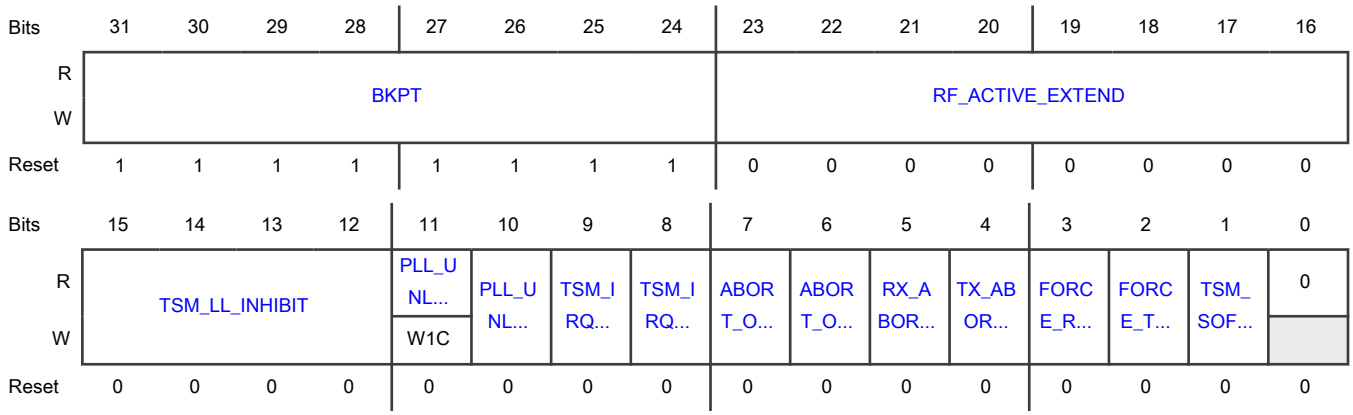
Offset

Register	Offset
CTRL	0h

Diagram



Fields

Field	Function
31-24 BKPT	TSM Breakpoint Temporarily halt a TSM sequence during the warmup or warmdown phase. When the TSM counter matches the value of BKPT[7:0], breakpoint will take effect and the TSM counter will stop and hold its count. Breakpoint will remain in effect as long as BKPT[7:0] matches the TSM counter value. The TSM Breakpoint can be lifted by modifying the contents of this register. The default value of this register, 0xFF, is greater than the length of the longest possible sequence, so a breakpoint will never be triggered unless BKPT[7:0] is programmed to a value less than the length of sequence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 RF_ACTIVE_EXTEND	TSM RF_ACTIVE Extension Duration When TSM output RF_ACTIVE is enabled to assert during any TX or RX sequence and TSM_SPARE1_EXTEND[7:0] > 0, this register specifies the number of microseconds for which RF_ACTIVE is to remain asserted beyond the end of the TSM warmdown. This extension is intended to close any gap in the coexistence output RF_ACTIVE that may occur between consecutive TX/RX or RX/TX TSM operations.
15-12 TSM_LL_INHIBIT	TSM Per-Link-Layer Inhibit Nominally, any protocol engine can request TSM to start a TX or RX sequence at any time. In a multiprotocol setting, individual protocol engines can (optionally) be selectively blocked from accessing TSM by setting one of the following bits of TSM_LL_INHIBIT[3:0]: xxx1: Bluetooth LE commands to TSM are inhibited xxx0: Bluetooth LE commands to TSM are permitted 1xxx: GENERIC_FSK commands to TSM are inhibited 0xxx: GENERIC_FSK commands to TSM are permitted
11 PLL_UNLOCK_IRQ	PLL Unlock IRQ PLL Un-lock Interrupt Status bit. A '1' indicates an unlock event has occurred in the PLL. This is write a '1' to clear bit. 0b - A PLL Unlock Interrupt has not occurred 1b - A PLL Unlock Interrupt has occurred
10 PLL_UNLOCK_IRQ_EN	PLL Unlock Interrupt Enable 0b - allows PLL unlock event to generate an interrupt 1b - A PLL unlock event will set the PLL_UNLOCK_IRQ status bit, but an interrupt is not generated
9 TSM_IRQ1_EN	TSM_IRQ1 Enable/Disable bit TSM_IRQ1 Enable/Disable bit. Intended for debug purposes only. 0b - TSM_IRQ1 is disabled 1b - TSM_IRQ1 is enabled
8 TSM_IRQ0_EN	TSM_IRQ0 Enable/Disable bit TSM_IRQ0 Enable/Disable bit. Intended for debug purposes only. 0b - TSM_IRQ0 is disabled 1b - TSM_IRQ0 is enabled
7 ABORT_ON_FREQ_TARG	Abort On Frequency Target Lock Detect Failure 0b - don't allow TSM abort on Frequency Target Unlock Detect 1b - allow TSM abort on Frequency Target Unlock Detect

Table continues on the next page...

Table continued from the previous page...

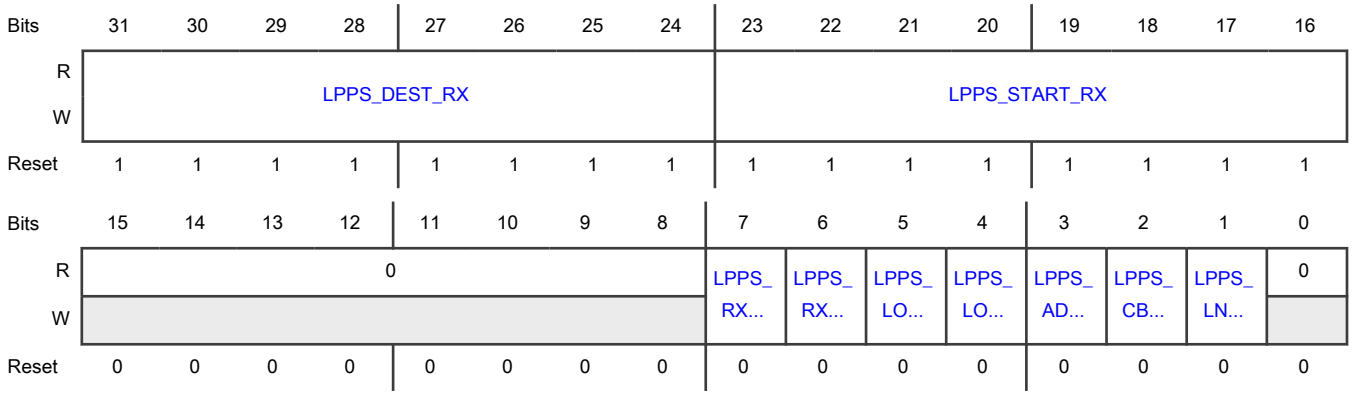
Field	Function
6 ABORT_ON_CTUNE	Abort On Coarse Tune Lock Detect Failure 0b - don't allow TSM abort on Coarse Tune Unlock Detect 1b - allow TSM abort on Coarse Tune Unlock Detect
5 RX_ABORT_DIS	Receive Abort Disable RX Abort disable. When set, prevents PLL unlock events during RX sequences from aborting the sequence.
4 TX_ABORT_DIS	Transmit Abort Disable TX Abort disable. When set, prevents PLL unlock events during TX sequences from aborting the sequence.
3 FORCE_RX_EN	Force Receive Enable Direct software control to launch a RX TSM sequence. Initiates RX Warmup on a 0 to 1 transition and RX Warmdown on a 1 to 0 transition. 0b - TSM Idle 1b - TSM executes a RX sequence
2 FORCE_TX_EN	Force Transmit Enable Direct software control to launch a TX TSM sequence. Initiates a TX Warmup sequence on a 0 to 1 transition and a TX Warmdown sequence on a 1 to 0 transition. 0b - TSM Idle 1b - TSM executes a TX sequence
1 TSM_SOFT_RESET	TSM Soft Reset Writing 1 to this bit returns TSM to its IDLE state, with TSM_COUNT=0. Writing 0 to this bit removes the forced-reset condition and resumes normal operation. The bit is not self-clearing. For contingency purposes only 0b - TSM Soft Reset removed. Normal operation. 1b - TSM Soft Reset engaged. TSM forced to IDLE, and holds there until the bit is cleared.
0 —	Reserved

52.4.4.2.2.4.3.1.3 TSM CONTROL (LPPS_CTRL)

Offset

Register	Offset
LPPS_CTRL	4h

Diagram



Fields

Field	Function
31-24 LPPS_DEST_RX	LPPS Fast TSM RX Warmup "Jump-to" Point During a LPPS Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. In an LPPS Fast RX Warmup, LPPS_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: LPPS_START_RX = 10 LPPS_DEST_RX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
23-16 LPPS_START_RX	LPPS Fast TSM RX Warmup "Jump-from" Point During a LPPS Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. In an LPPS Fast RX Warmup, this count will never be reached; its place in the TSM warmup will be replaced by the contents of LPPS_DEST_RX[7:0], thereby executing the jump.
15-8 —	Reserved
7 LPPS_RX_PHY_ALLOW	LPPS_RX_PHY_ALLOW When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_phy_en
6 LPPS_RX_DIG_ALLOW	LPPS_RX_DIG_ALLOW When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: rx_dig_en
5 LPPS_LO_RXDRV_ALLOW	LPPS_LO_RXDRV_ALLOW When set to one, allows the following TSM outputs to be controlled by the LPPS state machine: seq_lo_pup_vlo_rxdrv

Table continues on the next page...

Table continued from the previous page...

R W	END_OF_TX_WD								END_OF_TX_WU							
Reset	0	1	1	1	0	0	1	0	0	1	1	1	0	0	0	0

Fields

Field	Function
31-24 END_OF_RX_WD	End of RX Warmdown This register defines the point at which the TSM RX sequence warmdown completes, and the TSM returns to idle. The duration of the TSM warmdown phase is determined by: END_OF_RX_WD – END_OF_RX_WU.
23-16 END_OF_RX_WU	End of RX Warmup This register defines the length of the TSM RX warmup sequence. After the assertion of a RX sequence-initiating event, when the TSM counter reaches the count matching this register, it will stop and hold its count, and the TSM will transition from the WARMUP to the ON phase.
15-8 END_OF_TX_WD	End of TX Warmdown This register defines the point at which the TSM TX sequence warmdown completes, and the TSM returns to idle. The duration of the TSM warmdown phase is determined by: END_OF_TX_WD – END_OF_TX_WU.
7-0 END_OF_TX_WU	End of TX Warmup This register defines the length of the TSM TX warmup sequence. After the assertion of a TX sequence-initiating event, when the TSM counter reaches the count matching this register, it will stop and hold its count, and the TSM will transition from the WARMUP to the ON phase.

52.4.4.2.2.4.3.1.5 WARMUP LATENCY (WU_LATENCY)

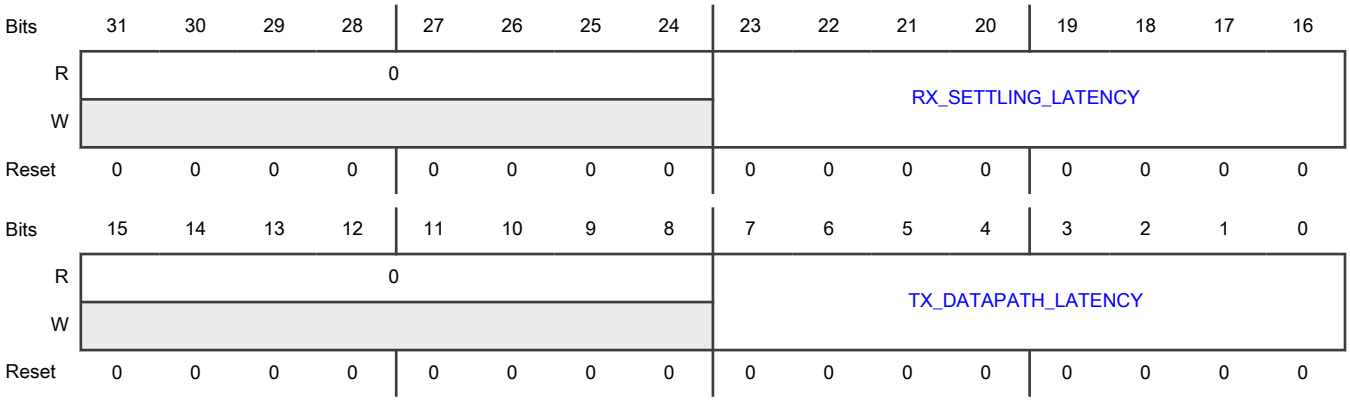
Offset

Register	Offset
WU_LATENCY	Ch

Function

This register contains the RX and TX latency values. These are added to the TSM's warmup duration to provide the Generic link layer a total warmup time.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RX_SETTLING_LATENCY	RX Settling Latency RX_SETTLING_LATENCY allows for a bulk delay value (in microseconds) to be added to the RX TSM warm-up time for link layer scheduling. The programmed value corresponds to the time that the RX data path may need for RX filters and clocks to settle and/or any post-warm-up RX activities that need to be completed before a valid RF signal can be correctly processed.
15-8 —	Reserved
7-0 TX_DATAPATH_LATENCY	TX Datapath Latency TX_DATAPATH_LATENCY allows for a bulk delay value (in microseconds) to be added to the TX TSM warm-up time for link layer scheduling. This value comprises cumulative TX data path processing latency including contributions by RBME, TX-Dig, PLL and Antenna Interface as per TX configuration.

52.4.4.2.2.4.3.1.6 TSM RECYCLE COUNT (RECYCLE_COUNT)

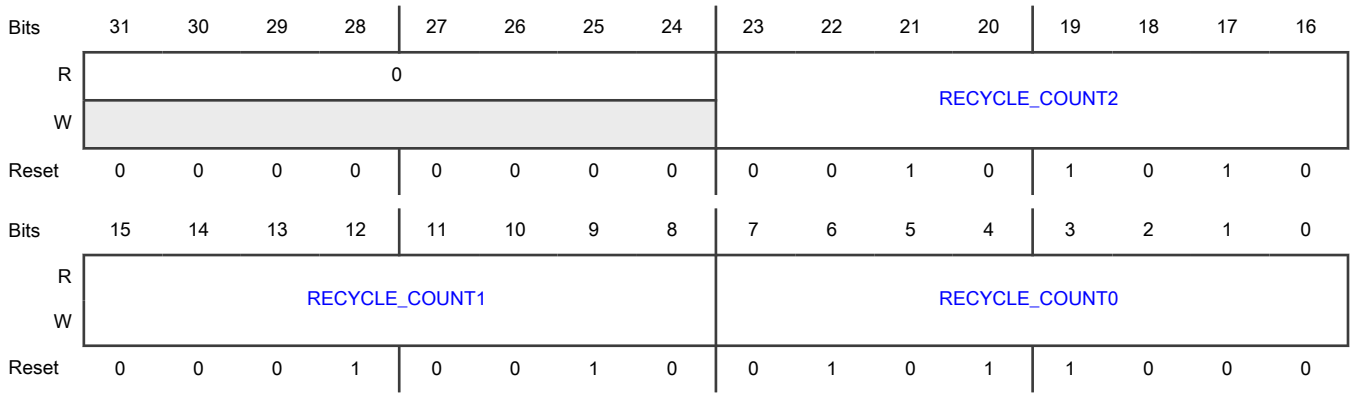
Offset

Register	Offset
RECYCLE_COUNT	10h

Function

This register contains the TSM Recycle "Jump-to" points for the different types of TSM Recycle

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RECYCLE_COUNT2	TSM RX Recycle Count 2 The RECYCLE_COUNT2[7:0] register determines the TSM count value to which the TSM "recycles" when, in LPPS mode, an LPPS power save cycle completes and the receiver is switched back on, necessitating a foreshortened RX warmup. The intention is for this register to be programmed to a TSM count value that is just prior to the assertion of rx_lna_en, but there are no restrictions on programming this register. An LPPS recycle is a command from the LPPS state machine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there.
15-8 RECYCLE_COUNT1	TSM RX Recycle Count 1 The RECYCLE_COUNT1 register determines the TSM count value to which the TSM "recycles" when a link layer asserts the tsm_recycle[1] signal. The intention is for RECYCLE_COUNT1 to be programmed to a TSM count value such that the TSM de-asserts, and then re-asserts its "pll_dig_en" output, to effectuate a Dual PAN on-the-fly channel change, but there are no restrictions on programming this register. For 802.15.4 Sequence Manager (ZSM), tsm_recycle[1] is associated with the "RX_PAN1" state. For Generic_FSK Link Layer, tsm_recycle[1] is associated with the "RX_PAN1" state.
7-0 RECYCLE_COUNT0	TSM RX Recycle Count 0 The RECYCLE_COUNT0[7:0] register determines the TSM count value to which the TSM "recycles" when the 802.15.4 Sequence Manager (ZSM) state "RX_CYC" is reached and the ZSM asserts tsm_recycle[0] to TSM. This register also determines the TSM count value to which the TSM recycles when the ZSM state RX_CCCA is reached because tsm_recycle[0] is also asserted in this state. This register also determines the TSM count value to which the TSM recycles when the Generic_FSK Link Layer asserts a tsm_recycle to TSM. The intention is for this register to be programmed to a TSM count value such that the TSM re-asserts its "rx_init" output, but there are no restrictions on programming this register. An RX recycle is a command from any protocol engine to TSM, requesting a jump from the TSM ON phase back to a programmable point in the WARMUP phase, and resume counting from there. A recycle will result from the reception of a packet with bad CRC or one which fails packet-filtering rules, or the end of a CCA operation in Continuous CCA mode which results in a channel indicating "busy".

52.4.4.2.2.4.3.1.7 TSM FAST WARMUP CONTROL 1 (FAST_CTRL1)

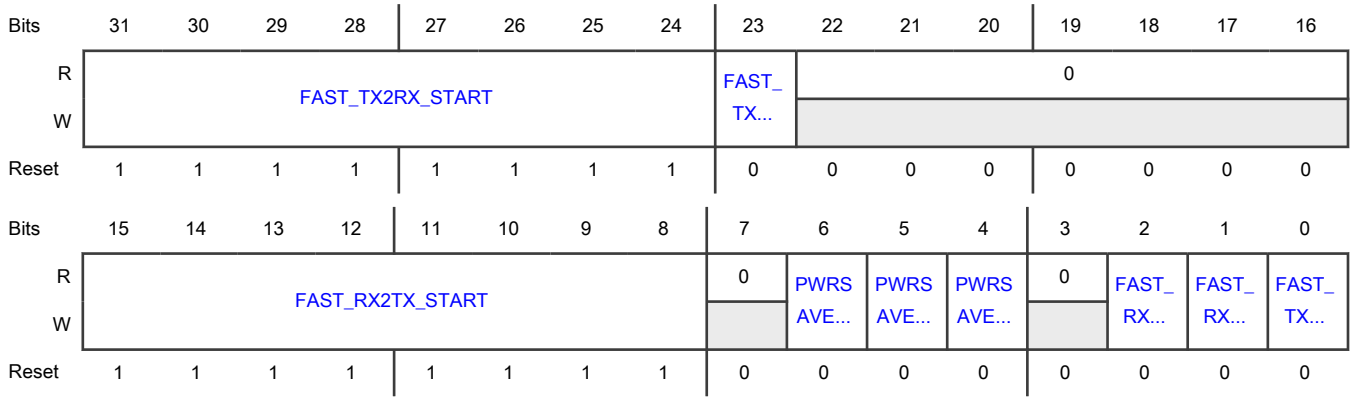
Offset

Register	Offset
FAST_CTRL1	14h

Function

This register provides enabling and control for Fast TSM Mode

Diagram



Fields

Field	Function
31-24 FAST_TX2RX_START	TSM "Jump-to" point for a Fast TSM TX-to-RX Transition. During a Fast TX-to-RX transition (FAST_TX2RX_EN=1), the contents of this register represent the entry point (TSM count) in the RX warmup sequence to which the TSM jumps to when Ranging sequence manager asserts fast_tx2rx_wu. The TSM will jump from the TX “ON” phase to the RX “WARMUP” phase, starting at this count.
23 FAST_TX2RX_EN	Fast TSM TX-to-RX Transition Enable This bit enables a special state transition in the Ranging Sequence Manager, combined with a TSM jump from the TX "ON" phase to the RX "Warmup" phase 0b - Disable Fast TX-to-RX transitions 1b - Enable Fast TX-to-RX transitions (if fast_tx2rx_wu is asserted by Ranging sequence manager)
22-16 —	Reserved
15-8 FAST_RX2TX_START	TSM "Jump-to" point for a Fast TSM RX-to-TX Transition. During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when fast_rx2tx_wu is asserted by the Link Layer state machine. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
7 —	Reserved
6 PWRSAVE_WU_CLEAR	PowerSave TSM Warmup Clear State This bit clears the RF channel memory in the PLL Digital Block, forcing the next TSM TX Warmup to be normal (not powersave), and the next TSM RX Warmup to be normal (not powersave), regardless of whether the RF channel has actually changed or not. This bit is not self-clearing. Write '1' to clear channel memory, then write '0' to proceed with TSM operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 PWRSAVE_RX_WU_EN	Power Save TSM RX Warmup Enable 0b - PowerSave TSM RX Warmups are disabled 1b - PowerSave TSM RX Warmups are enabled, if the RF channel has not changed since the last RX warmup.
4 PWRSAVE_TX_WU_EN	Power Save TSM TX Warmup Enable 0b - PowerSave TSM TX Warmups are disabled 1b - PowerSave TSM TX Warmups are enabled, if the RF channel has not changed since the last TX warmup.
3 —	Reserved
2 FAST_RX2TX_EN	Fast TSM RX-to-TX Transition Enable This bit enables a special state transition in the Link Layer, combined with a TSM jump from the RX "ON" phase to the TX "Warmup" phase, to accelerate the CCA-to-TX transition in the Link Layer autosequences 0b - Disable Fast RX-to-TX transitions 1b - Enable Fast RX-to-TX transitions (if fast_rx2tx_wu is asserted by the Link Layer)
1 FAST_RX_WU_EN	Fast TSM RX Warmup Enable 0b - Fast TSM RX Warmups are disabled 1b - Fast TSM RX Warmups are enabled, if the RF channel has not changed since the last RX warmup, and for Bluetooth LE mode, the RF channel is not an advertising channel.
0 FAST_TX_WU_EN	Fast TSM TX Warmup Enable 0b - Fast TSM TX Warmups are disabled 1b - Fast TSM TX Warmups are enabled, if the RF channel has not changed since the last TX warmup, and for Bluetooth LE mode, the RF channel is not an advertising channel.

52.4.4.2.2.4.3.1.8 TSM FAST WARMUP CONTROL 2 (FAST_CTRL2)

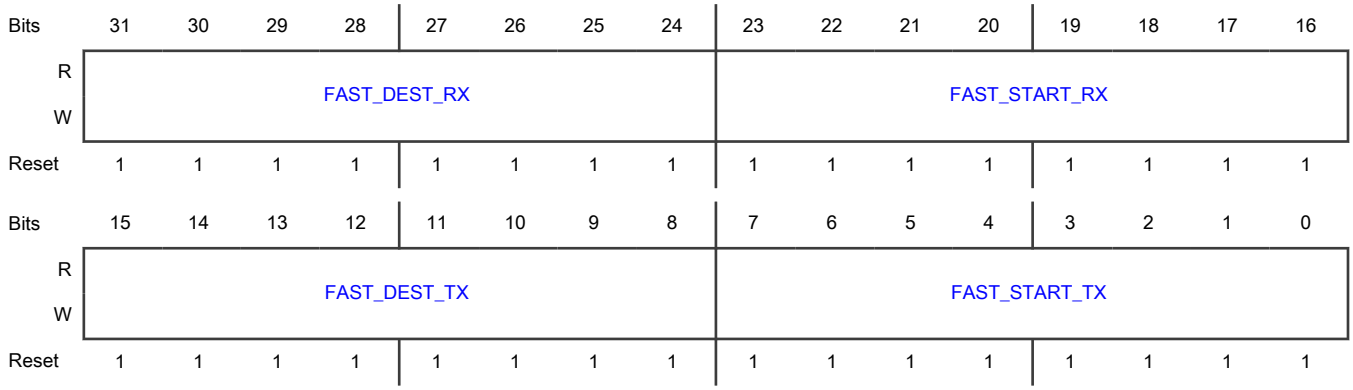
Offset

Register	Offset
FAST_CTRL2	18h

Function

This register provides configuration for Fast TSM Mode

Diagram



Fields

Field	Function
31-24 FAST_DEST_RX	Fast TSM RX "Jump-to" Point During a Fast RX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, FAST_START_RX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_RX = 10 FAST_DEST_RX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
23-16 FAST_START_RX	Fast TSM RX "Jump-from" Point During a Fast RX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast RX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_RX[7:0], thereby executing the jump.
15-8 FAST_DEST_TX	Fast TSM TX "Jump-to" Point During a Fast TX Warmup, this value represents the ending TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, FAST_START_TX[7:0] will never be reached and will instead be replaced by the contents of this register, thereby executing the jump. Example: FAST_START_TX = 10 FAST_DEST_TX = 15 The TSM will count as follows: … 7,8,9,15,16,17 …
7-0 FAST_START_TX	Fast TSM TX "Jump-from" Point During a Fast TX Warmup, this value represents the starting TSM count for the portion of the warmup that is to be skipped over. If Fast TX Warmups are enabled, this count will never be reached; its place in the TSM warmup will be replaced by the contents of FAST_DEST_TX[7:0], thereby executing the jump.

23-16 —	Reserved
15-8 FAST_RX2TX_START_FC	TSM "Jump-to" point for RSM's FC RX-to-TX Transition During a Fast RX-to-TX transition (FAST_RX2TX_EN=1) the contents of this register represent the entry point (TSM count) in the TX warmup sequence to which the TSM jumps to when the Ranging Sequence Manager asserts fast_rx2tx_wu and fast_fc_wu. The TSM will jump from the RX “ON” phase to the TX “WARMUP” phase, starting at this count.
7-0 —	Reserved

52.4.4.2.2.4.3.1.10 TSM_TIMING00 (TIMING00)

Offset

Register	Offset
TIMING00	20h

Function

This register contains the timing values to control the assertion and deassertion times for both TX and RX sequences for the RF_ACTIVE TSM signal or signal group.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 RF_ACTIVE_RX_LO	De-assertion time setting for RF_ACTIVE (RX) This field sets the point during a TSM RX sequence (the tsm_count[7:0] value) at which the RF_ACTIVE signal or group will transition from HI to LO.
23-16 RF_ACTIVE_RX_HI	Assertion time setting for RF_ACTIVE_EN (RX) This field sets the point during a TSM RX sequence (the tsm_count[7:0] value) at which the RF_ACTIVE signal or group will transition from LO to HI.
15-8 RF_ACTIVE_TX_LO	De-assertion time setting for RF_ACTIVE (TX) This field sets the point during a TSM TX sequence (the tsm_count[7:0] value) at which the RF_ACTIVE signal or group will transition from HI to LO.
7-0 RF_ACTIVE_TX_HI	Assertion time setting for RF_ACTIVE (TX) This field sets the point during a TSM TX sequence (the tsm_count[7:0] value) at which the RF_ACTIVE signal or group will transition from LO to HI.

Field	Function
24 RX_INIT_EN_OVRD_EN	Override control for RX_INIT_EN 0b - Normal operation. 1b - Use the state of RX_INIT_EN_OVRD to override the signal "rx_init_en".
23 FREQ_TARG_LD_EN_OVRD	Override value for FREQ_TARG_LD_EN When FREQ_TARG_LD_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "freq_targ_ld_en". This bit is ignored when FREQ_TARG_LD_EN_OVRD_EN==0.
22 FREQ_TARG_LD_EN_OVRD_EN	Override control for FREQ_TARG_LD_EN 0b - Normal operation. 1b - Use the state of FREQ_TARG_LD_EN_OVRD to override the signal "freq_targ_ld_en".
21 TX_DIG_EN_OVRD	Override value for TX_DIG_EN When TX_DIG_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "tx_dig_en". This bit is ignored when TX_DIG_EN_OVRD_EN==0.
20 TX_DIG_EN_OVRD_EN	Override control for TX_DIG_EN 0b - Normal operation. 1b - Use the state of TX_DIG_EN_OVRD to override the signal "tx_dig_en".
19 DCOC_CAL_EN_OVRD	Override value for DCOC_CAL_EN When DCOC_CAL_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "dcoc_cal_en". This bit is ignored when DCOC_CAL_EN_OVRD_EN==0.
18 DCOC_CAL_EN_OVRD_EN	Override control for DCOC_CAL_EN 0b - Normal operation. 1b - Use the state of DCOC_CAL_EN_OVRD to override the signal "dcoc_cal_en".
17 SIGMA_DELTA_EN_OVRD	Override value for SIGMA_DELTA_EN When SIGMA_DELTA_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "sigma_delta_en". This bit is ignored when SIGMA_DELTA_EN_OVRD_EN==0.
16 SIGMA_DELTA_EN_OVRD_EN	Override control for SIGMA_DELTA_EN 0b - Normal operation. 1b - Use the state of SIGMA_DELTA_EN_OVRD to override the signal "sigma_delta_en".
15 PLL_DIG_EN_OVRD	Override value for PLL_DIG_EN When PLL_DIG_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "pll_dig_en". This bit is ignored when PLL_DIG_EN_OVRD_EN==0.
14	Override control for PLL_DIG_EN 0b - Normal operation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
PLL_DIG_EN_OVRD_EN	1b - Use the state of PLL_DIG_EN_OVRD to override the signal "pll_dig_en".
13 LDO_CAL_EN_OVRD	Override value for LDO_CAL_EN When LDO_CAL_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "ldo_cal_en". This bit is ignored when LDO_CAL_EN_OVRD_EN==0.
12 LDO_CAL_EN_OVRD_EN	Override control for LDO_CAL_EN 0b - Normal operation. 1b - Use the state of LDO_CAL_EN_OVRD to override the signal "ldo_cal_en".
11 DCOC_GAIN_CFG_EN_OVRD	Override value for DCOC_GAIN_CFG_EN When DCOC_GAIN_CFG_EN_OVRD_EN=1, this value overrides the mission mode state of the signal "dcoc_gain_cfg_en". This bit is ignored when DCOC_GAIN_CFG_EN_OVRD_EN==0.
10 DCOC_GAIN_CFG_EN_OVRD_EN	Override control for DCOC_GAIN_CFG_EN 0b - Normal operation. 1b - Use the state of DCOC_GAIN_CFG_EN_OVRD to override the signal "dcoc_gain_cfg_en".
9 TSM_IRQ1_STOP_TRIG_OVRD	Override value for TSM_IRQ1_STOP_TRIG When TSM_IRQ1_STOP_TRIG_OVRD_EN=1, this value overrides the mission mode state of the signal "tsm_irq1_stop_trig". This bit is ignored when TSM_IRQ1_STOP_TRIG_OVRD_EN==0.
8 TSM_IRQ1_STOP_TRIG_OVRD_EN	Override control for TSM_IRQ1_STOP_TRIG 0b - Normal operation. 1b - Use the state of TSM_IRQ1_STOP_TRIG_OVRD to override the signal "tsm_irq1_stop_trig".
7 TSM_IRQ0_START_TRIG_OVRD	Override value for TSM_IRQ0_START_TRIG When TSM_IRQ0_START_TRIG_OVRD=1, this value overrides the mission mode state of the signal "tsm_irq0_start_trig". This bit is ignored when TSM_IRQ0_START_TRIG_OVRD==0.
6 TSM_IRQ0_START_TRIG_OVRD_EN	Override control for TSM_IRQ0_START_TRIG 0b - Normal operation. 1b - Use the state of TSM_IRQ0_START_TRIG_OVRD to override the signal "tsm_irq0_start_trig".
5 TSM_RF_PRIORITY_OVRD	Override value for TSM_RF_PRIORITY When TSM_RF_PRIORITY_OVRD_EN=1, this value overrides the mission mode state of the signal "tsm_rf_priority". This bit is ignored when TSM_RF_PRIORITY_OVRD_EN==0.
4	Override control for TSM_RF_PRIORITY

Table continues on the next page...

52.4.4.2.2.5 Ranging Sequence Manager (RSM)

52.4.4.2.2.5.1 Introduction

The Ranging Sequence Manager (RSM) automates RX and TX operations across a set of frequencies in order to allow two devices to capture samples and other data for distance measurement calculations performed by software. To perform this task, the RSM acts like a small link layer, directing the transceiver to perform RX and TX as needed. The figure and list below shows the modules to which the RSM interfaces:

- To control the RSM's behavior in each frequency step, the RSM reads information stored in the configuration buffer located in the Packet RAM.
  - This configuration data consists of the desired CS mode, frequency, tone extension information, antenna permutation pattern, unidirectional mode, CFO setting, frequency calibration information (ext_ctune and ext_hpm_cal_factor in the figure) and phase adjustment used by the PLL.
  - If some packet exchange is expected in the step, RSM reads also Access Address and Payload for the two parts of the step in the Packet RAM.
- To store the result in each frequency step, RSM writes some statuses during the step processing in result buffer located in the Packet RAM. This information consists on the step number, the size of the step result, the AGC index, the Access Address detection flag, If the ext_ctune info is not used and the PLL performs ctune calibration, then on each frequency change the ctune_best_diff value is saved to Packet RAM by the RSM.
- The RSM provides control signals to the TSM to start receive or transmit operations, to switch between receive and transmit operations, and to end receive and transmit operations.
- For transmit, the RSM uses the tx_mod_disable signal to tell the TXDIG whether to modulate data (packet transmit) or not (tone transmit). For packet transmit, the RSM provides data included Access Address and payload informations to transmit to the TXDIG. Note that the RSM does not control the transmit power; that should be programmed in the TXDIG

- When receiving packets, the RSM reads packet configuration information from the Packet RAM which is used by the PHY as the access address (AA) and is also provided as "RTT bits" to the PHY. Depending on RTT type, RSM provides also expected payload to RX_DIG. It also directs the RTT (round trip time) results from the PHY, the NADM results from RX_DIG, AA_matched status, the TPM and CFO_EST values to the Packet RAM.
- When receiving tones, the RSM provides a dma_trigger and a dma_mask output for use by the Transceiver DMA module. The dma_trigger asserts whenever RSM's RX_EN or TX_EN bitfields are set. The dma_mask asserts at a programmable delay (DMA_DLY or DMA_DLY0 bitfields) from the start of receive, and remains asserted for a programmable duration (DMA_DUR or DMA_DUR0 bitfields). The delay is programmed to allow the receiver analog and digital time to settle, and the duration programmed for the desired sample capture duration. The RSM also sends a signal to the PLL (ext_rx_lpm_mod_dis in the figure) which indicates that for tone reception the PLL should disable low port modulation and instead use a constant value (programmed in PLL) for high port modulation. RSM directs the PCT computation from RX_DIG to the Packet RAM.
- For ranging operations which use antenna switching, the RSM provides triggers to the Localization Control module; lcl_rx_trigger is used in PM_RX states and lcl_tx_trigger is used in PM_TX states. Since the PM duration can take four different values (T_PM0-3), the RSM also outputs a signal (lcl_alt_reg_sel[1:0]) to the Localization Control module to indicate which T_PM duration is currently being used. Note that if the Localization Control module is used in conjunction with RSM, in PM_RX states the Localization Control module will provide the DMA mask control to the Transceiver DMA and the RSM's DMA mask feature should be disabled. Refer to Antenna Control Used With RSM for more information on LCL_CTRL usage with RSM.
- The RSM "active" output is used by RXDIG and TXDIG in order to keep the Rx/Tx clocks running while the RSM is active. This is required for timestamping continuity for RTT (i.e., the relationship of fine time-stamp to the corresponding integer reference clock timestamp is maintained) as well as tone exchange (i.e., digital down mixing of the IF frequency & CIC clocking randomness do not contribute additional phase jitter). This doesn't require any software configuration except for the RXDIG control bit CIC_CNTR_FREE_RUN_EN which resets to 1, and should remain set to ensure the clocks remain running.

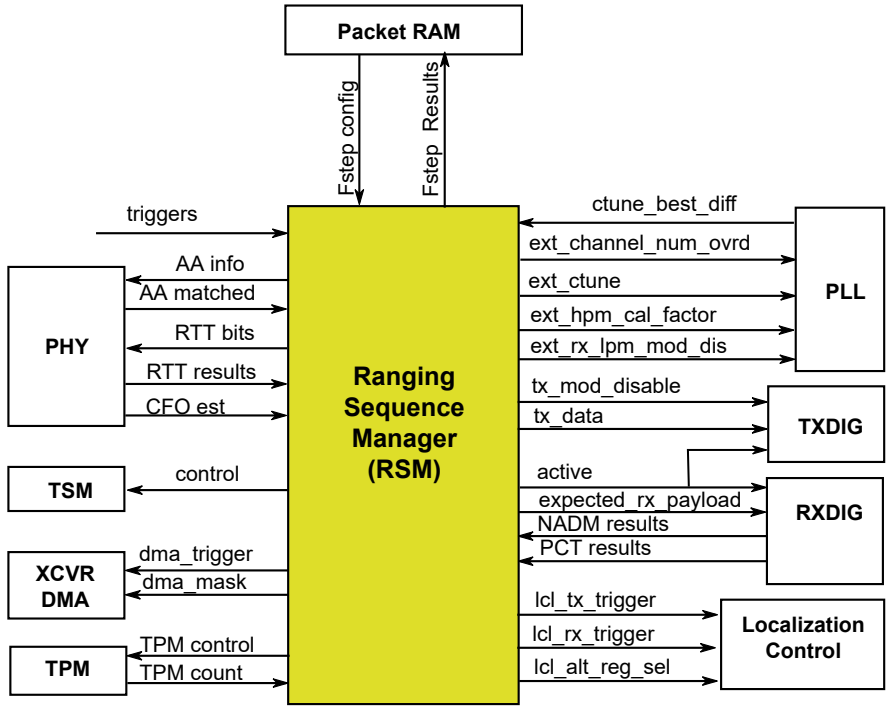

Figure 322. RSM Interfaces

The RSM supports two modes of operation: SQTE (Secure Quick Tone Exchange) and PDE (Phase-based Distance Estimation). These modes, which are described in detail in the following sections, have a good deal in common, including the following:

- The RSM can be configured to begin with a transmit operation (TX_EN bitfield programmed to 1) or receive operation (RX_EN bitfield programmed to 1). These correspond to the Initiator and Reflector roles for SQTE, and to Measuring Device (MD) and Reflector Device (RD) roles for PDE, respectively.

- The number of frequency steps is configurable in RSM_CTRL0[RSM_STEPS] register.
- The durations of the states associated with receive, transmit, frequency change transition and role swap transition (RX to TX or TX to RX) are configurable in RSM_CTRL1 and RSM_CTRL2 registers (T_PM, T_FC, and T_IP2 bitfields), though SQTE has additional configurability (T_IP1 and T_S bitfields).
- We will have possibility to manage T_IP1 independent of T_IP2 . The TSM is now aligned with RSM functionality and the TSM is updated automatically with jump_forward mechanism in link with T_IP1 and T_IP2 values . This is transparent for the software. This mechanism is only compatible with generic TSM and not classic mode which is not used anymore.
- The format used for each frequency step is configurable, though for PDE this only includes tone exchanges, while for SQTE this includes tone and/or packet exchanges.

52.4.4.2.2.5.2 Secure Quick Tone Exchage (SQTE) Mode

The MODE=0 setting is for SQTE, which is shown in the figure below from the Bluetooth LE standards body. In this mode, two devices (one assuming the role of "Initiator" and the other the role of "Reflector") take turns exchanging packets and/or tones. The first set of exchanges are referred to as the Frequency Compensation Step (FCS), which consists of a bidirectional packet exchange and a unidirectional Frequency Measurement (FM) step which is a tone transfer from Reflector to Initiator. The main purpose of FCS is to allow the Initiator to determine the frequency offset of the Reflector with respect to the frequency of the Initiator.

There are a programmable number of SQTE Steps, each of which are individually configured to take one of four formats, as shown in the figure: the FCS step, a Pk-Pk step which only has packet exchange; a Tn-Tn step which only has tone exchange; or a Pk-Tn-Tn-Pk which has both packet and tone exchanges. Usually, the FCS is only used in the first step, but the RSM can be programmed so that it is also used in other steps. Note that T_RD defined in the Channel Sounding standard is not shown in this figure but it is already included in T_FC , T_IP1 and T_IP2.

Data is collected during packet reception and tone reception for each "SQTE Step" by both Initiator and Reflector for later post-processing by software. Note that the packets exchanged during SQTE are not normal Bluetooth LE packet; they are comprised of an 8bit (or 16bit for 2Mbps operation) preamble, a 32bit Access Address sequence, a 4bit trailer and followed by a potential 32-bit/64-bit/96-bit/128-bit payload which is known a priori by both Initiator and Reflector

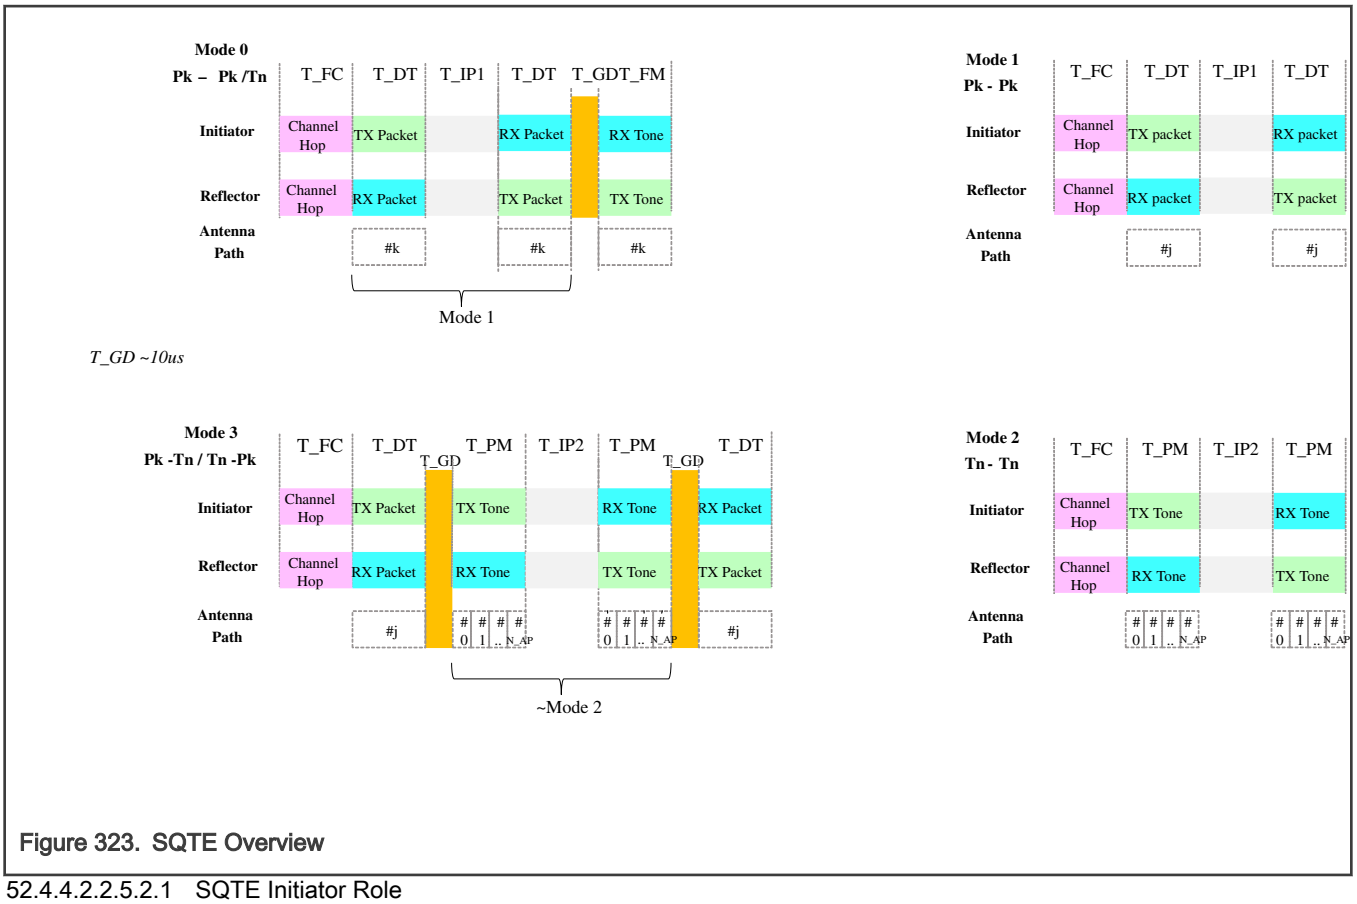

Figure 323. SQTE Overview

52.4.4.2.2.5.2.1 SQTE Initiator Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Initiator role (TX_EN=1). Some of the states are duplicated in the figure to more clearly show the state transition sequence for the four different step format types (FCS, Pk-Pk, Tn-Tn, and PkTn-Tn-Pk). The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- DELAY. If a trigger delay is used, after the selected trigger is recognized, the RSM will stay in the DELAY state for TRIG_DLY microseconds.
- WU (Warmup). The RSM asserts its tx_en output to the TSM and then waits for the TSM's wu_complete signal before leaving this state. The figure shows that WU always transitions to the DT_TX state of the FCS step format but this assumes that the FCS step format is selected for the first frequency step (which is the expected behavior).
- FC_RX2TX (Frequency Change RX-to-TX transition). In this state the RSM directs the TSM to switch from RX to TX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- DT_TX (Packet Transmit). In this state the RSM directs the transceiver to transmit a "packet" with a preamble, an Access Address, a trailer and a potential payload. The duration of this state depends on the RATE and RTT_TYPE bitfields.
- DT_RX (Packet Receive). In this state the RSM directs the transceiver to receive a "packet" with a preamble, an Access Address data, a trailer and a potential payload. The nominal duration of this state depends on the RATE and RTT_TYPE bitfields.
- FM_RX (Tone Receive for FCS). In this state, the RSM directs the transceiver to receive a "tone". The nominal duration of this state is the value defined in RSM_CTRL5[RSM_T_FM] register.
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1 depending on the t_pm_sel bitfield in the configuration step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1 depending on the t_pm_sel bitfield in the configuration step data stored in Packet RAM

- IP1_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP1
- IP2_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP2
- S_TX2TX (Short TX-to-TX transition). In this state, the RSM transitions between packet and tone transmit. The duration of this state is T_S
- S_RX2RX (Short RX-to-RX transition). In this state, the RSM transitions between packet and tone receive. The nominal duration of this state is T_S
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

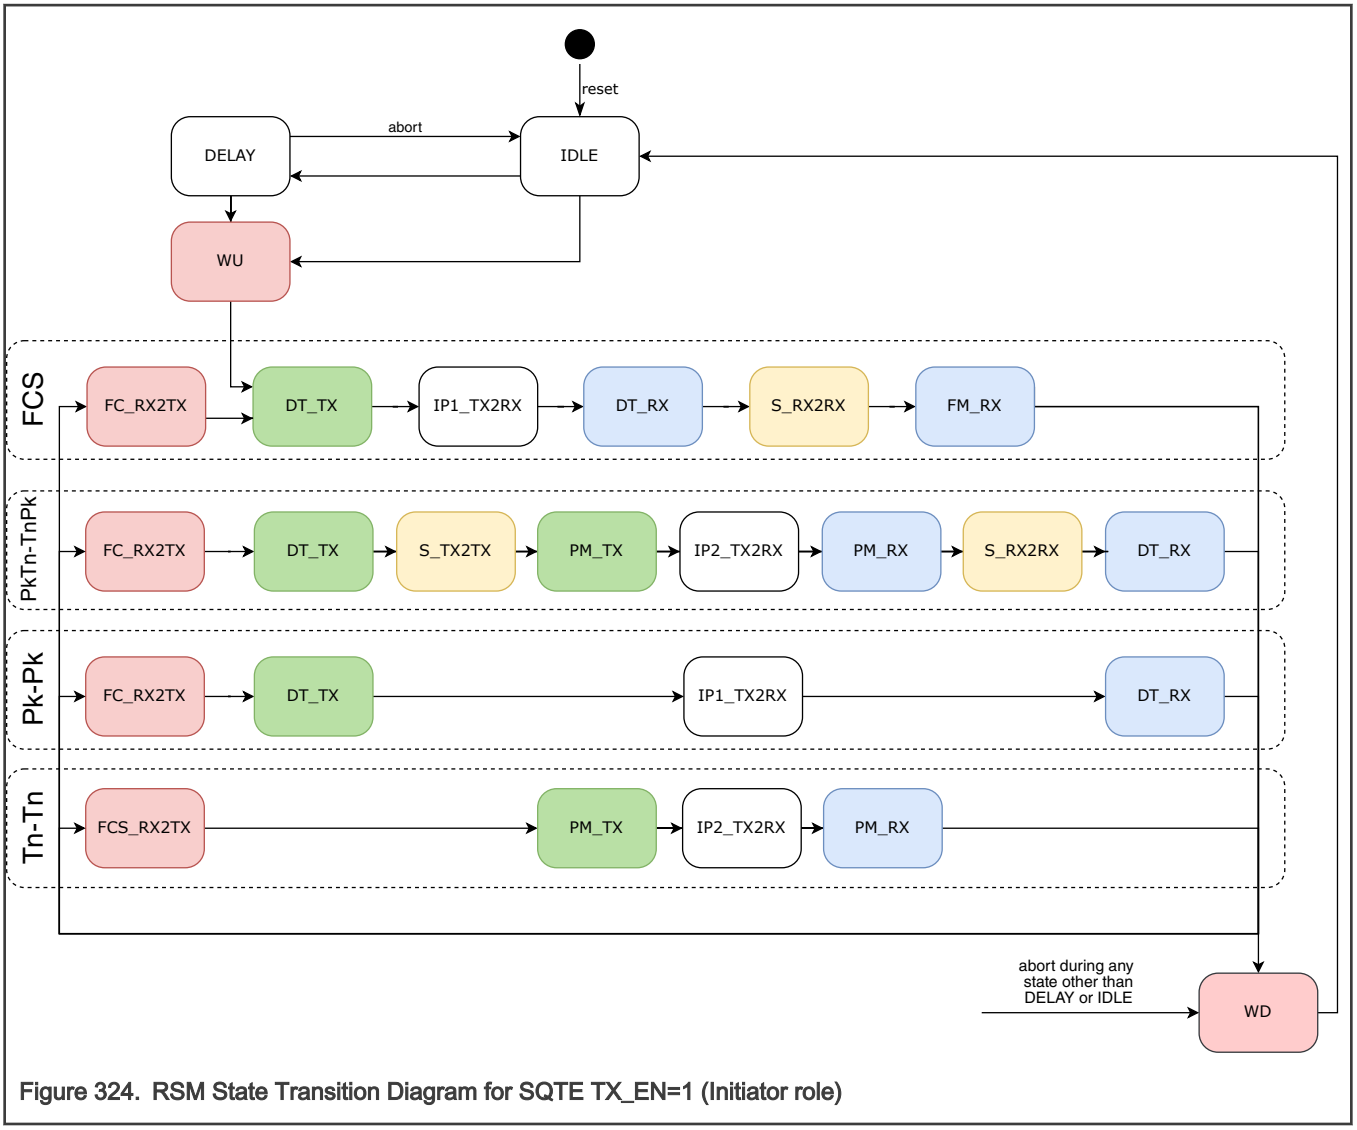

Figure 324. RSM State Transition Diagram for SQTE TX_EN=1 (Initiator role)

Any one of three methods can be used to start RSM operation when the module is configured for SQTE in the Initiator role (TX_EN=1).

1. The RSM is initiated by a hardware trigger (TRIG_SEL>0) which asserts during a previous RX or TX operation controlled by the Bluetooth or Generic LL
2. The RSM is initiated by a software trigger (TRIG_SEL=0)

3. The RSM is initiated immediately (TRIG_DLY=0) by a hardware trigger (TRIG_SEL=seq_spare3) which asserts during a dummy TX operation controlled by the Bluetooth or Generic LL

The figure below shows the timing corresponding to method #1 above. During a previous RX or TX operation controlled by the Bluetooth or Generic LL, a trigger to the is RSM asserted, and then the LL completes it RX or TX operation as usual. Meanwhile, upon recognizing the trigger, the RSM's trigger delay counter starts. After a programmable TRIG_DLY, the RSM will direct the TSM to start a transmit operation with a fast warmup if FAST_FC_TX_WU is set or a normal warmup if not. The state transitions associated with the four frequency step formats when TX_EN=1 are as described in the previous state transition diagram figure; note that the timing figure below only shows the Frequency Compensation Step and Pk-Tn-Tn-Pk step formats.

After the last frequency step, the RSM transitions to the WD state where the TSM is warmed down, and then to the IDLE state.

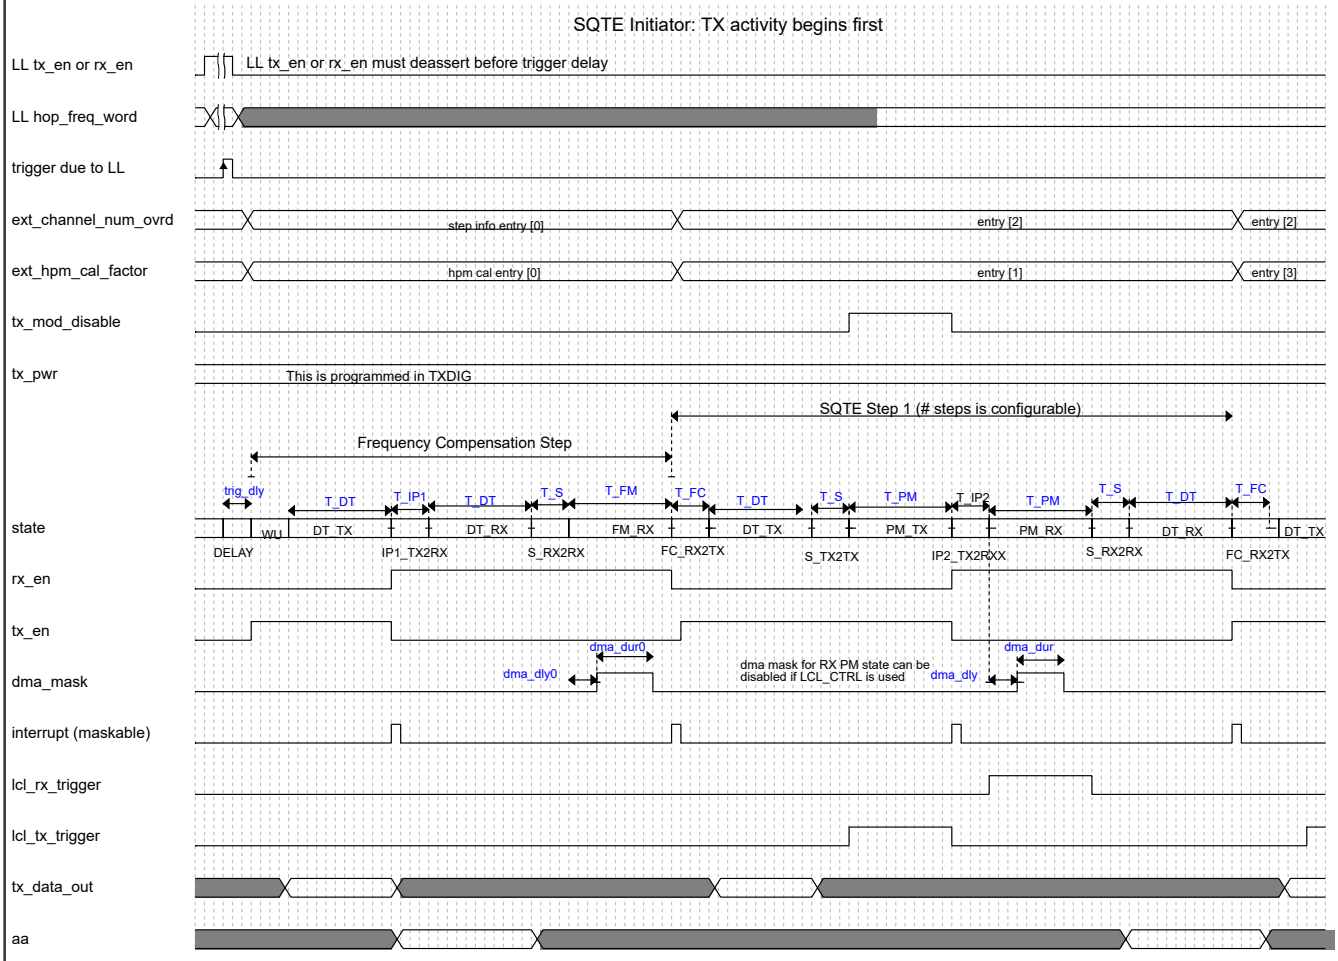

Figure 325. SQTE Mode Timing with TX_EN=1 (Initiator role)

The timing for method #2 (software trigger) is similar to above, but no link layer operation is required. Instead, if TRIG_SEL=0, then the TRIG_DLY counter begins as soon as RSM's TX_EN is programmed to 1.

The timing for method #3 (hardware trigger with dummy LL event) is also similar to above, but differs in the link layer and trigger operation. In this case, the link layer begins a "dummy" TX operation which is only used to trigger the RSM. The RSM trigger for seq_spare3 should be used and the RSM's TRIG_DLY programmed to 0. The TSM should be programmed so that seq_spare3 asserts at time 0. (Seq_spare3 can be programmed to de-assert at any time after 0.) The link layer only needs to assert its "tx_en" signal to the TSM long enough to generate the seq_spare3 trigger to the RSM; after that the link layer can "abort" its TX operation. (Any duration for link layer tx_en from 4us to ~40us should be okay.) The trigger timing for method #2 is shown in the figure below.

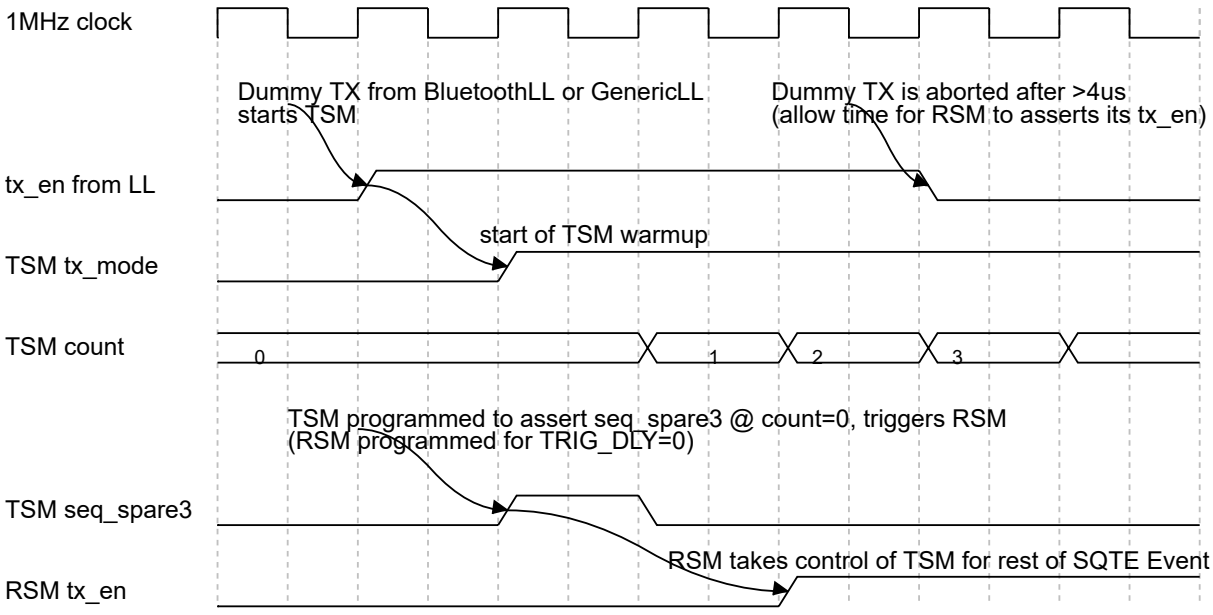

Figure 326. SQTE TX trigger method #3: Dummy LL TX Event for TX_EN=1 (Initiator role)

52.4.4.2.2.5.2.2 SQTE Reflector Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Reflector role (RX_EN=1). Some of the states are duplicated in the figure to more clearly show the state transition sequence for the four different step format types (FCS, Pk-Pk, Tn-Tn, and PkTn-Tn-Pk). The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- DELAY. If a trigger delay is used, after the selected trigger is recognized, the RSM will stay in the DELAY state for TRIG_DLY microseconds.
- WU (Warmup). The RSM asserts its rx_en output to the TSM and then waits for the TSM's wu_complete signal before leaving this state. The figure shows that WU always transitions to the DT_RX state of the FCS step format but this assumes that the FCS step format is selected for the first frequency step (which is the expected behavior).
- FC_TX2RX (Frequency Change TX-to-RX transition). In this state the RSM directs the TSM to switch from TX to RX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- DT_TX (Packet Transmit). In this state the RSM directs the transceiver to transmit a "packet" with a preamble, an Access Address, a trailer and a potential payload. The duration of this state depends on the RATE and RTT_TYPE bitfields.
- DT_RX (Packet Receive). In this state the RSM directs the transceiver to receive a "packet" with a preamble, an Access Address, a trailer and a potential payload. The nominal duration of this state depends on the RATE and RTT_TYPE bitfields.
- FM_TX (Tone Transmit for FCS). In this state, the RSM directs the transceiver to transmit a "tone". The duration of this state is the value defined in RSM_CTRL5[RSM_T_FM] register.
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1 depending on the t_pm_sel bitfield in the configuration step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1dependening on the t_pm_sel bitfield in the configuration step data stored in Packet RAM
- IP1_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP1

- IP2_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP2
- S_TX2TX (Short TX-to-TX transition). In this state, the RSM transitions between packet and tone transmit. The duration of this state is T_S
- S_RX2RX (Short RX-to-RX transition). In this state, the RSM transitions between packet and tone receive. The nominal duration of this state is T_S
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

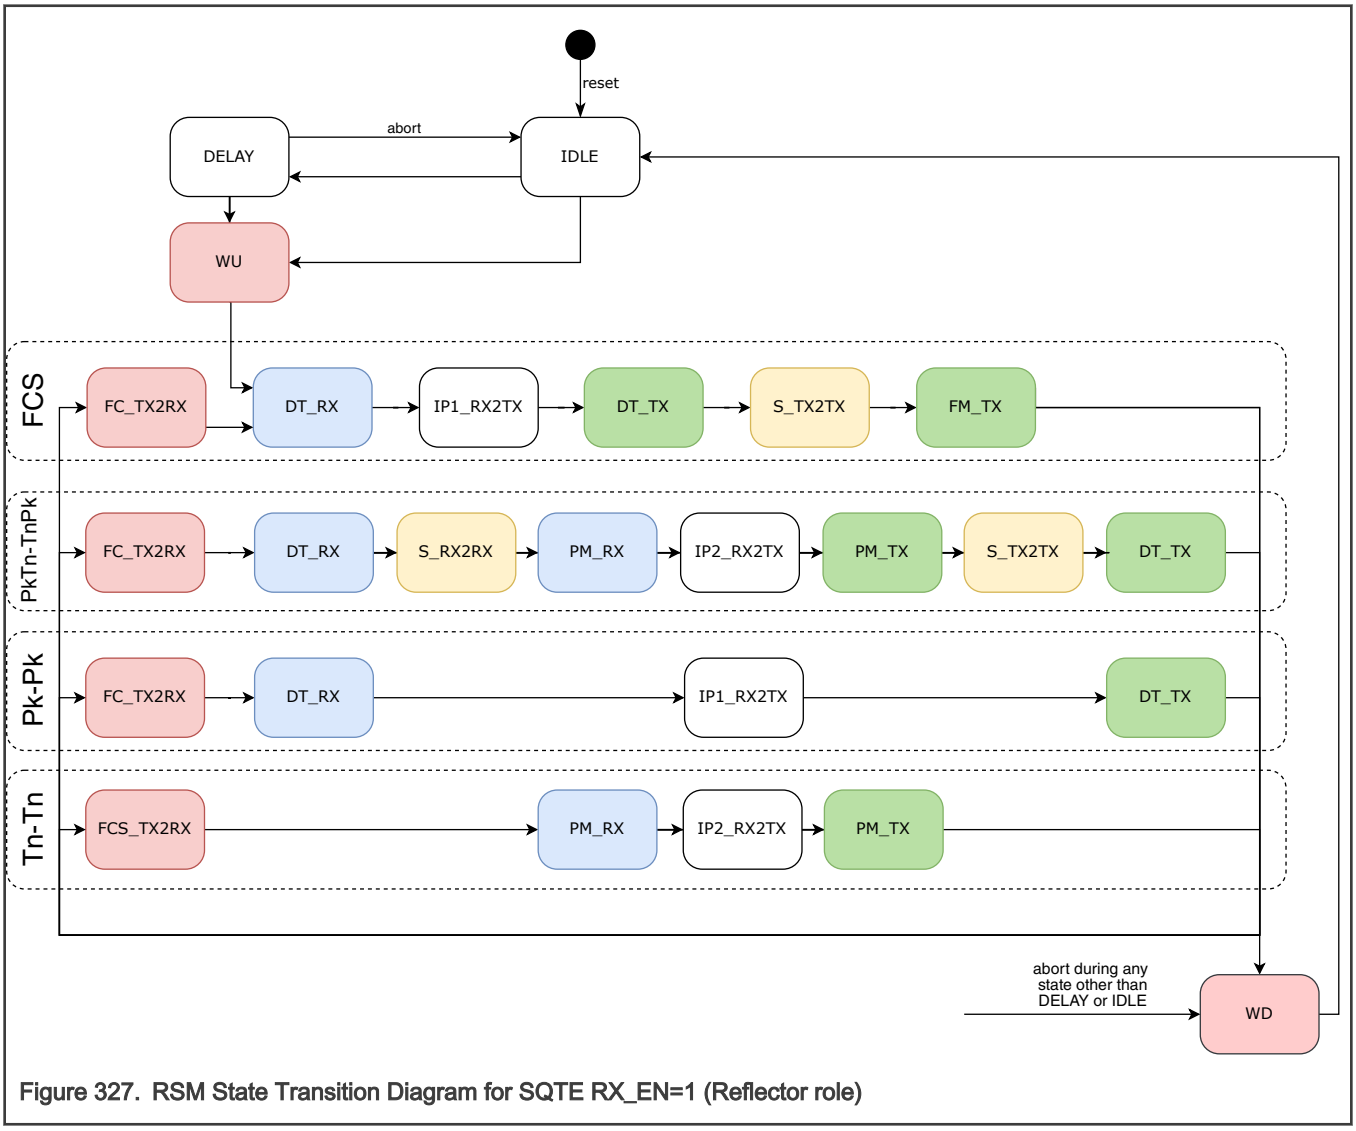

Figure 327. RSM State Transition Diagram for SQTE RX_EN=1 (Reflector role)

Any one of three methods can be used to start RSM operation when the module is configured for SQTE in the Reflector role (RX_EN=1).

1. The RSM is initiated by a hardware trigger (TRIG_SEL>0) which asserts during a previous RX or TX operation controlled by the Bluetooth or Generic LL
2. The RSM is initiated by a software trigger (TRIG_SEL=0)
3. The RSM is initiated immediately (TRIG_DLY=0) by a hardware trigger (TRIG_SEL=seq_spare3) which asserts during a dummy RX operation controlled by the Bluetooth or Generic LL

The figure below shows the timing corresponding to method #1 above. During a previous RX or TX operation controlled by the Bluetooth or Generic LL, a trigger to the is RSM asserted, and then the LL completes it RX or TX operation as usual. Meanwhile, upon recognizing the trigger, the RSM's trigger delay counter starts. After a programmable TRIG_DLY, the RSM will direct the TSM to start a receive operation with a fast warmup if FAST_FC_RX_WU is set or a normal warmup if not. Unless the DT_RX_SYNC_DIS bit is set, then during the FCS RX packet, the RSM will sync the timing using the AA matched signal from the PHY. When SQTE begins with receive, the RSM also utilizes the DMA_DLY0 and DMA_DUR0 to define when and how long dma_mask asserts during the Frequency Error Measurement (T_FM) Step. The state transitions associated with the four frequency step formats when RX_EN=1 are as described in the previous state transition diagram figure; note that the timing figure below only shows the Frequency Compensation Step and Pk-Tn-Tn-Pk step formats.

After the last frequency step, the RSM transitions to the WD state where the TSM is warmed down, and then to the IDLE state.

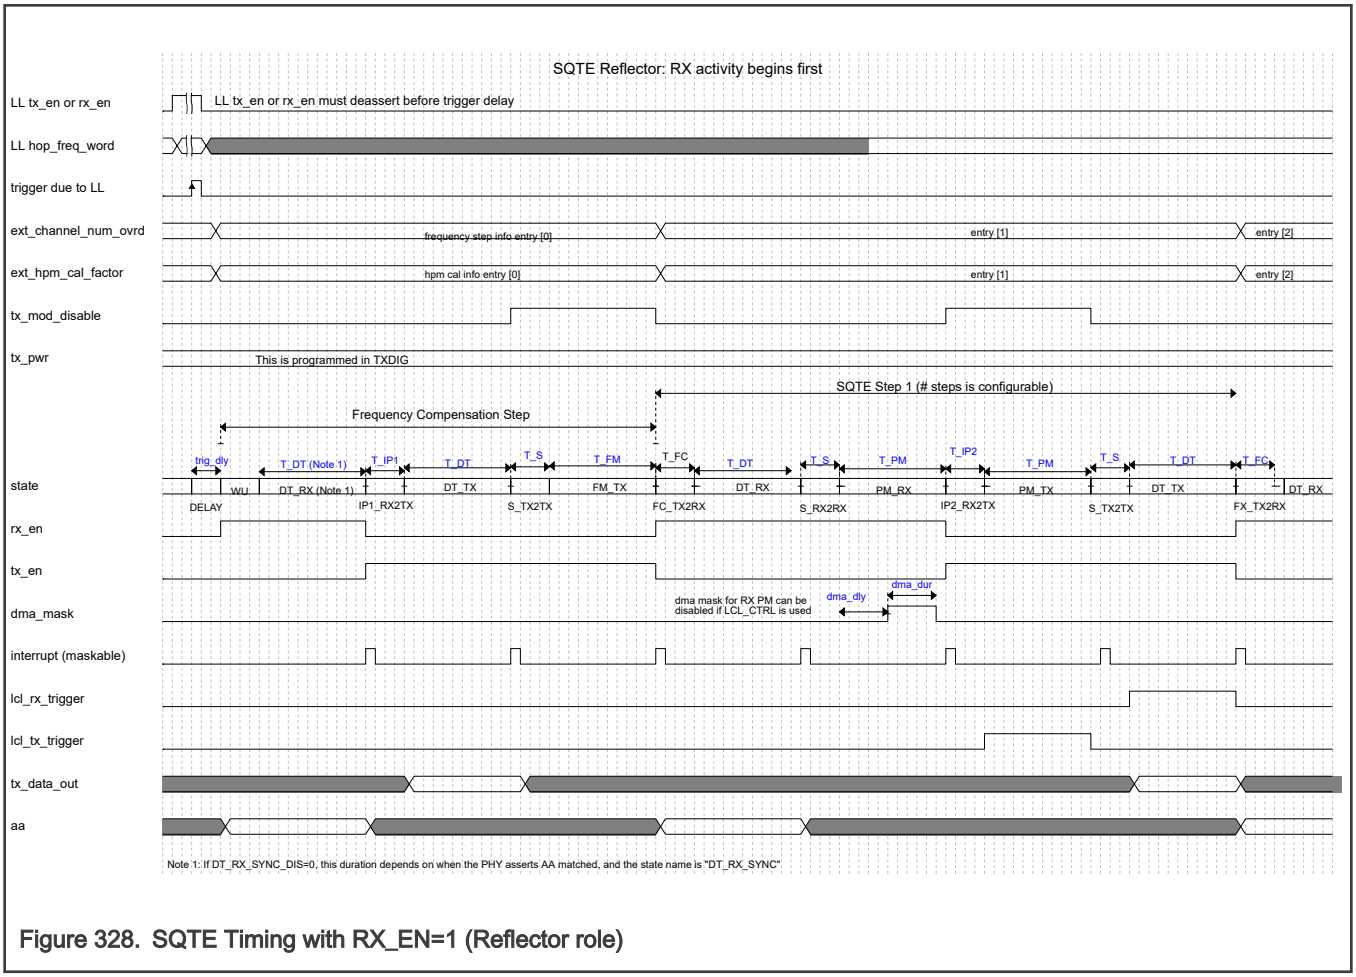

Figure 328. SQTE Timing with RX_EN=1 (Reflector role)

The timing for method #2 (software trigger) is similar to above, but no link layer operation is required. Instead, if TRIG_SEL=0, then the TRIG_DLY counter begins as soon as RSM's RX_EN is programmed to 1.

The timing for method #3 (hardware trigger with dummy LL event) is also similar to above, but differs in the link layer and trigger operation. In this case, the link layer begins a "dummy" RX operation which is only used to trigger the RSM. The RSM trigger for seq_spare3 should be used and the RSM's TRIG_DLY programmed to 0. The TSM should be programmed so that seq_spare3 asserts at time 0. (Seq_spare3 can be programmed to de-assert at any time after 0.) The link layer only needs to assert its "rx_en" signal to the TSM long enough to generate the seq_spare3 trigger to the RSM; after that the link layer can "abort" its RX operation. (Any duration for link layer rx_en from 4us to ~40us should be okay.) The trigger timing for method #2 is shown in the figure below.

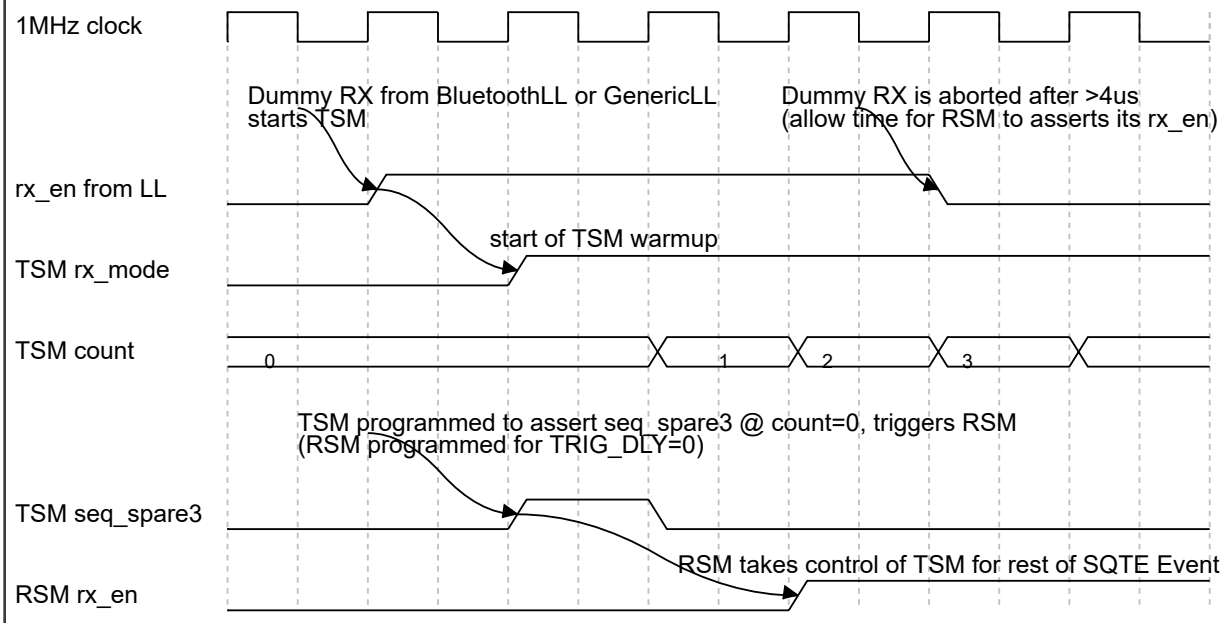

Figure 329. SQTE RX trigger method #3: Dummy LL RX Event for RX_EN=1 (Reflector role)

52.4.4.2.2.5.2.3 SQTE Tone extension

To support the standard wit h tone extension management , an interaction between LCL and RSM is managed to take into account the tone extension.

Modes 2 and 3 will need to manage antenna switching in an order defined in the standard, the permutation will be done according to configuration information in packet ram STEP_CFG[ANT_PERMUT[4:0]].

For packets and mode 0, we will use the configuration packet_ram STEP_CFG[[ANT_CS_SYNC[1:0]].

Then, in mode 3 we have a mixed between packets and tone , that means that ant_cs_sync pktram field will manage antenna number for packets and ant_permut pktram field will manage antenna number during tones.

The tone extension parameter will come from packet ram configuration STEP_CFG[TONE_EXT[1:0]]. The bit 0 will indicate if we have a tone extension during the Initiator transmission (the first part of the transfer between t_fc and t_ip) and the bit 1 will indicate if tone extension is present or not during the Reflector transmission (after t_ip). In the device in reception, the measurement will be available whatever the tone extension (to be able to detect attacks by checking if power is present or not without tone extension) .

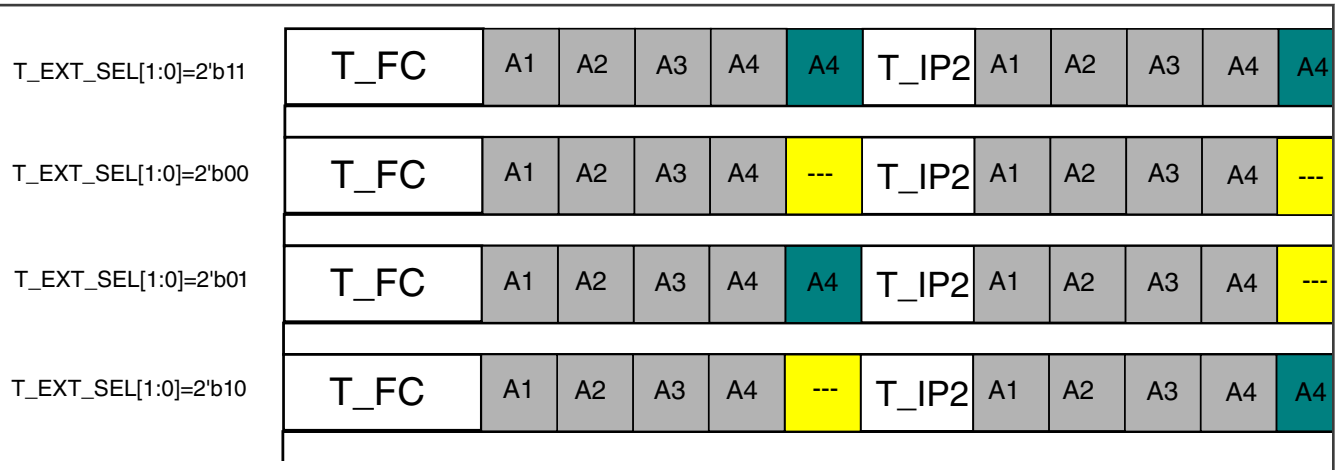

Figure 330. Tone extension mode 2 (example 4 antennas)

Concerning mode 3 , we have asymmetric management after t_ip2, this can lead to empty slot at the end of the step after the packet, as we can show below:

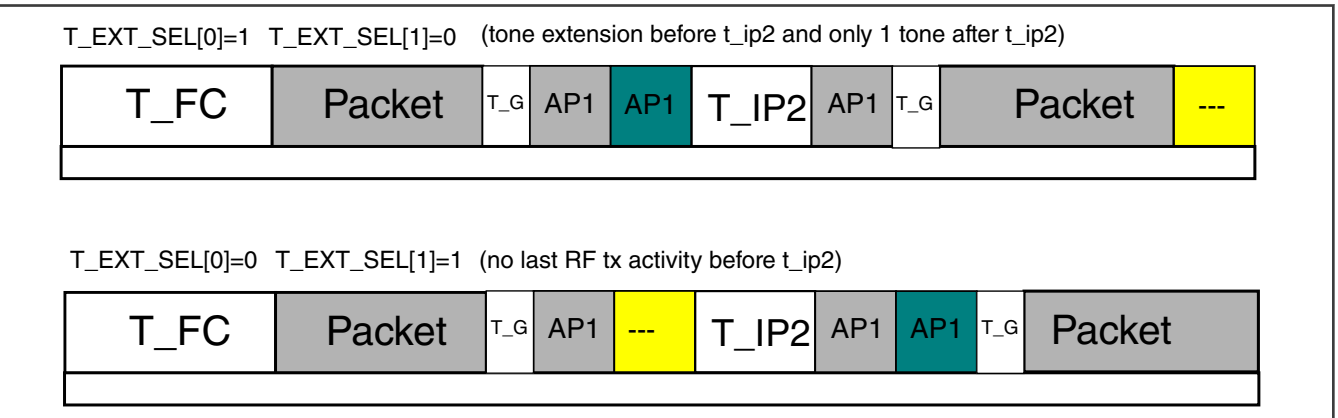

Figure 331. Tone extension mode 3 (example 1 antenna)

For tone extension part, the TX must be switched OFF when t_ext_sel from pktram is set to 0 , for modes 2 and 3. Therefore, a rx measurement will still occur and could be also used for security as we should not detect any activity during this period.

The antenna order will be managed by antenna permutation during tones described in LCL chapter, the order will be defined depending on the number of antenna , defined in the Bluetooth Low Energy Channel Sounding standard.

The tone_ext[1:0] from the Packet Ram configuration buffer allows more possibilities than the current standard definition. So, some restrictions on tone_ext[1:0] field have to be taken into account during the programmation of this field to be aligned with the Channel Sounding standard and the fact that a device in RX mode has always to check the presence or not of the tone extension.

```
If (mode==2) begin
   if (device==reflector)
       tone_ext={tone_ext_part2, 1'b1};
   else if (device==initiator)
       tone_ext={1'b1, tone_ext_part1};
   else if (device==sniffer)
       tone_ext={2'b11};
end
else if (mode==3) begin
   if (device==reflector)
       tone_ext={tone_ext_part2, 1'b1};
   else if (device==initiator)
       tone_ext={tone_ext_part2, tone_ext_part1};
   else if (device==sniffer)
       tone_ext={tone_ext_part2, 1'b1};
end
```

52.4.4.2.2.5.3 Phase-based Distance Estimation (PDE) Mode

The MODE=1 setting is for PDE mode. In this mode the transceiver is not warmed down from the LL receive or transmit operation prior to the RSM taking control. Instead, the RSM is allowed to extend the receive or transmit operation initiated by the LL. For this to work correctly, the frequency used by the LL must match the frequency information in the first set of frequency step information read by the RSM from the Packet RAM (seeConfiguration Stored in Packet RAM).

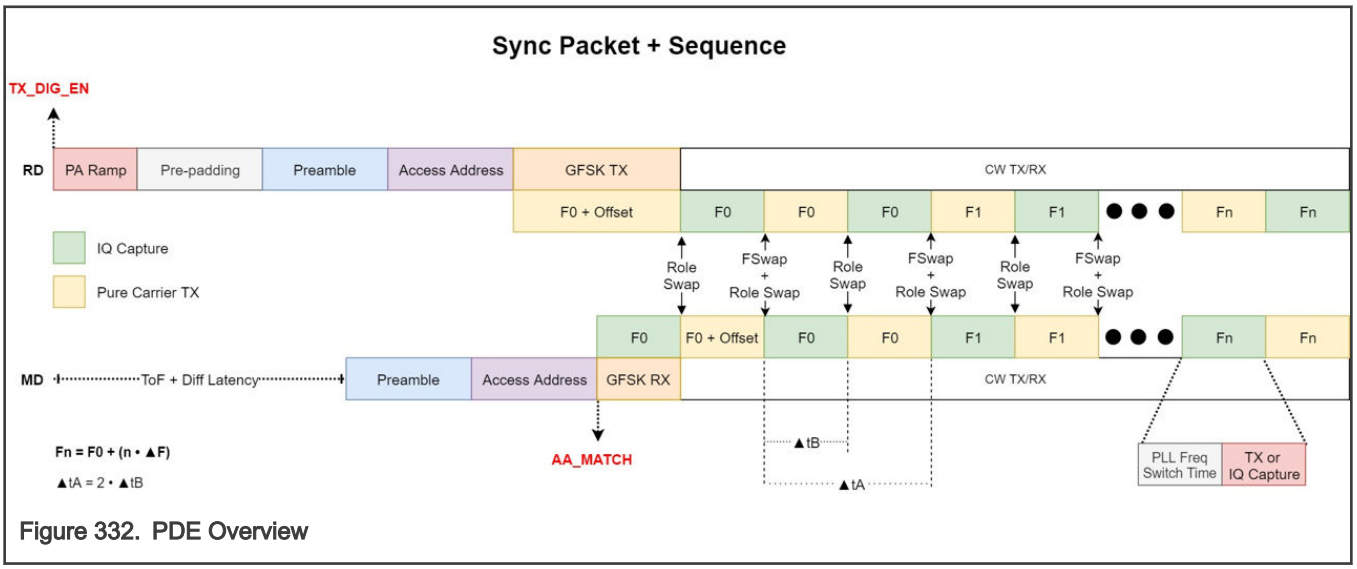

Figure 332. PDE Overview

52.4.4.2.2.5.3.1 PDE TX_EN=1 (RD Role)

The RSM state diagram below illustrates the RSM states used for PDE with TX_EN=1 (RD Role). Note that unlike SQTE, only one step format (Tn-Tn) is used, so the state diagram is greatly simplified. The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- EXT_TX. After the trigger is recognized, the RSM will enter and stay in this state for TRIG_DLY microseconds. During this state, the RSM will assert its tx_en output to the TSM. The link layer continues to control the transceiver at entry to this state, but is expected to de-assert its tx_en output by the time the TRIG_DLY timer expires.

- FC_RX2TX (Frequency Change RX-to-TX transition). In this state the RSM directs the TSM to switch from RX to TX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 depending on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 depending on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP2_TX2RX (Role swap TX-to-RX transition). In this state, the RSM directs the TSM to switch from TX to RX mode. The nominal duration of this state is T_IP2
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

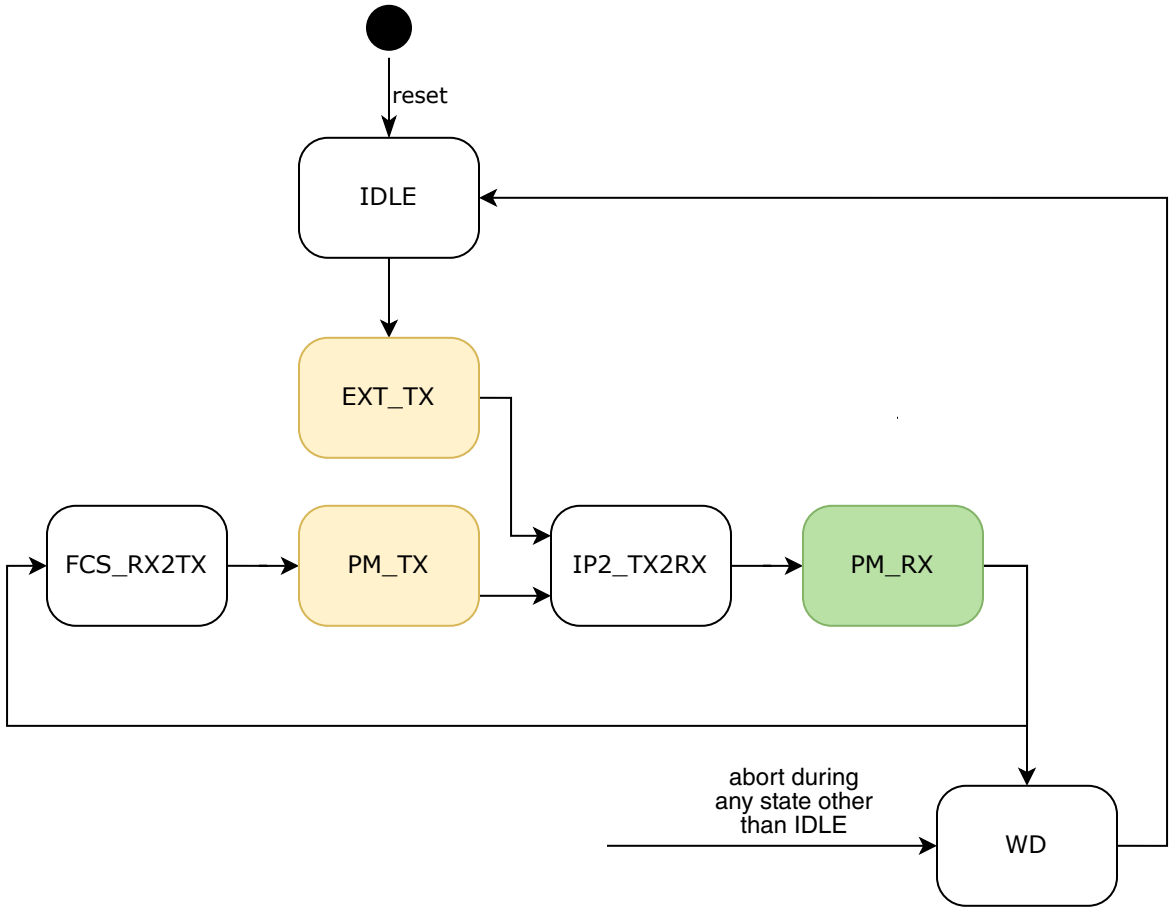

Figure 333. RSM State Transition Diagram for PDE TX_EN=1 (RD role)

The figure below shows PDE operation when the RSM is configured to begin with transmit operation. On assertion of the trigger (for example, TX_DIG_EN from the TSM), the RSM will assert its tx_en signal to keep the transmit operation active until TRIG_DLY expires. By that time, the LL's tx_en should be de-asserted so that the RSM can take full control of the transceiver. When the RSM is configured to begin with transmit, frequency steps occur on RX2TX transitions. Role swaps without frequency changes occur on TX2RX transitions.

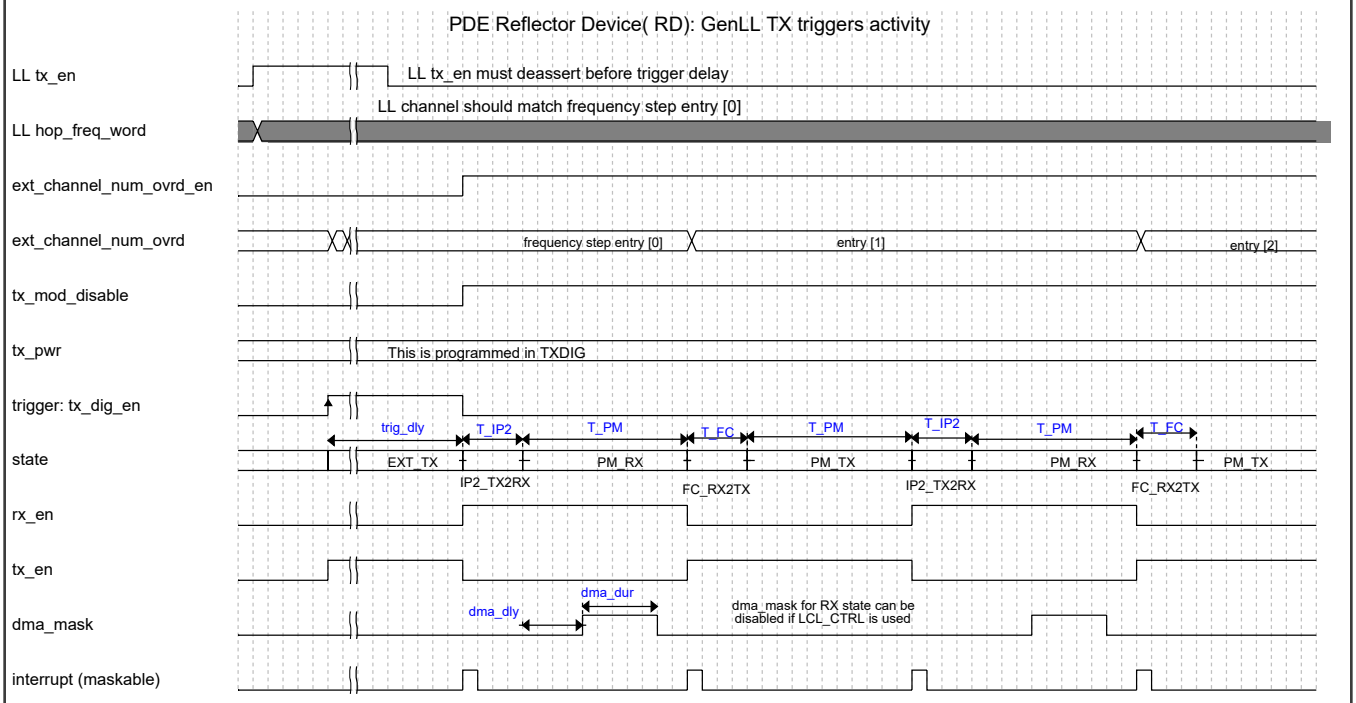

Figure 334. PDE Timing with TX_EN=1 (RD Role)

52.4.4.2.2.5.3.2 PDE RX_EN=1 (MD Role)

The RSM state diagram below illustrates the RSM states used for PDE with RX_EN=1 (MD Role). Note that unlike SQTE, only one step format (Tn-Tn) is used, so the state diagram is greatly simplified. The states are described as follows:

- IDLE. This is the state the RSM is in after a reset and after a sequence has completed (or been aborted).
- EXT_RX. After the trigger is recognized, the RSM will enter and stay in this state for TRIG_DLY microseconds. During this state, the RSM will assert its rx_en output to the TSM. The link layer continues to control the transceiver at entry to this state, but is expected to de-assert its rx_en output by the time the TRIG_DLY timer expires.
- FC_TX2RX (Frequency Change TX-to-RX transition). In this state the RSM directs the TSM to switch from TX to RX mode, change the radio frequency, and start a new step. The nominal duration of this state is T_FC
- PM_RX (Tone Transmit). In this state the TSM directs the transceiver to receive a "tone". The nominal duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 depending on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- PM_TX (Tone Transmit). In this state the TSM directs the transceiver to transmit a tone. The duration of this state is T_PM0, T_PM1, T_PM2, or T_PM3 depending on the t_p_sel[1:0] bitfield in the frequency step data stored in Packet RAM
- IP2_RX2TX (Role swap RX-to-TX transition). In this state, the RSM directs the TSM to switch from RX to TX mode. The nominal duration of this state is T_IP2
- WD (Warmdown). The RSM de-asserts its rx_en or tx_en (depending on what state it was in prior to warmdown) directing the TSM to warm down the transceiver

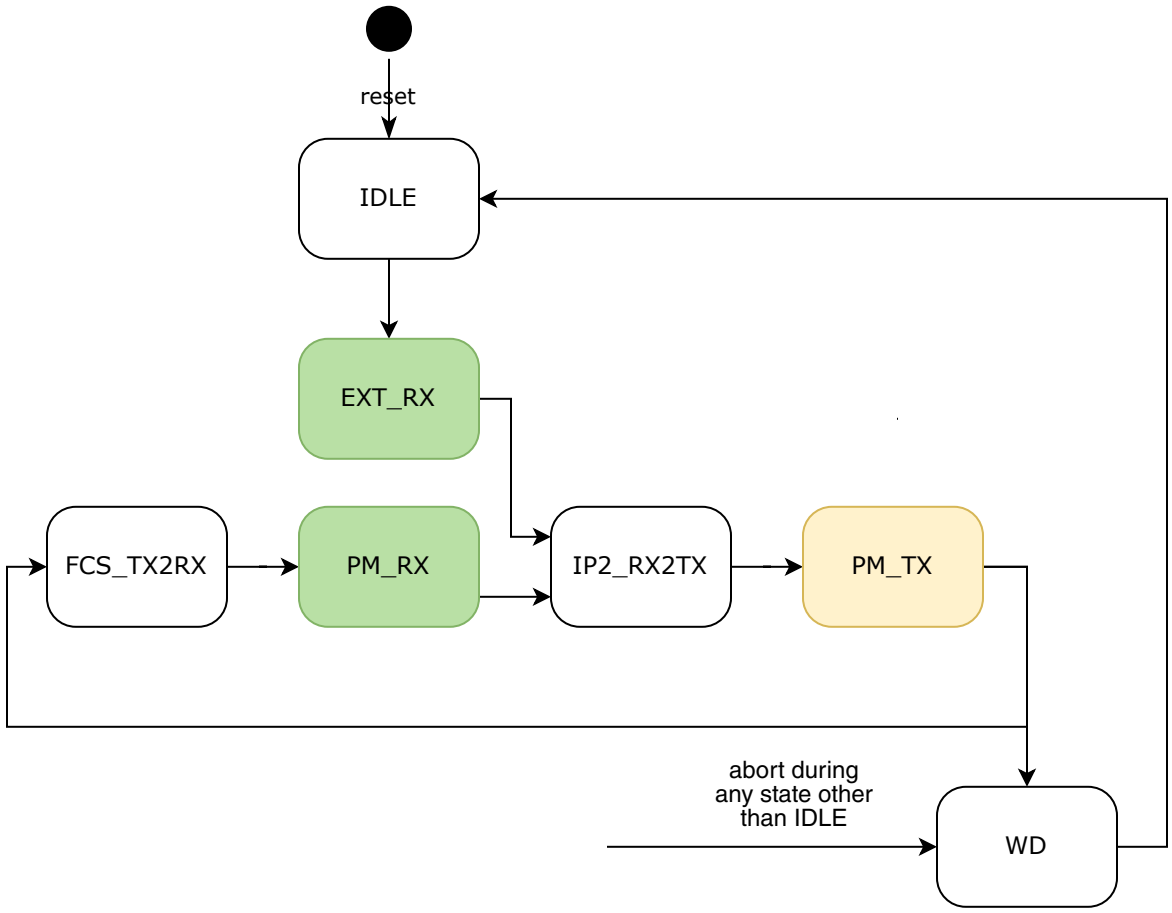

Figure 335. RSM State Transition Diagram for PDE RX_EN=1 (MD role)

The figure below show PDE operation when the RSM is configured to begin with receive operation. On assertion of the trigger (for example, crc_valid), the RSM will assert its rx_en signal to keep the receive operation active until TRIG_DLY expires. By that time, the LL's rx_en should be de-asserted so that the RSM can take full control of the transceiver. When the RSM is configured to begin with receive, frequency steps occur on TX2RX transitions; role swaps without frequency changes occur on RX2TX transitions. When PDE begins with receive, the trigger is also a timing reference for DMA_DLY0 and DMA_DUR0, which define when and how long the dma_mask will be asserted for the initial receive operation.

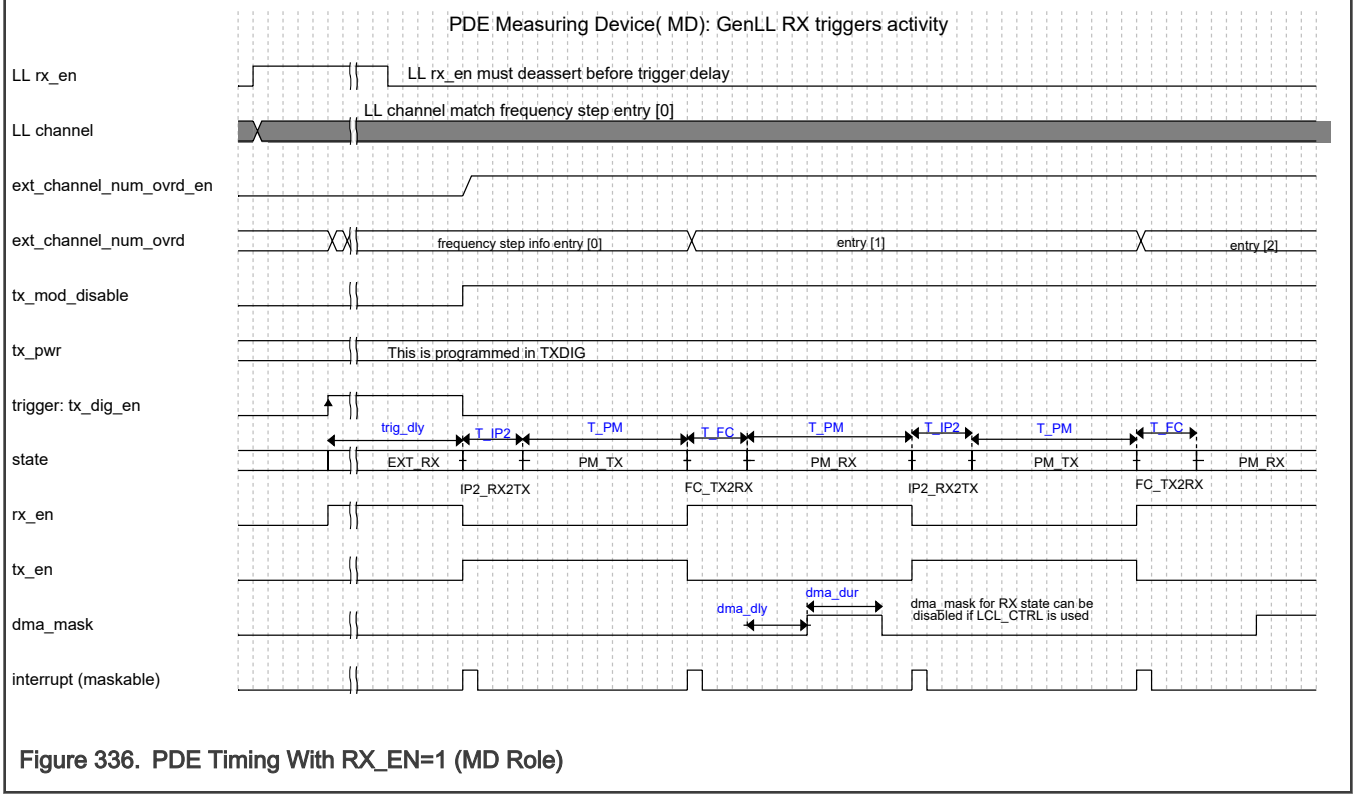

Figure 336. PDE Timing With RX_EN=1 (MD Role)

52.4.4.2.2.5.4 Payload demodulation (Sounding/Random sequence)

52.4.4.2.2.5.4.1 Overview

The Channel Sounding standard defines two optional sequences which extends the packet length by adding payload after Access Address and the trailer bits in order to improve the time of arrival estimation as well as to detect potential MITM attacks.

- The optional sounding sequence is a sequence of bit alternating between 0 and 1 bits, The first bit of the sounding sequence is always 0 and the last bit of the sounding sequence is always a 1. For each packet, one or more 4-bit marker signal shall be added at a random location with a random polarity which is unknown to an attacker. The position and the polarity of these markers are determined cryptographically by the two devices through a lock-step symmetric key mechanism.
- The optional random sequence payload is a sequence of randomized bits for each packet. This random bit sequence is completely unknown to an attacker as it is determined cryptographically by the two devices through a lock-step symmetric key mechanism.

Enabling the demodulation mechanism allows FW to detect an attack through the error detection by comparing demodulated bits with expected bits of the sounding sequence.

The payload demodulation can also be activated during random sequence to improve the attack detection by using a higher-sensitivity symbol demodulator.

52.4.4.2.2.5.4.2 GEN4_PHY programming

In order to provide the received payload of the sounding or random sequences to FW, radio shall support the payload demodulation of RTT packets with a random bit sequence payload (32, 64, 96 or 128 bit) . This packet demodulation can be applied in mode 1 or mode 3 in case of non-null payload length.

If register bitfield RTT_CTRL[RTT_SEQ_SEQ_LEN] is set then demodulation is started at the same time as RTT computation otherwise payload is not demodulated and only RTT computation is performed.

Some registers have to be programmed in GEN4_PHY in order to demodulate payload

- GEN4_PHY_DMD_CTRL2[WAIT_DMD_CLKEN_ADJ] = 0x7 : valid value to ensure correct demodulation of the fist payload bit
- GEN4_PHY_DMD_CTRL1[TTRK_INT_RANGE] = 0x2 : valid value to ensure correct demodulation of the fist payload bit
- GEN4_PHY_RTT_CTRL[RTT_SEQ_LEN] = 0x1 : enables Payload demodulation during RTT computation. In order to ensure the correct demodulator behavior, RTT_SEQ_LEN bitfield must be set only after Mode0 if rtt_type /=0. It should be written in the same time as the AGC_GAIN_ IDX_OVRD bi

52.4.4.2.2.5.4.3 RX PAYLOAD

Payload can be stored in memory by GenFSK.

Rx payload stored by GENFSK

If the demodulated packet demodulation mode is enabled then GENFSK link Layer has to be programmed during CS initialization to store the demodulated payload in Rx Packet RAM by setting the register bitfield MULT_PKT_CTRL[MULT_PKT_EN] which enables the feature “Send and Receive multiple packets” in GENFSK link Layer.

In this configuration, the first packet received is stored in the Segment 0. The second packet is stored in Segment 1, and so on. Register MULT_PKT_CTRL[PKT_INDEX] is initially 0 and is automatically increased by 1 after successfully received a packet. So MULT_PKT_CTRL[PKT_INDEX] has two meanings: the number of packet received and the segment number to store the next coming packet. FW can check PKT_INDEX to identify the location of the latest received payload in RX Packet RAM.

FW has also to write MULT_PKT_CTRL[RESET_PKT_IDX] to clear the PKT_INDEX to 0 before starting a CS sub-event with payload demodulation mode.

Since the maximum payload size is 128 bits, FW has also to set the RAM Segment Size for each packet to the minimum segment size which is 32bytes (MULT_PKT_CTRL[SEG_SZ]=0). This setting optimizes the memory space in Rx Packet RAM for RTT packet reception.

If the payload demodulation is enabled with GenFSK then it’s preferable to put circular config and result RSM buffers in Tx packet RAM to avoid that GenFSK Link layer overrides the content of these buffers when it stores payload in the different segments of the Rx packet RAM.

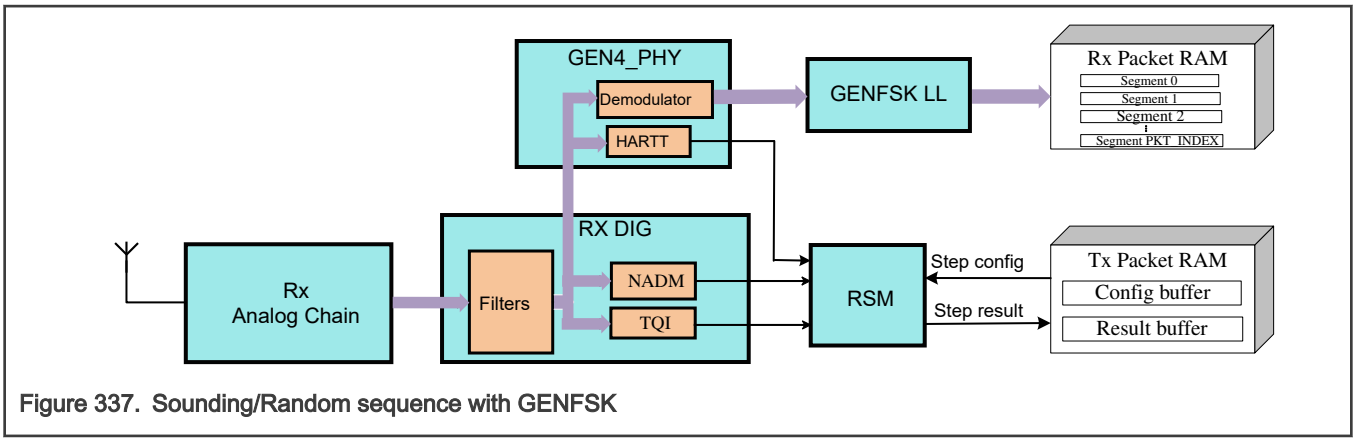

Figure 337. Sounding/Random sequence with GENFSK

Some additional registers have also to be programmed in order that GenFSK Link Layer stores correctly payload in Rx Packet RAM during channel sounding sub-events. An example of programming is described below:

- XCVR_TSM_CTRL[TSM_LL_INHIBIT]=x8 : disables GenFSK LL command at TSM level.
- GENFSK_ENH_FEATURE[STAY_IN_RX]=1 : forces GenFSK LL to stay in Rx state after a correct RX packet
- GENFSK_PACKET_CFG[LENGTH_SZ]=0 : indicates there is no length field in Header
- GENFSK_PACKET_CFG[H0_SZ]=0 : indicates there is no H0 field in Header

- GENFSK_PACKET_CFG[H1_SZ]=0 : indicates there is no H1 field in Header
- RBME_CRCW_CFG3[CRC_SZ]=0 : indicates there is no CRC field in Packet
- GENFSK_PACKET_CFG[AA_PLAYBACK_CNT]=1 : indicates that AA is playback to Link Layer.
- GENFSK_PACKET_CFG[SYNC_ADDR_SZ]=0 : reduces AA size to 1 byte
- GENFSK_LENGTH_ADJ = Payload length -1 (in bytes) depends on RSM_CTRL2[RSM_RTT_TYPE] value
- GENFSK_MULT_PKT_CTRL[MULT_PKT_EN] =1 : enables feature “Send and Receive multiple packets” in GENFSK link Layer
- GENFSK_MULT_PKT_CTRL[SEG_SZ]=0 : reduces the Segment depth to 32 bytes
- GENFSK_XCVR_CTRL[SEQCMD] = 0x5 : puts GenFSK LL in Rx mode
- GEN4_PHY_DMD_CTRL2[WAIT_DMD_CLKEN_ADJ] = 0x7 : valid value to ensure correct demodulation of the fist payload bit
- GEN4_PHY_DMD_CTRL1[TTRK_INT_RANGE] = 0x2 : valid value to ensure correct demodulation of the fist payload bit
- GEN4_PHY_RTT_CTRL[RTT_SEQ_LEN] = 0x1 : enables Payload demodulation during RTT computation. In order to ensure the correct demodulator behavior, RTT_SEQ_LEN bitfield must be set only after Mode0 if rtt_type /=0. It should be written in the same time as the AGC_GAIN_ IDX_OVRD bitfield.

52.4.4.2.2.5.5 Timestamp Packet Module

52.4.4.2.2.5.5.1 Overview

The TPM block is basically a counter that allows to get the packet detection time. Having this feature embedded in the radio allows to add the TPM collected information to the packet ram results, as part of the CS information, collected by the hardware at each step and needed for RTT.

52.4.4.2.2.5.5.2 Functional Description

The TPM counter is a 32-bits counter clocking by transceiver clock that measures the ToD-ToA and ToA-ToD time. The start/stop conditions depend on the initiator or reflector role:

52.4.4.2.2.5.5.2.1 Initiator mode

The behavior of the TPM counter in Initiator mode is the same whatever the step number or the modes 0, 1, or 3.

The Initiator needs to report ToA-ToD, the counter is therefore :

- reset on rsm_tx_on assertion which corresponds to the beginning of data transfer from RSM to TX_DIG.
- counts from the DT_TX state of first half part of the step until next access address detection in the DT_RX state of the second half part of the CS step .

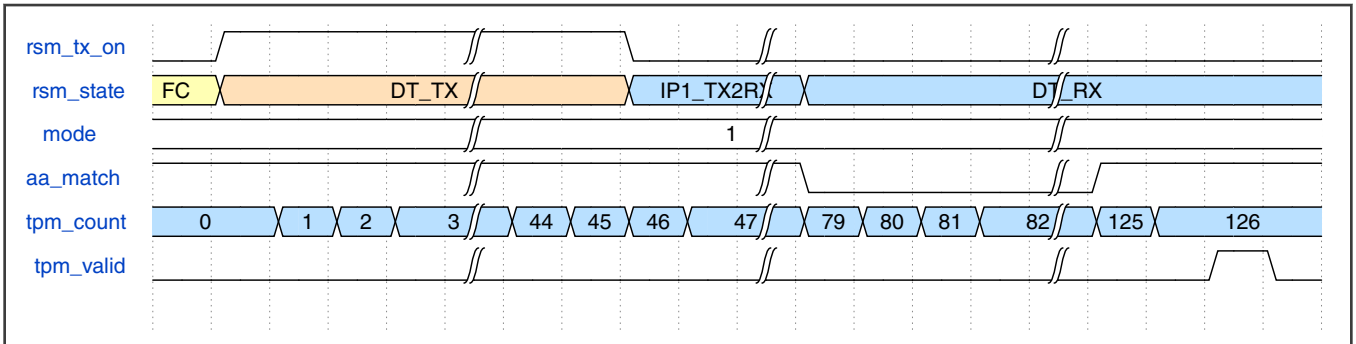

Figure 338. TPM behavior in Initiator mode

52.4.4.2.2.5.5.2.2 Reflector mode

The behavior of the TPM counter in Reflector mode differs for the first CS step than the others steps.

- For the first step, the TPM starts counting from the beginning of the warm-up sequence until the access address detection in the DT_RX state of the first half part of the CS step.

  This specific TPM value is used by FW to compute the timestamp of the beginning of the reflector sub-event .

  Note that in case of mode0 timeout configuration, TPM counter is still counting until the first Access Address detection which can occur after several FCS steps instead of the first FCS Step.

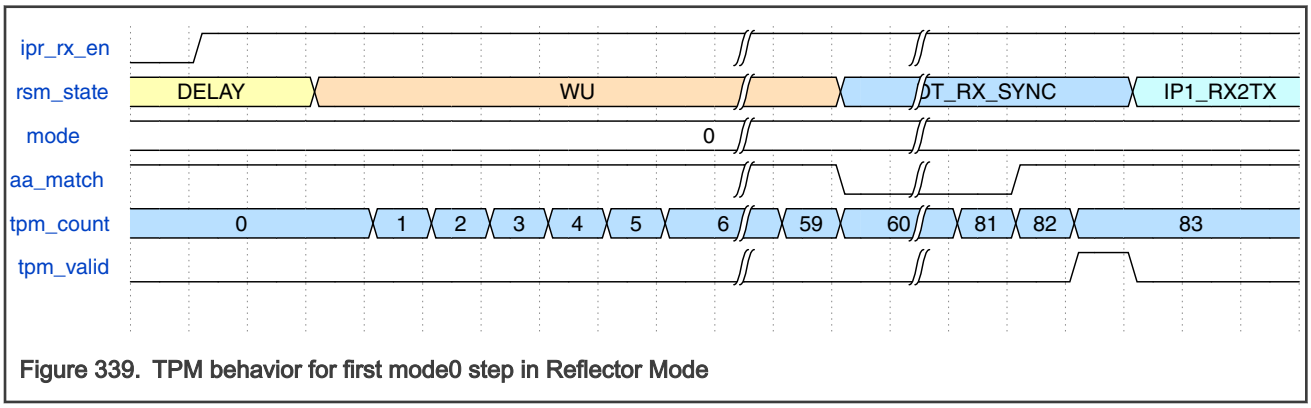

Figure 339. TPM behavior for first mode0 step in Reflector Mode

- For the others steps, the Reflector needs to report ToD-ToA, so the counter is therefore :
  - reset on rsm_tx_on assertion which corresponds to the beginning of data transfer from RSM to TX_DIG.
  - counts from the access address detection in DT_RX state of first half part of the step until the beginning of data transfer from RSM to TX_DIG in the second half part of the CS step .

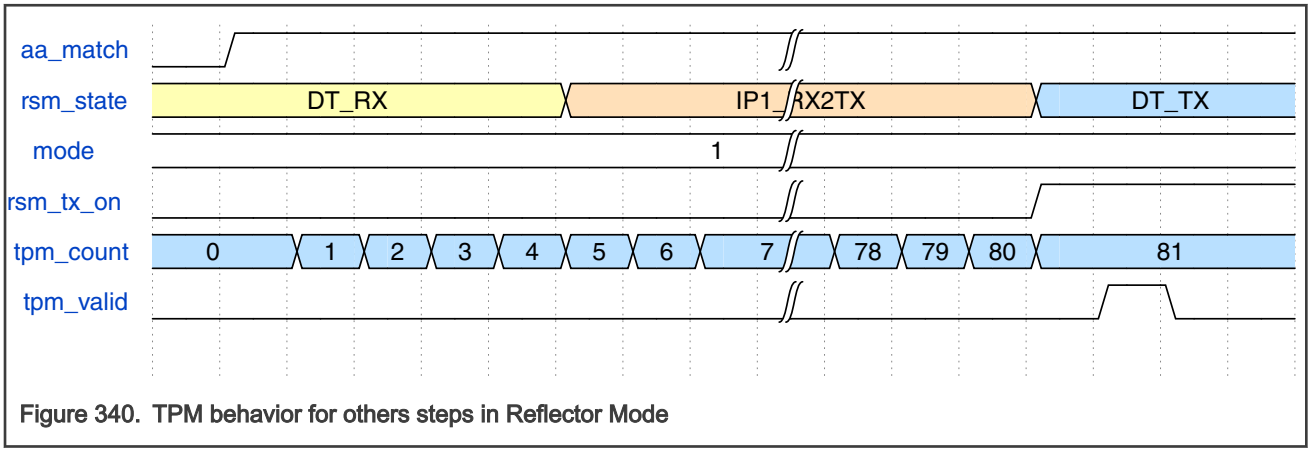

Figure 340. TPM behavior for others steps in Reflector Mode

52.4.4.2.2.5.6 Sniffer Capability

52.4.4.2.2.5.6.1 Overview

The RSM block has been updated to support the sniffer capability. When set to sniffer mode, the RSM basically works in rx mode only, and collects data from both the initiator and the reflector:

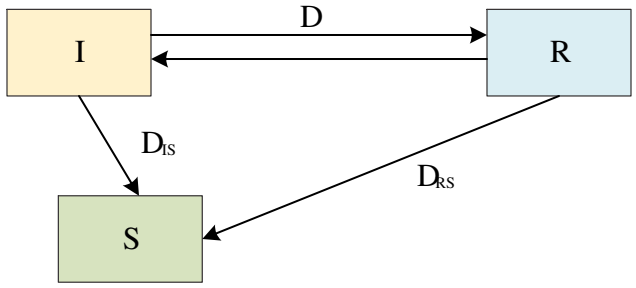

Figure 341. Sniffer Role

52.4.4.2.2.5.6.2 Functional Description

The sniffer mode is enabled by the RSM_SN_EN bitfield of RSM_CTRL0 register.

The RSM state machine has been updated in order to support the features required by the sniffer mode. For mode 0, the synchronization mechanism is the same as a reflector . The sniffer will mainly replace tx_mode with rx_mode for all modes. Next picture gives an overview of the sniffer behavior for all modes

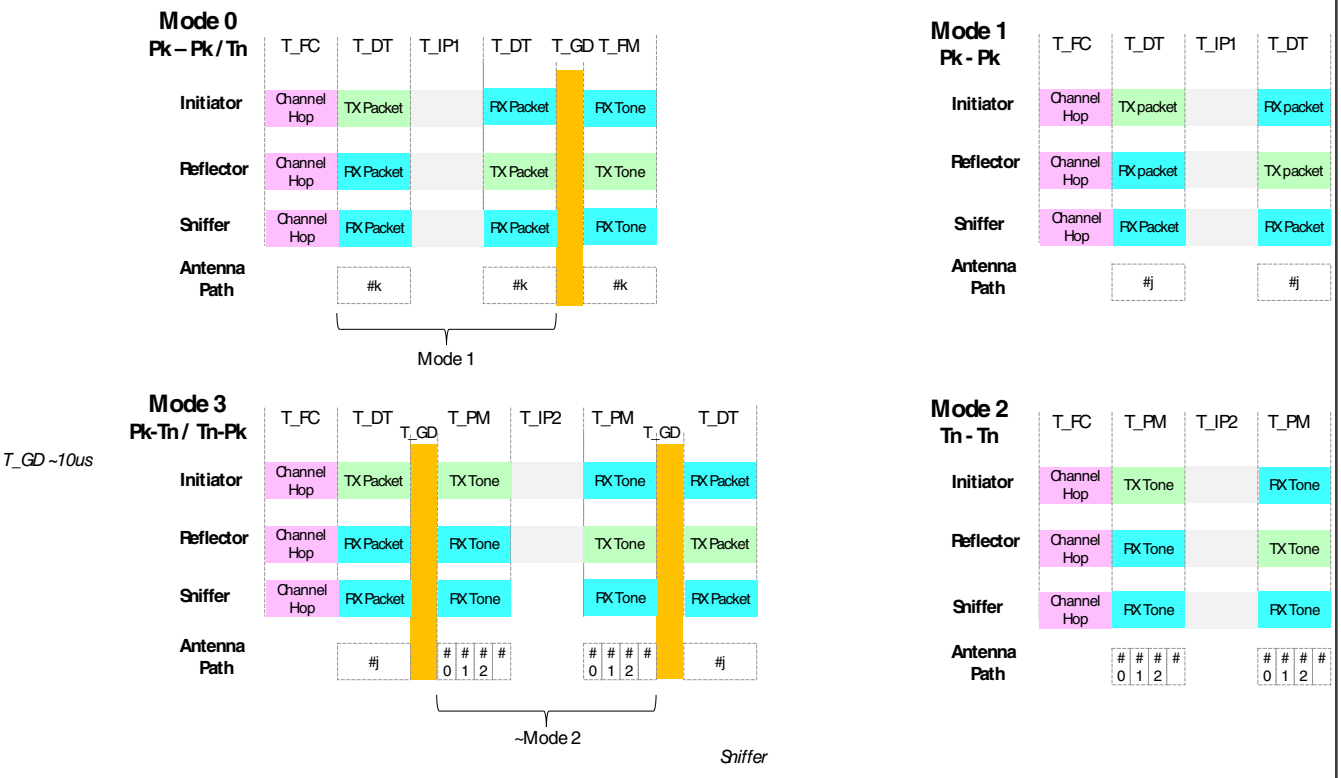

Figure 342. Overview of Sniffer Role for all modes

The details about the RSM states and evolution, for all the modes, when Sniffer role is active, is shown just below:

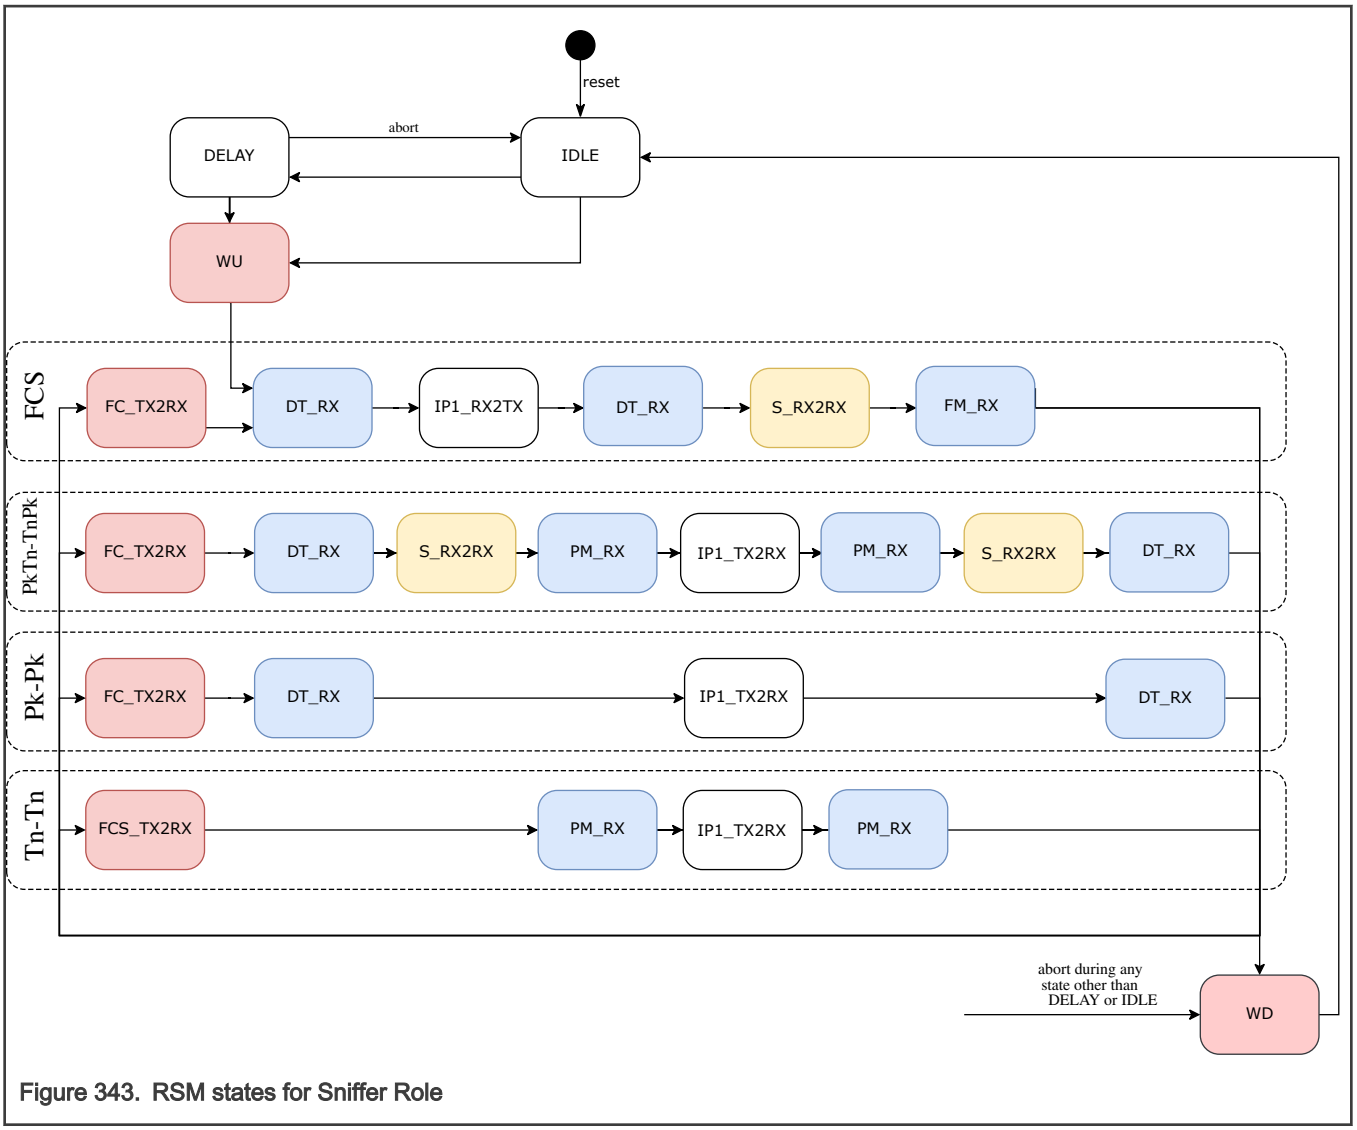

Figure 343. RSM states for Sniffer Role

The sniffer must collect data from both the initiator and the reflector, thus it needs to manage two different receptions and AGC gains. In Mode 0 the sniffer computes both the initiator and reflector gain. After mode 0, the gain to apply to the Reflector transmission part of the step is stored in the SN_AGC_INIT_IDX2 bitfield of the RXDIG CTRL2 register.

52.4.4.2.2.5.7 Unidirectional Mode

52.4.4.2.2.5.7.1 Overview

The MCXW72 Radio supports a custom unidirectional ranging mode, also called "one way". The RSM state machine fully supports this feature, independently if it acts as Initiator, Reflector or Sniffer.

52.4.4.2.2.5.7.2 Functional Description

The unidirectional mode is activated by a new field (step_one_way) in the configuration buffer of the Packet RAM.

Note that unidirectional mode is not supported in mode 3, as shown by the following picture:

Following, an overview of the different modes for Initiator, Reflector and Sniffer, when unidirectional mode is active. The Mode 0 does not change with respect to the bidirectional mode, because the device needs to sync, in any case.

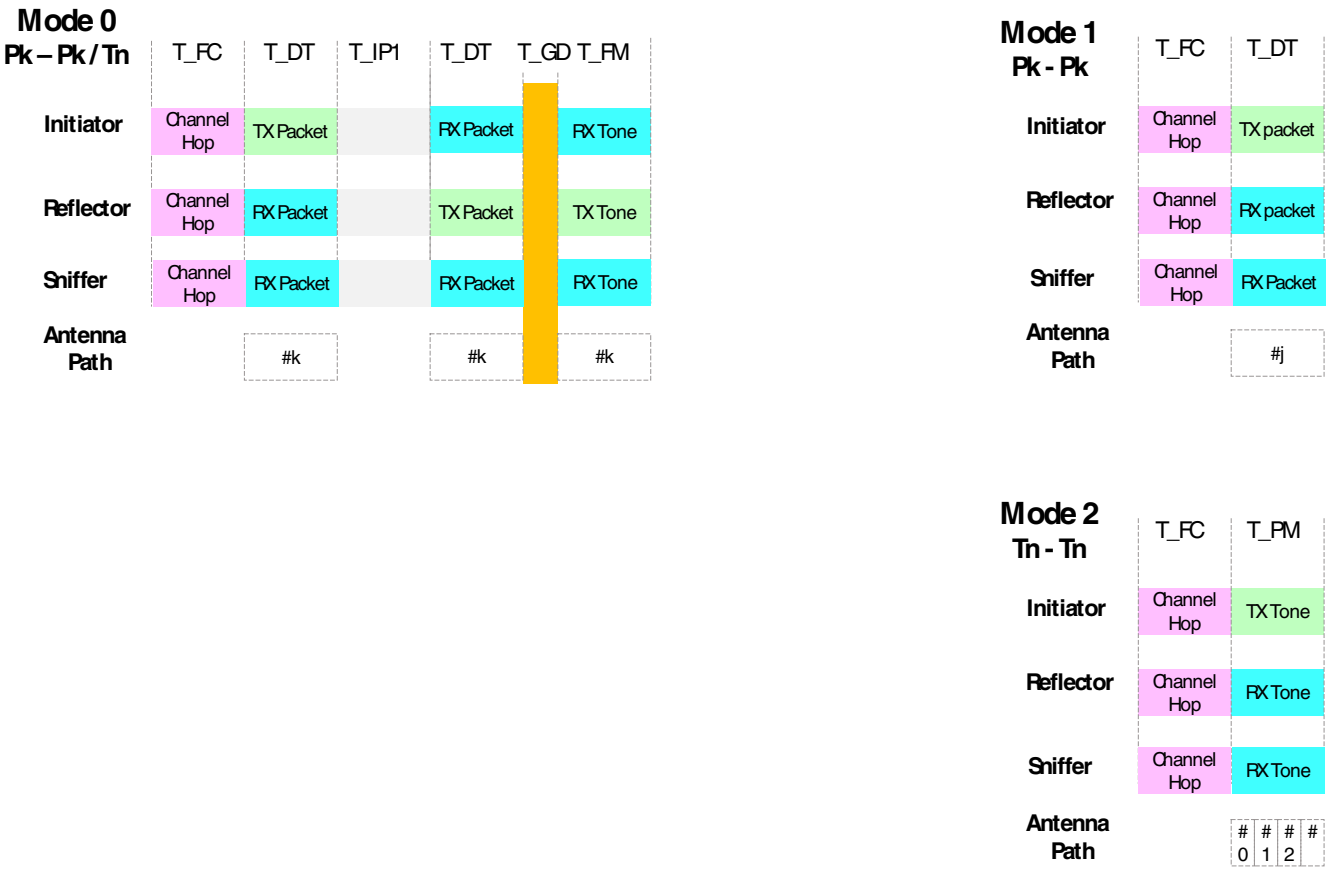

Figure 344. Overview of undirectional mode

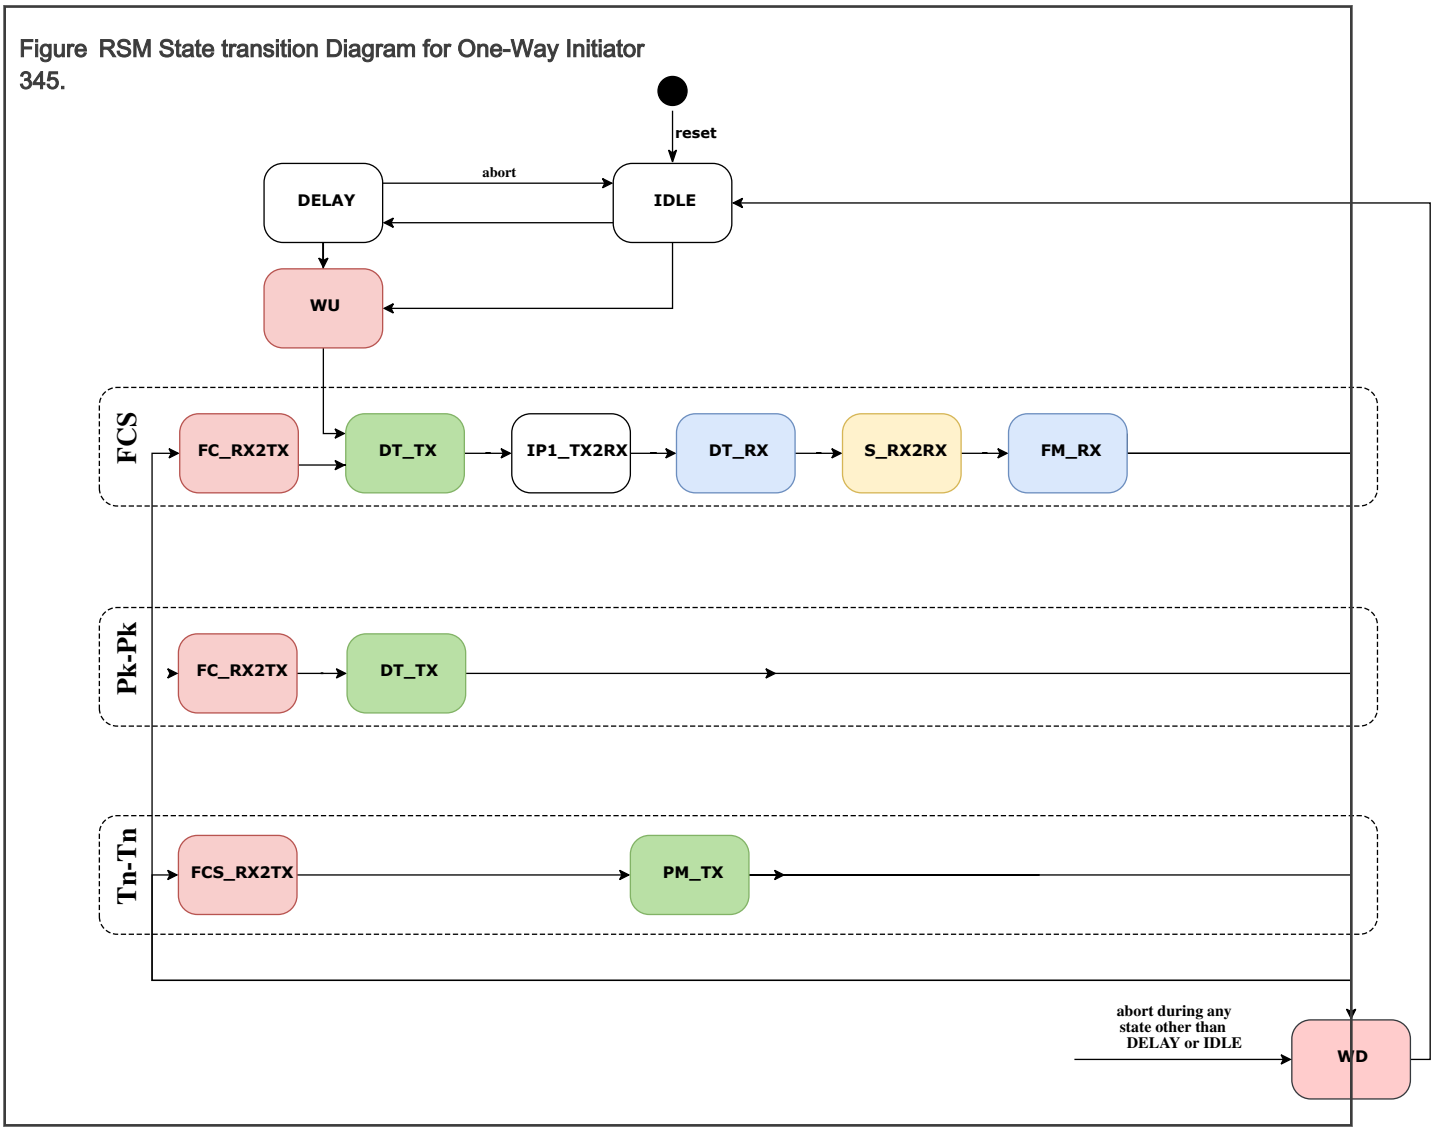
SQTE Unidirectional Initiator Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Initiator role (TX_EN=1) when the one-way mode is activated. Some of the states are duplicated in the figure to more clearly show the state transition sequence for the supported step format types (FCS, Pk-Pk and Tn-Tn).

The description of each state can be found in the SQTE mode related chapter

Figure RSM State transition Diagram for One-Way Initiator 345.



SQTE Unidirectional Reflector Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Reflector role (RX_EN=1) when the one-way mode is activated. Some of the states are duplicated in the figure to more clearly show the state transition sequence for the supported step format types (FCS, Pk-Pk and Tn-Tn). The description of each state can be found in the SQTE mode related chapter.

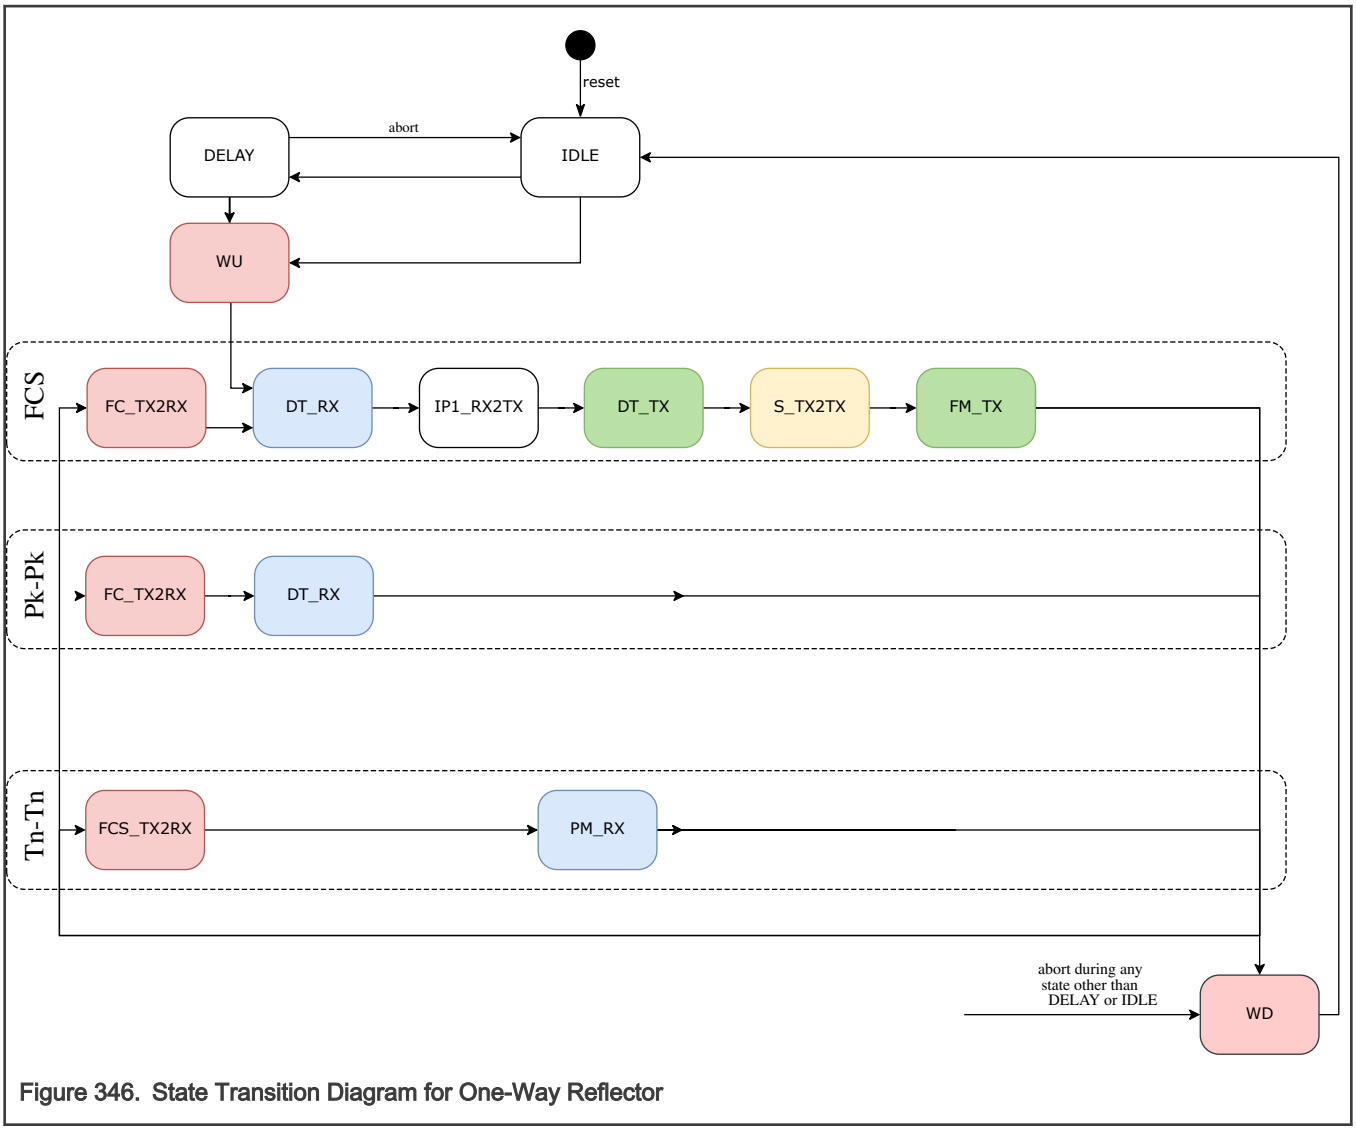


Figure 346. State Transition Diagram for One-Way Reflector

SQTE Unidirectional Sniffer Role

The RSM state diagram below illustrates the RSM states used for SQTE in the Sniffer role (RX_EN=1) when the one-way mode is activated. Some of the states are duplicated in the figure to more clearly show the state transition sequence for the supported step format types (FCS, Pk-Pk and Tn-Tn). The description of each state can be found in the SQTE mode related chapter.

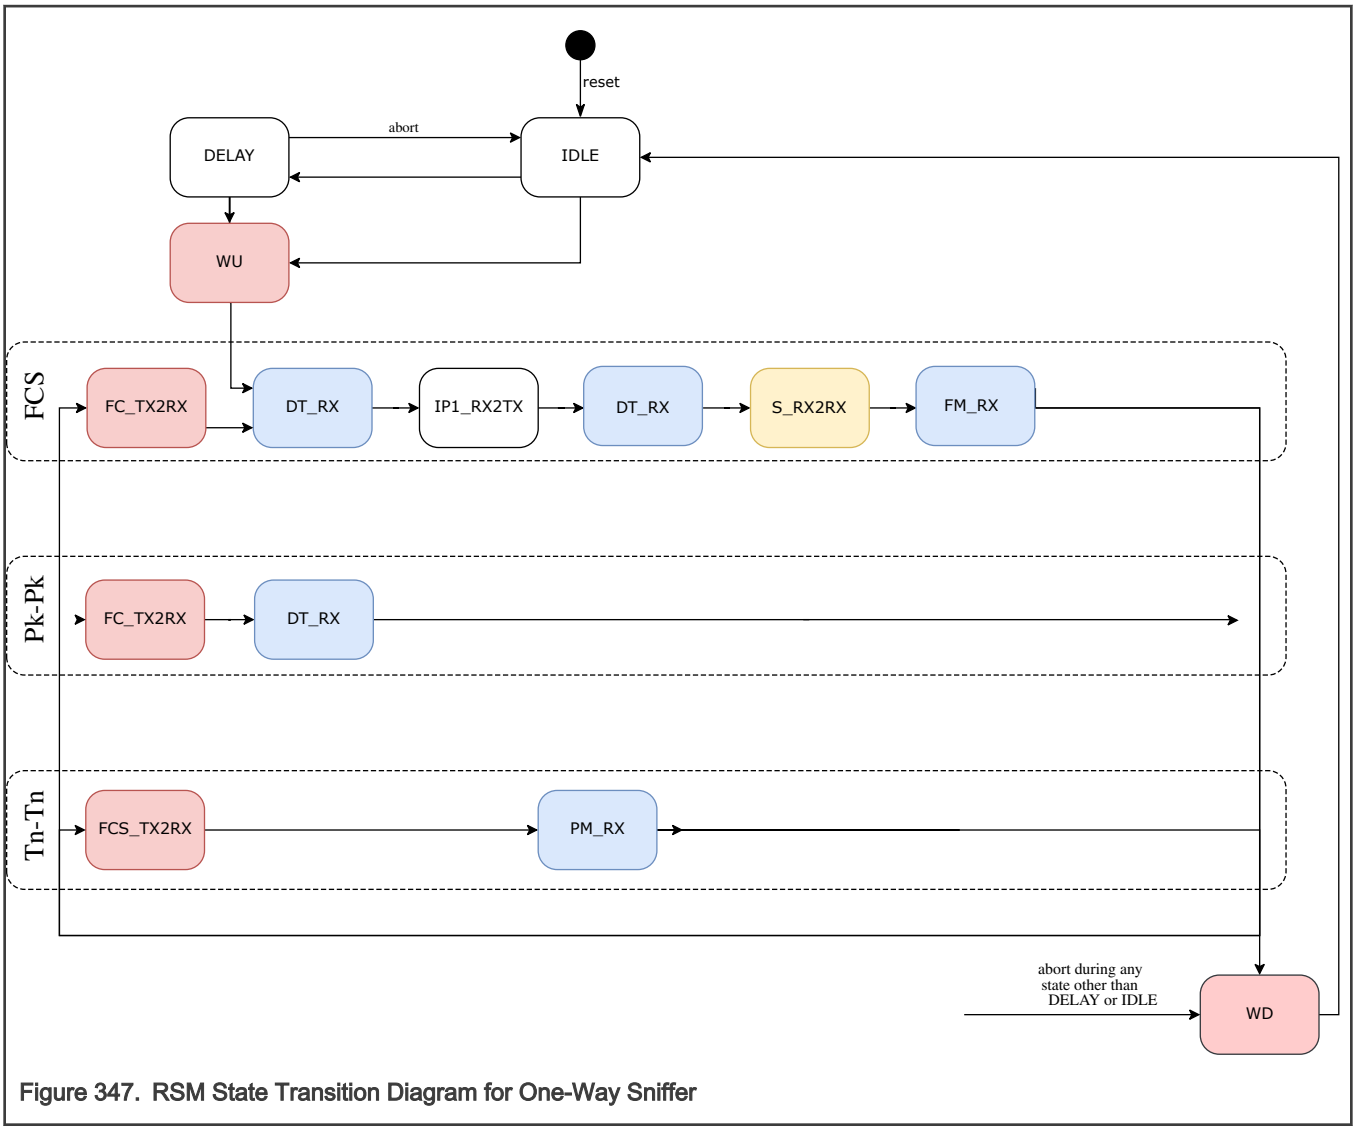

Figure 347. RSM State Transition Diagram for One-Way Sniffer

52.4.4.2.2.5.8 Role Swap and Frequency Change Transitions

This section provides information on the role swap (changing from receive to transmit or vice versa, from receive packet to receive tone or vice versa, or from transmit packet to transmit tone or vice versa) and frequency change transitions (with or without role swap) and their timings in more detail. These transitions are all intended to be handled by the RSM logic without software involvement; however, as a fallback, it is also possible to trigger interrupts at the beginning of different states so that software can perform any additional tasks. Note that fewer transitions are supported for PDE than for SQTE, and that the transitions used depends also on the role (whether RX_EN or TX_EN bit is set).

52.4.4.2.2.5.8.1 TSM Features Utilized

The RSM utilizes several TSM features to control these transitions and to minimize the transition durations: fast RX2TX and fast TX2RX; recycle events; and fast RX and TX warmups. RSM usage of these features is described in the next three paragraphs.

First, for role swap the RSM always directs the Transceiver Sequence Manager (TSM) to perform fast RX2TX and fast TX2RX transitions. In these transitions, the TSM jumps from a recieve (transmit) sequence already warmed up to a programmable starting point in the transmit (receive) sequence. The starting points are programmed in the TSM: FAST_TX2RX_START for IP1_TX2RX or IP2_TX2RX, FAST_TX2RX_START_FC for FC_TX2RX, FAST_RX2TX_START for IP1_RX2TX or IP2_RX2TX, and FAST_RX2TX_START_FC for FC_RX2TX. For the FC_RX2TX and FC_TX2RX, the start value is expected to be programmed such that the TSM's pll_dig_en is de-asserted for 1us and then re-asserted, coincident with new frequency information provided

to the PLL from the RSM; for the other transitions a frequency change is not performed, so the start time value should be such that the TSM's pll_dig_en does not de-assert.

Second, for S_RX2RX transitions (which are only used in SQTE), the RSM can direct the TSM using a "recycle0" event. In these transitions, the TSM jumps from a receive sequence already warmed up to a programmable starting point in the receive sequence. The starting count is programmed in the TSM's RECYCLE_COUNT0 bitfield such that rx_dig_en cycles and rx_init pulses to reset the receiver. (Note that S_TX2TX does not require a recycle event; the transmitter is not reset during this transition)

Third, to further minimize the duration of the RX2TX and TX2RX transitions, the RSM can direct the TSM to perform a fast TX or fast RX warmup. Fast RX or TX warmups allow the TSM to skip some TSM counts in the middle of the TSM warmup sequence (after the RX2TX and TX2RX start times described above). For example, during a fast RX warmup the DCOC calibration time can be skipped. The skip times are programmed in the TSM: FAST_TX_START and FAST_TX_DEST for transmit, and FAST_RX_START and FAST_RX_DEST for receive. The use of fast RX or TX warmups during RSM transitions is an optional feature. It is enabled through the RSM's FAST_IP_TX_WU (for IP1_RX2TX and IP2_RX2TX transitions), FAST_IP_RX_WU (for IP1_TX2RX and IP2_TX2RX transitions), FAST_FC_RX_WU (for FC_TX2RX transitions), and FAST_FC_TX_WU (for FC_RX2TX transitions) bitfields.

In below discussion of the transition timings, the following assumptions are made concerning the configuration of the TXDIG ramp:

- TXDIG is programmed for 1us ramp (PA_RAMP_SEL=2'b01).

NOTE

The 1us ramp setting is a requirement for proper operation of the RSM with the TXDIG

- For PA ramp-up: PAD_DLY (delay from tx_dig_en to PA enable) is assumed to be programmed to 0

The RX2TX transition states (IP1_RX2TX, IP2_RX2TX, and FC_RX2TX) are described as follows:

- The RSM signals to the TSM to initiate a fast RX2TX transition. In response the TSM will change from rx_mode to tx_mode and change its count to FAST_RX2TX_START (IP1_RX2TX, IP2_RX2TX) or FAST_RX2TX_START_FC (FC_RX2TX). FAST_RX2TX_START and FAST_RX2TX_START_FC are programmed in the TSM
- If RSM's FAST_IP_TX_WU bit is set (IP1_RX2TX, IP2_RX2TX) or FAST_FC_TX_WU bit is set (FC_RX2TX), the RSM will also signal to the TSM to perform a fast warmup during the TX warmup. As the TSM count increments it will skip from FAST_TX_START to FAST_TX_DEST (which are programmed in the TSM)
- The TSM reaches the end of warmup when its count reaches END_OF_TX_WU and after the TXDIG has asserted the pa_wu_complete signal.

The time needed for the RX2TX transitions are shown in the table below, where the term "pa_ru" accounts for any additional time after END_OF_TX_WU before the PA ramp-up completes:

- if (RAMP_UP_DLY + 2us >= END_OF_TX_WU - TX_DIG_EN_TX_HI) pa_ru = (RAMP_UP_DLY + 2us) - (END_OF_TX_WU - TX_DIG_EN_TX_HI)
- else pa_ru = 0us

Transition	Time needed for transition	Roles
IP1_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru	SQTE Reflector
IP2_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru	SQTE Reflector, PDE MD
FC_RX2TX	(END_OF_TX_WU - FAST_RX2TX_START_FC) - (FAST_DEST_TX - FAST_START_TX_FC)*FAST_FC_TX_WU + pa_ru	SQTE Initiator, PDE RD

The TX2RX transition states (IP1_TX2RX, IP2_TX2RX, and FC_TX2RX) are described as follows:

- The RSM directs the TXDIG to ramp-down the PA

- The RSM signals to the TSM to initiate a fast TX2RX transition. In response the TSM will change from tx_mode to rx_mode and change its count to FAST_TX2RX_START (IP1_TX2RX, IP2_TX2RX) or FAST_TX2RX_START_FC (FC_TX2RX). FAST_TX2RX_START and FAST_TX2RX_START_FC are programmed in the TSM
- If RSM's FAST_IP_RX_WU bit is set (IP1_TX2RX, IP2_TX2RX) or FAST_FC_RX_WU bit is set (FC_TX2RX), the RSM will also signal to the TSM to perform a fast warmup during the RX warmup. As the TSM count increments it will skip from FAST_RX_START to FAST_RX_DEST (which are programmed in the TSM)
- The TSM reaches the end of warmup when its count reaches END_OF_RX_WU.

The time needed for the TX2RX transitions are shown below. The 2us + TX_DATA_FLUSH_DLY is related to PA ramp-down at the beginning of the transition .

Transition	Time needed for transition	Roles
IP1_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Initiator
IP2_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Inititator, PDE RD
FC_TX2RX	(END_OF_RX_WU - FAST_TX2RX_START_FC) - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 2us + TX_DATA_FLUSH_DLY	SQTE Reflector, PDE MD

The RX2RX transition state (S_RX2RX) is described as follows.

- The RSM signals to the TSM using recycle0. In response the TSM will change its count to RECYCLE_COUNT0
- The TSM reaches the end of warmup when its count reaches END_OF_RX_WU.

The TX2TX transition state (S_TX2TX), doesn't require a recycle event; the TX_DATA_FLUSH_DLY accounts for the flushing delay in the transition. The time needed for the RX2RX and TX2TX transitions are shown below.

Transition	Time needed for transition	Roles
S_RX2RX	(END_OF_RX_WU - RECYCLE_COUNT0)	SQTE Initiator, SQTE Reflector
S_TX2TX	TX_DATA_FLUSH_DLY	SQTE Initiator, SQTE Reflector

For SQTE, the RSM has to warmup the transceiver from the TSM IDLE state. For SQTE Initiator role, if RSM's FAST_FC_TX_WU bit is set, the RSM will signal to the TSM to perform a fast warmup during the TX warmup. For SQTE Reflector role, if RSM's FAST_FC_RX_WU bit is set, the RSM will signal to the TSM to perform a fast warmup during the RX warmup.

Transition	Time needed for transition	Roles
WU	END_OF_TX_WU - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + 3us	SQTE Initiator (TX warmup)
WU	END_OF_RX_WU - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 1us	SQTE Reflector (RX warmup)

52.4.4.2.2.5.8.2 RX and TX Latency Handling

When transmitting, in order to be "on air" beginning at the desired time, it is necessary to account for the latency through the TXDIG and PLL. To account for this, the RSM uses the TXDIG programmable value TX_DATA_FLUSH_DLY which is specified in terms of microseconds. The RSM will shift TX states (DT_TX, FM_TX, PM_TX) to begin earlier in time by TX_DATA_FLUSH_DLY to ensure that transmit information is "on air" at the correct time.

When receiving is it necessary to account for latency through the receiver and PHY. The RSM uses the TSM programmable value RX_SETTLING_LATENCY (which is specified in terms of microseconds) for this. The RSM will extend RX states (DT_RX, FM_RX, PM_RX) by RX_SETTLING_LATENCY to ensure that the last "on air" information during T_DT, T_FM, or T_PM can be processed by the receiver. Please note that RSM_RXLAT_DIG has no impact on RSM states duration, but it maintains active some radio processing modules (for instance HARTT computation) after the end of PM_STATE or RX_DT_STATE, even if RSM state has changed. Note that the RX_SYNC_DLY value depends on RX_SETTLING_LATENCY and they both must be changed in order to properly align reflector timings.

These concepts are illustrated in the example figure below for a SQTE step of type Pk-Tn-Tn-Pk. In both Initator and Reflector roles, the TX (DT_TX, FM_TX, and PM_TX) states are shifted early by TX_DATA_FLUSH_DLY with respect to the "nominal time", while the RX (DT_RX, FM_RX, and PM_RX) states are extended by RX_SETTLING_LATENCY.

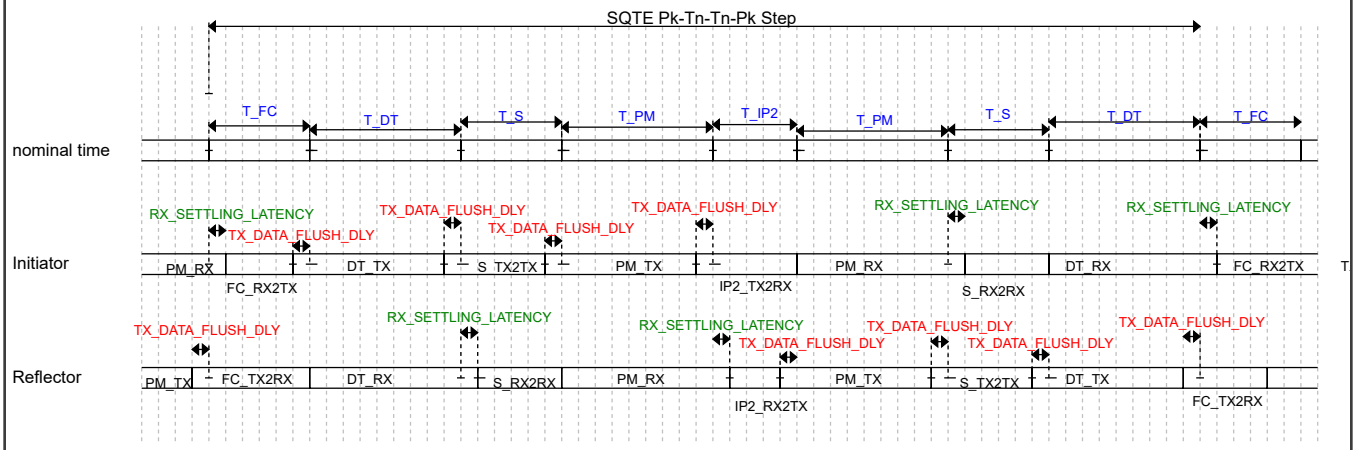

Figure 348. RX and TX Latency

As shown in the timing figure above, after taking into account the RX and TX latencies some of RSM state's durations are different than the "nominal" durations. This is summarized in the table below

Table 481. RSM Actual State Durations

State	Nominal Duration	Actual Duration
FC_RX2TX	T_FC	T_FC - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
IP1_RX2TX	T_IP1	T_IP1 - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
IP2_RX2TX	T_IP2	T_IP2 - RX_SETTLING_LATENCY - TX_DATA_FLUSH_DLY
FC_TX2RX	T_FC	T_FC + TX_DATA_FLUSH_DLY
IP1_TX2RX	T_IP1	T_IP1 + TX_DATA_FLUSH_DLY
IP2_TX2RX	T_IP2	T_IP2 + TX_DATA_FLUSH_DLY
S_RX2RX	T_S	T_S - RX_SETTLING_LATENCY
S_TX2TX	T_S	
PM_RX	T_PM[1]	T_PM[1] + RX_SETTLING_LATENCY
FM_RX	T_FM[2]	T_FM[2] + RX_SETTLING_LATENCY

Table continues on the next page...

Table 481. RSM Actual State Durations (continued)

State	Nominal Duration	Actual Duration
DT_RX	T_DT[3]	T_DT[3] + RX_SETTLING_LATENCY
PM_TX	T_PM[1]	
FM_TX	T_FM[2]	
DT_TX	T_DT[3]	

1. T_PM0, T_PM1, T_PM2, or T_PM3 depending on T_PM_SEL[1:0] for the current step format
2. T_FM0 or T_FM1 depending on T_PM_SEL[0] for the current step format
3. T_DT is a function of RATE and RTT_TYPE programmable bitfields.
   - 1Mbps rate, RTT_TYPE=0 : 8bit preamble + 32bit data + 4bit trailer = 44us
   - 1Mbps rate, RTT_TYPE=1 or 3 : 8bit preamble + 32bit data + 4bit trailer + 32bit payload = 76us
   - 1Mbps rate, RTT_TYPE=4 : 8bit preamble + 32bit data + 4bit trailer + 64bit payload = 108us
   - 1Mbps rate, RTT_TYPE=2 or 5: 8bit preamble + 32bit data + 4bit trailer + 96bit payload = 140us
   - 1Mbps rate, RTT_TYPE=6: 8bit preamble + 32bit data + 4bit trailer +128bit payload = 172us
   - 2Mbps rate, RTT_TYPE=0: 16bit preamble + 32bit data + 4bit trailer = 26us
   - 2Mbps rate, RTT_TYPE=1 or 3 : 16bit preamble + 32bit data + 4bit trailer + 32bit payload= 42us
   - 2Mbps rate, RTT_TYPE=4 : 16bit preamble + 32bit data + 4bit trailer + 64bit payload= 58us
   - 2Mbps rate, RTT_TYPE=2,5 : 16bit preamble + 32bit data + 4bit trailer + 96bit payload= 74us
   - 2Mbps rate, RTT_TYPE=6 : 16bit preamble + 32bit data + 4bit trailer + 128bit payload= 90us

52.4.4.2.2.5.8.3 Transition Time Summary

The following tables show the transition duration requirements, taking into account the TSM and PA ramp timing, and the TX and RX latency, for different SQTE and PDE roles.

Table 482. SQTE Initiator

Transition Time	Must be programmed to a value no less than
WU[1]	END_OF_TX_WU - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + 3us
T_IP1	IP1_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us
T_S	Maximum of .. S_RX2RX + RX_SETTLING_LATENCY = (END_OF_RX_WU - RECYCLE_COUNT0) + RX_SETTLING_LATENCY S_TX2TX = TX_DATA_FLUSH_DLY
T_IP2	IP2_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us
T_FC	FC_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START_FC) - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY

1. The Warmup transition time is shown here for reference, but there is no programmable "WU" bitfield for this in the RSM programming model

Table 483. SQTE Reflector

Transition Time	Must be programmed to a value no less than
WU[1]	END_OF_RX_WU - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 1us
T_IP1	IP1_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY
T_S	Maximum of .. S_RX2RX + RX_SETTLING_LATENCY = (END_OF_RX_WU - RECYCLE_COUNT0) + RX_SETTLING_LATENCY S_TX2TX = TX_DATA_FLUSH_DLY
T_IP2	IP2_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY = (END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY
T_FC	FC_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START_FC) - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 2us

1. The Warmup transition time is shown here for reference, but there is no programmable "WU" bitfield for this in the RSM programming model

Table 484. PDE MD

Transition Time	Must be programmed to a value no less than
T_IP1	(Not used)
T_S	(Not used)
T_IP2	IP2_RX2TX + RX_SETTLING_LATENCY = (END_OF_TX_WU - FAST_RX2TX_START) - (FAST_DEST_TX - FAST_START_TX)*FAST_IP_TX_WU + pa_ru + RX_SETTLING_LATENCY
T_FC	FC_TX2RX - TX_DATA_FLUSH_DLY = (END_OF_RX_WU - FAST_TX2RX_START_FC) - (FAST_DEST_RX - FAST_START_RX)*FAST_FC_RX_WU + 2us

Table 485. PDE RD

Transition Time	Must be programmed to a value no less than
T_IP1	(Not used)

Table continues on the next page...

Table 485. PDE RD (continued)

Transition Time	Must be programmed to a value no less than
T_S	(Not used)
T_IP2	IPS_TX2RX = (END_OF_RX_WU - FAST_TX2RX_START) - (FAST_DEST_RX - FAST_START_RX)*FAST_IP_RX_WU + 2us
T_FC	FC_RX2TX + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY= (END_OF_TX_WU - FAST_RX2TX_START_FC) - (FAST_DEST_TX - FAST_START_TX)*FAST_FC_TX_WU + pa_ru + RX_SETTLING_LATENCY + TX_DATA_FLUSH_DLY

52.4.4.2.2.5.9 Timing adjustment

For ranging consideration , we have some timings constraints that need to be handled during measurement. We need to adjust timing drift and alignment to ensure correct behavior in ranging and RTT mode. The CFO compensation need also to be done over channels. A timeout will also be managed in case RX not correctly received during mode 0.

52.4.4.2.2.5.9.1 Timing drift

Timing misalignment due to Xtal cannot be fully compensated in the -50 to 50 ppm so a digital time tracking mechanism can be used in place. We need to adjust RSM drift depending on CFO, the RSM sequence counter can be advanced or delayed based upon a software scheduling. Software can determine when to advance/delay based upon the residual ppm which is left after the crystal trimming.

In KW45, there is a software approach to manage this limitation but with some drawbacks in term of accuracy and real time software.

To cover the maximum drift possible (~160 mode 3 worst case), below we can see how the time adjustment will be managed:

a) **RSM mode** : RSM_CTRL7.RSM_TIME_CORR_MODE=1 : enable drift compensation via RSM

RSM_CTRL7.RSM_TIME_CORR[16:0] : register @ 1us resolution is used to ease software to manage internal hardware timeout_counter signed and computed by software based on CFO value. This will start an internal counter in RSM from rsm_start and stops at rsm_end sequence without any reset, it will wrap when reach max val.

When timeout elapse, we will freeze or jump one value on the internal rsm_counter (used for state counting) depending on cfo sign : 0 -> freeze value, 1 -> jump value , in order to slow or speed up the rsm counter. Note that the adjustment will be done at end t_fc and not during t_pm to avoid signal alignment issues.

b) **CGM mode**: possibility is to adjust drift via CGM (RSM_CTRL7.RSM_TIME_CORR_MODE=2)

The granularity will be 250 ns granularity inside CGM and not on RSM counter. It can help for better accuracy. In this case, the adjustment will be done by modifying the 4 MHz rate time to time in hardware to adjust the rate depending on RSM_TIME_CORR value.

Below an example of programming to enable modes :

```
RSM_CTRL7[RSM_TIME_CORR_MODE] = time_drift
if (time_drift>=1) begin
  if (xtal_freq_ppm>0)       val_time_corr = 1e6/xtal_freq_ppm
  else if (xtal_freq_ppm<0) val_time_corr = -1e6/xtal_freq_ppm
  else                            val_time_corr = 0;
  if (xtal_freq_ppm>0) delta_time_corr = 1 else -1;
  RSM_CTRL7[RSM_TIME_CORR_DELTA] = delta_time_corr;
end
if (time_drift==1) //rsm  mode , 1 us granularity count adjust
  RSM_CTRL7[RSM_TIME_CORR]=val_time_corr;
else if (time_drift==2)  // cgm mode , 250 us granularity
  RSM_CTRL7[RSM_TIME_CORR] = val_time_corr/4);
```

Figure 349. Timing drift software setting example

52.4.4.2.2.5.9.2 Timing alignment

We need to reach a better accuracy than 1 us if we want to have a correct alignment between initiator and reflector whatever the CFO. Because of AA detection on 4/8 MHz grid, we will have an uncertainty on the alignment , which could be centered [-0.5 us ..0.5 us] but also shifted [0 ..1 us] or [-1 us .. 0] (this is in fact a result of all rx delay).

To adjust alignment , we use Access Adress detection method described as below:

- the first aa_detection will be compared to 1 us grid and realigned to improve alignment accuracy (RSM_CTRL7.RSM_TIME_ALIGN_MODE). We will have possibility also to program an offset for the calibration if needed (RSM_CTRL7.RSM_TIME_ALIGN_OFFSET[1:0]) . Once the alignment is done on reflector after the Rx synchro state in mode 0, we keep it until the end of subevent.

52.4.4.2.2.5.9.3 Timing compensation over channels

We need to adjust CFO depending on channel frequency. The register pll_numerator_offset[27:0] can adjust the frequency, it uses a signed value that allows for a carrier frequency offset of up to +/-100ppm be added to the PLL numerator to allow for a SW controlled static shift of PLL frequency. A mux is added on this register to take the control from RSM with a value embedded in pktram configuration for each channel (step_cfo[15:0]) . These values will be filled by software after the mode 0 (to get the cfo) and pre-computed in linear way with channel number. This functionality will avoid to post process data to compensate CFO over channels as it was done in KW45.

52.4.4.2.2.5.9.4 Timeout mode 0

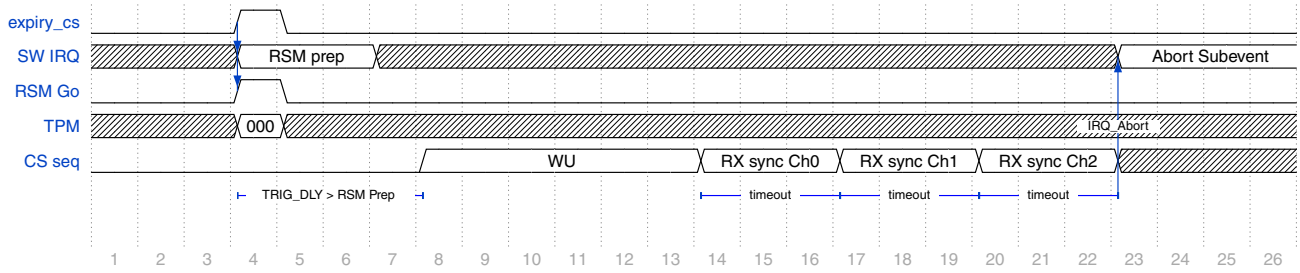
We need a timeout mechanism in the RSM in case we missed the mode 0 synchronization (first mode 0 rx_sync state). Main steps to enable the feature are detailed below :

The field RSM_CTRL6.RSM_MODE0_TIMEOUT[11:0] must be set by software to adjust the exact value for timeout; the 0 value will mean the feature is bypass and we come back to legacy mode as in KW45 (no timeout). For now the range of identified values is within 247 to 483 us, but a 12 bits register will give extra margin if needed.

An internal counter inside RSM will start from the end of WU state and a new mode 0 will be retried if we reached the mode0_timeout 0 value. This counter will be reloaded with timeout value for the next mode0.

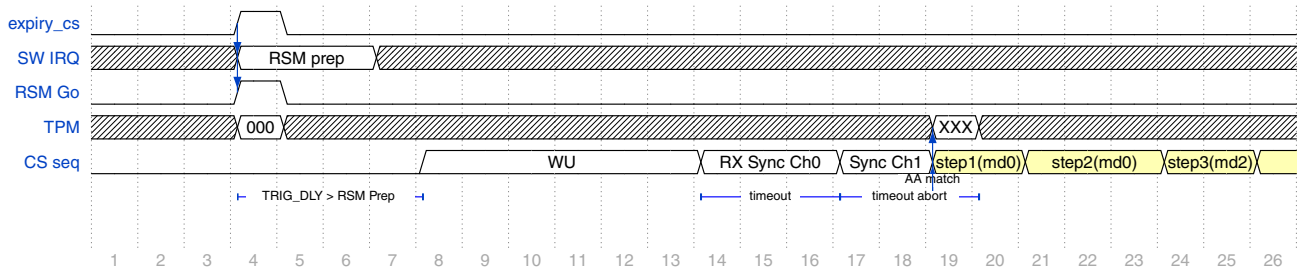
The AGC will be reseted to max gain on next mode 0 , which can be done with a rx_init reset on rx_digital part. We can achieve this by sending a recycle to the TSM from the RSM after the mode0_timeout.

In case all mode 0 are missed, an abort will occur.



CS Sync case 1: 3 mode0 steps missed, abort CS Subevent - timeout is set to mode0 duration (247 to 483 us)

Figure 350. Mode FCS timeout abort



CS Sync case 2: 1 mode0 step missed, 2nd mode0 step matched, starting CS subevent - timeout is set to mode0 duration (247 to 483 us)

Figure 351. Mode FCS timeout retry

52.4.4.2.2.5.10 RSM Configuration

52.4.4.2.2.5.10.1 Register Bitfields

The following table describes the control bits used in software configuration of the RSM for PDE and SQTE operation

Table 486. Register Bitfields

Field	Access	Description
MODE	RW	Mode of Operation- 0 - SQTE 1 - PDE
RX_EN	RW	Enables and arms the module for operation starting with Receive. This corresponds to the SQTE "Reflector" role, and the PDE "RD" role. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
TX_EN	RW	Enables and arms the module for operation starting with Transmit. This corresponds to the SQTE "Initiator" role, and the PDE "MD" role. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
RATE	RW	Only used for SQTE. Indicates how the transceiver is configured, and the transfer rate for packets 0 - 1Mbps 1 - 2Mbps
RTT_TYPE	RW	Only used for SQTE. Indicates the payload packet length.

Table continues on the next page...

Table 486. Register Bitfields (continued)

Field	Access	Description
		0 - no payload 1 - 32-bit payload (souding sequence) 2 - 96-bit payload (souding sequence) 3 - 32-bit payload (random sequence) 4 - 64-bit payload (random sequence) 5 - 96-bit payload (random sequence) 6 - 128-bit payload (random sequence)
STEPS[7:0]	RW	Number of frequency steps. (For SQTE this also includes the FCS.) The maximum number supported is 256, limited by RX Packet RAM used by RSM. A value of 0 should not be used
T_PM0[9:0], T_PM1[9:0]	RW	PM (phase measurement) durations, in microseconds. For SQTE, this is the T_PM*N_AP duration shown in the figures. The T_PM used (T_PM0, T_PM1) depends on t_pm_sel field. The minimum value is 10us. The programmed T_PM0/ T_PM1 value is required to be N_AP multiplied by the desired T_PM per antenna slot (see Configuration Stored in Packet RAM)
T_FM[7:0]	RW	FM (frequency measurement) duration, in microseconds. This field should be set to 80us. (see Configuration Stored in Packet RAM).
T_FC[7:0]	RW	FC (frequency change) duration, in microseconds. This field should be programmed between 40us to 150us.
T_IP1[7:0]	RW	Only applies to SQTE. IP1 (interlude period 1) duration, in microseconds. This field should be programmed between 25us to 150us.
T_S[4:0]	RW	Only applies to SQTE. S (Gard Time period) duration, in microseconds. This field should be set to 10us.
T_IP2[7:0]	RW	IP2 (interlude period 2) duration, in microseconds. This field should be programmed between 25us to 150us.
FAST_IP_RX_WU	RW	If set, forces TSM to perform a fast RX warmup during IP1_TX2RX and IP2_TX2RX transitions
FAST_IP_TX_WU	RW	If set, forces TSM to perform a fast TX warmup during IP1_RX2TX and IP2_TX2RX transitions
FAST_FC_RX_WU	RW	If set, forces TSM to perform a fast RX warmup during FC_TX2RX transitions (and for SQTE with ipr_rx_en=1 during WU state)
FAST_FC_TX_WU	RW	If set, forces TSM to perform a fast TX warmup during FC_RX2TX transitions (and for SQTE with ipr_tx_en=1 during WU state)
RX_SETTLING_LATENCY	RW	Receiver latency. (In a TSM register)
TX_DATA_FLUSH_DLY	RW	TX data flush delay / TX latency. (IN a TXDIG register)
AA_HAMM[2:0]	RW	Only applies to SQTE. Indicates the Access Address Hamming distance to be used by the PHY when RSM is active

Table continues on the next page...

Table 486. Register Bitfields (continued)

Field	Access	Description
CTUNE	RW	If set, RSM will send coarse tune values read from the Packet RAM to the PLL. If clear, the PLL will perform coarse tune.
HPM_CAL	RW	If set, RSM will send hpm calibration values read from the Packet RAM to the PLL. If clear, the PLL will perform hpm calibration.
TRIG_SEL[2:0]	RW	Selects which trigger to use. 0 - Software trigger (immediate trigger) 1- Trigger on CRC pass 2- Trigger on PHY access address found 3- Trigger on seq_spare3 (tx_dig_en from TSM) 4- Trigger on tx_done 5- Trgger on LCL pattern found 6- Trigger on NBU Start trigger
TRIG_DLY[10:0]	RW	SQTE mode: delay in microseconds from trigger to the beginning of the warm-up sequence. PDE mode: delay in microseconds from trigger to when the first RX2TX or TX2RX transition occurs, in microseconds. For PDE mode, this should be programmed to a value greater than 0.
DMA_DLY[7:0]	RW	Delay from end of RX warmup to assertion of dma_mask signal, in microseconds. Used in PM_RX state.
DMA_DLY0[7:0]	RW	Same as DMA_DLY[7:0] but used for the SQTE Frequency Measurement (FM) step (in FCS), and for PDE in the handoff from the LL.
DMA_DUR[9:0]	RW	Duration of the dma_mask signal, in microseconds. Used in the PM_RX state. NOTE: If used in conjunction with the RXDIG's window averager, to ensure that the same number of samples are captured during each time the dma_mask asserts, the duration should be a multiple of the window averager's duration.
DMA_DUR0[9:0]	RW	Same as DMA_DUR[6:0] but used for the SQTE Frequency Error Measurement Step, and for PDE in the handoff from the LL
DMA_RX_EN	RW	Enable dma_mask to assert in PM_RX State. (Note that the DMA mask is always allowed to assert in the SQTE Frequency Measurement (FM) step in FCS.) This bit is expected to be set in SQTE events where the device does not perform antenna switching (LCL_CTRL is not used).
SW_ABORT	RW	Used to gracefully shut down the module prior to a normal end of sequence. Once set, this bit should remain set until the RSM returns to the IDLE state at the end of the sequence.
DT_RX_SYNC_DIS	RW	Only applies to SQTE, and only used by the Reflector device (RX_EN=1) . Setting this bit disables the auto-sync feature for the Reflector device in the FCS RX packet
DT_RX_SYNC_DLY[3:0]	RW	Only applies to SQTE, and only used by the Reflector device (RX_EN=1) when DT_RX_SYNC_DIS=0.

Table continues on the next page...

Table 486. Register Bitfields (continued)

Field	Access	Description
		In this configuration the RSM uses the PHY's AA_MATCHED output to sync the Reflector device to the Initiator device's timing. This corresponds to the delay in microseconds from the PHY's AA_MATCHED to the end of DT_RX duration (the packet duration including preamble and trailer, plus RX_SETTLING_LATENCY).
RX_PHY_EN_MASK_DIS	RW	Only applies to SQTE. If set, the rx_phy_en_mask output is always asserted
SEQ_RCCAL_PUP_MASK_DIS	RW	If set, TSM signal seq_rccal_pup is not modified by RSM. If clear, seq_rccal_pup is masked to 0 for all RSM states except IDLE, WU, and FC
RX_SIGNALS_MASK_DIS	RW	If set, TSM signals dcoc_gain_cfg_en, dcoc_cal_en, seq_bg_pup_ibg_rx, seq_cbpf_en_dcoc, and rx_gang_pup are not modified by RSM. If clear, these signals are masked to 0 during RSM's IP1/IP2_RX2TX states
IRQ_IP1_EN	RW	If set, requests an interrupt at the beginning of the IP1_RX2TX or IP1_TX2RX state
IRQ_IP1	W1C	The bit is set on entry to IP1_RX2TX or IP1_TX2RX states. Write 1 to clear the bit[1].
IRQ_IP2_EN	RW	If set, requests an interrupt at the beginning of the IP2_RX2TX or IP2_TX2RX state
IRQ_IP2	W1C	The bit is set on entry to IP2_TX2RX or IP2_RX2TX states. Write 1 to clear the bit[1].
IRQ_FC_EN	RW	If set, requests an interrupt at the beginning of the FC_RX2TX or FC_TX2RX state
IRQ_FC	W1C	The bit is set on entry to FC_RX2TX or FC_TX2RX states. Write 1 to clear the bit[1].
IRQ_FM_RX_EN	RW	If set, requests an interrupt at the beginning of the FM_RX state
IRQ_FM_RX	W1C	The bit is set on entry to FM_RX state. Write 1 to clear the bit[1].
IRQ_FM_TX_EN	RW	If set, requests an interrupt at the beginning of the FM_TX state
IRQ_FM_TX	W1C	The bit is set on entry to FM_TX state. Write 1 to clear the bit[1].
IRQ_PM_RX_EN	RW	If set, requests an interrupt at the beginning of the PM_RX state
IRQ_PM_RX	W1C	The bit is set on entry to PM_RX state. Write 1 to clear the bit[1].
IRQ_PM_TX_EN	RW	If set, requests an interrupt at the beginning of the PM_TX state
IRQ_PM_TX	W1C	The bit is set on entry to PM_TX state. Write 1 to clear the bit[1].
IRQ_DT_RX_EN	RW	If set, requests an interrupt at the beginning of the DT_RX state
IRQ_DT_RX	W1C	The bit is set on entry to DT_RX state. Write 1 to clear the bit[1].
IRQ_DT_TX_EN	RW	If set, requests an interrupt at the beginning of the DT_TX state
IRQ_DT_TX	W1C	The bit is set on entry to DT_TX state. Write 1 to clear the bit[1].
IRQ_EOS_EN	RW	If set, requests an interrupt at the end of the sequence
IRQ_EOS	W1C	The bit is set to indicate that the sequence is complete. It sets when the RSM transitions from the WD to the IDLE state. Write 1 to clear the bit[1].
IRQ_ABORT_EN	RW	If set, requests an interrupt if the sequence is interrupted due to a PLL abort
IRQ_ABORT	W1C	The bit is set when the sequence is aborted due to pll_abort. This condition can occur during any RSM state except for the IDLE or WD states. Write 1 to clear the bit[1].

Table continues on the next page...

Table 486. Register Bitfields (continued)

Field	Access	Description
IRQ_STEP_EN	RW	If set, requests an interrupt every N steps processed by RSM
IRQ_STEP	W1C	The bit is set every N steps processed by RSM. Write 1 to clear the bit[1].
IRQ_RF_DENY_RISE_EN	RW	If set, requests an interrupt at the assertion of rf_not_allowed signal
IRQ_RF_DENY_RISE	W1C	The bit is set on the assertion of rf_not_allowed signal. Write 1 to clear the bit[1].
IRQ_RF_DENY_FALL_EN	RW	If set, requests an interrupt at the deassertion of rf_not_allowed signal
IRQ_RF_DENY_FALL	W1C	The bit is set on the deassertion of rf_not_allowed signal. Write 1 to clear the bit[1].
IRQ_RF_DENY_BTA_EN	RW	If set, requests an interrupt if a CS/BLE transfer is requested while rf_not_allowed signal is already set
IRQ_RF_DENY_BTA	W1C	The bit is set on a CS/BLE transfer request while rf_not_allowed signal is already set. Write 1 to clear the bit[1].

1. To clear RSM's W1C bits, RX_EN or TX_EN must be set. It is therefore recommended that software ensures that all the RSM W1C bits are cleared at the end of each RSM sequence prior to clearing RX_EN or TX_EN to disable the module.

52.4.4.2.2.5.10.2 Configuration Stored in Packet RAM

In addition to the configuration information stored in registers as described in the previous section, the RSM also relies on configuration information stored in the Packet RAM to control the behavior of each individual frequency step. So, there is a specific area of the Packet RAM used for this configuration information.

52.4.4.2.2.5.10.2.1 Circular Config Buffer

A channel sounding sub-event can support up to 160 steps, but RSM doesn't need all the steps at the same time. Therefore, the step configuration is stored in a circular buffer to use less memory space.

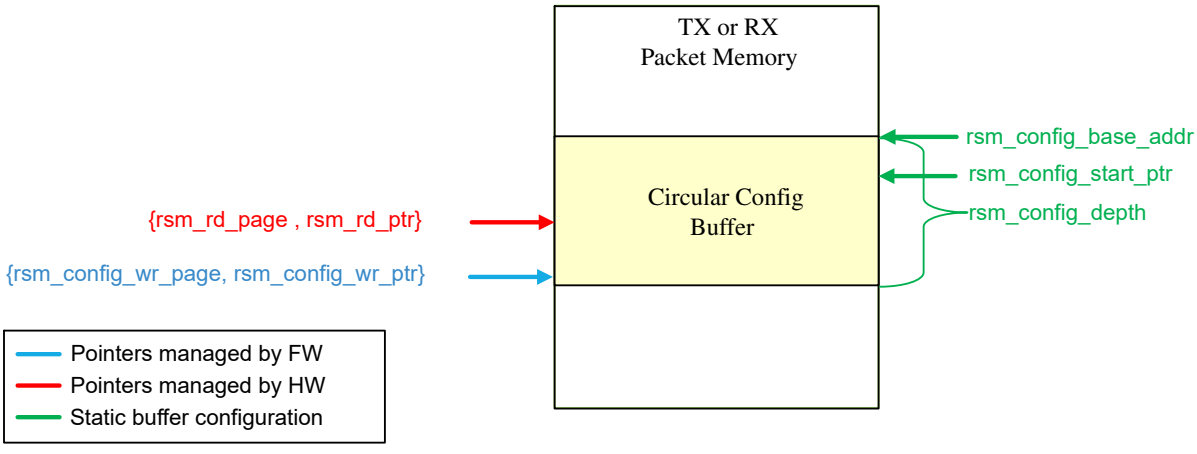


Figure 352. Circular Config Buffer

The circular config buffer is fully programmable for each sub-event to add more FW flexibility depending on memory size and applications. The RSM config buffer address, pointers and depth are word aligned in order to ease the HW implementation.

The registers below must be updated only when RSM is in IDLE and must remain unchanged until the end of a sub-event.

- RSM_CONFIG_LOC register indicates the location of the config buffer. It can be mapped in TX or RX Packet RAM.

- RSM_CONFIG_BASE_ADDR[9:0] register provides the base address of the circular config buffer to allow FW to duplicate configuration buffers or to use the same buffer but with a different start address for the next sub-events.
- RSM_CONFIG_DEPTH[8:0] register indicates the circular buffer depth to optimize the size in memory depending on FW latency
- RSM_CONFIG_START_PTR[9:0] register provides the address to read in the config buffer to get the first step configuration at the beginning of a new sub-event.

FW can used the step interrupt generated by RSM to determine when next steps configuration has to be filled in the buffer of the Packet RAM. This interrupt is generated every N steps to inform FW that N steps have been executed by RSM. The RSM_INT_NBSTEP[7:0] register indicates when this irq is set (in number of steps – value 0 is legacy mode).

An underrun error can occur during a sub-event if RSM reads a new step configuration while this information is not yet written by FW or is not anymore present in the config buffer. RSM detects easily an underrun error by comparing the current FW and HW config pointer registers and their associated config buffer wrap registers:

- CONFIG_WR_PTR [9:0] and CONFIG_RD_PTR[9:0] registers indicate respectively the current FW and HW pointers on config circular buffer. These pointers wrap to the beginning of the buffer when the space remaining at the end of the buffer is less than the maximum step size supported by the sub-event. Therefore, a step config is never split with a part at the end of the buffer and the rest at the beginning of the buffer.
- CONFIG_WR_PAGE and CONFIG_RD_PAGE registers which indicate the page number(0 or 1) are toggling each time their respective pointer is wrapping at the beginning of the circular buffer.

If an underrun error occurs, the RSM is aborted and an abort interrupt is generated and RSM_UNDR_ERR status register is set. An underrun error occurs when RSM reads config buffer when (CONFIG_WR_PAGE=CONFIG_RD_PAGE & CONFIG_WR_PTR < CONFIG_RD_PTR) or when (CONFIG_WR_PAGE!=CONFIG_RD_PAGE.& CONFIG_WR_PTR > CONFIG_RD_PTR).

The RSM always performs 32-bit read access to the config buffer, located in the TX or RX Packet RAM, to get the configuration information for the current frequency step.

Due to a specific HW management, the config buffer can not be mapped in the last 52 bytes of the TX Packet RAM. This size corresponds to the maximum configuration size of a mode3 step.

The fact that configuration buffer is circular prevents the allocation of a huge memory space and doesn't restrict the maximum STEPS number of a sub-event .

52.4.4.2.2.5.10.2.2 Step configuration

The size of configuration information can vary at each frequency step. This requires between 3 words to 13 words per frequency step depending on step mode, and RTT_TYPE mode as described in below table:

Table 487. Step Configuration Size

Step Mode	RTT Type (payload length in bit)	Step Configuration Size (in word)
0	X	5
1	0	5
	32	7
	64	9
	96	11
	128	13
2	X	3
3	0	5

Table continues on the next page...

Table 487. Step Configuration Size (continued)

Step Mode	RTT Type (payload length in bit)	Step Configuration Size (in word)
	32	7
	64	9
	96	11
	128	13

The step configuration can be split in 2 parts.

- common configuration required for every frequency steps whatever the step mode.
- packet configuration required only for frequency steps containing a packet exchange

52.4.4.2.2.5.10.2.2.1 Common configuration description

The frequency step information consists of the following mandatory fields which are present in every configuration step whatever the mode or RTT_TYPE values.

- channel_num[15:0]. This defines the frequency to be used for this step. This is decoded by the PLL using the format defined in the PLL's CHAN_MAP[HOP_TBL_CFG_OVRD] bitfield. NOTE: to ensure proper PLL operation when using the RSM, the PLL's CHAN_MAP[CHANNEL_NUM_OVRD] bitfield should be programmed to 0.
- mode[1:0]. This defines the step mode.
  - 00b - Mode 0 : Frequency Compensation Step (FCS) mode.
  - 01b - Mode 1 : Pk-Pk format.
  - 10b - Mode 2 : Tn-Tn format.
  - 11b - Mode 3 : Pk-Tn-Tn-Pk format.
- tone_ext[1:0] : This selects the tone extension mode for the TX portion of the step
  - 00b - Tone extension is not present for either role in TX.
  - 01b - Tone extension is present for initiator TX only.
  - 10b - Tone extension is present for reflector TX only.
  - 11b - Tone extension is present for both roles in TX.
- ant_permut[4:0] : This defines the antenna permutation pattern for the step
- ant_cs_sync[1:0] : This defines the Antenna CS sync value
- step_one_way: This defines if the step is in one_way or two_way mode
  - 1b : One way step
  - 0b : Two way step.
- t_pm_sel : For Tn-Tn or Pk-Tn-Tn-Pk, this selects whether T_PM0 or T_PM1 is used for the tone duration in this frequency step.
  - 1b : T_PM is associated to T_PM1.
  - 0b : T_PM is associated to T_PM0.
- step_cfo[15:0]: This define the CFO setting for the step.
- hpm_cal_factor[12:1]. This defines the 12 MSBs of the PLL high port modulation calibration factor. The LSB is assigned to 0. It is used only if RSM_HPM_CAL register is set. Note that this has the same format as PLL's HPM_CAL_FACTOR_MANUAL bitfield

- ctune_manual[8:0]. This defines the PLL coarse tune value for this frequency step. It is used only if RSM_CTUNE register is set.
- phase_add[7:0] : This allows FW to adjust phase with first antenna on a multiple antenna context.

Allowing the coarse tune value and hpm calibration factor for each step to be read from RAM reduces the T_FC duration since the PLL does not have to perform these calibration. Note that even if RSM's CTUNE and HPM_CAL bits are cleared (indicating PLL will perform these calibrations), these information are still fetched by RSM at each step.

Table 488. Frequency Step Configuration

Step Mode	Address Offset	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
Mode 0/1/2/3	0	channel_num[7:0]							
	1	channel_num[15:8]							
	2	ant_permut[4:0]				tone_ext[1:0]		mode[1:0]	
	3	-			t_pm_sel	step_one_way	ant_cs_sync[1:0]		
	4	step_cfo[7:0]							
	5	step_cfo[15:8]							
	6	hpm_cal_factor[8:1]							
	7	-				hpm_cal_factor[12:9]			
	8	ctune_manual[8:0]							
	9	-							
	10	phase_add[7:0]							
	11	-							

Refer to COMMON_MODE_CONFIG_HEADER section of General description for more information.

52.4.4.2.2.5.10.2.2.2 Packet configuration description

For SQTE steps which have packet exchanges, there is additional information regarding the packet contents in the configuration of each frequency step. This information is located in the configuration buffer from step base address +12. The content depth varies from 2 words when there is no Payload to 10 words when Payload length is 128bit. Each packet exchange consists of the Initiator sending a packet to the Reflector, and the Reflector sending a packet to the Initiator. So, the first word or words stored in Packet RAM are for the Initiator-to-Reflector packet, and the next word or words are for the Reflector-to-Initiator packet.

Note that the packet format also includes a 8bit (or 16bit in the case of 2Mbps) preamble and a 4bit trailer. The bit sequence in the preamble and trailer is not read from the Packet RAM; it is determined by hardware based on the AA sequence.

The additional information provided for packet exchanges are:

- aa_init[31:0] : This corresponds to the Access Address sent by Initiator to Reflector.
- aa_refl[31:0] : This corresponds to the Access Address sent by Reflector to Initiator.
- payload_init[127:0] : This corresponds to the payload sent by Initiator to the Reflector. The field size depends on RSM_RTT_TYPE register
- payload_refl[127:0] : This corresponds to the payload sent by Reflector to Initiator. The field size depends on RSM_RTT_TYPE register

Table 489. Additional step configuration for packets depending on RSM_RTT_TYPE

Step Mode	RSM_RTT_TYPE	Address Offset (from step config base address)	bits [31:0]
Mode 0/1/3	0, 1, 2, 3, 4, 5, 6	12	aa_init[31:0] for Initiator-to-Reflector packet
		16	aa_refl[31:0] for Reflector-to-Initiator packet
Mode 1 /3	1, 3	20	payload_init[31:0] for Initiator-to-Reflector packet

52.4.4.2.2.5.11 RSM Results

During each individual frequency step, some statuses are written by RSM in Packet RAM to provide information about the computed step. So, a specific area is allocated in the Packet RAM to store the frequency step results.

52.4.4.2.2.5.11.1 Circular Result Buffer

A channel sounding sub-event can support up to 160 steps, but FW doesn't need all the step results at the same time. Therefore, the step results are stored in a circular buffer to use less memory space.

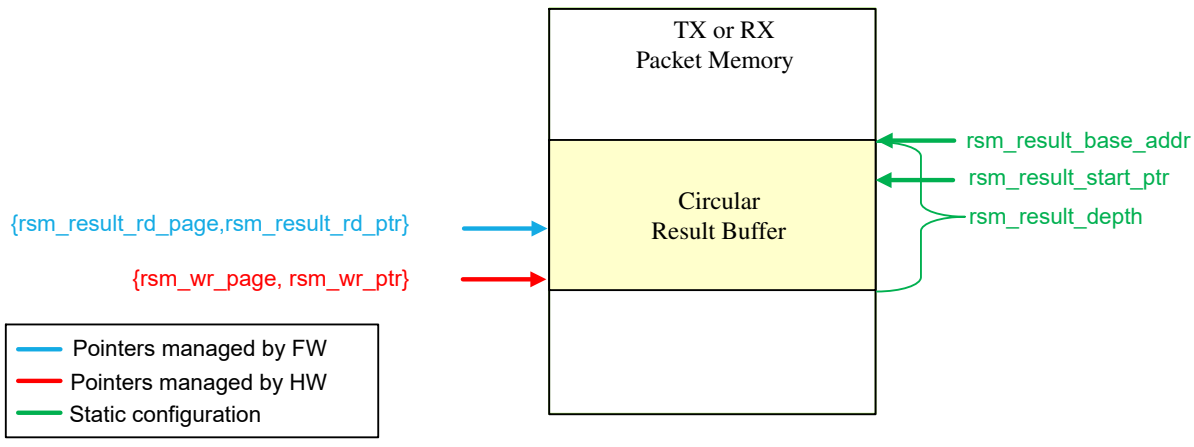

Figure 353. Circular Result Buffer

The circular result buffer is fully programmable for each sub-event to add more FW flexibility depending on memory size and applications. The RSM result buffer address, pointers and depth are word aligned in order to ease the HW implementation.

The registers below must be updated only when RSM is in IDLE and must remain unchanged until the end of a sub-event.

- RSM_RESULT_LOC register indicates the location of the result buffer. It can be mapped in TX or RX Packet RAM.
- RSM_RESULT_BASE_ADDR[9:0] register provides the base address of the circular result buffer to allow FW to duplicate result buffers or to use the same buffer but with a different start address for the next sub-events.
- RSM_RESULT_DEPTH[8:0] register indicates the circular result buffer depth to optimize the size in memory depending on FW latency

- RSM_RESULT_START_PTR[9:0] register provides the address to read in the result buffer to get the first step result at the beginning of a new sub-event.

In overflow error can occur during a sub-event if RSM writes step results while there is not anymore place in the result buffer. RSM detects easily an overflow error by comparing the current FW and HW result pointer registers and their associated result buffer wrap registers:

- RESULT_WR_PTR [9:0] and RESULT_RD_PTR[9:0] registers indicate respectively the current HW and FW pointers on result circular buffer. These pointers wrap to the beginning of the buffer when the space remaining at the end of the buffer is less than the maximum result size supported by the sub-event. Therefore, a step result is never split with a part at the end of the buffer and the rest at the beginning of the buffer.
- RESULT_WR_PAGE and RESULT_RD_PAGE registers which indicate the page number(0 or 1) are toggling each time their respective pointer is wrapping at the beginning of the circular buffer.

If an overrun error occurs, the RSM is aborted and an abort interrupt is generated and RSM_OVRD_ERR status register is set. An overflow error occurs when RSM reads config buffer when (RESULT_WR_PAGE=RESULT_RD_PAGE & RESULT_WR_PTR < RESULT_RD_PTR) or when (RESULT_WR_PAGE!=RESULT_RD_PAGE.& RESULT_WR_PTR > RESULT_RD_PTR).

The RSM performs 8/16/24/32-bit write access to the result buffer, located in the TX or RX Packet RAM, to update the status information for the current frequency step.

Due to a specific HW management, the result buffer can not be mapped in the last 80bytes of the TX Packet RAM. This size corresponds to the maximum result size of a mode3 step in sniffer role.

The fact that result buffer is circular prevents the allocation of a huge memory space and doesn't restrict the maximum STEPS number of a sub-event.

The procedure to manage the rollover of the circular result buffer is the following :

- Calculate (or look up) the Mode 3 step size (RES_SIZE) as a function of NUM_AP.
- When reading RESULT space, if the pointer (before the read) points to a location < RES_SIZE away from the end of the result buffer end, the pointer is reset to the base of the result buffer.

52.4.4.2.2.5.11.2 RSM statuses

The size of result information can vary at every frequency step. This requires between 3 words to 20 words per frequency step depending on step mode, the number of antenna paths and the ranging role as described in below table:

Table 502. Step Result Size Table

Mode	Antenna path number	Step Result Size (in word)	
		Reflector/ Initiator role	Sniffer role
Mode 0	X	5	10
Mode 1	X	5	10
Mode 2	1	3	6
	2	4	8
	3	5	10
	4	6	12
Mode 3	1	7	14
	2	8	16
	3	9	18
	4	10	20

Note that in sniffer configuration, the result size of a frequency step is duplicated since RSM stores first part and second part of the step.

The channel sounding results can be split in 3 kind of status reported by RSM.

- common status reported for every frequency steps whatever the step mode.
- packet status reported for every frequency steps containing a packet exchange
- tone status reported for every frequency steps containing a tone exchange

52.4.4.2.2.5.11.2.1 Common status

Some fields are always present in the result buffer whatever the mode in the frequency step results.

- step_id[7:0] : This indicates the frequency step number.
- result_len[3:0] : This indicates the result length in words of the frequency step.
- agc_idx[3:0] : This indicates the AGC index applied during the RX part of the frequency step.
- pcbd[8:0] / ctune[8:0] : In the configuration where the PLL performs coarse tune during the RSM operation (CTUNE=0), the RSM will capture the coarse tune best diff value or the vco ctune value depending on RSM_PCBD_CTUNE_SEL register.
- time_drift[1:0] : Indicates the timing drift delta value for this step (00b: 0us, 01b : +1 us, 11b: -1us).
- aa_det : This indicates if a packet access address has been detected during the frequency step. This field is expected to be set in mode 0/1/3 if the access address of the RX packet is correctly received, otherwise it is expected to be 0.

Table 503. Common Results Table

Step Mode	Address Offset	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
Mode 0/1/2/3	0	step_id[7:0]							
	1	agc_idx[3:0]				result_len[3:0]			
	2	pcbd[7:0] / ctune[7:0]							
	3	aa_det	-	time_drift		-			pcbd[8] / ctune[8]

Refer to COMMON_MODE_RESULT_HEADER section of General description for more information.

52.4.4.2.2.5.11.2.2 Packet status

Some fields are only present in channel sounding mode 0/1/3 when packet transfer is expected during frequency step. This information is located in the status buffer from step status base address +4. In that case, additional fields are written by RSM in circular result buffer:

- rssi_nb[7:0] : This indicates the narrowband RSSI value computed during the access address reception
- raw_nadm[23:0] : This describes all the statuses computed by NADM module.
  - raw_nadm[7:0] indicates the NADM FM correlator value. This is the NADM correlation result of the received signal with a local reference signal.
  - raw_nadm[8] indicates if the NADM FM correlator value is valid.
  - raw_nadm[12:9] indicates to the NADM FM symbol error value. This is the NADM check result between the received signal payload and a reference payload.
  - raw_nadm[13] indicates if the NADM FM symbol error value is valid.
  - Raw_nadm[23:14] indicates the NADM pdelta value. It corresponds to the difference of correlations around maximum correlator instance

- rtt_data[31:0] : This describes all the RTT(round trip time) statuses computed by PHY module.
  - rtt_data[0] indicates if rtt_data[31:1] is valid.
  - rtt_value[1] indicates the ha_rtt_found value. This flag indicates that the HARTT operation is done through the Cordic algorithm.
  - rtt_value[17:2] indicates the ha_rtt_cfo[15:0]. It corresponds to the high accuracy CFO computed by the HARTT block through the Cordic algorithm.
  - rtt_value[19:18] indicates rtt_int_adj[1:0]. It corresponds to an integer adjustment of the timing which takes a value different of 0 when the early-late mechanism in the HARTT block chooses a peak different of the one chosen in the acquisition module (possible values are {-1,0,+1}).
  - rtt_value[21:20] indicates ham_rtt_dist_sat[1:0]. It corresponds to the Computed Hamming distance saturated to 2 bits.
  - rtt_value[31:22] indicates rtt_pdelta[9:0]. It corresponds to the difference between the squared correlation magnitude values, pm-pp, provided by the HARTT block.
- cfo_est[9:0] : This indicates the CFO estimate computed by the AA0 detector
- tpm[31:0] : This indicates the ToA-ToD time. The unit of this time is the Transceiver clock period (31.25ns).
  - In initiator configuration, it corresponds to the time between the beginning of Tx packet and the access address detection of the RX packet.
  - In reflector configuration,
    - at the first CS step, it corresponds to the time between the beginning of the warm-up sequence to the access address detection of the Rx packet.
    - after the first CS step, it corresponds to the time between the access address detection of the Rx packet to the beginning of TX packet.

Table 504. Packet Results

Step Mode	Address Offset	bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
Mode 0 (FCS) or Mode 1 (Pk-Pk) or Mode 3 (Pk-Tn-Tn-Pk)	4	rssi_nb[7:0]

Refer to COMMON_MODE_013_RESULT_BODY section of General description for more information.

52.4.4.2.2.5.11.2.3 Tone Status

Some fields are only present in channel sounding mode 2/3 when tone transfer is expected during frequency step. This information is located in the status buffer from step status base address +4 or step status base address +20 depending on step mode. In that case, additional tone statuses per antenna paths are also written by RSM in circular result buffer:

- tqi_N[1:0] : This indicates the Tone Quality indicator for Antenna path N.
- pct_i_N[11:0] : This indicates in-phase component of the PCT for Antenna path N.
- pct_q_N[11:0] : This indicates quadrature component of the PCT for Antenna path N.

The PCT results are stored in Packet RAM from the first (permuted) antenna path to last (permuted) antenna path followed by the extension field.

PCT for the Tone Extension is always computed even if Tone Extension is not expected.

Table 505. Tone Results

Step Mode	Antenna path Number	Address Offset		bit 7	bit 6	bit 5	bit 4	bit 3	bit 2	bit 1	bit 0
		Mode2	Mode3								
Mode2 (Tn-Tn) or Mode 3 (Pk-Tn-Tn-Pk)	X	4	20	pct_i_1[3:0]				-		tqi_1[1:0]

52.4.4.2.2.5.12 Packet Ram Data Structures

52.4.4.2.2.5.12.1 General description

The main point of communication between RSM and Channel Sounding Link Layer Software is the Packet RAM. The config and result buffers are built in Packet RAM for each step by using specific data structures depending on step mode, the payload size and the number of antenna paths

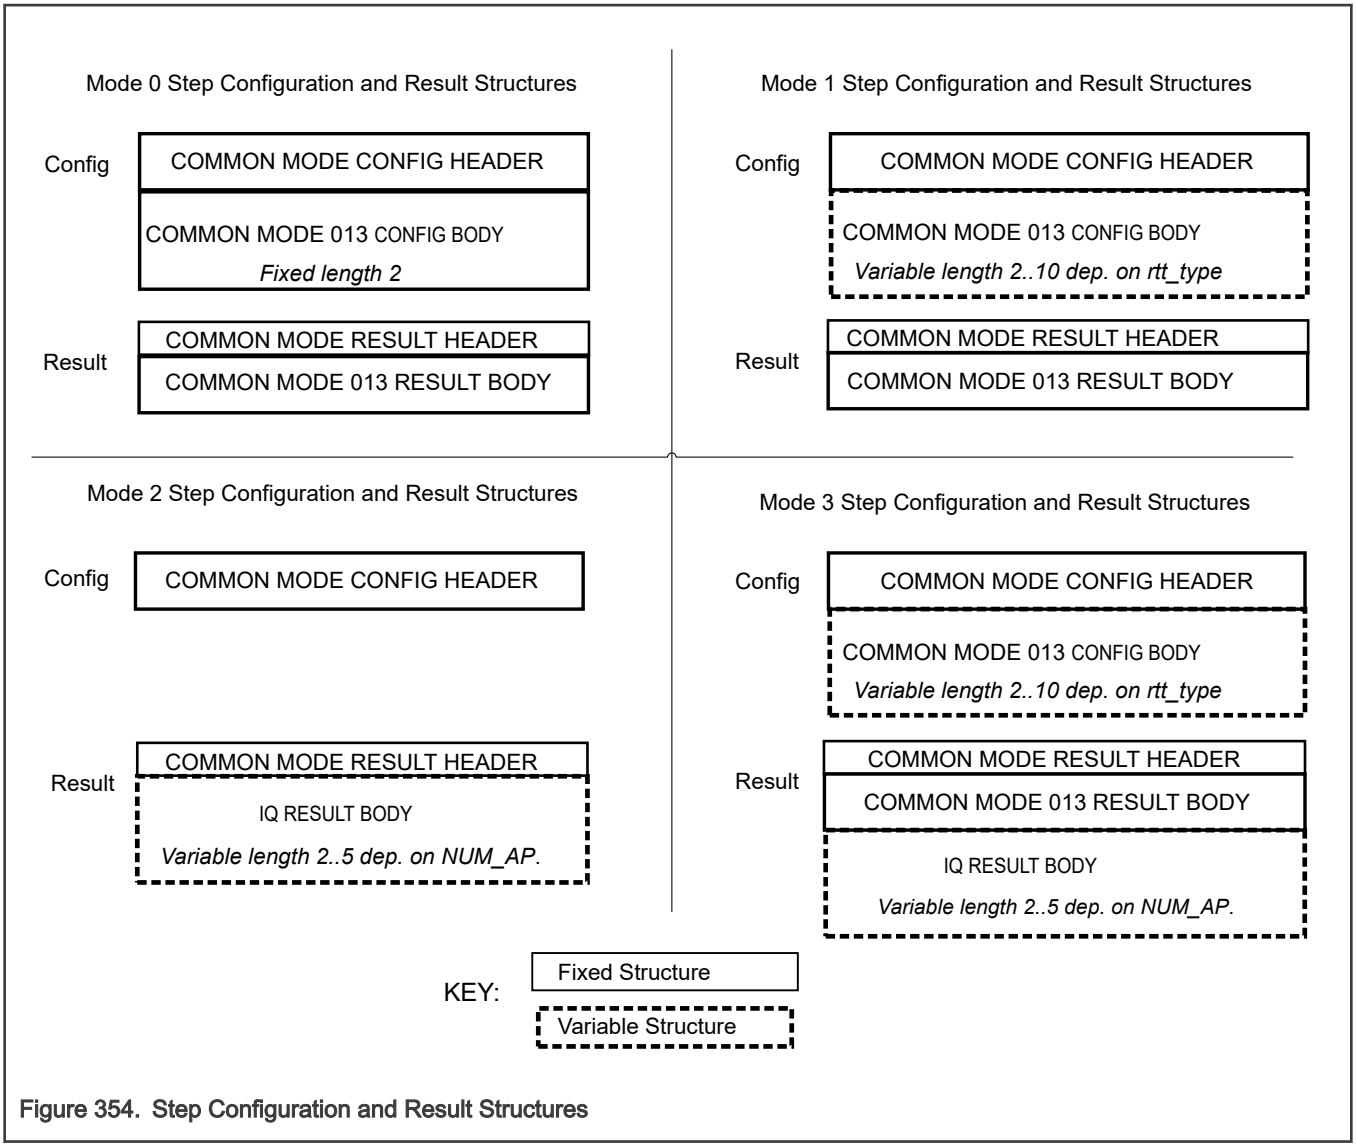

Figure 354. Step Configuration and Result Structures

52.4.4.2.2.5.12.2 COMMON MODE CONFIG HEADER

52.4.4.2.2.5.12.2.1 register descriptions

52.4.4.2.2.5.12.2.1.1 CommMode Configuration Header Indices

Data structure definition for the common header used in the configuration of all Channel Sounding Steps. Defines the format of bitfields in PKT_RAM memory for these step types. This header structure may be followed by a variable length structure representing the access address and payload contents for RTT steps.

Index	Register	Width (In bits)	Access	Reset value
0h	Channel number for the step. (CHANNEL_NUM)	16	RW	See section
2h	Configuration for the step. (STEP_CFG)	16	RW	See section
4h	CFO setting for the step (STEP_CFO)	16	RW	See section

Table continues on the next page...

Table continued from the previous page...

Index	Register	Width (In bits)	Access	Reset value
6h	HPM CAL factor to apply for the step. (HPM_CAL_FACTOR)	16	RW	See section
8h	CTUNE manual to inject for the step. (CTUNE_MANUAL)	16	RW	See section
Ah	Phase adder for the step. (PHASE_ADD)	16	RW	See section

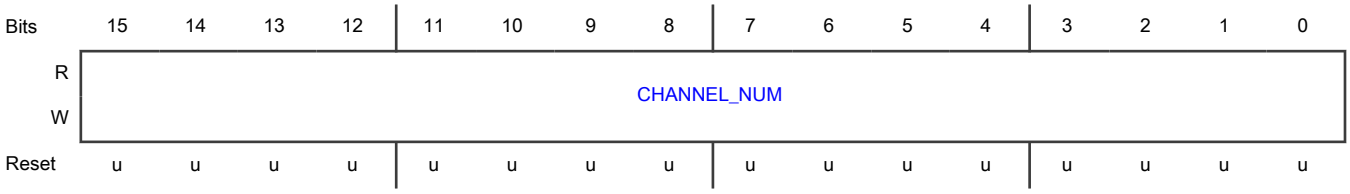
52.4.4.2.2.5.12.2.1.2 Channel number for the step. (CHANNEL_NUM)

Index

Register	Index
CHANNEL_NUM	0h

Function
Configuration fields for the Mode 2 step type.

Diagram



Fields

Field	Function
15-0 CHANNEL_NUM	Channel number for the step. This defines the frequency to be used for this step. This is decoded by the PLL using the format defined in the PLL's CHAN_MAP[HOP_TBL_CFG_OVRD] bitfield. NOTE: to ensure proper PLL operation when using the RSM, the PLL's CHAN_MAP[CHANNEL_NUM_OVRD] bitfield should be programmed to 0.

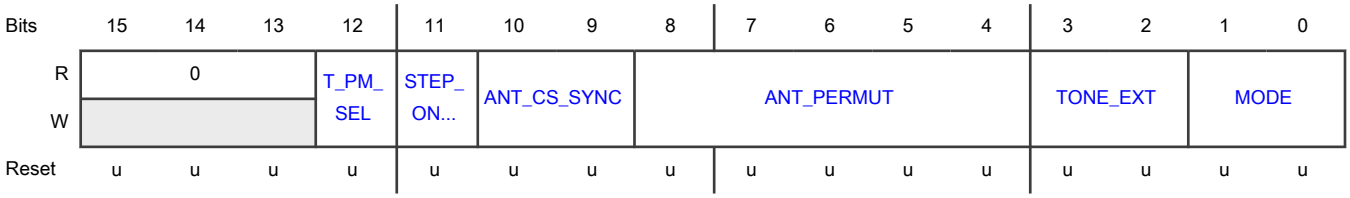
52.4.4.2.2.5.12.2.1.3 Configuration for the step. (STEP_CFG)

Index

Register	Index
STEP_CFG	2h

Function
Various configuration fields valid for the all CS modes.

Diagram



Fields

Field	Function
15-13 —	Reserved
12 T_PM_SEL	Selection of T_PM choices. For Tn-Tn and Pk-Tn-Tn-Pk formats, this selects whether T_PM0 or T_PM1 is used for the tone duration in this frequency step. 0b - T_PM0 is used 1b - T_PM1 is used
11 STEP_ONE_WAY	Unidirectional Mode When this bit is set, the Unidirectional Mode is enabled for the step. Only mode 1 and 2 support the unidirectional mode, so this bit must be always set to 0 in mode 0 and in mode 3. 0b - Unidirectional Mode is disabled 1b - Unidirectional Mode is enabled
10-9 ANT_CS_SYNC	Antenna cs Sync Selects the default antenna for modes 0,1 (and 3 for packet transmission) -> antenna 0 to antenna 3 00b - A0 01b - A1 10b - A2 11b - A3
8-4 ANT_PERMUT	Antenna permutation pattern for the step. This field is used only in mode 2 or mode 3 when LCL_CFG0[LCL_ANT_PERMUT_EN] is set. It indicates the index of antenna permutation table which is used to select the specific antenna paths position order.
3-2 TONE_EXT	Choice of tone extension for the initiator portion of the step. Used only in mode 2 or mode 3 Since the presence of the Tone Extension is always checked by the RX device then TONE_EXT[0]=0x1 for Reflector and sniffer in mode 2 and mode 3 TONE_EXT[1]=0x1 for Initiator only in mode 2 and sniffer in mode 2 and mode 3 00b - Tone extension is not present for either role TX. 01b - Tone extension is present for initiator TX only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Tone extension is present for reflector TX only. 11b - Tone extension is present for both roles TX.
1-0 MODE	Mode for the step 00b - Frequency Compensation Step (Mode 0) 01b - Pk-Pk step (Mode 1) 10b - Tn-Tn step (Mode 2) 11b - Pk-Tn-Tn-Pk step (Mode 3)

52.4.4.2.2.5.12.2.1.4 CFO setting for the step (STEP_CFO)

Index

Register	Index
STEP_CFO	4h

Function

This field is 16 bits signed. It can be added to pll_numerator_offset to adjust the PLL frequency (0.9536 Hz/step @ 32 Mhz) during RX whatever the step mode.

Diagram

Fields

Field	Function
15-0 STEP_CFO	CFO setting for the step. This field can be added to pll_numerator_offset to adjust the PLL frequency (0.9536 Hz/step @ 32 Mhz) during RX whatever the step mode.

52.4.4.2.2.5.12.2.1.5 HPM CAL factor to apply for the step. (HPM_CAL_FACTOR)

Index

Register	Index
HPM_CAL_FACTOR	6h

Function

This defines the 12 MSBs of the PLL high port modulation calibration factor. The LSB is assigned to 0. It is used only if RSM_HPM_CAL register is set. Note that this has the same format as PLL's HPM_CAL_FACTOR_MANUAL bitfield

Diagram

Fields

Field	Function
15-12 —	Reserved
11-0 HPM_CAL_FACTOR	HPM CAL factor to apply for the step This defines the 12 MSBs of the PLL high port modulation calibration factor. The LSB is assigned to 0. Note that this has the same format as PLL's HPM_CAL_FACTOR_MANUAL bitfield

52.4.4.2.2.5.12.2.1.6 CTUNE manual to inject for the step. (CTUNE_MANUAL)

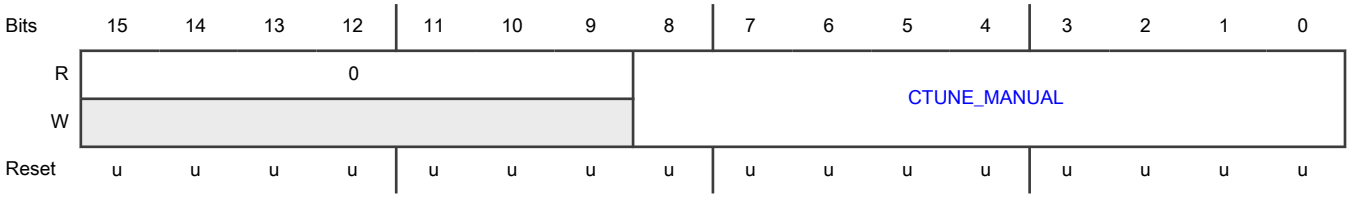
Index

Register	Index
CTUNE_MANUAL	8h

Function

This defines the PLL coarse tune value for this frequency step

Diagram



Fields

Field	Function
15-9	Reserved

Field	Function
—	
8-0 CTUNE_MANUAL	CTUNE manual to inject for the step. This defines the PLL coarse tune value for this frequency step. It is used only if RSM_CTUNE register is set

52.4.4.2.2.5.12.2.1.7 Phase adder for the step. (PHASE_ADD)

Index

Register	Index
PHASE_ADD	Ah

Function

It can be added to rx_phase_return signal computed for Inline Phase Return. This offset is 8 bits signed

Diagram

Fields

Field	Function
15-8 —	Reserved
7-0 PHASE_ADD	Phase adder for the step. This allows FW to adjust phase with first antenna on a multiple antenna context

52.4.4.2.2.5.12.3 PAYLOAD CONFIG BODY

52.4.4.2.2.5.12.3.1 register descriptions

52.4.4.2.2.5.12.3.1.1 Payload Configuration Body Indices

Data structure definition for AA and payload configuration storage for Mode 1 and 3 Channel Sounding Steps. Defines the format of bitfields in PKT_RAM memory for the payload portion of these steps. This structure is intended to be used after the common_mode_config_hdr structure and may be variable length depending on the RTT payload length.

Index	Register	Width (In bits)	Access	Reset value
0h	Access address used for the Initiator transmission phase (AA_INIT)	32	RW	See section
4h	Access address used for the reflector transmission phase (AA_REF)	32	RW	See section
8h	32bit word of payload for the initiator for the step. (PAYLOAD_INIT0)	32	RW	See section
Ch	32bit word of payload for the reflector for the step. (PAYLOAD_REFL0)	32	RW	See section
10h	32bit word of payload for the initiator for the step. (PAYLOAD_INIT1)	32	RW	See section
14h	32bit word of payload for the reflector for the step. (PAYLOAD_REFL1)	32	RW	See section
18h	32bit word of payload for the initiator for the step. (PAYLOAD_INIT2)	32	RW	See section

52.4.4.2.2.6 Localization Control Module (LCL)

52.4.4.2.2.6.1 Introduction

The transceiver supports two antenna control mechanisms: Fast Antenna Diversity (FAD), and Localization Control. FAD allows an optimal choice between two antennas during the PHY's preamble search. Localization Control refers to direction finding (angle of arrival / angle of departure) and ranging. Only one of these is enabled at any given time.

A high level figure illustrating the transceiver modules involved is shown below. The FAD algorithm is in the PHY, which provides an output to control the antenna through the FAD Common pin interface. The Localization control outputs "lant_lut_gpio[3:0]" (to control an external antenna switch) plus a start trigger and DMA mask signal to the XCVR DMA to facilitate capture of receiver samples. For Bluetooth LE direction finding, the Localization Control module accepts CTE control signals from the Bluetooth LE link layer. For ranging, a Ranging Sequence Manager sequences the transceiver between RX and TX operations across a set of programmable frequencies for the purpose of the capturing phase samples (when tones are transmitted) and RTT measurements (when packets are transmitted) in the receiving device, and also provides a trigger to the Localization Control module for optional antenna switching. In addition, the Localization Control module provides a trigger to the SOC (to be connected to a timer) for time-of-flight timestamping; this trigger is a mux of several signals in the transceiver as shown in the figure. The four FAD outputs and LCL_CTRL's lant_lut_gpio[3:0] outputs go to SOC pins via the RF_GPO muxes described in the Coexistence/FEM/LANT connections section of the Radio Control chapter.

The Localization Control , Ranging Sequence Manager and FAD Common Pin Interface are described in the sections below. For more info on the PHY's FAD algorithm refer to the PHY chapter.

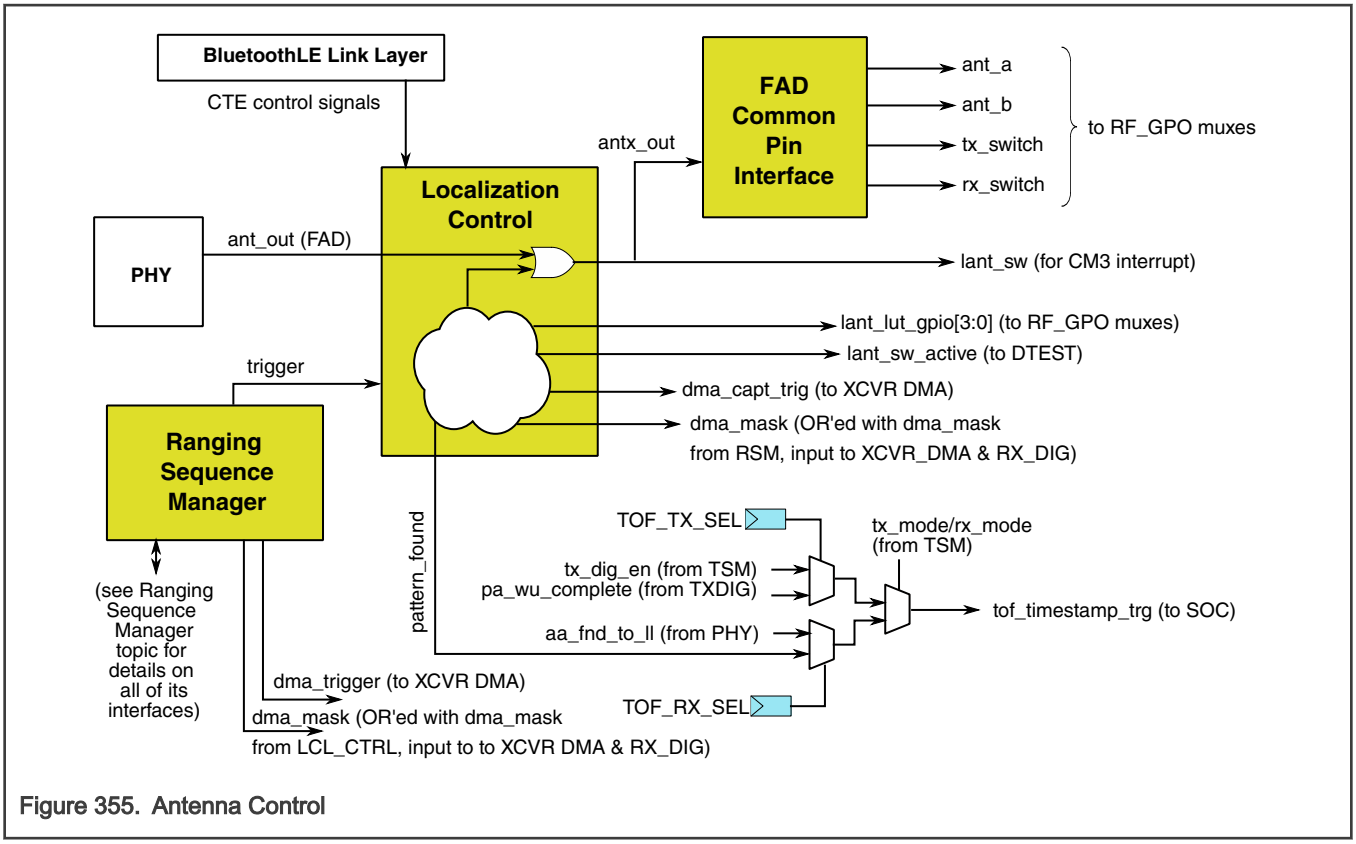

Figure 355. Antenna Control

52.4.4.2.2.6.2 Functional description

The LCL_CTRL module implements various controls intended to assist with antenna control and sample capture.

There are 3 significant functions of this module:

1. Scan the bit stream for a pattern
2. Control the switching of the antenna output (lant_lut_gpio[3:0])
3. Provide a data valid mask signal for the XCVR DMA

Within the LCL_CTRL there is pattern matching logic that will assert a pattern found signal when the incoming bit stream matches the pre-programmed pattern. The pattern can be 4, 5, 6, or 8 bytes (setting PM_NUM_BYTES). The pattern must be programmed in the LCL_PM_MSB and LCL_PM_LSB registers and pattern matching must be enabled. If COMP_EN is set, then pattern matching will operate during RX. For pattern matching in TX, both COMP_EN and COMP_TX_EN must be set. The pattern_match output asserts when a pattern match has occurred. For RX, when the pattern_match output asserts the dma_capt_trig to the XCVR_DMA also asserts.

For antenna control, the LCL_CTRL module can be configured using the MODE bit to operate with or without use of the Bluetooth LE Link Layer's Constant Tone Extension (CTE) control signals.

52.4.4.2.2.6.2.1 Antenna Control Without BLE CTE Signals

For antenna control without using the Bluetooth LE CTE control signals, various settings must be programmed prior to operation. The significant fields are:

- CTE_DUR : Duration of switching activity in doublets, where a doublet = RX/TX_HI_PER + RX/TX_LO_PER
- LANT_INV : When set to 1, the lant_sw signal is inverted
- RX/TX_LCL_EN : Enables antenna switching control in RX and/or TX
- LCL_EN : Enable for the entire LCL_CTRL module

- RX/TX_DELAY_OFF : Extra offset (in samples) to fine tune the RX/TX_DELAY
- RX/TX_DELAY : Delay, in intervals, before antenna switching is to begin
- RX/TX_LO_PER : Number of intervals for which lant_sw should be 0, when switching is active. For RX, RX_LO_PER also indicates the number of intervals that the dma_mask should be 0.
- RX/TX_HI_PER : Number of intervals for which lant_sw should be 1, when switching is active. For RX, RX_HI_PER also indicates the number of intervals that the dma_mask should be 1.
- RX/TX_ANT_TRIG_SEL : Selects the trigger to be observed to begin counting DELAY
- RX/TX_SPINT : Defines the number of samples per interval. This is realized using the sample clock associated with either RX or TX, (typically 4MHz or 8MHz).
- M_ON_DELAY/N_ON_DELAY: The rx/tx_lco_on output will de-assert M_ON_DELAY intervals + N_ON_DELAY doublets earlier than the antenna switching stops.
- LUT_0 to LUT_31: state of lant_lut_gpio[3:0] for the switching activity doublet from 0 to 31
- LUT_WRAP_PTR: Wrap point for the LUT_0 to LUT_31. If programmed to value "N", output will be LUT_0, ..., LUT_N, LUT_0, ...

When enabled, the LCL_CTRL control module begins monitoring the selected trigger source as indicated by RX/TX_ANT_TRIG_SEL. When the trigger occurs, a timer begins. When the timer reaches DELAY+DELAY_OFF, the system will align to the next available sample clock and the antenna switching begins. The switching is described by asserting as 1 for HI_PER, then de-asserting as 0 for LO_PER. One of these cycles is termed a 'doublet'. This initial process is depicted in the figure below.

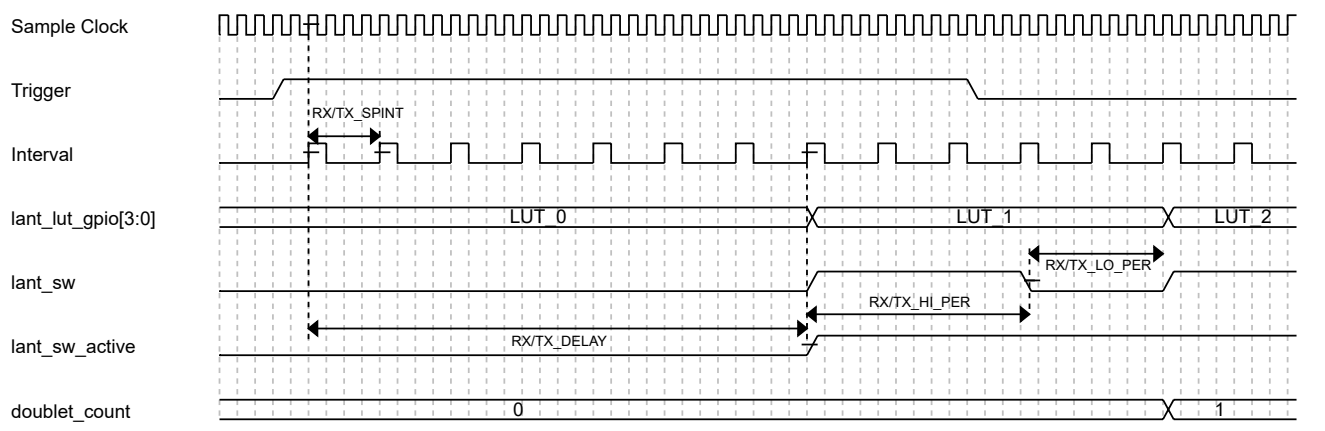

Figure 356. LCL_CTRL startup

After antenna switching has begun, another counter will count the doublets. When the CTE_DUR is reached, switching will stop as depicted in the following figure.

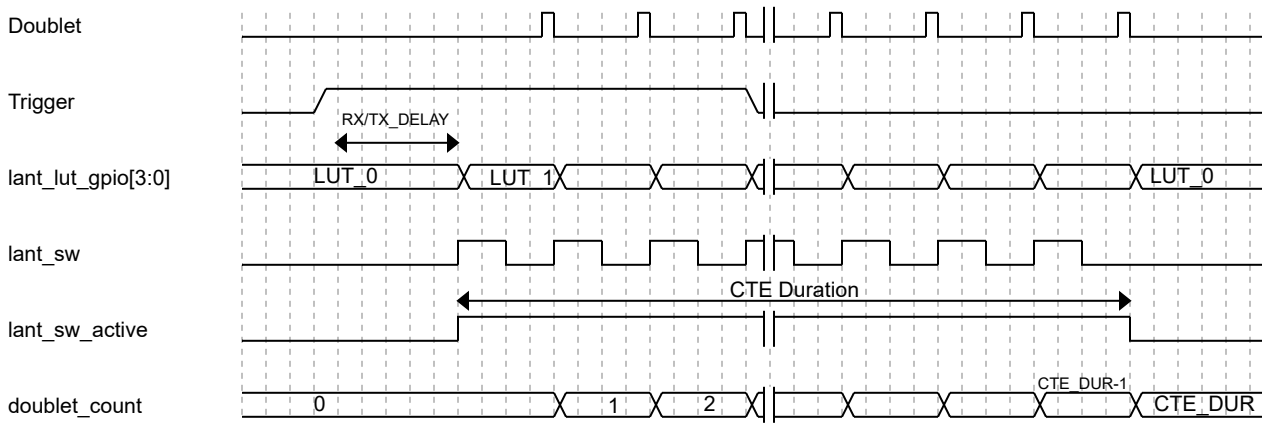

Figure 357. LCL_CTRL shutdown

The LCL_CTLR provides a data valid mask signal for the XCVR DMA so the DMA can avoid capturing unwanted data in the Guard period, and immediately after antenna is switched ("switching slots"). For this feature, there are several additional control settings:

- DMA_MASK_DELAY_OFF: Extra offset (in samples) to fine tune the DMA_MASK_DELAY
- DMA_MASK_DELAY: Delay, in intervals, from RX trigger to the time at which DMA mask asserts
- DMA_MASK_REF_PER: Duration, in intervals, of the reference period after DMA_MASK_DELAY expires during which the dma_mask remains asserted

The following figure depicts the dma_mask signal behavior in a CTE example. As can be seen, the dma_mask allows data to be captured during the reference period and sampling slots while avoid the guard period and switching slots.

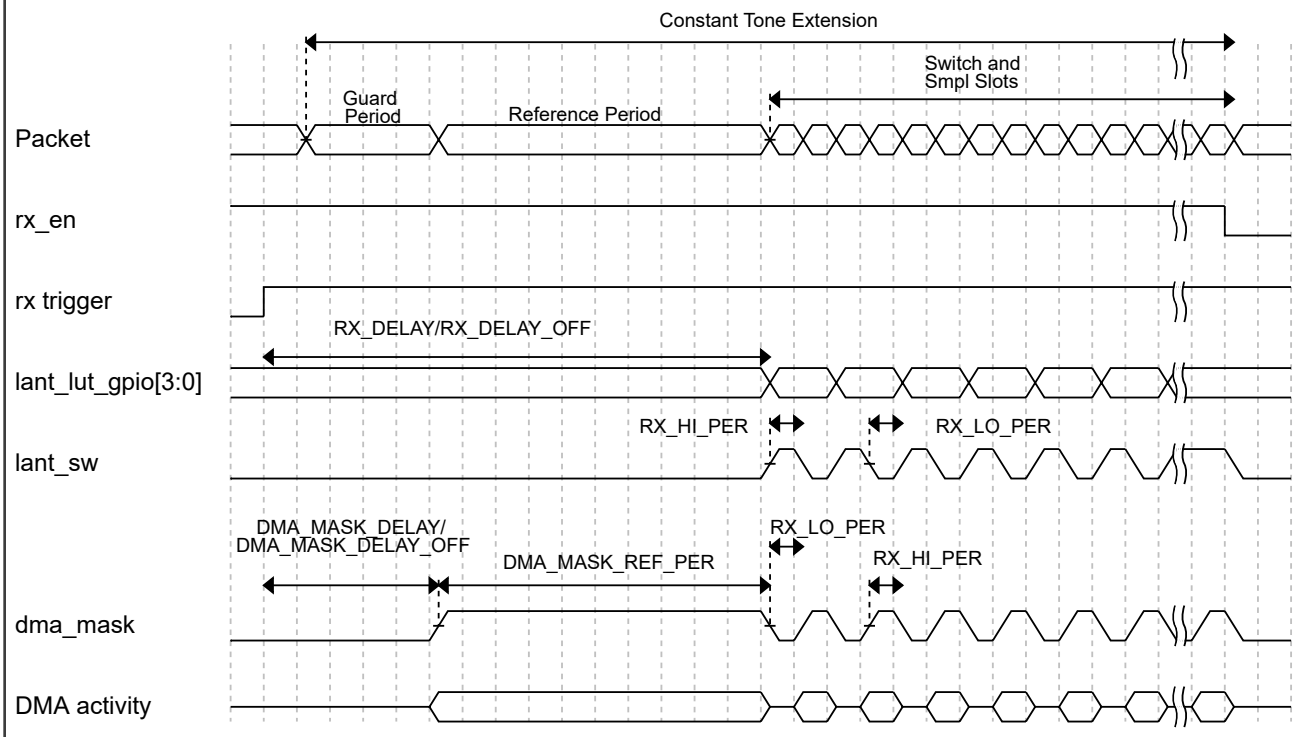

Figure 358. LCL_CTRL dma_mask

52.4.4.2.2.6.2.1.1 Antenna Control Used With RSM

Using LCL_CTRL with the RSM is considered a special case of "Antenna Control Without Bluetooth LE CTE Signals."

The RSM's rx and tx trigger output to the LCL_CTRL are expected to be used in this configuration. The RSM will trigger the LCL during it's T_PM (tone exchange) states. Since the RSM supports dynamically switching between 4 different T_PM durations while it is active, the LCL_CTRL include the following registers which are used only in conjunction with RSM:

- RX/TX_LO_PER1-3 : Alternate number of intervals for which lant_sw should be 0, when switching is active. For RX, RX_LO_PER also indicates the number of intervals that the dma_mask should be 0. These are used when RSM signals the LCL_CTRL that it is using T_PM1-3 durations instead of T_PM0 duration. (When T_PM0 duration is used, LCL_CTRL's RX/TX_LO_PER are used.) Refer to Introduction for more information on T_PM durations.
- RX/TX_HI_PER1-3 : Alternate number of intervals for which lant_sw should be 1, when switching is active. For RX, RX_HI_PER also indicates the number of intervals that the dma_mask should be 1. These are used when RSM signals the LCL_CTRL that it is using T_PM1-3 durations instead of T_PM0 duration. (When T_PM0 duration is used, LCL_CTRL's RX/TX_LO_PER are used.) Refer to Introduction for more information on T_PM durations.

The figures below illustrate the LCL_CTRL behavior when used with the RSM. Note that the delay from the trigger to the start of antenna switching is different when the RSM is used (as signalled by RSM's "active" output being high) : it includes the LO_PER and HI_PER durations in addition to DELAY/DELAY_OFF. Note that there are two figures for RX: the first one doesn't use DMA_MASK_REF_PER, and the second does.

For Figure 360, the DMA_MASK_REF_PER is not used (programmed to 0). Since the trigger asserts immediately on entry to RSM's T_PM states, the DELAY/DELAY_OFF and DMA_DELAY/DMA_DELAY_OFF values are expected to be programmed to 0 (or very small values), and the DMA mask will be asserted at the end of each LUT_x window.

For Figure 361, the samples captured during the first antenna switching period correspond to DMA_MASK_REF_PER (which would be expected to be programmed to the same value as RX_HI_PER). As compared to the other figure, the DMA mask is centered within the antenna LUT_x window. However, since there is only one DMA_MASK_REF_PER, the logic doesn't support the use of different RX_HI_PER durations / different T_PM durations.

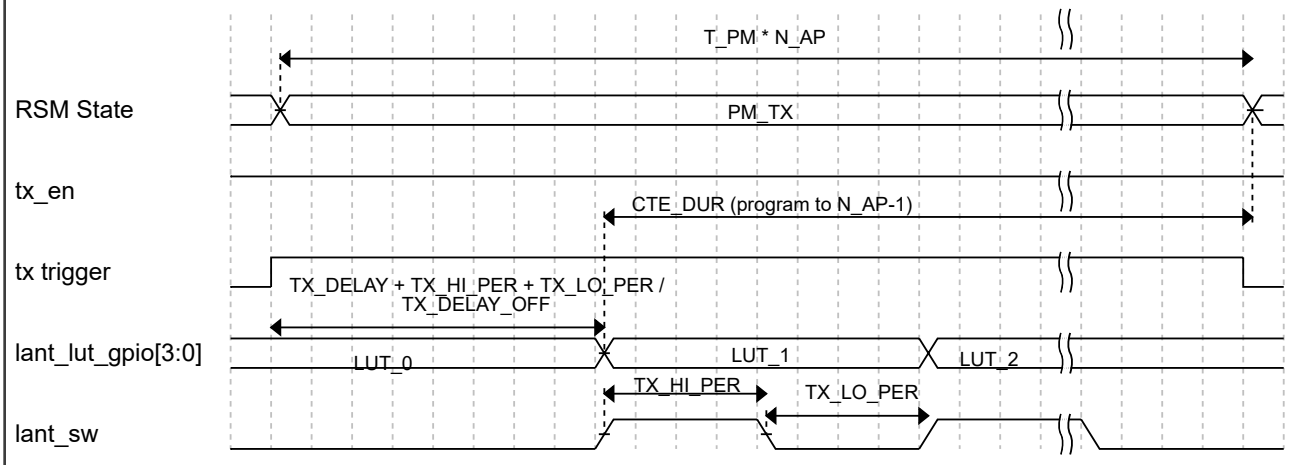

Figure 359. LCL_CTRL Operation with RSM - TX

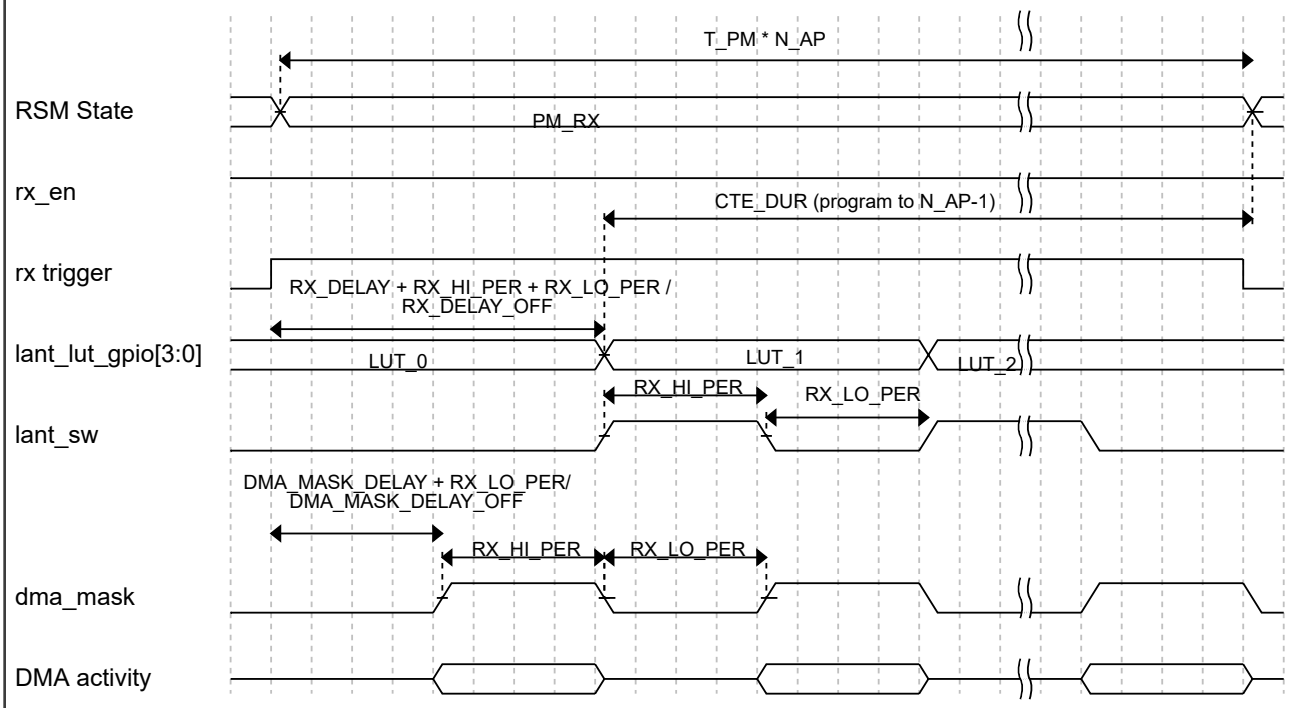

Figure 360. LCL_CTRL Operation with RSM - RX

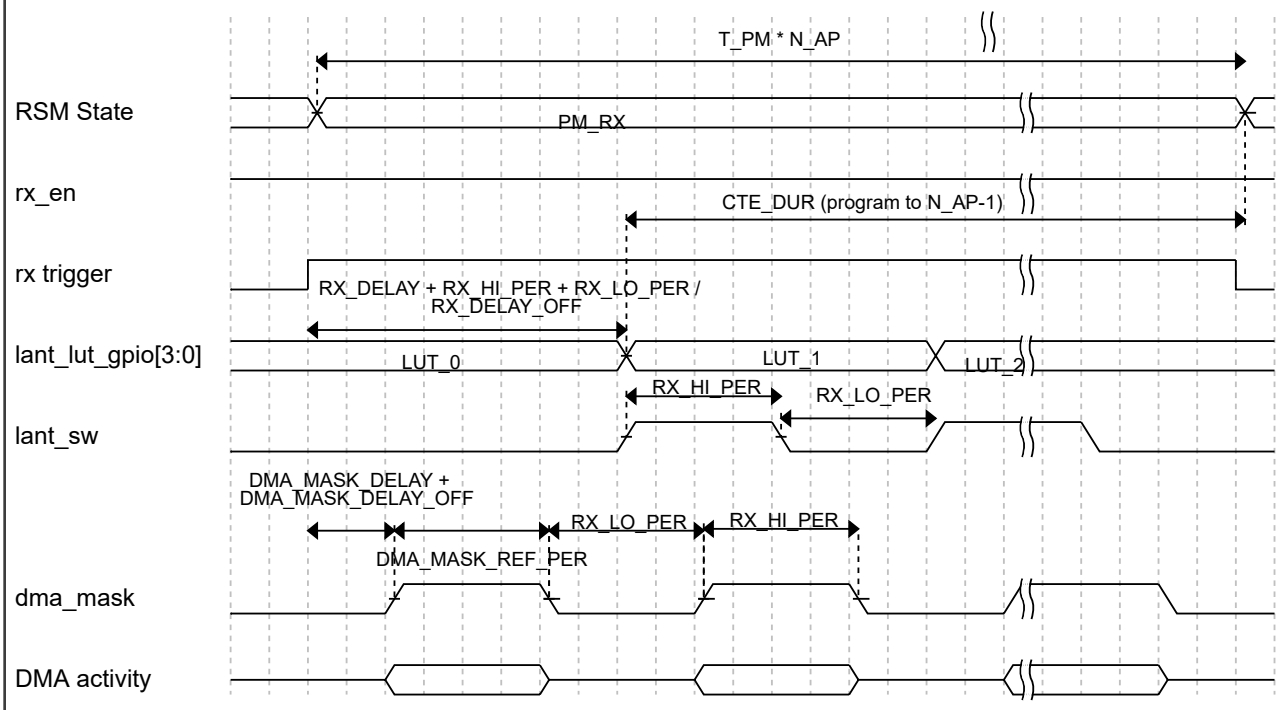

Figure 361. LCL_CTRL Operation with RSM - RX (Alternate Usage)

52.4.4.2.2.6.2.1.2 Antenna Switch Used with RSM

All fields used below for Antenna Switching are contained in LCL_TX_CFG0 and LCL_TX_CFG1 registers.

Using Antenna Switch with RSM by enabling :

- TX_SW_ACTIVE : To enable antenna switch only during T_PM.
- ANT_SW_RF : To enable switching at each gpio toggle outside T_PM.
- TX_SW_ACTIVE & ANT_SW_RF : Enable both to ensure full PA Switch feature with localization.

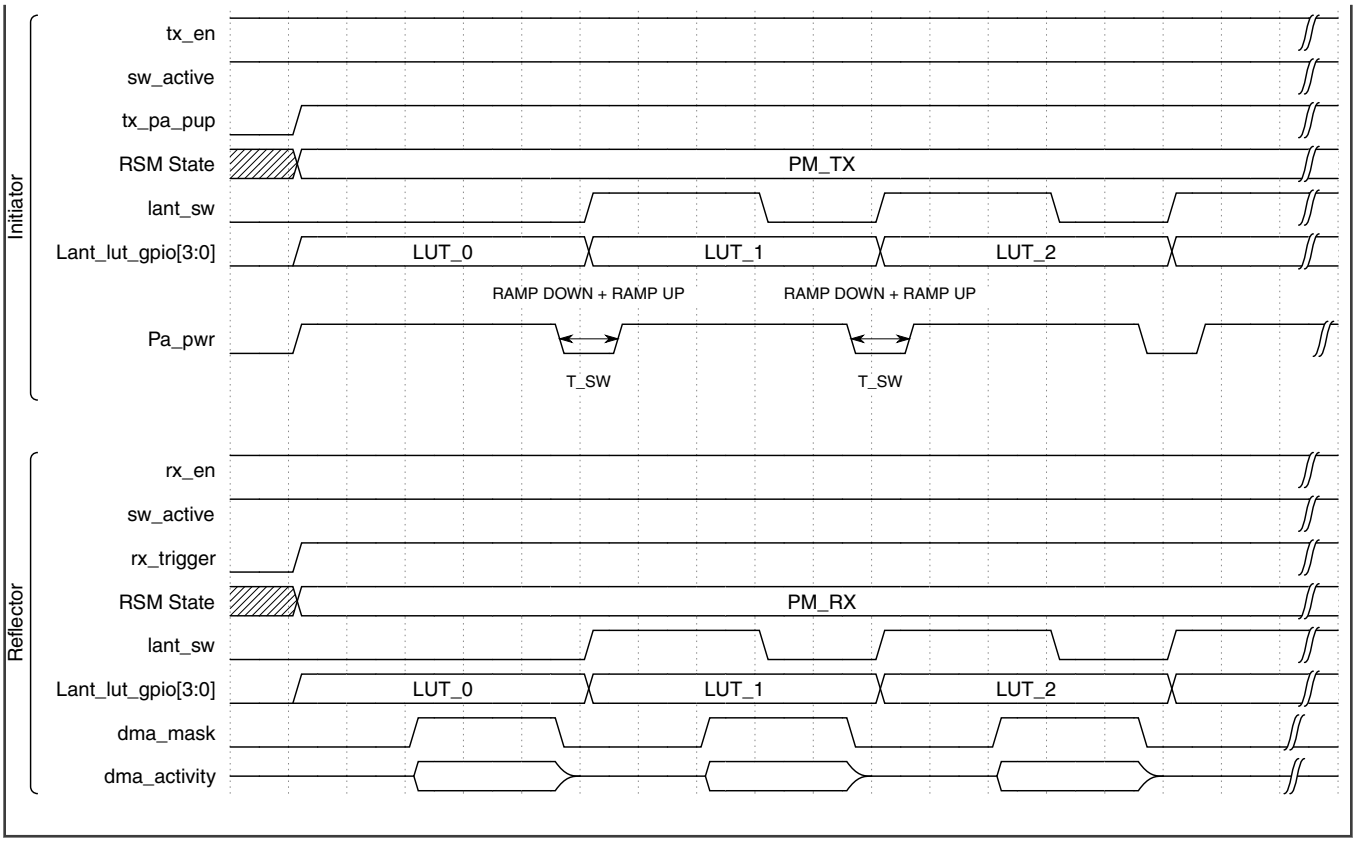
While switching antennas (between each lant_sw risings) , no high power is allowed in the antennas. This is supported by doing ramping (up and down) while switching antennas.

When switching antennas is allowed , a time of switch (T_SW) is defined : 1/2/4/10 us.

If T_SW = 1us : the ramping will cut 0.5 us from both T_PMs (previous and next one) to satisfy the T_SW timing and also the Ramping's one .

lcl_dma_mask_center[3:0] will be used to center the dma_mask (1/2/4/8/16/32/64/128 in us granularity) .This will be automatically handled by hardware (taking into account T_PM register value) to get optimum window for dma_mask without changing TX/RX_LO_PER and TX/RX_HI_PER values.

Figure 362. Antenna Switch TX-RX Sequence



While T_SW , antennas will do a proper ramp (up and down) and allow multiple configurations of the rampings and low power windows :

TX_SW_OFFSET[3:0]	A signed register that allows two cases : • ***TX_SW_OFFSET <0***: widens low power duration up to 2*8us, symmetrically to *'lant_sw'* (1us before and 1us after thus 2us granularity). • ***TX_SW_OFFSET>0***: shifts start of ramp down after *'lant_sw'*, by steps of 1us, note that maximum value depends on **PA_RAMP_SEL** and are respectively 1/2/4 (above these values, no ramp down/up is done) . • ***TX_SW_OFFSET=0***: corresponds to the end of ramp down being aligned with *'lant_sw'*.
TX_SW_ADD_OFFSET_UP[2:0]	Depending on **TX_SW_OFFSET**'s value : • ***TX_SW_OFFSET<0*** : shortens low power duration after *'lant_sw'* by steps of 1us . • ***TX_SW_OFFSET>0*** : widens low power duration after *'lant_sw'* (opposite direction as previous case). Note that there is a dependency with **PA_RAMP_SEL** (Lowest values may have no impact) .

- Alignment for antenna switch

  To have the optimum switch during t_pm , the antenna alignment needs to be in accord with t_pm value. We can play with register tx_sw* to do that , below an example of software sequence to match with different t_switch and t_ramp_sel values:

```
# general registers values :  t_sw =2/4/10 ,t_ramp_sel=1/2/3/4 ,t_flush=3/4 :

t_ramp_us = t_ramp_sel
if (t_ramp_sel==3} { t_ramp_us = 4 }
if (t_ramp_sel==4) { t_ramp_us = 3 }  # emulated 3 us (reprog pa_ramp table )

lcl_ctrl.cfg_tx_delay_off =  (t_flush+t_ramp_us)*8  #method 1, coarse
lcl_ctrl.cfg_tx_delay_off =  (t_flush_real_in_ns/125+t_ramp_us*8) #method 2 , fine

add_up  = (t_sw -2*t_ramp_us)
if (add_up==8) { add_up=7}   # limit high
if (add_up<0)   { add_up=0}   # limit low
lcl_ctrl.cfg_tx_sw_add_offset_up = add_up
```

Figure 363. LCL PA switch settings

Below the waveform concerning the PA switch during t_pm mechanism:

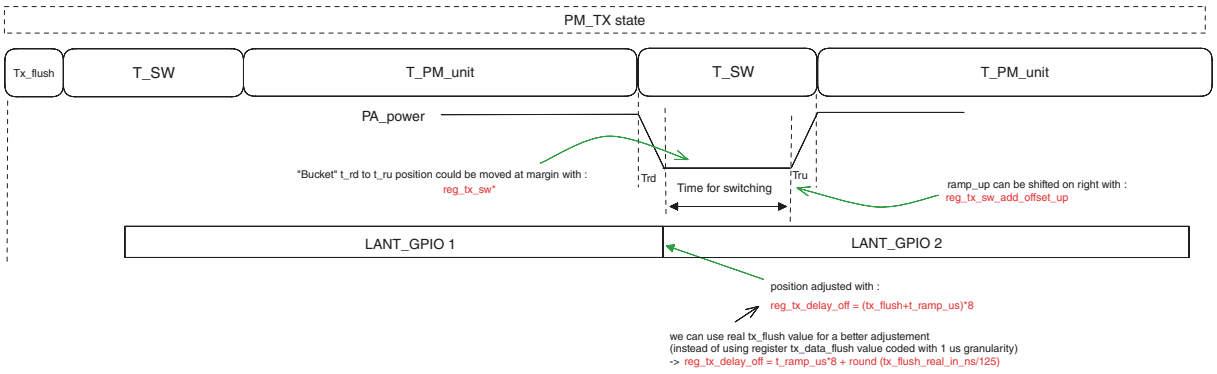


Figure 364. LCL PA switch during t_pm

- For Fine Tuning :
  - **TX_SW_FRAC_OFFSET_DN [2:0]** : adjusts low power duration before *'lant_sw'* by steps of a fraction of us .
  - **TX_SW_FRAC_OFFSET_UP [2:0]** : adjusts low power duration after *'lant_sw'* by steps of a fraction of us .

52.4.4.2.2.6.2.1.3 Antenna Shuffle Order with RSM

Antenna path permutation using rsm:

Each device may switch between up to four antenna paths within a CS step, The randomized antenna path permutation in a CS step shall be selected using the random number generation function

The number of antenna paths used within the permutation is the maximum number of N_AP antenna paths

nb_ant_perm = cfg_ap_max+1; to use nb 2 antenna path, should programme 1 (cfg start from 0) where Ap_max [1:0] , the field LCL_CFG0.AP_MAX which correspond to the bit [22: 21] in LCL_CFG0[31:0] register.

An antenna path permutation index is used to look up the specific antenna paths position order used . These lookup tables are defined based on the number of antenna paths being used as described bellow:

Table 509. Antenna path permutation according to number of antenna path (N_AP)

N_AP	Antenna Path Permutation index	Antenna Path Position After Permutation
N_AP=2	0	A1 A2
	1	A2 A1
N_AP=3	0	A1 A2 A3
	1	A2 A1 A3
	2	A1 A3 A2
	3	A3 A1 A2
	4	A3 A2 A1
	5	A2 A3 A1
N_AP=4	0	A1 A2 A3 A4
	1	A2 A1 A3 A4
	2	A1 A3 A2 A4
	3	A3 A1 A2 A4
	4	A3 A2 A1 A4
	5	A2 A3 A1 A4
	6	A1 A2 A4 A3
	7	A2 A1 A4 A3
	8	A1 A4 A2 A3
	9	A4 A1 A2 A3
	10	A4 A2 A1 A3
	11	A2 A4 A1 A3
	12	A1 A4 A3 A2
	13	A4 A1 A3 A2
	14	A1 A3 A4 A2
	15	A3 A1 A4 A2
	16	A3 A4 A1 A2
	17	A4 A3 A1 A2
	18	A4 A2 A3 A1
	19	A2 A4 A3 A1
	20	A4 A3 A2 A1
	21	A3 A4 A2 A1
	22	A3 A2 A4 A1
	23	A2 A3 A4 A1

This feature allow the possibility to manage N:M antenna , in the range 1:{1:4} , {1:4}:1, 2:2. an automatic antenna switch as defined in the standard , for mode 2, mode 3 , which should occur at each step.

The maximum index of the antenna permutation is idx_max_order((AP_MAX+1)! - 1) and it was programmed to increment from 0 to idx_max_order for a succession of tones. when transmitted or received.

The antenna permutation is valid only for tones (pm). To enable the antenna permutation feature, you should program "1" in the field "ant_permut_en" which correspond to the field LCL_CFG0.LCL_ANT_PERMUT_EN (LCL_CFG0[28] bit).

Mode 0 & 1:

if the antenna permutation is enabled, the antenna path is selected from the ant_cs_sync[1:0] of the pktram fields (bit[26:25]) as an index for the LCL_GPIO_CTRL0 [4*ant_cs_sync +: 4]. Otherwise the Antenna default num will be selected from LCL_GPIO_CTRL0 [LUT_0]

Mode 2 & 3:

The index of the antenna path permutation (ant_permut[4:0]) is figured in the pktram bit field [24:20] used at each step according the current mode (2,3) and PM transaction. After the selection of right antenna path order, the antenna path is selected from the packet ram which is configured in the register LCL_GPIO_CTRL0 [31:0] to configure the fields ; LUT_0 (3 -> 0 register bit), LUT_1 (7 -> 4 register bit), LUT_3 (11 -> 8 register bit), LUT_4 (15 -> 12 register bit) respectively to select the Antenna value (A1, A2, A3, A4) , then outputted using lant_lut_gpio[3:0] according to the antenna permutation order selected.

When ant_permut_en is disabled the antenna order is selected sequentially from lut_0 to lut_3.

The Antenna permutation is only valid for Tones (T_Pm) and not for Packets (DT) as described in the following.

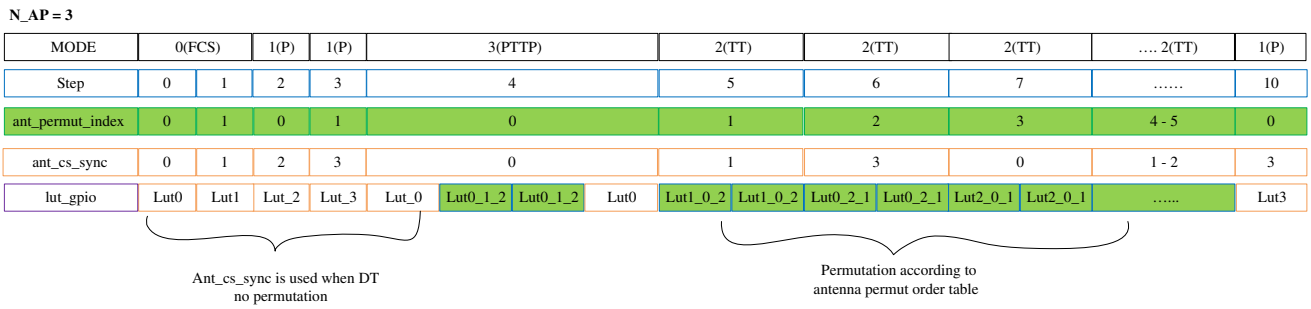

Figure 365. Example for Antenna Permutation Enabled & N_AP = 3:

52.4.4.2.2.6.2.2 Antenna Control With BLE CTE Signals

In this mode, cte_type[2:0] and cte_sample_dur[2:0] signals from the Bluetooth LE link layer are used to provide configuration of the LCL_CTRL module. The definition for cte_type[2:0] and cte_sample_dur[2:0] are shown in the table below

Table 510. CTE Signal cte_type[2:0]

cte_type[2:0]	Description
0x0	AoA Constant Tone Extension
0x1	AoD Constant Tone Extension with 1us slots
0x2	AoD Constant Tone Extension with 2us slots
0x3	Reserved

Table continues on the next page...

Table 510. CTE Signal cte_type[2:0] (continued)

cte_type[2:0]	Description
0x4	Reserved
0x5	AoD Constant Tone Extension with 4us slots
0x6	AoD Constant Tone Extension with 8us slots
0x7	Reserved

Table 511. CTE Signal cte_sample_dur[2:0]

cte_sample_dur[2:0]	Description
0x0	Reserved
0x1	For AoA receive, sampling duration is 1us
0x2	For AoA receive, sampling duration is 2us
0x3	Reserved
0x4	Reserved
0x5	For AoA receive, sampling duration is 4us
0x6	For AoA receive, sampling duration is 8us
0x7	Reserved

For antenna control using the Bluetooth LE CTE control signals, various settings must be programmed prior to operation. The significant fields are:

- LANT_INV : When set to 1, the lant_sw signal is inverted
- RX/TX_LCL_EN : Enables antenna switching control in RX and/or TX. For Bluetooth LE CTE configuration, both bits should be set.
- LCL_EN : Enable for the entire LCL_CTRL module
- RX/TX_DELAY_OFF : Extra offset (in samples) to fine tune the RX/TX_DELAY
- RX/TX_DELAY : Delay, in intervals, before antenna switching is to begin
- RX/TX_ANT_TRIG_SEL : Selects the trigger to be observed to begin counting DELAY
- RX/TX_SPINT : Defines the number of samples per interval. This is realized using the sample clock associated with either RX or TX, (typically 4MHz or 8MHz). For proper operation, RX/TX_SPINT need to be programmed so that the interval is 1us for RX and TX.
- LUT_0 to LUT_31: state of lant_lut_gpio[3:0] for the switching activity doublet from 0 to 31
- LUT_WRAP_PTR: Wrap point for the LUT_0 to LUT_31
- DMA_MASK_REF_PER: Duration, in intervals, of the reference period after DMA_MASK_DELAY expires during which the dma_mask remains asserted. For CTE the reference period is expected to be programmed for 8us.
- DMA_MASK_DELAY_OFF: Extra offset (in samples) to fine tune the DMA_MASK_DELAY
- DMA_MASK_DELAY: Delay, in intervals, from RX trigger to the time at which DMA mask asserts

Note that the following LCL_CTRL fields are not used in this configuration:

- CTE_DUR : In this configuration, the duration is controlled by the Bluetooth LE link layer
- RX/TX_LO_PER : In this configuration, the low period is determined by the CTE control signals

- RX/TX_HI_PER : In this configuration, the high period is determined by the CTE control signals
- M_ON_DELAY/N_ON_DELAY: In this configuration, switching activity stops at the end of the RX or TX burst.
- LANT_BLOCK_RX/TX: In this configuration, for RX lant output is blocked for AoD, and for TX lant output is blocked for AoA

The figures below illustrate the antenna switching operation for Bluetooth LE CTE during Transmit and Receive operations, and an addition figure illustrating the dma_mask behavior for Receive. In the Receive and Transmit figures, three examples of lant_sw / lant_lut_gpio[3:0] behavior are shown for different cte_type (and cte_sample_dur for Receive) input values. In the dma_mask figure, dma_mask and DMA activity behaviors are shown for two example cte_type and cte_sample_dur inputs. Note that these figures show example tx_trigger and rx_trigger signals which assert at the start of the guard period; the actual trigger used in the application (such as "cte_en" from the Bluetooth LE) will likely have different timing so the delays will need to be programmed accordingly.

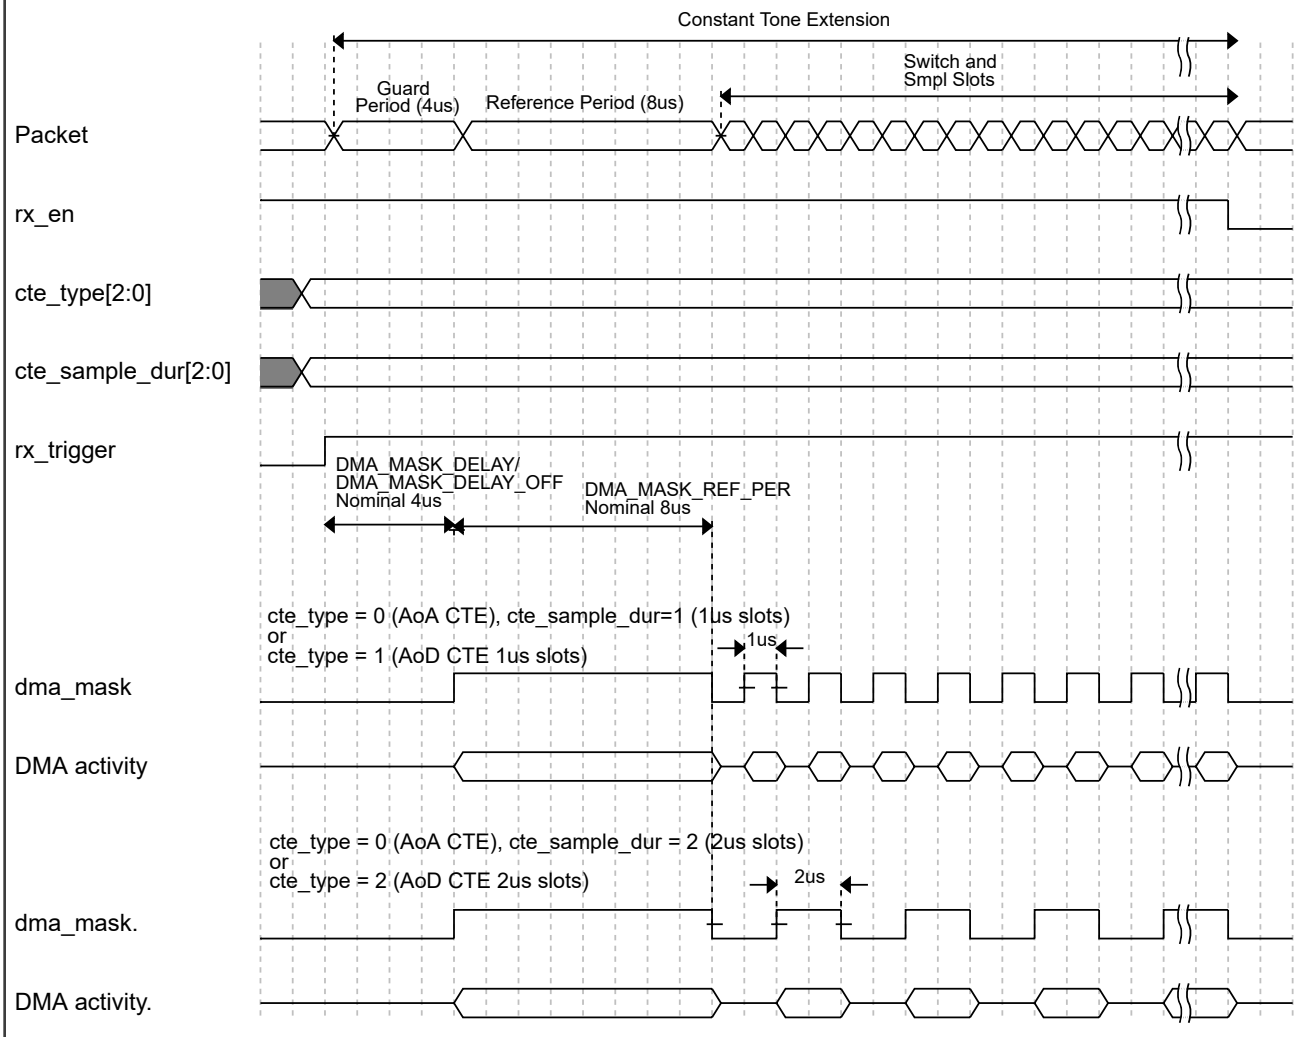

Figure 368. LCL_CTRL CTE - Receive dma_mask

52.4.4.2.2.7 Fast Antenna Diversity (FAD)

52.4.4.2.2.7.1 Introduction

The Fast Antenna Diversity (FAD) mode, when enabled, allows the optimal choice between two antennae to be selected during the PHY's preamble search. The output of the PHY's FAD algorithm is a 1-bit signal which indicates the selected antenna. This output is provided to the FAD Common Pin Interface logic. Refer to the PHY chapter(s) for more information on the FAD algorithm.

The localization control output (lant_sw) can also be used as the input to the FAD Common Pin Interface instead of the PHY signal, but the primary use case is for FAD.

52.4.4.2.2.7.2 Common Pin Interface

The FAD Common Pin Interface consists of 4 pins: ANT_A, ANT_B, TX_SWITCH, and RX_SWITCH. All pins are outputs from the device. The switch outputs convey timing information to the external module directly interfacing to the antennae, and they also can be used to control an external LNA or PA, via use of a Front End Module, or FEM. The FAD Common Pin Interface offers multiple configurations that allow for a wide range of FEM control schemes. Each of the 4 FAD-related outputs can be configured to be in FAD or TSM mode; in FAD mode, ANT_A and ANT_B are controlled by the selected FAD algorithm through signal antx_out;

in TSM mode, ANT_A and ANT_B are pure timing outputs with programmable timing configurable in the TSM. The 4-bit register FAD_CTRL[FAD_NOT_GPIO] determines whether each FAD-related output is in FAD or TSM mode:

In FAD mode (FAD_NOT_GPIO[0]=1), ANT_A is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[1]=1), ANT_B is controlled by the FAD algorithm, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[2]=1), TX_SWITCH output is derived from TSM output **gpio2_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In FAD mode (FAD_NOT_GPIO[3]=1), RX_SWITCH output is derived from TSM output **gpio3_trig_en**, modified by the register settings {ANTX_CTRLMODE, ANTX_EN, and ANTX_POL}.

In TSM mode, ANT_A and ANT_B become pure TSM timing-controlled outputs, similar to TX_SWITCH and RX_SWITCH, and with independently-controlled timing and capable of providing signalling in TX mode, RX mode, or both; for pins in TSM mode, the ANTX_CTRLMODE, ANTX_EN, and ANTX_POL register settings have no effect.

In TSM mode (FAD_NOT_GPIO[0]=0), ANT_A output is a pure timing signal, derived from TSM output **gpio0_trig_en**.

In TSM mode (FAD_NOT_GPIO[1]=0), ANT_B output is a pure timing signal, derived from TSM output **gpio1_trig_en**.

In TSM mode (FAD_NOT_GPIO[2]=0), TX_SWITCH output is derived from TSM output **gpio2_trig_en**.

In TSM mode (FAD_NOT_GPIO[3]=0), RX_SWITCH output is derived from TSM output **gpio3_trig_en**.

The control register XCVR_CTRL[DEMOD_SEL] determines which FAD algorithm drives the FAD Common Pin Interface: 0b10 = 802.15.4 FAD, 0b01 = FSK FAD.

The state of the antenna selection can be ascertained at any time by reading the FAD_CTRL[ANTX] bit: 0 = ANT_A, 1 = ANT_B.

Antenna selection can be placed under direct software control: Setting the FAD_CTRL[ANTX_OVRD_EN]=1 allows FAD_CTRL[ANTX_OVRD] to substitute for the algorithm-driven antenna selection; in this case, ANTX_OVRD=0 asserts ANT_A, and ANTX_OVRD=1 asserts ANT_B. Note that the algorithm-driven state of the antenna is not lost while ANTX_OVRD_EN=1. The override is temporary, for as long as the override enable is set, and control over antenna state reverts to the antx_out when ANTX_OVRD_EN is cleared to 0. The FAD_CTRL register resides in XCVR space.

The following diagram illustrates the FAD pinout, register controls, and FAD/TSM-mode multiplexing.

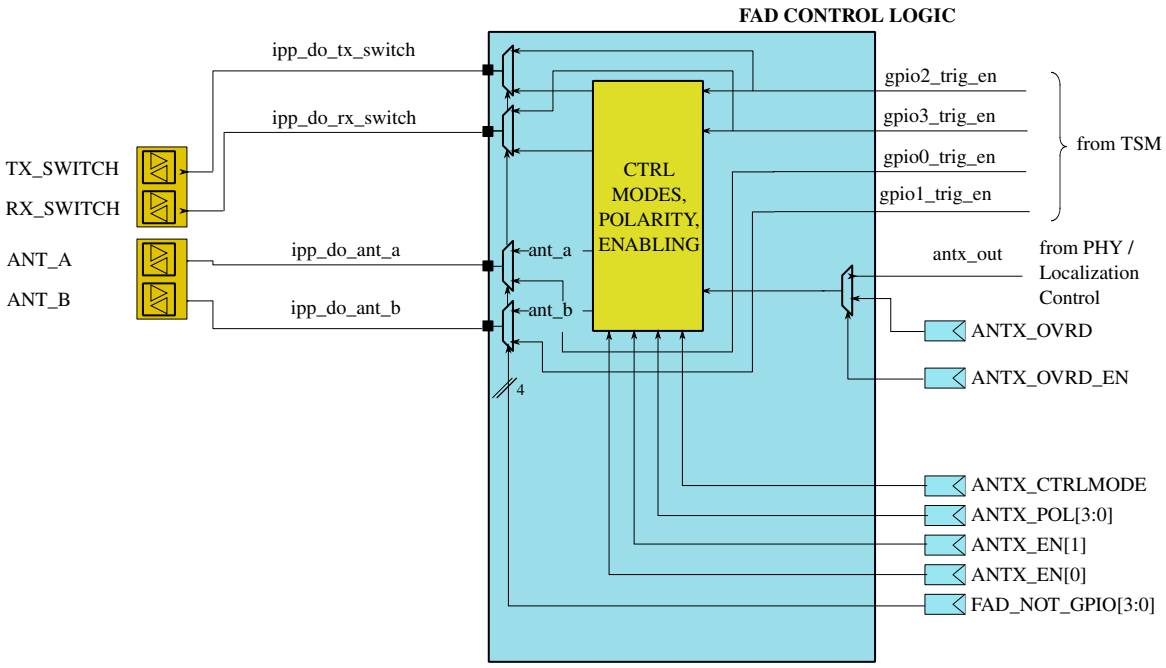

Figure 369. FAD Common Pin Interface

52.4.4.2.2.7.3 Control Bits

The following table describes the programmable registers which control FAD Common Pin Interface:

Table 512. FAD Common Pin Interface Control Bits

Field	R/W	Description
ANTX_CTRLMODE	rw	**FAD control mode-** selects the single or dual mode **0 : single mode.** ANT_A = NOT(antx) AND(gpio2_trig_en OR gpio3_trig_en) TXSWITCH = gpio2_trig_en RXSWITCH= (gpio2_trig_en OR gpio3_trig_en) **1:dual mode:** ANT_A = NOT(antx) AND(gpio2_trig_en OR gpio3_trig_en) ANT_B = antx AND(gpio2_trig_en OR gpio3_trig_en) TX_SWITCH = gpio2_trig_en RX_SWITCH = gpio3_trig_en
ANTX_EN[1:0]	rw	**FAD Pin Enable-** 00: all disabled

Table continues on the next page...

Table 512. FAD Common Pin Interface Control Bits (continued)

Field	R/W	Description
		01:only RX_SWITCH/TX_SWITCH enabled 10:only ANT_A/ANT_B enabled 11: all enabled
ANTX_POL[3:0]	rw	**Antenna controls mode-** Control the polarity of the FAD pins: ANTX_pol<0>=1 : invert the ANT_A output ANTX_pol<1>=1 : invert the ANT_B output ANTX_pol<2>=1 : invert the TX_SWITCH output ANTX_pol<3>=1 : invert the RX_SWITCH output
FAD_NOT_GPIO[3:0]	rw	**xxx1**: The ANT_A pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xxx0**: The ANT_A pad is controlled directly by the TSM output gpio0_trig_en **xx1x**: The ANT_B pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **xx0x**: The ANT_B pad is controlled directly by the TSM output gpio1_trig_en **x1xx**: The TX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **x0xx**: The TX_SWITCH pad is controlled directly by the TSM output gpio2_trig_en **1xxx**: The RX_SWITCH pad is controlled by the antenna-selection algorithm, modified by the register settings above {ANTX_CTRLMODE, ANTX_EN, ANTX_POL} **0xxx**: The RX_SWITCH pad is controlled directly by the TSM output gpio3_trig_en
ANTX	ro	**Antenna Selection State-** The ANTX bit reflects the state of the antx_out signal.
DEMOD_SEL[1:0]	rw	**These bits select the demodulator used during reception. Also select which FAD engine is used to select the antenna-** • 0b00: No demodulator selected

Table continues on the next page...

Table 512. FAD Common Pin Interface Control Bits (continued)

Field	R/W	Description
		• 0b01: Use NXP Multi-standard PHY demodulator, and its FAD engine • 0b10: Use Legacy 802.15.4 demodulator, and the 802.15.4 FAD engine • 0b11: Reserved
ANTX_OVRD_EN	rw	**FAD ANTX Override Enable-** • 0: antx_out controls the antenna selection (mission mode) • 1: ANTX_OVRD controls the antenna selection. 0 = ANT_A, 1 = ANT_B.
ANTX_OVRD	rw	**FAD ANTX Override -** If ANTX_OVRD_EN=1, this bit is used instead of antx_out

52.4.4.2.2.7.4 FEM Example Use Cases

In 2.4GHz systems, the Radio Frequency (RF) Front-End Module is one of the most critical parts. Acting as an interface between the antenna and RF transceiver, the RF front-end module, or FEM, includes sensitive components such as an antenna Low Noise Amplifier (LNA) , power amplifiers (PA), antenna tuning switches, and a power management unit.

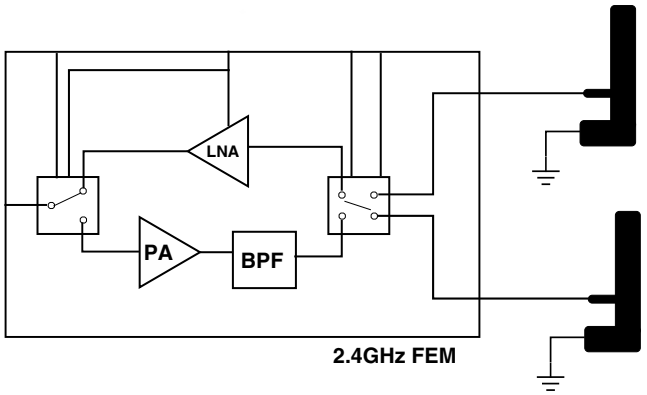

Figure 370. FEM Block Diagram

To accommodate multiple FEM interfaces and control schemes, Fast Antenna Diversity incorporates 2 Antenna Pin Control Modes, which are governed by the register control bit ANTX_CTRLMODE

Some FEM devices use a single input pin to switch the antenna selection. This is called single-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=0. A timing diagram of single-mode operation is shown below (note: FAD output ANT_B is not used). In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immediately following reception.

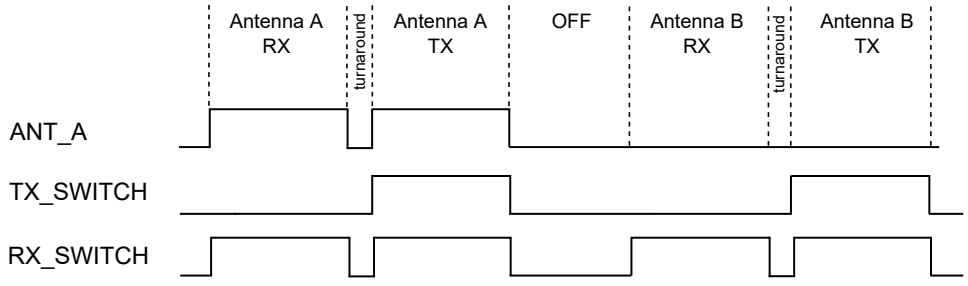

Figure 371. FAD Single Mode Timing

An example FEM Interface diagram, with FAD operated in single mode, is shown below.

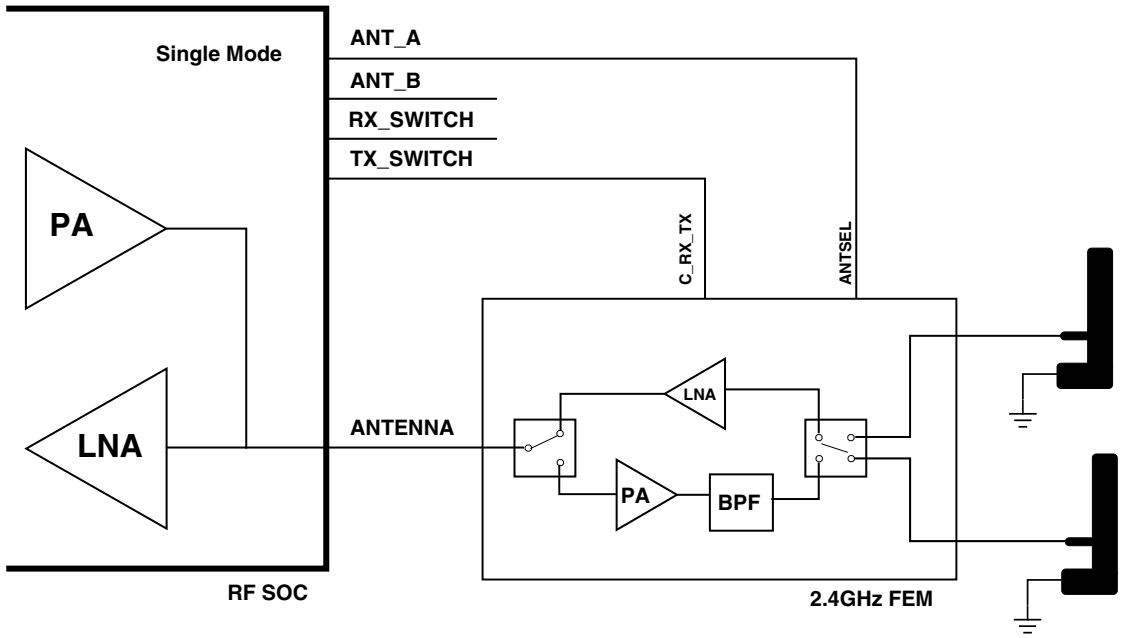

Figure 372. FEM Interface Single Mode

Other FEM devices use 2 input pins to switch the antenna selection. This is called dual-mode operation. Operate Fast Antenna Diversity in this mode by programming ANTX_CTRLMODE=1. A timing diagram of dual-mode operation is shown below. In this example, one packet is received on Antenna A, followed by another packet received on Antenna B. Both packets require an auto-Acknowledge packet to be transmitted immediately following reception.

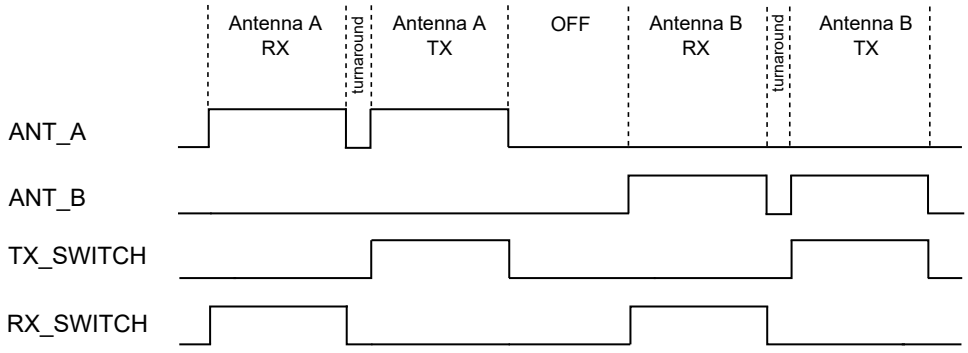

Figure 373. FAD Dual Mode Timing

An example FEM Interface diagram, with FAD operated in dual mode, is shown below.

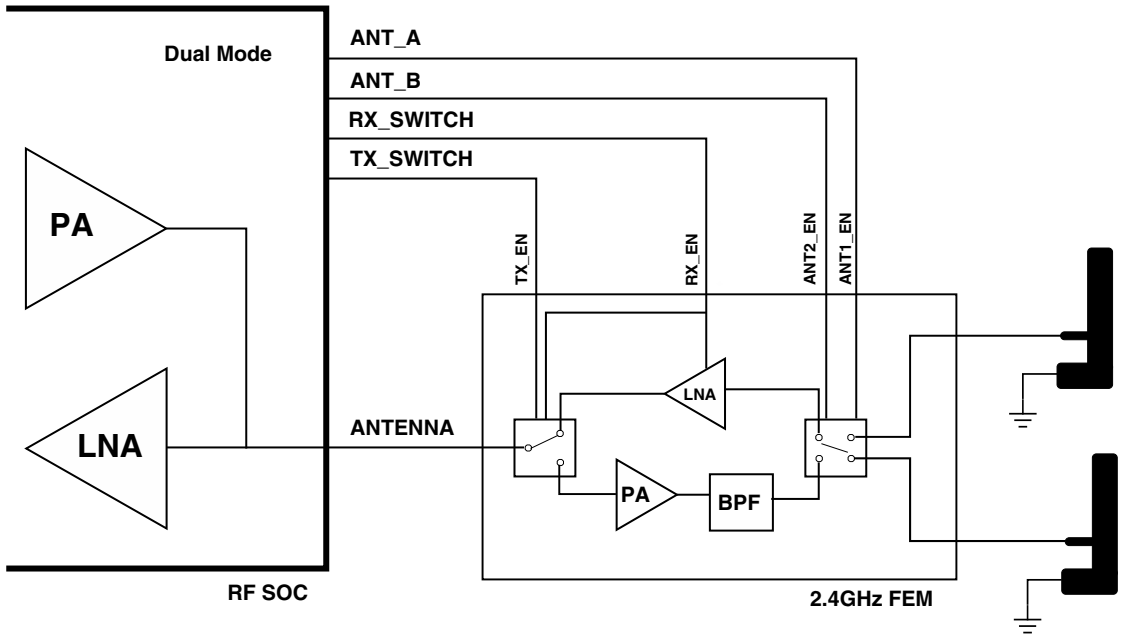

Figure 374. FEM Interface Dual Mode

Other FEM use cases, include external PA only, external LNA only, or external PA plus LNA. In such cases, ANT_A and ANT_B are not required, FAD can be disabled, and TX_SWITCH and RX_SWITCH pins can be operated in TSM mode (pure timing signals). This is called Single Antenna configuration. An example FEM interface diagram illustrating such a use case, is shown below.

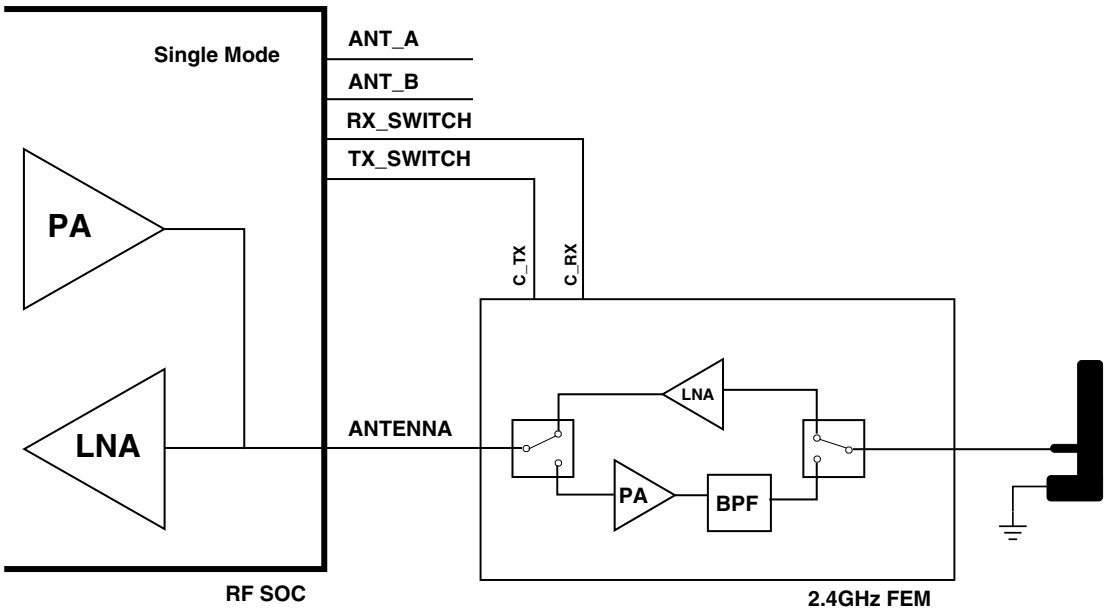

Figure 375. FEM Interface Single Antenna Configuration

52.4.4.2.2.8 Fast Overwrite Module (FOM)

The IPS_FOM module provides the capability to pre-store several address/data pairs that are quickly applied when RX or TX operation begins. Each entry consists of 3 parts:

- Address and config: The ADDR field contains the address to be written, and the ENTRY_TX/RX bits denote if the entry is to be used in TX, RX, or both modes.
- DRS0_DATA: Contains the full 32-bit word that will be written to ADDR as RX/TX begins and the data rate select is 0.
- DRS1_DATA: Contains the full 32-bit word that will be written to ADDR as RX/TX begins and the data rate select is 1.

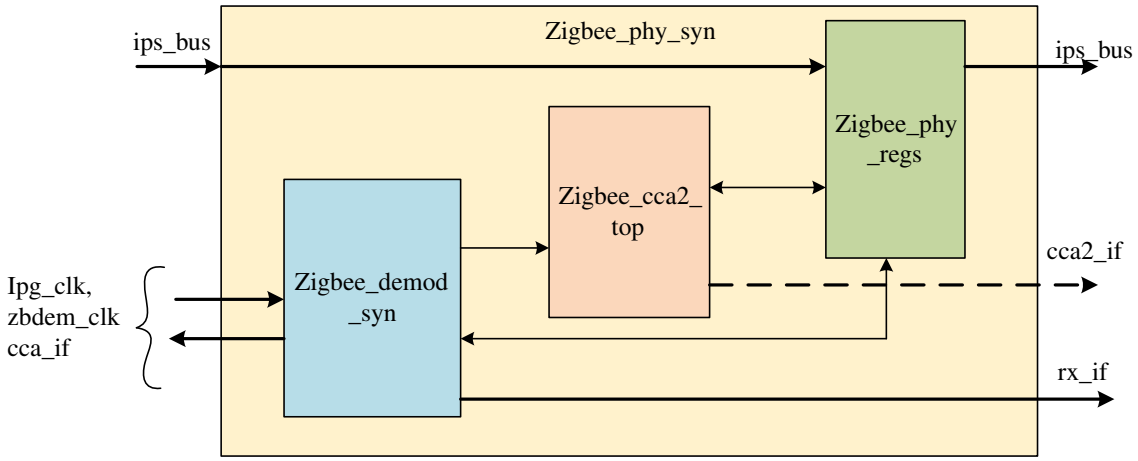
52.4.4.2.2.9 Zigbee PHY

52.4.4.2.2.9.1 Overview

This chapter is about the Zigbee Phy. This layer performs the task of modulation as well as demodulation of various transmitted and received signals,

52.4.4.2.2.9.1.1 Block Diagram

This block guide has the details for the Zigbee Demodulator function feature registers, which include multi CTRL registers.



.

The PHY data service enables the transmission and reception of PHY protocol data units (PPDUs) across the physical radio channel. The features of the PHY are activation and deactivation of the radio transceiver, energy detection (ED), link quality indication (LQI), channel selection, clear channel assessment (CCA) and transmitting as well as receiving packets across the physical medium.

52.4.4.2.2.9.1.2 Feature

The PHY data service enables the transmission and reception of PHY protocol data units (PPDUs) across the physical radio channel.

The features of the PHY are :

- Activation and deactivation of the radio transceiver.
- Energy detection (ED).
- Link quality indication (LQI).
- Channel selection.
- Clear channel assessment (CCA) and transmitting as well as receiving packets across the physical medium.

52.4.4.2.2.9.2 Functional Description

52.4.4.2.2.9.2.1 Zigbee Demodulator

This section describes the zigbee demodulator sub-blocks.

52.4.4.2.2.9.2.1.1 The receiver energy detection (ED):

The receiver energy detection (ED) measurement is intended for use by a network layer as part of channel selection algorithm. It is an estimate of the received signal power within the bandwidth of an IEEE 802.15.4 channel. No attempt is made to identify or decode signals on the channel. The ED time should be equal to 8 symbol periods.

The ED result shall be reported as an 8-bit integer ranging from 0x00 to 0xff. The minimum ED value (0) shall indicate received power less than 10dB above the specified receiver sensitivity. The range of received power spanned by the ED values shall be at least 40dB. Within this range, the mapping from the received power in decibels to ED values shall be linear with an accuracy of + - 6dB.

52.4.4.2.2.9.2.1.2 Link Quality Indication (LQI):

Upon reception of a packet, the PHY sends the PSDU length, PSDU itself and link quality (LQ) in the PD-DATA.indication primitive. The LQI measurement is a characterization of the strength and/or quality of a received packet. The measurement may be implemented using receiver ED, a signal-to-noise estimation or a combination of these methods. The use of LQI result is up to the network or application layers.

The LQI result should be reported as an integer ranging from 0x00 to 0xff. The minimum and maximum LQI values should be associated with the lowest and highest quality IEEE 802.15.4 signals detectable by the receiver and LQ values should be uniformly distributed between these two limits.

52.4.4.2.2.9.2.1.3 Clear Channel Assessment (CCA):

The clear channel assessment (CCA) is performed according to at least one of the following three methods:

- Energy above threshold. CCA shall report a busy medium upon detecting any energy above the ED threshold.
- Carrier sense only. CCA shall report a busy medium only upon the detection of a signal with the modulation and spreading characteristics of IEEE 802.15.4. This signal may be above or below the ED threshold.
- Carrier sense with energy above threshold. CCA shall report a busy medium only upon the detection of a signal with the modulation and spreading characteristics of IEEE 802.15.4 with energy above the ED threshold.

52.4.4.2.2.9.2.2 Clear channel assessment (CCA2 TOP)

Provide a control sub module for the clear channel assessment mode 2 (CCA2).

52.4.4.2.2.9.2.3 Operation

Defines the physical operation of the Zigbee device including receive sensitivity, channel rejection, output power, number of channels, chip modulation, and transmission rate specifications. Most Zigbee applications operate on the 2.4 GHz ISM band at a 250 kb/s data rate. See the IEEE 802.15.4 specification for details.

52.4.4.2.2.9.2.4 Mode

There are three CCA modes, and an IEEE 802.15.4-compliant PHY must be able to operate in any one of them:

CCA mode 1:

In this mode, only the ED result is taken into account. If the energy level is above the ED threshold, the channel is considered busy. The ED threshold level can be set by the manufacturer

CCA mode 2:

Mode 2 uses only the CS result, and the channel is considered busy only if the occupying signal is compliant with the PHY of the device that is performing the CCA.

CCA mode 3:

This mode is a logical combination (AND/OR) of mode 1 and mode 2. In other words, in mode 3, the PHY can use one the following as an indication of a busy channel:

- The detected energy level is above the threshold and a compliant carrier is sensed.
- The detected energy level is above the threshold or a compliant carrier is sensed.

52.4.4.2.2.9.2.5 Clocking

Table 513. table of clock signals

Signal name	Direction	Description
ck	input	Clock, nominally 32MHz
rx_gck	input	RX-only gated clock
ipg_clk_zbdem_cca	input	CCA/ED/LQI-only gated clock
ipg_clk_cca2_2m	input	2MHz for CCA2_TOP
input ipg_clk_cca2_32m	input	32MHz for CCA2_TOP
cg4m_en	input	Enable strobe 4MHz (ck)
cg1m_en	input	Enable strobe 1MHz (ck)

52.4.4.2.2.9.2.6 Reset

Table 514. table of reset signals

Signal name	Direction	Description
ipg_hard_async_reset_b	input	Hardware async reset for registers
soft_reset	input	soft reset

52.4.4.2.2.9.2.7 Interrupts

This Module has no interrupts.

The interrupts are handled with the transceiver IRQ and Zigbee_syn levels, look at the transceiver interrupts section.

52.4.4.2.2.9.2.8 DMA

This module has no DMA.

52.4.4.2.2.9.2.9 Module Signals

Here the table of the module's signal interface:

Signal name	direction	Description
ck	input	Clock, nominally 32MHz
rx_gck	input	RX-only gated clock
ipg_clk_zbdem_cca	input	CCA/ED/LQI-only gated clock
pg_clk_cca2_2m	input	2MHz for CCA2_TOP
ipg_clk_cca2_32m	input	32MHz for CCA2_TOP
cg4m_en	input	Enable strobe 4MHz (ck)
cg1m_en	input	Enable strobe 1MHz (ck)
ipg_hard_async_reset_b	input	Async chip reset
soft_reset	input	soft chip reset

Table continues on the next page...

Table continued from the previous page...

Signal name	direction	Description
ips_clk	input	Bus clock for IPS Register Interface
ips_module_en	input	IPS access enable
ips_byte_en	input [3:0]	IPS byte enable for write bits
ips_addr	input [11:0]	IPS Register Address
ips_rwb	input	IPS read/write enable
ips_wdata	input [31:0]	IPS interface write data.
ips_rdata	output [31:0]	IPS Interface read data.
ips_xfr_err	output	IPS Wait state.
ips_xfr_wait	output	This is unused in the PLL.
rxin_ph	input [4:0]	RX in phase
tsm_rx_init	input	Initialize Tsm Rx
fad_on	input	Came from RSM before.
lpps_on	input	Came from RSM before.
rx_data_ready	output	RX Symbol Ready Indicator
rx_data_out	output [3:0]	RX Symbol to RAM
zb_cca1_channel_state	input	Zigbee cca1 channel state

52.4.4.2.2.9.3 External Signals

This Module has no external signals.

52.4.4.2.2.9.4 Initialization

To initialize the Zigbee phy : Configure the xcvr for zigbee and program_tsm_for_zigbee.

The initialization is done with the configuration required by the active link layer before performing any transmit or receive operations.

52.4.4.2.2.9.5 Application information

The physical layer is responsible for transmitting and receiving data over the airwaves

The procedures to use this module are described in the 802.15.4 link layer documentations.

52.4.4.2.2.9.6 Register Descriptions

The Zigbee Demodulator module memory map and detailed descriptions of all its registers are as follows.

52.4.4.2.2.10 BLE/MULTI_FSK PHY

52.4.4.2.2.10.1 Overview

This documents describes the PHY and its operation. modules of the 2.4GHz PHY receiver supporting the demodulation of a wide range of use cases employing FSK modulation:

- acquisition (timing and frequency synchronization)
- symbol demodulation interfacing with the PrePHY,
- RBME and LL

The Following protocols are supported: Non-coded Bluetooth LELong range Bluetooth LEANTcustom FSK modulation schemesMSK

52.4.4.2.2.10.1.1 Block Diagram

Figure 376 shows the interface signals and the integration of the PHY module with other blocks of the radio:

- Front-end module
- Receiver
- Radio bit manipulation engine
- Link-layer
- Antenna selection logic for the estimation of the angle-of-arrival

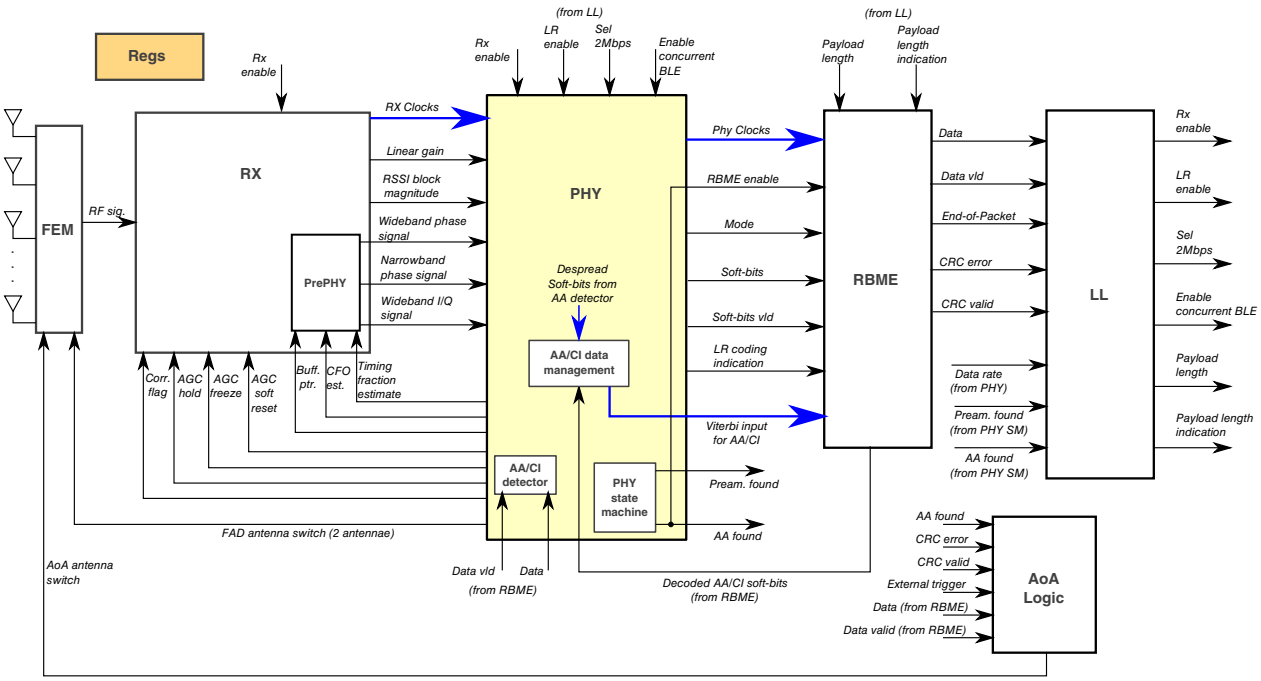

Figure 376. Block diagram

Figure 377 shows the block diagram of the PHY module. It consists of the following components:

- State-machine and clocks responsible with:
  - generation of control signals
  - generation of clock signals for the PHY processing blocks

- Time/frequency synchronization, responsible with the frame time synchronization and CFO estimation for non-coded packets, that consists of:
  - Power threshold responsible with channel energy sensing
  - Phase domain preamble detection
  - Discriminated phase (FM) domain preamble detection
  - AA detection
- Time/frequency synchronization, responsible with the frame time synchronization and CFO estimation for LR packets, that consists of:
  - LR preamble detection
  - LR AA search
- GFSK demodulator, responsible with the symbol demodulation at the over-the-air baud rate
- AA/CI data parallel to serial conversion, responsible with the data and data valid generation for the RBME module, on the AA/CI portion of the long range Bluetooth LE packets
- AA/CI detection, responsible with the decoded AA matching and CI field extraction for the long range Bluetooth LE packets

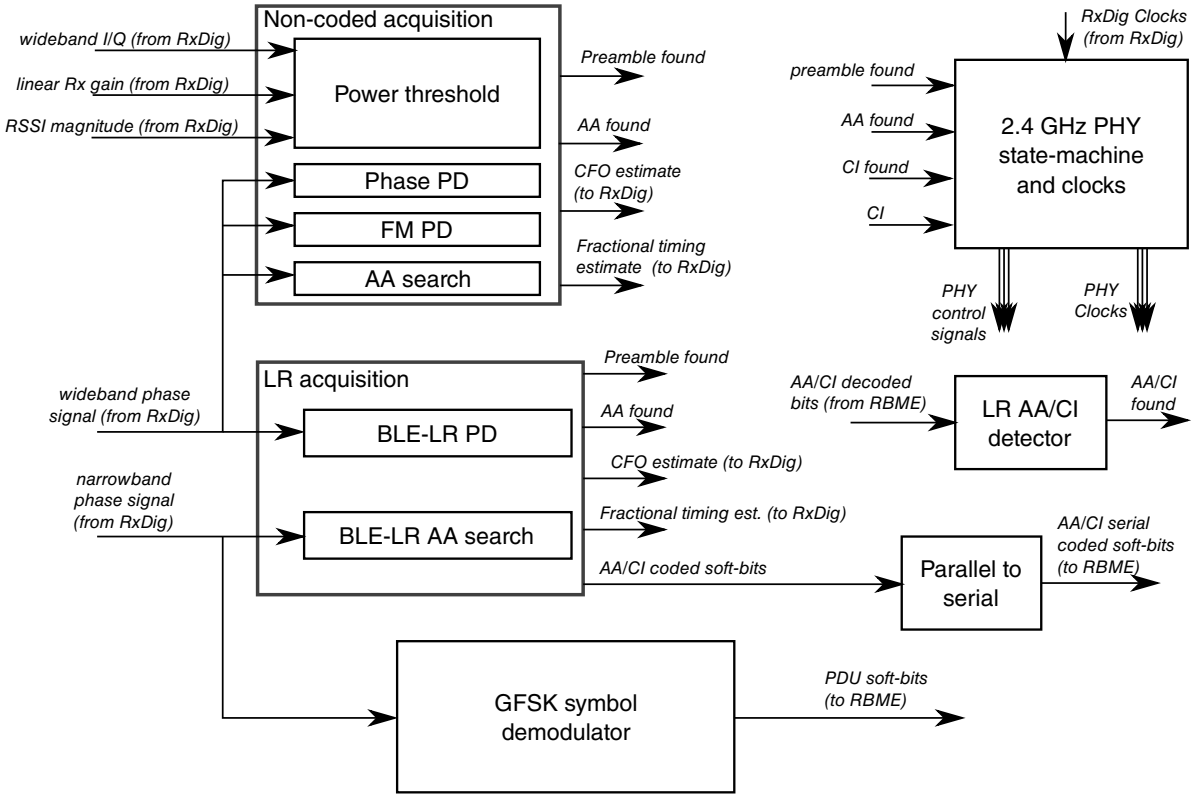

Figure 377. PHY block diagram

A "look-back" buffer provides the required latency of the frequency correction and timing acquisition engines. A pointer is provided from the PHY to the PrePHY via the interface illustrated in Figure 376. The pointer to the IQ buffer has the role of tapping the CFO mixer at the correct sample in the IQ buffer so that the CFO and the fractional timing are properly compensated. The pointer to the buffer is configured by the PHY registers and it is different for different use-cases and configurations. In general the pointer needs to be chosen to account for the following:

- Latency of a detection event, produced by the acquisition block, which is followed by:

  - the enable of the narrowband path
  - the enable of the blocks consuming the output of the narrowband path
- Channel filter pre-filling with enough history samples so that the output is computed using only CFO/fractional timing compensated samples
- The number of history samples has to be equal with at least half of the size of the CHF
- Enough history timing/frequency error compensated samples must be available for the FSK symbol demodulator
- The history needed by the FSK symbol demodulator is 2-symbols worth of samples
- A fine-tune adjustment that accounts for different latencies in the system, intended to ensure a smooth transition when switching from using the wide-band samples to using the narrow-band samples

The size of the IQ buffer needs to be chosen such that it covers for the worst-case scenario. The overall latency of the narrowband path equals the latency of the IQ buffer plus the channel filter latency plus the latencies introduced by the CFO mixer and timing frequency correction interpolator.

52.4.4.2.2.10.1.2 Features

The 2.4GHz PHY includes the following features:

- support preamble detect
- support address match
- support Bluetooth LE long range
- support Bluetooth LE none coded up to 4 address
- support demodulate to RBME/LL
- support custom FSK modulation schemes
- support MSK
- high-accuracy CFO estimation using known sequences embedded in the PDU

52.4.4.2.2.10.2 Functional description

The PHY is made up of several sub-modules. These modules can be viewed as members of two classes: datapath (the flow of the signal and the resultant bits) and control (enable/ disable logic and state control).

52.4.4.2.2.10.2.1 PHY Datapath

There are two data paths used by the PHY. The wide-band path and the narrow-band path. The PHY uses the one of the two data paths at a time or both of them simultaneously depending on the process(acquisition or payload demodulation) and use-case(coded or non-coded).

The signal of interest is passed through the PHY along the data paths. The overall objective is to process phase samples that are presented and create bits that are sent out. The significant sub-systems are here presented in generally chronological order as the signal passes through.

Initially, the phase samples are input, sequentially, at the sampling rate, one at a time. The first step is to buffer the wide-band samples, so they can be used all at once for certain computations.

The buffer of samples is then presented to the acquisition logic. The acquisition module is responsible for detecting the presence of a signal and then indicating the timing and frequency offset when a signal is detected.

Up to 4 AA's can be searched for in the case of non-coded packets and one AA can be searched for in the case of long range Bluetooth LE packets. When an match occurs, the bit timing (the sample offset at which each bit is optimally demodulated) is recorded. The symbol timing information thus determined is used by the symbol demodulator block to perform payload demodulation.

When a packet is detected, the CFO estimate is presented to the corrector and the correction is applied to the incoming samples. In this fashion, the samples leaving the corrector, which is placed on the narrowband data path, will be optimally corrected for any frequency offset before beginning demodulation.

Demodulation is performed on frequency corrected samples, provided by the narrowband data path, and after a packet is detected, the demodulator produces soft-bits information, at the symbol rate, which is presented to the RBME block. More details are provided in the functional description section.

52.4.4.2.2.10.2.2 PHY Control

The control of the PHY blocks is realized from a single place denoted the PHY state-machine. the purpose of this block is to provide:

1. triggers(data valid signals)
2. enable/disable signals
3. indications to the processing blocks of the PHY module

Another aspect of the PHY stat machine is to fast antenna diversity(FAD) preamble search feature. FAD is a mechanism that allows antenna selection on fly.

A more detailed description of the PHY control is provided in the functional description section.

52.4.4.2.2.10.2.1 Protocol Configuration

The PHY has several configurable parameters that can be changed based on the desired protocol behavior. The details of these parameters are described in the following sections and a summary table is provided here for quick reference.

Table 515. FSK schemes supported by the demodulator

Scheme	baud rate (kbps) R	Data rate (kbps) DR	modulation index *h*	Frequency pulse	LO error (ppm)
Bluetooth LE	1000	1000	0.50	Gaussian; BT=0.5	62.50

52.4.4.2.2.10.2.2 Timing and frequency synchronization

52.4.4.2.2.10.2.2.1 General description

Figure 378 illustrates the block diagram of the timing/frequency synchronization (acquisition) block. It may be configured to operate in any one of the following three operation modes:

1. Acquisition for non-coded use cases only
2. Acquisition for long range Bluetooth LE only
3. Simultaneous acquisition for non-coded and long range Bluetooth LE use cases

The main inputs to the block are:

1. Wideband phase signal - phase domain signal not compensated for CFO
2. Wideband IQ signal - IQ domain signal not compensated for CFO
3. Narrowband phase signal: phase domain signal compensated for CFO and filtered using the channel filter

Acquisition for non-coded and long range Bluetooth LE use cases is handled by separate blocks. The *Power Threshold* block provides two outputs that are used by these blocks to:

1. Disqualify any detection events that may occur when the input signal level is below a specified level because they are deemed unreliable
2. Enable Hamming distance check during AA detection when the input signal level is above a specified threshold

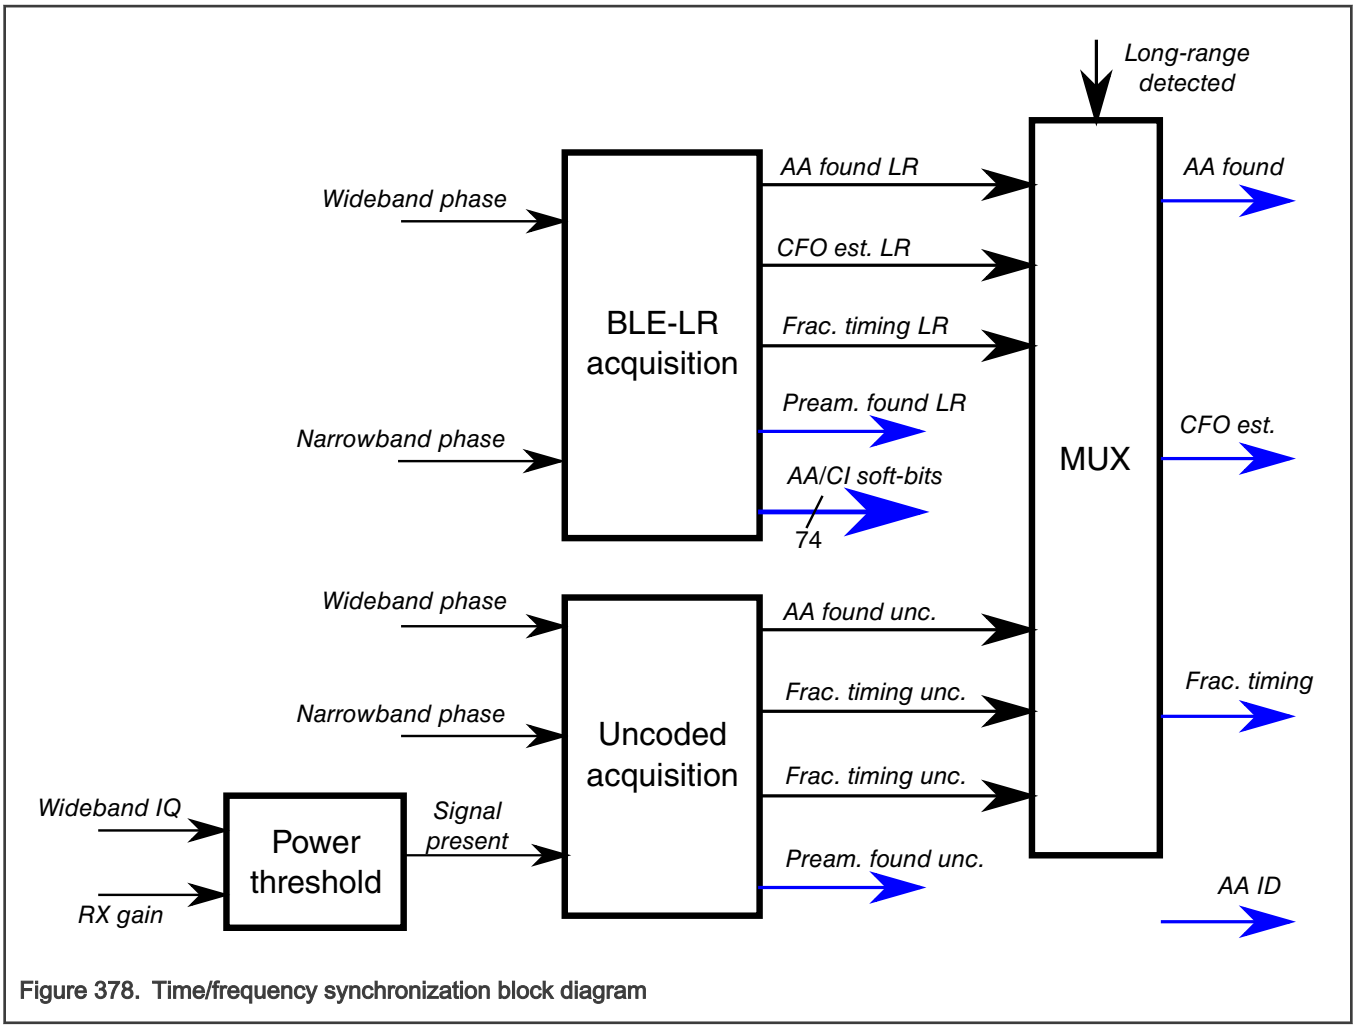

Figure 378. Time/frequency synchronization block diagram

Acquisition for non-coded and long range Bluetooth LE use cases is described later in this section.

52.4.4.2.2.10.2.2.2 Acquisition for non-coded use cases

52.4.4.2.2.10.2.2.2.1 Functional Description

Figure 379 illustrates the three main processing stages involved in the processing of non-coded use cases.

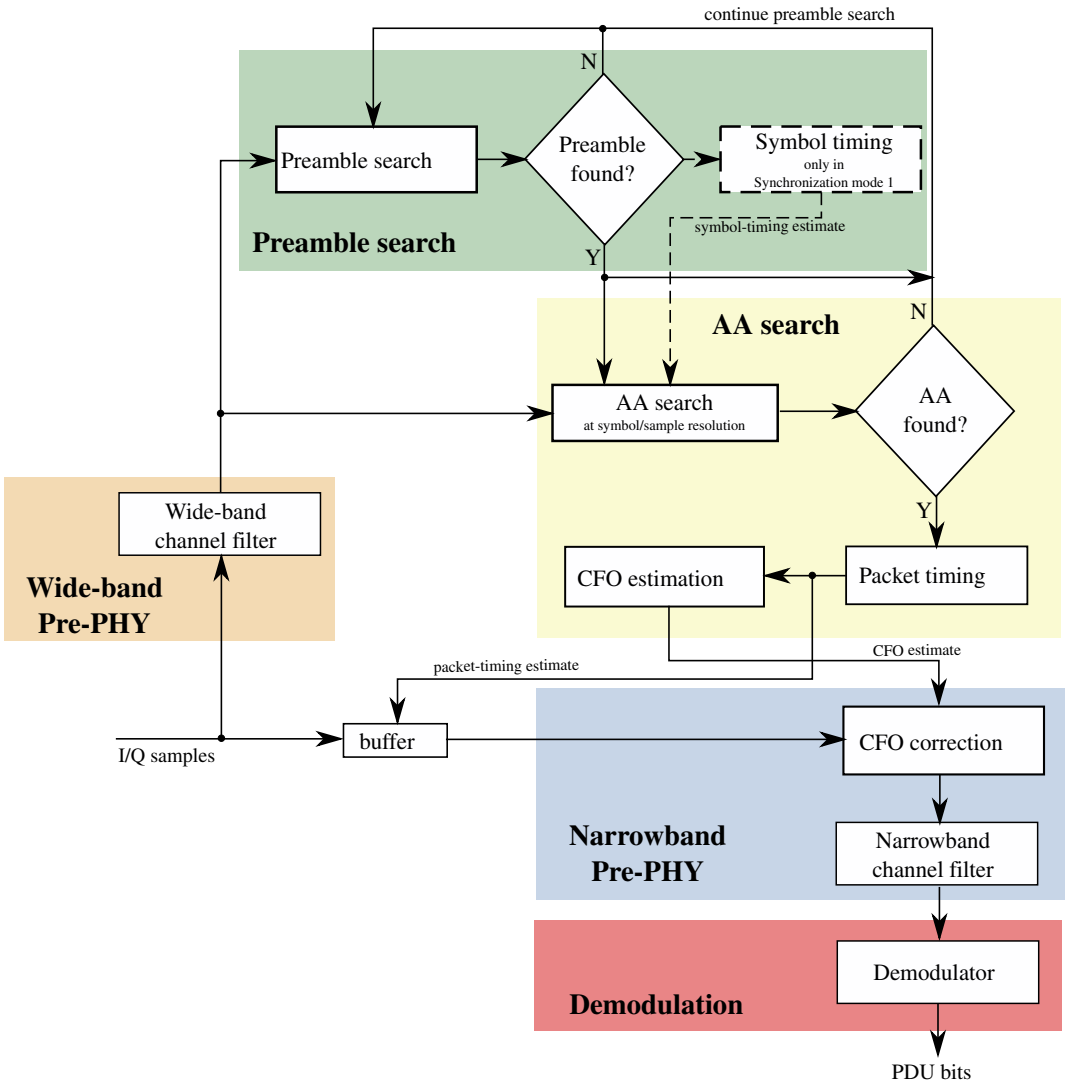

Figure 379. Processing stages of non-coded use cases

52.4.4.2.2.10.2.2.2.1.1 Preamble detection

During the preamble detection stage, the input phase values are processed to detect the preamble pattern and, if detected, AA search is triggered. No frequency acquisition is performed during this step but a timing estimate may be produced. The process shall continue even after starting AA search and is only terminated when AA is found or if *phy_enable* is de-asserted by the MAC.

52.4.4.2.2.10.2.2.2.1.2 AA search

During AA search, the PHY searches for one or more AA's to (i) achieve packet timing synchronization, and (ii) produce a CFO estimate. If the preamble detection stage is also active, its symbol timing estimate may be used during this stage to reduce the search complexity. The receiver can simultaneously search for up to four unique AA's of the same size. The number of AA's to be searched and their patterns need to be programmed *a priori* by the MAC.

This stage gets terminated upon either (i) a successful AA detection and synchronization following which the PHY proceeds to the demodulation stage, or (ii) if the *phy_enable* signal is de-asserted by the MAC.

The quality of the timing and CFO estimates obtained from AA search is strongly dependent on the correlation properties of the AA pattern used. So it is important to choose an AA with good correlation properties; refer to AA requirements & guidelines for related notes.

52.4.4.2.2.10.2.2.2.1.3 Demodulation

During the demodulation stage, using the timing & frequency estimates from the preceding stages, the PHY begins to demodulate the PDU and produces bits which are then sent to the MAC for further processing. In case there is significant timing and/or frequency drift in the PDU, the demodulator can simultaneously perform timing and/or frequency tracking as well.

The demodulator continues its operation until the *phy_enable* signal is de-asserted by the MAC.

52.4.4.2.2.10.2.2.2.2 AA requirements & guidelines

To ensure good synchronization performance, it is important that the AA used during the connection possesses good auto-correlation and cross-correlation properties. In general terms, if the auto-correlation of a candidate AA pattern, for a non-zero lag, exceeds a pre-defined threshold, then it should not be used. A suggested threshold value is 0.40 but recommended to be no more than 0.50.

For AA's of sizes 3 and 4 octets and For AA's of sizes 1 and 2 octets list some requirements which will reduce the likelihood of generating a candidate AA with poor auto-correlation properties.

52.4.4.2.2.10.2.2.2.2.1 For AA's of sizes 3 and 4 octets

The following requirements applicable to AA's of sizes 3 and 4 octets are adopted from Bluetooth specification v5.2; vol 6, part B.

The AA shall:

1. have no more than six consecutive 0's or 1's.
2. not be the advertising channel packet's AA.
3. not be a sequence that differs from the advertising channel packet's AA by only one bit.
4. not have all octets identical.
5. have no more than:
   - twenty-four bit transitions in case of 4-octet AA's.
   - eighteen bit transitions in case of 3-octet AA's.
6. have a minimum of two transitions in the most significant six bits.

The following additional requirements ensure better synchronization performance. Each AA shall:

1. contain no more than two contiguous instances of a bit sequence of length seven or more bits.
2. not contain two instances of a bit sequence, contiguous or otherwise, of length
   - thirteen or more bits in case of 4-octet AA's.
   - ten or more bits in case of 3-octet AA's.
3. have no more than four consecutive 0's or 1's within the least significant octet.
4. have no more than 6 transitions in the least significant octet.
5. have at least one transition in the most significant four bits.

52.4.4.2.2.10.2.2.2.2.2 For AA's of sizes 1 and 2 octets

Below are the requirements applicable to AA's of sizes 1 and 2 octets. Each AA shall:

1. have no more than four consecutive 0's or 1's.
2. not be the advertising channel packet's AA.
3. not be a sequence that differs from the advertising channel packet's AA by only one bit.
4. in case of 2 octets AA's, the two octets shall not be identical.
5. have no more than:
   - eleven bit transitions in case of 2-octet AA's.

- five bit transitions in case of 1-octet AA's.

6. have a minimum of two transitions in the most significant four bits.
7. contain no more than two contiguous instances of a bit sequence of length five or more bits (not applicable to 1-octet AA's).
8. not contain two instances of a bit sequence, contiguous or otherwise, of length:
   - six or more bits in case of 2-octet AA's.
   - four bits in case of 3-octet AA's.
9. have no more than three consecutive 0's or 1's within the least significant octet.
10. no more than 6 transitions in the least significant octet.

52.4.4.2.2.10.2.2.2.3 Synchronization for non-coded use cases

For non-coded use cases, three different modes of synchronization are provided to support the general packet structure. Each mode involves one or two of the following three processes.

1. Correlation-based preamble detection in frequency-domain (Freq-PD)
2. Correlation-based preamble detection in phase-domain (Phase-PD)
3. Correlation-based AA detection (AAD)

52.4.4.2.2.10.2.2.2.3.1 Synchronization modes - functional description, state machines and implementation

52.4.4.2.2.10.2.2.2.3.1.1 Synchronization mode 1

In ACQ mode 1, the Freq-PD and AAD processes are used to achieve synchronization. This mode is only useful, and is especially recommended, when a long preamble is available because it can significantly reduce power consumption.

####### 52.4.4.2.2.10.2.2.2.3.1.1.1 Functional description

Figure 380 shows a functional block diagram of the PHY in mode 1. First, the preamble is searched in the frequency-domain (*i.e.*, using phase-discriminated inputs) and when detected, a symbol-timing estimate is produced. The symbol-timing estimate is then used to begin AA search at symbol resolution thereby achieving significant reduction in computational complexity compared to searching the AA at sample resolution. Upon detecting an AA, an AA-based CFO estimate and a packet-timing estimate are generated.

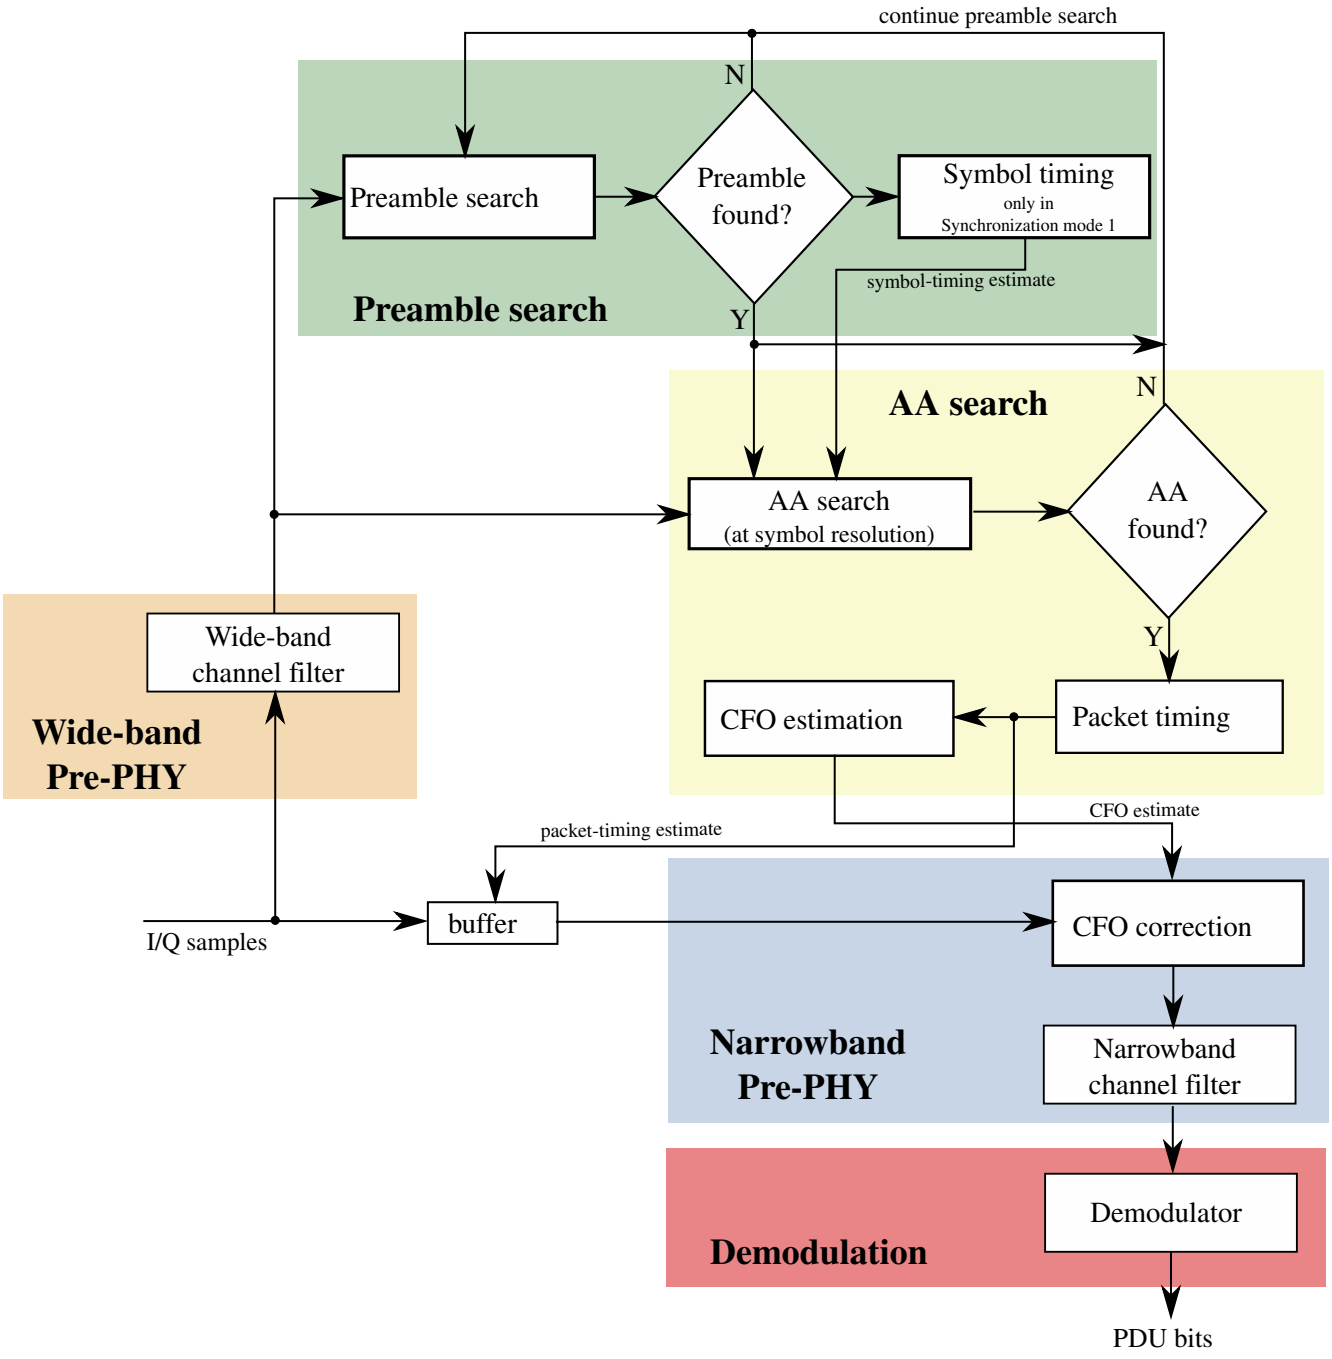

Figure 380. ACQ mode 1 block diagram

52.4.4.2.2.10.2.2.2.3.1.1.2 State machine

Figure 396 shows the state-machine of the PHY operating in mode 1.

52.4.4.2.2.10.2.2.2.3.1.2 Synchronization mode 2

In ACQ mode 2, only the AAD process is used to achieve synchronization. This ACQ mode may be used regardless of the length of the preamble but is recommended only when the preamble is short.

52.4.4.2.2.10.2.2.2.3.1.2.1 Functional description

Figure 381 shows a functional block diagram of the PHY in ACQ mode 2. The receiver begins searching for the AA and, upon detection, produces packet-timing and CFO estimates.

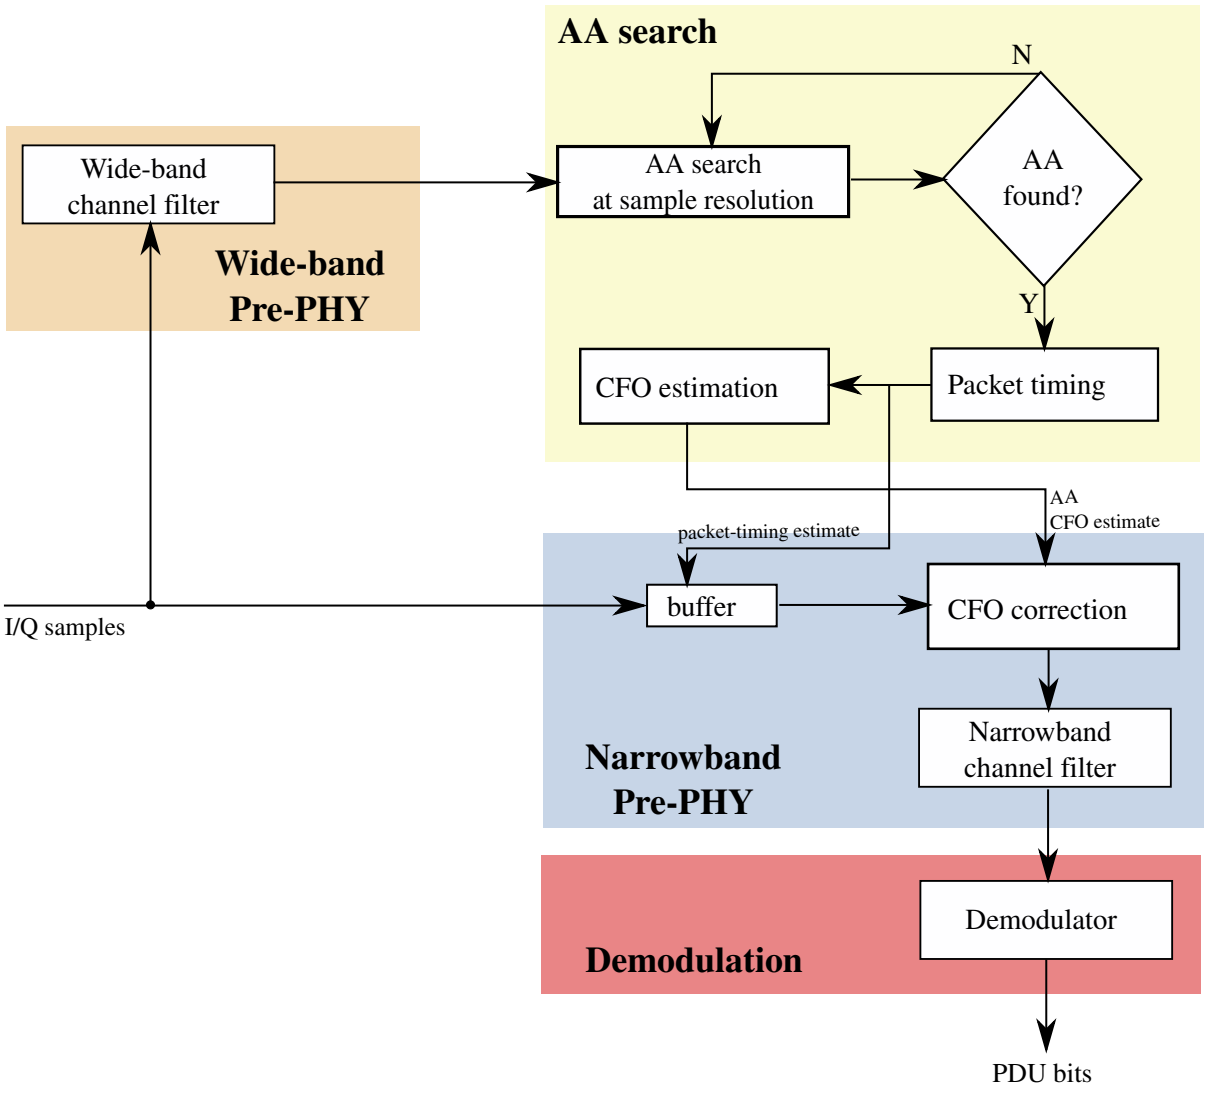

Figure 381. ACQ mode 2 block diagram

52.4.4.2.2.10.2.2.2.3.1.2.2 State machine

Figure 396 shows the state-machine of the PHY operating in mode 2.

52.4.4.2.2.10.2.2.2.3.1.3 Synchronization mode 3

In ACQ mode 3, the Phase-PD and AAD processes are used to achieve synchronization. But , unlike ACQ mode 1, this mode can be used when the preamble is short to quickly detect the arrival of a packet.

52.4.4.2.2.10.2.2.2.3.1.3.1 Functional description

Figure 382 shows a functional block diagram of the PHY in ACQ mode 3. First, the preamble is searched to identify the presence of a packet on the air but no timing or CFO estimate is generated. Like ACQ mode 2, the AA is searched at sample resolution and upon detecting an AA, an AA-based CFO estimate and a packet-timing estimate are generated.

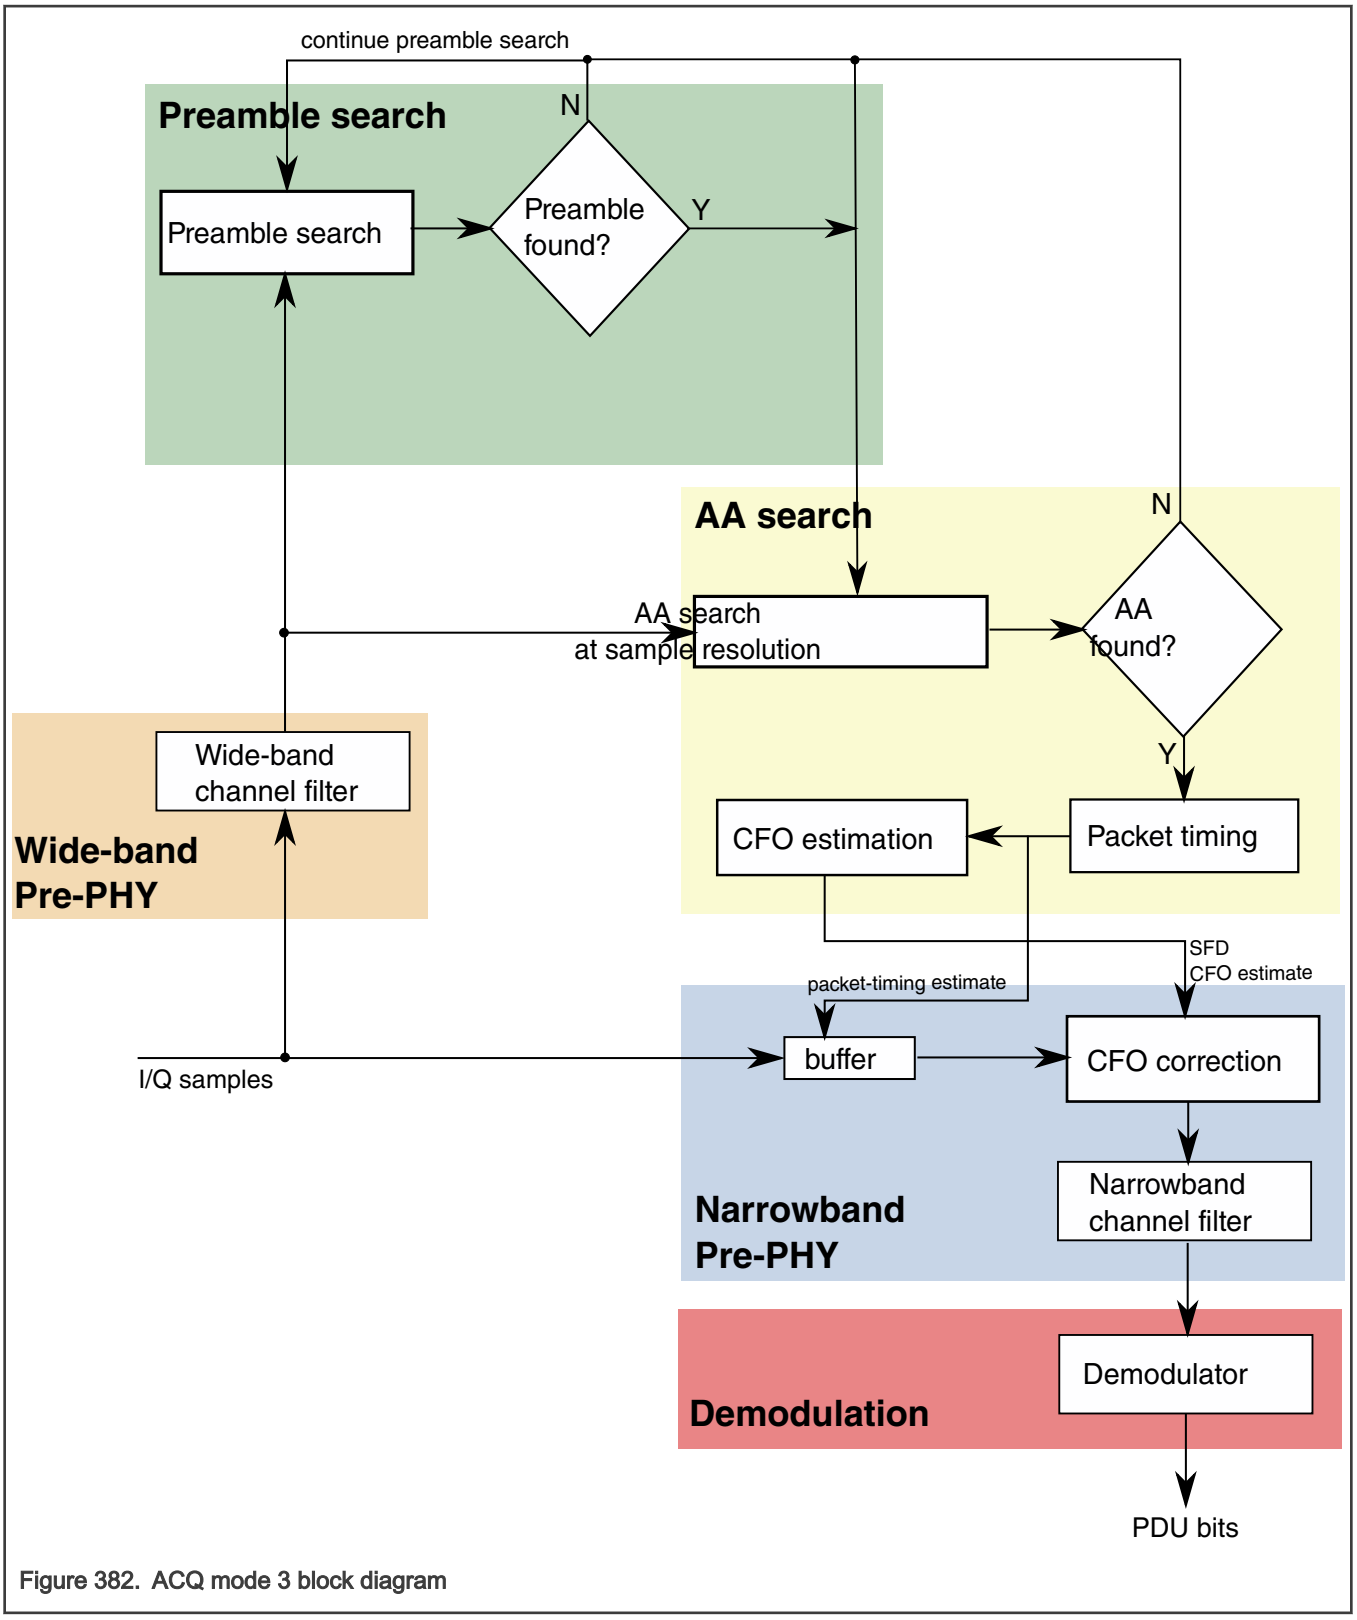

Figure 382. ACQ mode 3 block diagram

52.4.4.2.2.10.2.2.2.3.1.3.2 State machine

Figure 396 shows the state-machine of the PHY operating in mode 3.

52.4.4.2.2.10.2.2.2.3.2 Main component blocks

This section presents the details of the main component blocks used as the building blocks for realizing the various ACQ modes. There are six of them as listed below.

1. Power threshold
2. Pre-processor
3. Freq-PD preamble search engine
4. Phase-PD preamble search engine
5. AA search engine
6. Interpolator

52.4.4.2.2.10.2.2.2.3.2.1 Power threshold

The purpose of this block is to help avoid false preamble/AA detections in the respective search engines when the input signal is purely noise. The fixed-point formats of the block's inputs as well as those used at each internal stage are shown within parentheses.

It measures the input signal magnitude by passing the received I/Q samples through a single-pole IIR filter whose forgetting factor, α, is programmable. This magnitude is compared against two input thresholds - a low power threshold and a high power threshold which are both expected to be adjusted based on the AGC gain setting and the associated NF. If the measured signal magnitude is not less than the low threshold, then the boolean output *signal_present_low* gets asserted; if it is also not less than the high threshold, then both the boolean outputs, *signal_present_low* and *signal_present_high*, get asserted.

The block may alternatively use the narrowband RSSI measured by the RxDIG instead of the signal magnitude computed internally for comparing against the low and high power thresholds. This behavior is configurable through the input parameter BypassWithRSSI.

52.4.4.2.2.10.2.2.2.3.2.1.1 Register parameters

Table 516 lists the register parameters used by the power threshold block.

Table 516. Registers used by the power threshold block

Parameter	Notes
mag_window[3:0]	Indicates the forgetting factor used in received signal level measurement; forgetting factor used is 2^{-mag_window}. Note that *mag_window* values higher than 8 are not typically used.
pow_th_low[10:0]	Low power threshold specifies a power level below which the signal is considered too weak for reliable acquisition; uses (0,11,11) fixed-point format.
pow_th_high[10:0]	High power threshold specifies a power level above which the signal is considered strong enough that a stricter Hamming tolerance may be applied during acquisition; uses (0,11,11) fixed-point format.
bypass_with_rssi	Bypass signal power measurement with RSSI measurement; 0→no, 1→yes.
cond_sig_prst_enable	Enables special conditioning of signal power detection in the Power threshold block; 0→disable, 1→enable.

52.4.4.2.2.10.2.2.2.3.2.2 Pre-processor

It is used as the first step, in both Freq-PD and AAD processes, to pre-process the input I/Q samples and its output is then passed on to the respective search block.

52.4.4.2.2.10.2.2.2.3.2.2.1 Register parameters

Table 517 lists the only register parameter used by the pre-processor. It is used to obtain *1/2h* in the appropriate fixed-point format for providing as input to the pre-processor.

Table 517. Registers used by the pre-processor

Parameter	Notes
recip_mod_idx[8:0]	Reciprocal of modulation index; represented in (0,9,7) format.

52.4.4.2.2.10.2.2.2.3.2.3 Freq-PD preamble search engine

A block diagram of the Freq-PD preamble search engine is shown in Figure 383. It is used for correlation-based preamble detection in the frequency-domain. The fixed-point formats used at various internal points are also shown within parentheses.

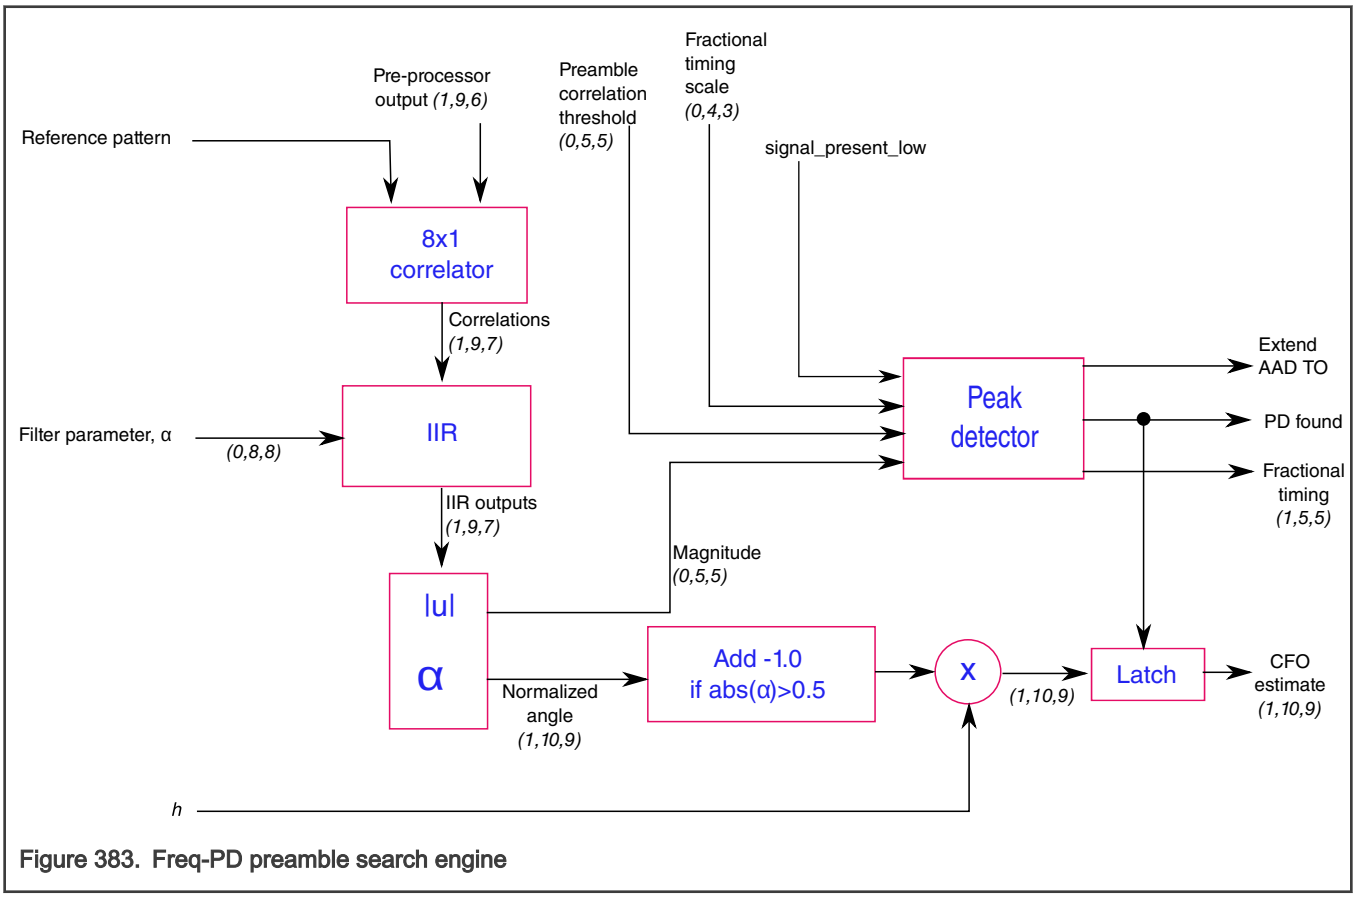

Figure 383. Freq-PD preamble search engine

An 8x1 binary reference pattern along with the pre-processor output phase values is provided as input to the engine. In the first step, each phase value is converted into its equivalent I/Q sample of unit magnitude and a correlation is performed between the I/Q values thus obtained and the reference pattern. The resultant complex correlation values are then passed through a single-pole IIR filter. The outputs of the IIR filter are long-term averages of its inputs and, therefore, are roughly equivalent to much longer correlations. Next, the magnitudes and angles of the complex IIR outputs are obtained using LUTs and passed to the timing detection and CFO estimation circuits respectively.

52.4.4.2.2.10.2.2.2.3.2.3.1 Register parameters

Table 518 lists the register parameters used by the preamble search engine.

Table 518. Registers used by the Freq-PD preamble search engine

Parameter	Notes
preamble_pattern[7:0]	8-bit preamble pattern used in FM-domain preamble detector.

Table continues on the next page...

Table 518. Registers used by the Freq-PD preamble search engine (continued)

Parameter	Notes
preamble_thresh[7:0]	Correlation threshold applicable to preamble detection; uses (0,5,5) fixed-point format which gets written in (0,8,8) format by zeroing out the LSB's.
preamble_frac_time_scale[3:0]	Scaling factor used for fractional time estimation during preamble search; represented in (0,4,3) format.
iir_alpha[7:0]	IIR filter parameter used during preamble detection; represented in (0,8,8) format.
mod_idx[10:0]	Modulation index; represented in (0,11,7) format.

Table 519 lists a suggested preamble correlation threshold value for each non-coded use case listed in Table 515. The values are applicable to ACQ mode 1 but it should be noted that they were optimized for the specific preamble length of 8 octets and, therefore, may need to be adjusted if a different preamble length is used.

Table 519. Suggested Freq-PD correlation thresholds for ACQ mode 1

Use case	Preamble threshold (fraction)	*preamble_thresh[7:0]* (hexadecimal notation)
Bluetooth LE	12/32	0x60
GFSK_05_07-500	14/32	0x70
GFSK_03_05-1000	12/32	0x60
MSK_05-500	10/32	0x50
GFSK_05_05-250	12/32	0x60
GFSK_05_10-250	16/32	0x80
GFSK_07_05-1000	16/32	0x80
GFSK_05_05-2000	16/32	0x80
MSK_05-250	14/32	0x70
GFSK_05_032-2000	16/32	0x80
FSK_05-500	10/32	0x50
FSK_05-500	10/32	0x50

Table 520 lists a suggested value for *preamble_frac_time_scale* applicable to all non_coded use cases. The length of the preamble does not influence this parameter and so the suggested value is applicable regardless of the preamble length.

Table 520. Suggested Freq-PD fractional timing scale for ACQ mode 1

Use case	Preamble fractional timing scale (decimal)	*preamble_frac_time_scale[3:0]* (hexadecimal notation)
All use cases	1.50	0xC

Table 521 lists a suggested value for *iir_alpha* for each non-coded use case listed in Table 515. It was optimized for a preamble length of 8 octets and may need to be adjusted if the preamble length is different.

Table 521. Suggested Freq-PD IIR forgetting factor for ACQ mode 1

Use case	IIR parameter, α (fraction)	*iir_alpha[7:0]* (hexadecimal notation)
Bluetooth LE	6/32	0x30
GFSK_05_07-500	6/32	0x30
GFSK_03_05-1000	4/32	0x20
MSK_05-500	3/32	0x18
GFSK_05_05-250	6/32	0x30

52.4.4.2.2.10.2.2.2.3.2.4 Phase-PD preamble search engine

A block diagram of the Phase-PD preamble search engine is shown in Figure 384. It is used for correlation-based preamble detection in the phase-domain. The fixed-point formats used at various internal points are also shown in the diagram.

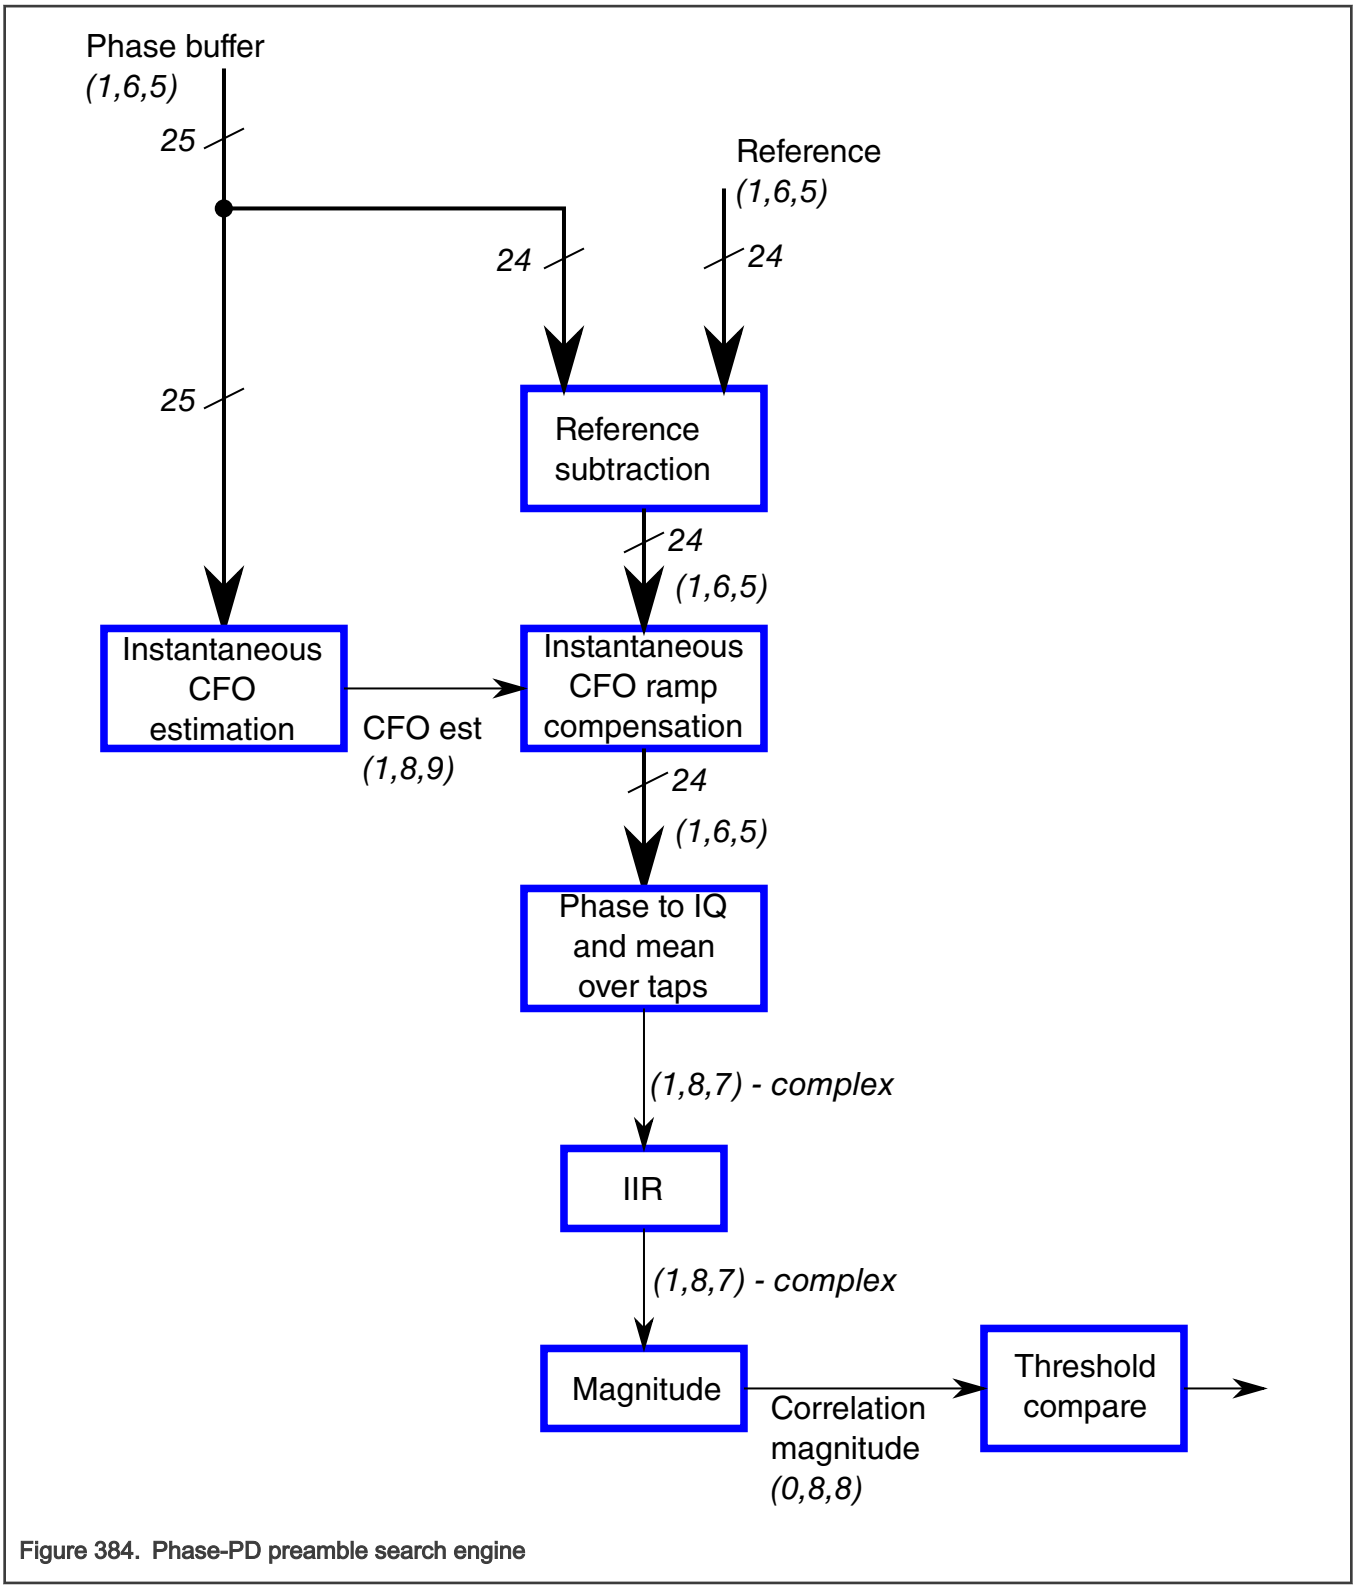

Figure 384. Phase-PD preamble search engine

An 24x1 phase-domain reference pattern along with the pre-processor output phase values is provided as input to the engine. Since the 24x1 vector is periodic with an 8x1 vector repeating three times, only 8 values need to be programmed, as shown in Table 522, in order to save register space. To be able to properly perform phase-domain correlation the phase ramp caused by CFO has to be compensated. In order to achieve that, an instantaneous CFO estimate is computed, by averaging differences between consecutive values in the phase buffer, and all correlation taps are simultaneously compensated by reconstructing the

ramp based upon the estimated CFO. As shown in Figure 384, the CFO is estimated on the input phase vector after the reference is subtracted. After the CFO compensation the phase values are converted to complex values and the taps are averaged over, thus transforming the vector input to a scalar output. An IIR can be optionally used, to average the complex correlation values, if preamble is longer. However it is expected that, for the use cases that use acquisition mode 3, the IIR will be bypassed.

Finally the complex correlation values are converted to real values through absolute operation ("Magitude" block) and compared with a threshold. Given the intrinsic behavior of the phase-domain correlator to output a large correlation magnitude when the buffer is filled with zeros (this happens when the preamble detector is being reset), a timer is used to gate the output of the block until the buffer gets filled with non-zeros samples.

52.4.4.2.2.10.2.2.2.3.2.4.1 Register parameters

Table 522 lists the register parameters used by the preamble search engine.

Table 522. Registers used by the Phase-PD search engine

Parameter	Notes
preamble_pattern[47:0]	8 reference phase values, 6-bits each; uses (1,6,5) fixed-point format.
preamble_thresh[7:0]	Correlation threshold applicable to preamble detection; uses (0,8,8) fixed-point format.
iir_alpha[7:0]	IIR filter parameter used during preamble detection; represented in (0,8,8) format.

Table 519 lists a suggested preamble correlation threshold value for each non-coded use case listed in Table 515.

52.4.4.2.2.10.2.2.2.3.2.5 AA search engine

A block diagram of the AA search engine is shown in Figure 385. It is used for correlation-based AA detection in AAD. The fixed-point formats used at various stages are also shown within parentheses in the diagram.

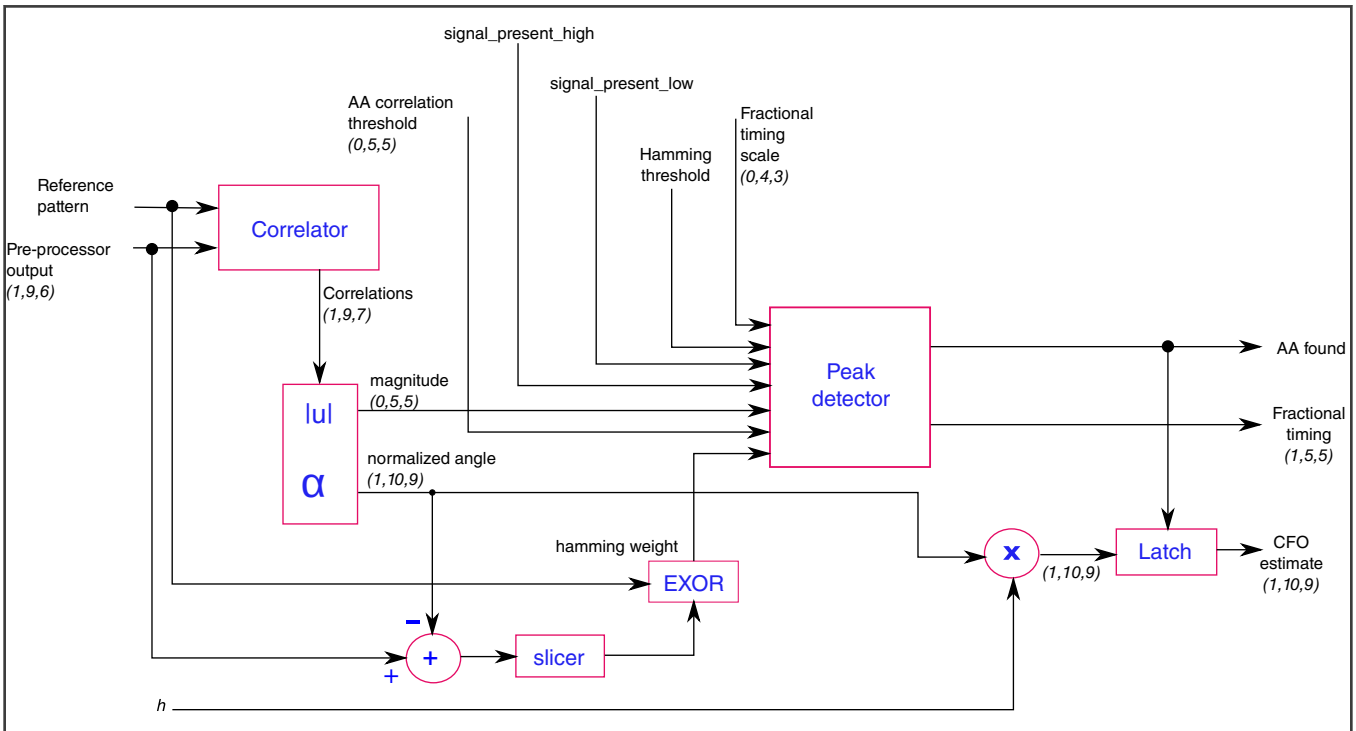

Figure 385. AA search engine

A binary AA reference pattern, along with the pre-processor output phase values, is provided as input to the engine. In the first step, each phase value is converted into its equivalent I/Q sample of unit magnitude and a correlation is performed between the I/Q values thus obtained and the reference pattern. Next, the magnitudes and angles of the complex correlations are obtained

using LUTs and passed to the peak detector and CFO estimation circuits respectively. In addition, a hamming weight is also computed between

1. the reference pattern, and
2. the pre-processor output vector (corresponding to the current correlation) after removing the bias due to CFO.

52.4.4.2.2.10.2.2.2.3.2.5.1 Register parameters

Table 526 lists the register parameters used by the AA search engine.

Table 526. Registers used by the AA search engine

Parameter	Notes
aa_0[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 0; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_1[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 1; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_2[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 2; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_3[31:0]	AA pattern of length 1, 2, 3 or 4 octets used for AA search in ACQ path 3; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
size_aa[1:0]	Indicates length of active AA's; 0→1 octet, 1→2 octets, 2→3 octets, 3→4 octets.
aa_thresh[4:0]	Correlation threshold applicable to AA detection; uses (0,5,5) fixed-point format.
aa_frac_time_scale[3:0]	Scaling factor used for fractional time estimation during AA search; represented in (0,4,3) format.
search_aa_0	Indicates whether aa_0 should be searched during acquisition; 0→no, 1→yes.
search_aa_1	Indicates whether aa_1 should be searched during acquisition; 0→no, 1→yes.
search_aa_2	Indicates whether aa_2 should be searched during acquisition; 0→no, 1→yes.
search_aa_3	Indicates whether aa_3 should be searched during acquisition; 0→no, 1→yes.
hamming_aa_high_pwr[2:0]	Maximum hamming distance from the given AA pattern that may still be accepted as a match; valid range is [0,7].
hamming_aa_low_pwr[3:0]	Hamming distance tolerance applicable around sensitivity and at low power levels during AA detection; valid range is [0,15].
mod_idx[10:0]	Modulation index; represented in (0,11,7) format.

Table 527 lists the suggested AA correlation threshold values for ACQ modes 2 & 3 while Table 528 lists suggested AA correlation threshold values for ACQ mode 1 for the non-coded use cases listed in Table 515. Note that they are not influenced by the length of the preamble.

Table 527. Suggested AA correlation thresholds for ACQ modes 2 & 3

52.4.4.2.2.10.2.2.2.3.2.6 Interpolator

A block diagram of the interpolator is shown in Figure 386. It is only used in ACQ mode 1 for interpolation in AAD. The fixed-point formats used at various internal stages are also shown within parentheses in the diagram.

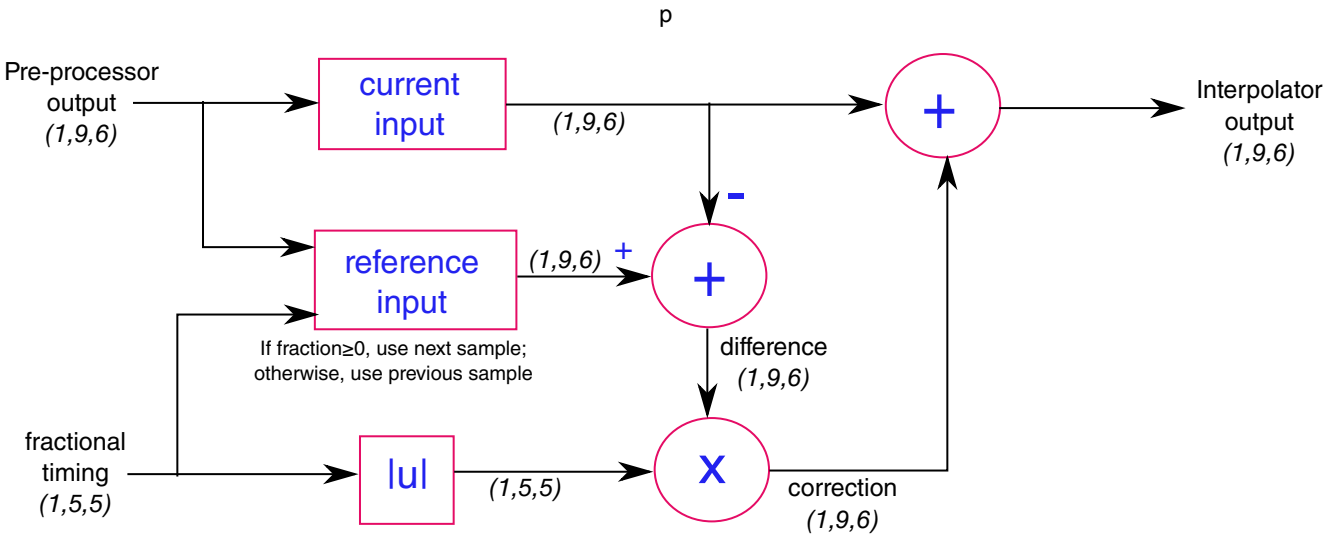

Figure 386. Interpolator

The interpolation in performed by using as reference the immediately preceding sample if the fractional timing estimated in PD is negative or the immediately succeeding sample if the fractional timing is non-negative. For interpolating each input sample, the difference between the itself and the reference is scaled by the fractional timing estimate and added back to itself.

52.4.4.2.2.10.2.2.3 Acquisition for BluetoothLE-LR

52.4.4.2.2.10.2.2.3.1 Long range Bluetooth LE preamble detection

The purpose of the preamble detector is to detect the presence of a long range Bluetooth LE packet and to estimate the CFO.

52.4.4.2.2.10.2.2.3.2 Long range Bluetooth LE AA detection

The soft-bits based AA detector performs AA detection for long range Bluetooth LE packets. It consists of the following components:

- Low complexity FSK symbol demodulator which produces the soft-bits, triggered at the sample rate
- Buffer which converts the scalar input to a vector used for correlation
- Long range Bluetooth LE AA correlator, used to perform long range Bluetooth LE AA detection after a long range Bluetooth LE preamble is detected

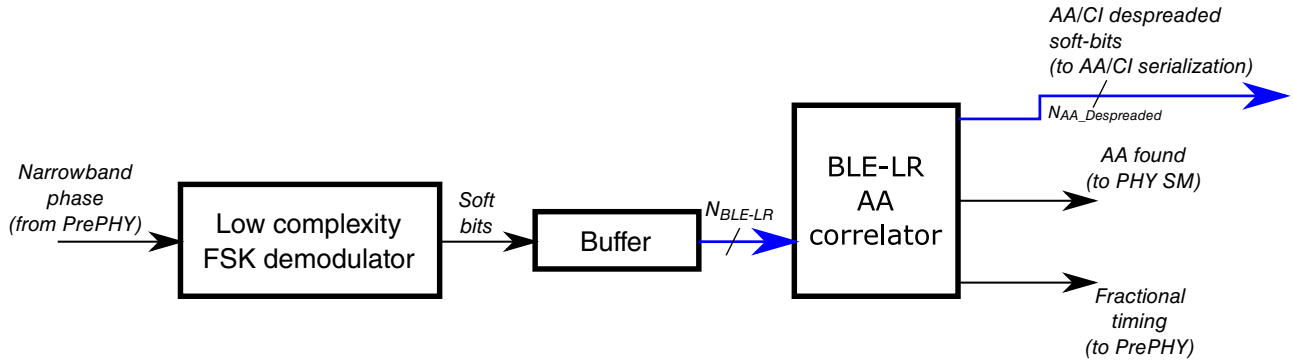

Figure 387. Soft-bits domain AA detector block diagram

It is being recalled here that the AA detection that uses soft-bits is done in parallel with continued preamble detection which has the purpose of improving the CFO estimate and extend the AA search time-out. These details are given in a more detailed manner in the PHY state-machine section. An important aspect to be mentioned is that the long range Bluetooth LE detector supports detection of a single AA pattern. When AA detection starts, the low complexity FSK demodulator and the buffer are first enabled and the correlator is enabled after enough samples are acquired into the buffer to allow a valid correlation product.

52.4.4.2.2.10.2.2.3.2.1 Low-Complexity FSK Symbol Demodulation

The soft-bits are generated at the sample rate *i.e.*, $1/T_s$ and they are used during AA detection. The FSK symbol demodulator takes the CFO-corrected phase-domain samples as input and produces soft-bits as described below. Since the PHY has no knowledge of the PDU size, the process continues until the *activate_search* signal is de-asserted by the MAC.

52.4.4.2.2.10.2.2.3.2.2 Long range Bluetooth LE AA detection

The AA/CI despreaded soft-bits are latched when AA is found and they are further used by the long range Bluetooth LE AA/CI decoding mechanism, which is described in a different section.

In order to match the AA, the despreaded soft-bits are selected in the "Select AA portion" block and 64 despreaded soft bits are provided to the correlation and Hamming distance circuits. The correlator performs real values correlation, against AA corresponding reference waveform, over the input vector and the Hamming distance uses hard-bits to measure the distance between the received vector and the expected, coded AA.

52.4.4.2.2.10.2.3 Long range Bluetooth LE AA/CI decoding

The AA/CI decoding process is illustrated in Figure 388. This process corresponds to state 3 in the PHY state machine and involves both the PHY and the RBME modules. The chronological steps are indicated by the red arrow. Note that the arrow is meant to show data flow not control. The steps are:

- When AA is detected the detector provides a vector containing the despreaded soft-bits corresponding to the AA and CI portions
- The parallel to serial conversion block in the AA/CI decoding block starts producing codewords (consisting of the pairs of soft-bits {Soft-bit 1, Soft-bit 2}) and data valids
- The RBME engine decodes the inputted codewords and provides back data and data valids to the AA/CI detection block
- AA/CI detection is performing AA matching and CI extraction
  - If AA is matched the CI information is sent to the state-machine together with a CI valid indication
    - Following this event, the PHY state-machine transitions to payload demodulation
  - If AA is not matched the CI valid is not sent and a time-out occurs in the PHY state-machine
    - This further leads to returning to the acquisition state and to RBME disable

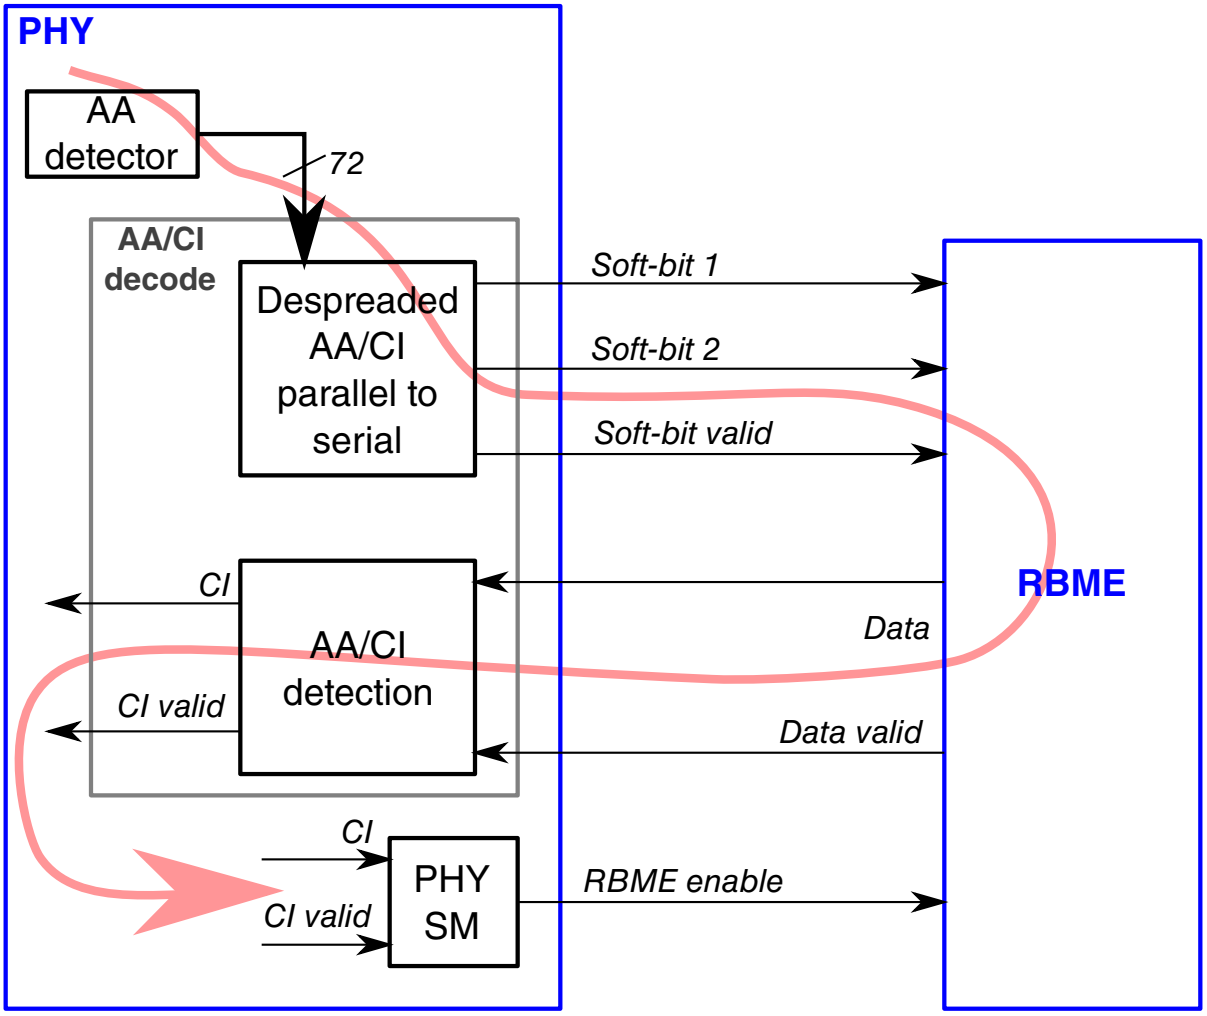

Figure 388. AA/CI decoding process

52.4.4.2.2.10.2.4 FSK payload demodulation

The demodulator consumes the received samples, at an oversampling rate (OSR) equal to 4, after the symbol timing and frame timing have been determined and after the CFO correction was applied. The I/Q samples are first converted to phase, by using the normalizer block.

The demodulator block supports:

- Symbol demodulation using input phase samples at OSR=4:
- Time tracking to compensate for residual timing error and for timing drift
  - Given that the timing drift needs to cover a various range of use-cases, from a maximum packet length perspective, the range is configurable via registers
- Frequency error detection and compensation to compensate for residual frequency error

Each supported feature will be detailed in the sequel of this section. Figure 389 shows the corresponding block diagram.

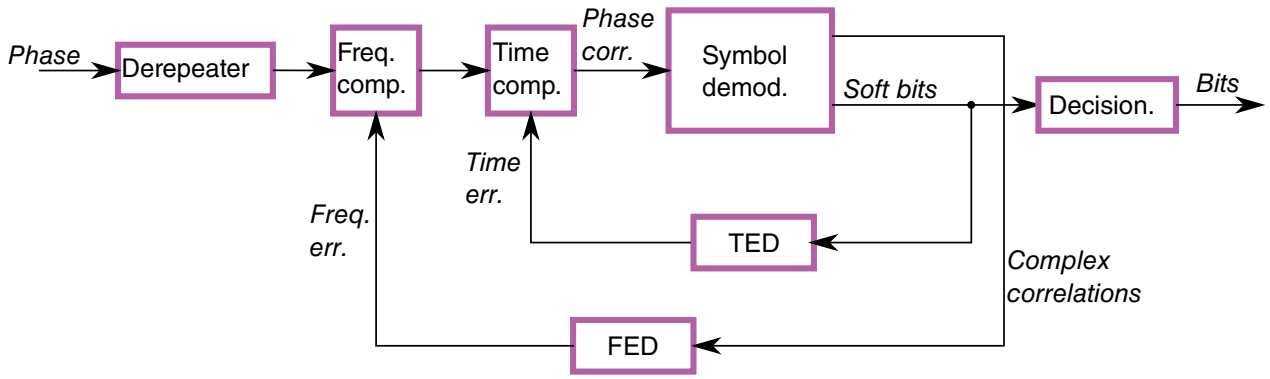

Figure 389. Demodulator block diagram

Symbol demodulation

The symbol demodulation mechanism will be referred to as M3c in the sequel. Figure 390 shows the block diagram of the symbol demodulator.

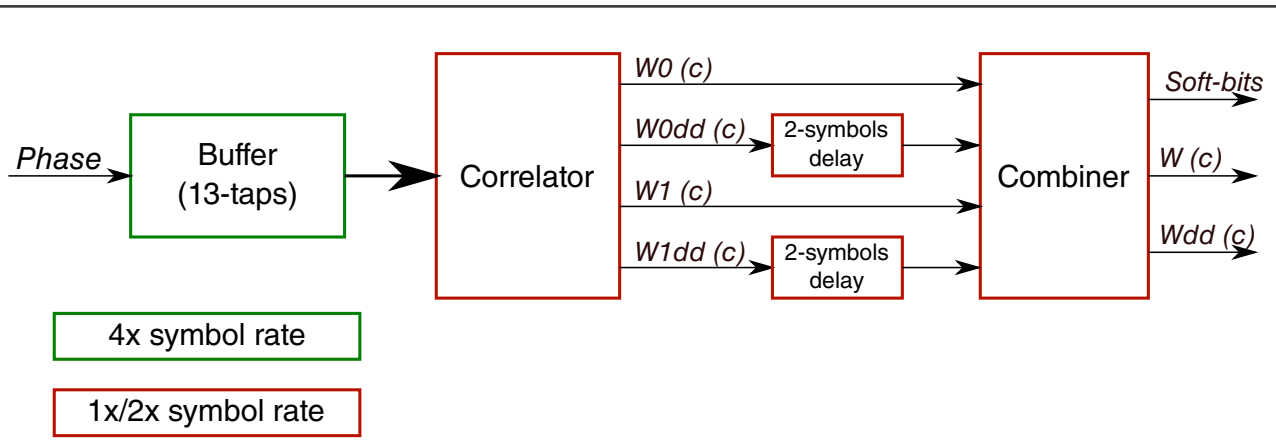

Figure 390. Symbol demodulator block diagram

From a correlation perspective, the symbol demodulator supports four modes:

- Mode 0: uses 12-taps (OSR in the adder tree is 4) and the reference phase vectors are shaped taking into consideration the modulation pulse and the receiver filtering
- Mode 1: uses 4-taps (OSR in the adder tree is 1) and no shaping is performed on the reference phase vectors
- Mode 2: uses 7-taps (OSR in the adder tree is 2) and no shaping is performed on the reference phase vectors
- Mode 4: uses 13-taps (OSR in the adder tree is 4) and no shaping is performed on the reference phase vectors

Some of the modes not only they provide a lower current drain in the correlation circuit but they can also provide a better performance.

Time/frequency error tracking

Following impairments need to be taken into consideration in the demodulator:

- Phase drift which is due to the residual carrier frequency offset, due to imperfect frequency synchronization in the acquisition block (initial frequency error)

- Crystal frequency drift which leads to carrier frequency offset accumulation over time (accumulated frequency error)
- Symbol timing residual error, due to imperfect time synchronization in the acquisition block (initial timing error)
- Timing drift due to misalignment of the frequency of the crystal at the transmitter and at the receiver (accumulated timing error)

The former two impairments are addressed through the frequency tracking mechanism whereas the latter two are handled by the timing tracking loop.

The frequency error tracking algorithm has two components: frequency error detection (FED) and frequency error correction (FED).

The most difficult use-case, from a frequency tracking perspective, is long range Bluetooth LE. This is because no frequency tracking is performed during the AA search. This means that there is a ~300 microseconds period between the moment when the CFO estimate is provided by the preamble detector and the start of the frequency tracking on the PDU portion. Long range Bluetooth LE 500 kbps is particularly affected due to the shorter duration of the informational symbol.

The timing error compensator provides:

1. integer compensation using a buffer
2. fractional compensation using a linear interpolator

The range of the timing error compensator is configurable and determines the latency of this block.

52.4.4.2.2.10.2.5 AA-confirmation block

The Bluetooth LE specification stipulates that a spec-compliant device be capable of detecting and rejecting a Bluetooth LE packet if the received AA is different from the desired AA even in only one bit position. But the AAD block requires a received power level which is at least 4-5 dB above sensitivity to fulfil this stipulation as it is a simple correlation-based detector. However, by using a symbol demodulator, a mechanism can be created to meet the stipulation even at 0.2 dB above sensitivity. The AA-confirmation block is a manifestation of such a mechanism.

52.4.4.2.2.10.2.5.1 Functional description

The AA-confirmation block may be used as a supplementary step with any of the three ACQ modes. It can be enabled/disabled using the parameter *dmd_aa_enable* (see Table 530 for a list of all the parameters used by this block) but will begin its operation only after a successful AA detection has occurred.

A block diagram of the AA-confirmation block is shown in Figure 391. If enabled and a successful AA detection is declared by the AAD block, the AA-confirmation block obtains the symbol timing and CFO estimates produced by the synchronization stage; and simultaneously, a buffer containing the recent history of incoming samples is frozen (or disabled). The buffer then holds all the samples required by the symbol demodulator for a successful demodulation of the AA bits.

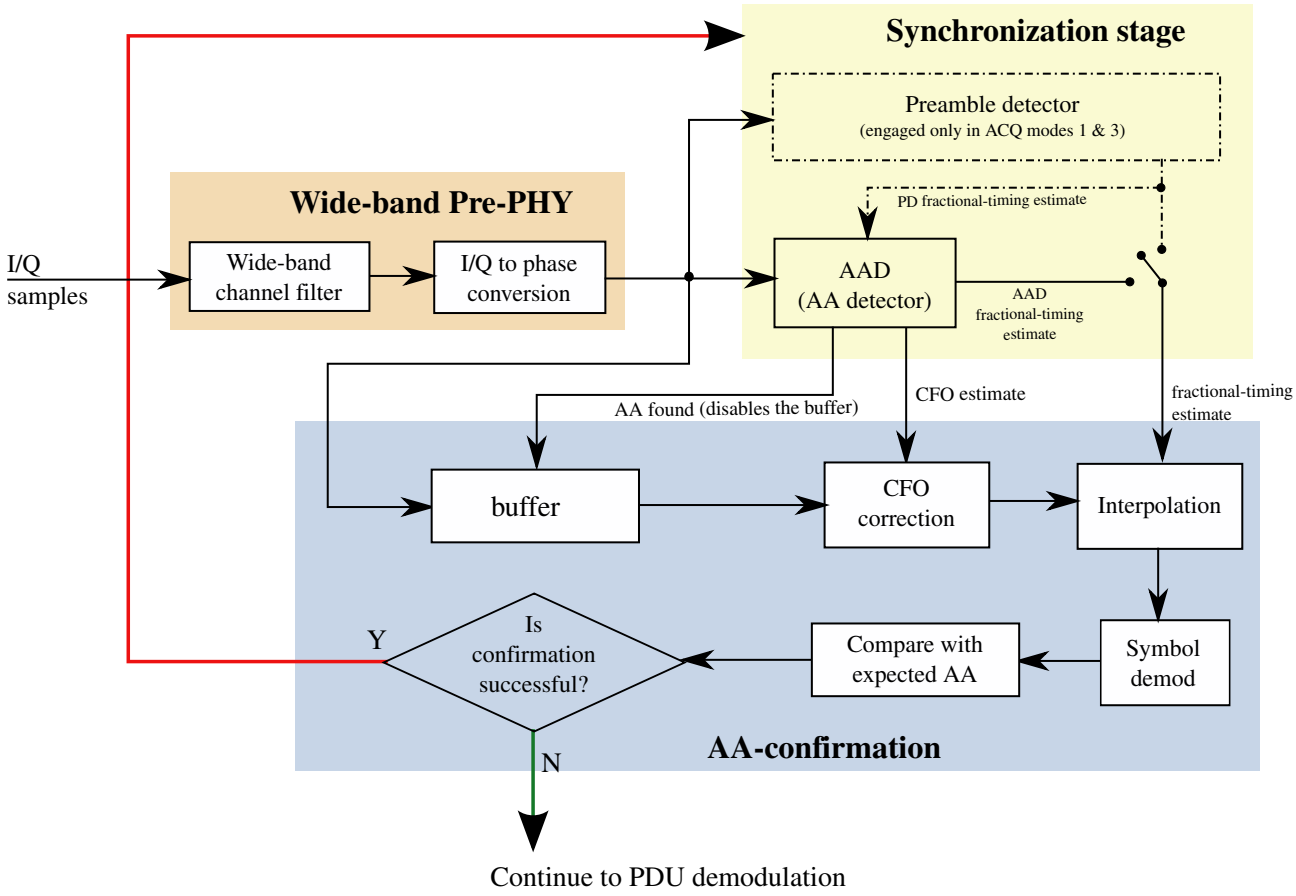

Figure 391. AA-confirmation functional block diagram

Next, the block begins operation by fetching successive samples from the frozen buffer and performs the following steps.

1. First, a CFO correction and timing interpolation is applied to compensate for the frequency offset and timing offset obtained from the synchronization stage.
2. The samples are then passed to a symbol demodulator which processes them and outputs one symbol decision for every *P* input samples.
3. The symbol decisions are then passed to a comparator which compares the demodulated sequence to the desired AA. If they match to within the Hamming distance specified, then AA-confirmation is declared successful and the PHY will continue with PDU demodulation; if not successful, then the AA-confirmation block sends a signal to the PHY state machine to resume acquisition.

52.4.4.2.2.10.2.5.2 Registers used by the AA-confirmation block

Table 530. AA-confirmation block parameters

Parameter	Notes
aa_0[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_1[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.

Table continues on the next page...

Table 530. AA-confirmation block parameters (continued)

Parameter	Notes
aa_2[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
aa_3[31:0]	AA pattern of length 1, 2, 3 or 4 octets; 1, 2 and 3 octet patterns in bits [7:0], [15:0] and [23:0] respectively.
size_aa[1:0]	Indicates length of active AA's; 0→1 octet, 1→2 octets, 2→3 octets, 3→4 octets.
acq_mode[1:0]	Indicates the ACQ mode used for timing & frequency synchronization in non-coded use cases; 1→mode 1, 2→mode 2, 3→mode 3.
dmd_aa_enable	Enables demodulator-based AA-confirmation; 0→disable, 1→enable.
dmd_aa_hamming_high_pwr[2:0]	Hamming distance tolerance allowed at high power level during AA-confirmation; valid range is [0,7].
dmd_aa_hamming_low_pwr[2:0]	Hamming distance tolerance applicable around sensitivity and at low power levels during AA-confirmation; valid range is [0,7].
dmd_aa_hipow_disable_ovrd	Overrides the default disablement of AA-confirmation at high power levels; 0→no override, 1→override.

52.4.4.2.2.10.2.6 High accuracy RTT (round-trip time) block (HARTT)

The purpose of this block is to determine an accurate estimate of the timing information and also of the CFO, upon detection of an expected GFSK modulated bit pattern. From a detection perspective, it can be used in two possible cases:

1. Regular packets (i.e. packets that are composed of a preamble, an access address and a PDU)
2. RTT packets (i.e. packets that contain only a preamble and a 32 or a 64 bit PN sequence that does not bear any information bits)

The CFO is directly estimated by the HARTT block. On the other hand, from a timing estimation perspective, the time-stamp is not directly determined by the HARTT block. Squared correlation magnitudes around the peak of the main lobe are instead provided to the application, which needs to further use this information to compute the accurate timing.

52.4.4.2.2.10.2.6.1 Block description

52.4.4.2.2.10.2.6.1.1 Introduction

In principle, the HARTT block re-uses the arithmetic from the AA detection blocks in the acquisition module. The main difference is that it has a much lower duty-cycle (to save power) and a much higher resolution on the fixed-point formats (to achieve increased time/frequency accuracy). The expected accuracy is <2 ns for the timing estimation and <600 Hz for the CFO. The operation is triggered by an AA found event, provided by the AA detector in the acquisition block. A re-evaluation of the correlation peak is performed, assuming that the peak may not have been correctly detected during acquisition.

52.4.4.2.2.10.2.6.1.2 I/Os and settings

Note that all the outputs in the input/output signals table are packed in a 31-bit result (rtt_data[30:0]) and provided to the system memory via DMA. The results provided to software are sents as {rtt_data[30:0],1'b1} if a valid RTT pattern was detected and as{rtt_data[30:0],1'b0} when a valid RTT pattern is not detected in the expected time-slot.

Table 531. Input/output signals

Signal name	Type	Dimension	Description
fm_buffer[7:0]	I	134	The content of the FM buffer shared between acquisition and HARTT

Table continues on the next page...

Table 531. Input/output signals (continued)

Signal name	Type	Dimension	Description
rtt_bits	I	64	The bit sequence which is expected by the HARTT block when *overrd_progr_aa* is true
progr_aa	I	32	The AA programmed for the AA0 detector in the acquisition module
aa_found	I	1	Flag that indicates that AA was found in the AA0 detector
cfo_est[9:0]	I	1	The CFO estimate computed by the AA0 detector
PDelta[9:0]	O	1	Difference between the squared correlation magnitude values, *pm-pp*, provided by the HARTT block (format is sfix10En9)
rtt_int_adj[1:0]	O	1	An integer adjustment of the timing which takes a value different of 0 when the early-late mechanism in the HARTT block chooses a peak different of the one chosen in the acquisition module (format is ufix2En0 and possible values are {-1,0,+1})
ham_rtt_dist_sat[1:0]	O	1	Computed Hamming distance saturated to 2 bits (ufix2)
ha_rtt_cfo[15:0]	O	1	The high accuracy CFO computed by the HARTT block through the CORDIC algorithm
ha_rtt_found	O	1	Flag that indicates that the HARTT operation is done and a valid PN pattern was detected

Table 532. HARTT parameters

Parameter	Description
en_hartt	Enables the HARTT block
overrd_progr_aa	Overrides the programmed AA with an input sequence, which is used as reference for both the AA detector and for the HARTT correlation
rtt_seq_len	Allows payload demodulation of channel sounding packets during RTT computation. 0 - no payload demodulation 1 - payload demodulation
first_pdu_bit	Allows providing to the HARTT block the value of the first bit of the PDU. This information is used to generate the HARTT correlator reference sequence when *overrd_progr_aa* is false
fm_ref_111[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when both the adjacent bits are the same
fm_ref_110[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when one of the adjacent bits is the same and the other one is different
fm_ref_010[7:0]	Weight applied to the current symbol, in the HARTT correlation sequence, when both the adjacent bits are different
ha_rtt_threshold[8:0]	Threshold used to compare p0 with in order to validate RTT found

52.4.4.2.2.10.2.6.1.3 Block diagram

Figure below shows the block diagram of the HARTT block, which has 4 main components:

- Control engine

- it is a state-machine which controls the behaviour of the correlator and of the combiner
- responsible of the generation of the enable/disable signal for the arithmetic
- it manages the generation of the reference sequences used by the correlator

- Correlator
  - responsible with computing the complex correlation values and the Hamming distances
  - the maximum supported correlation width is 32 bits
  - when the HARTT block is programmed to perform a 64-bit correlation, the correlator performs two 32-bits correlations
- Combiner
  - combines the results computed inside the correlator, when a 64-bits correlation is required
  - performs a peak selection based upon an early-late criterion
- IQ to phase conversion
  - determines the CFO using CORDIC algorithm

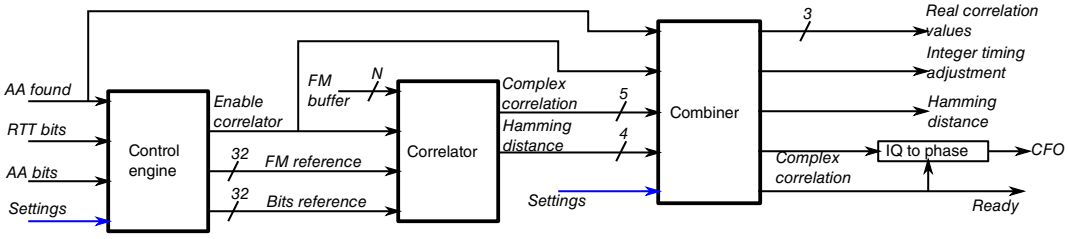

Figure 392. Block diagram

The "Ready" signal is asserted when the result is ready. One example of use of the HARTT block is to interface it with the RSM (ranging sequence manager) block which, when the "Ready" signal is asserted, manages the DMA transfer of the result, packed in a 32-bit word, to the packet RAM. When the HARTT block is used in conjunction with the RSM block, an interrupt is issued to soft-ware for every RSM step (RTT steps included).

More details about each component are provided in the following subsections.

52.4.4.2.2.10.2.6.1.3.1 Control engine

The state machine consists of 3 states. Two active states and an idle state. When the correlation width is 64 bits both the active states are being used. Otherwise only state 0 is necessary. During each active state, the correlator arithmetic is run for a 5 samples worth of time.

Besides the main states there are secondary states. Their purpose is, they represent transitional states which are meant for preparing the reference sequences or for wait periods. The most complex operation of the state machine is when a 64-bit correlation is required. In this case, after the first 32-bit correlation completes, the state machine manages the change of the reference sequence and also it manages the timing of the second 32-bit chunk correlation.

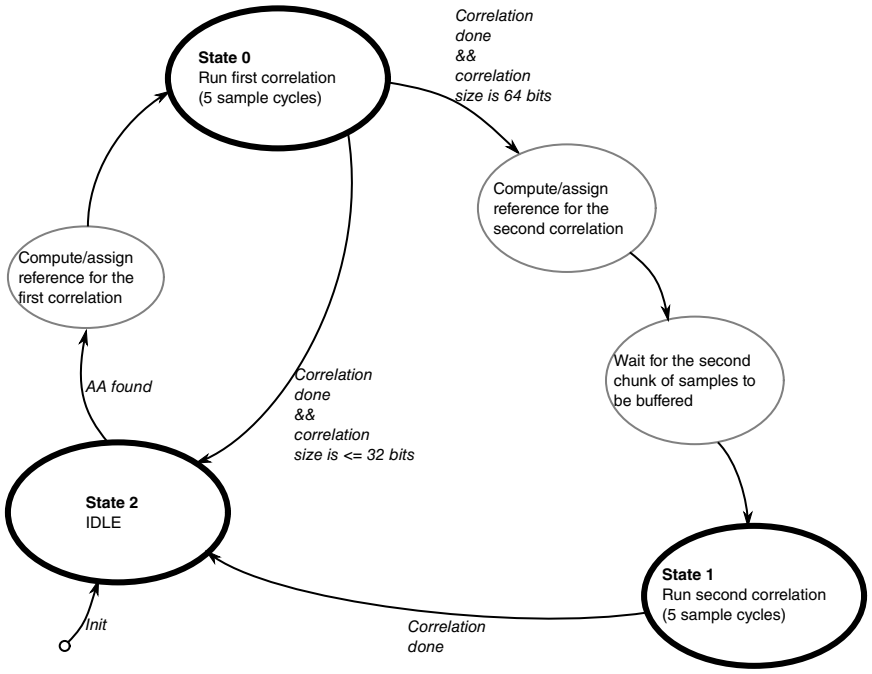

Figure 393. Control engine state-machine diagram

For each active state, an enable signal is sent to the correlator, which drives the computation of 5 complex correlation products at the PHY sampling rate. In order to compute the timing only 3 squared correlation magnitude values are required. However, 5 such values are being computed in order to be able to re-evaluate the position of the correlation peak. Computing 5 values allows moving the estimation of the peak timing by 1 sample at most.

The reference sequence used for correlation is computed by combining the reference symbols with the programmed FM weights. Table below shows an example of how the reference is being derived.

Table 533. Example of FM reference sequence computation

Bit	1	0	1	0	0	0	1	1	1
Bipolar symbol	+1	-1	+1	-1	-1	-1	+1	+1	+1
FM reference value	N/A	*-fm_ref_010*	*+fm_ref_010*	*-fm_ref_110*	*-fm_ref_111*	*-fm_ref_110*	*+fm_ref_110*	*+fm_ref_111*	N/A

A few comments on the reference waveforms:

- Reference values are the result of the multiplication between the bipolar symbols and the programmed weights
- Weights depend on the modulation scheme (more specifically they depend in the BT product and on the modulation index)
- Programmed reference values depend on the context
  - inter-symbol interference is considered negligible from symbols other than the immediate neighbours
  - in order to determine a certain value both the preceding and the succeeding bits need to be known
  - for the reason on the bullet above the values are indeterminate for the first and the last columns of the table above
- When determining an FM reference sequence corresponding to *N* bits, actually (*N*+2) bits need to be known
  - means that the last bit of the preamble and the first bit of the PDU (for regular packets) or the first bit of the post-padding (for the RTT packets) need to be known

— the best timing estimation is obtained when the sequence to be searched for starts and ends with a transition (i.e. the last bit of the preamble is the inverse of the first bit of the searched sequence and the first bit of the PDU/post-padding is the inverse of the last bit of the searched sequence)

- If *N*=64 the correlator needs to perform 2 correlation products of 32-bit width - the correct provisioning of the FM reference sequences, corresponding to the first and the second half, are managed by the control engine

Table below shows an example of FM reference values that correspond to BT=0.5/h=0.5 (RTT 1 Mbps) and BT=2/h=0.5 (RTT 2 Mbps).

Table 534. FM reference values for BT=0.5 / h=0.5

	fm_ref_111	*fm_ref_110*	*fm_ref_010*
Real value [rad]	*π*/2	1.22	0.88
Fixed point value [normalized]	0.5	0.387	0.281
Fixed point value [hex]	0x80	0x63	0x48

Table 535. FM reference values for BT=2 / h=0.5

	fm_ref_111	*fm_ref_110*	*fm_ref_010*
Real value [rad]	*π*/2	1.4	1.2
Fixed point value [normalized]	0.5	0.445	0.382
Fixed point value [hex]	0x80	0x72	0x61

52.4.4.2.2.10.2.6.1.3.2 Correlator

This sub-block is responsible with computing the complex correlation values and the Hamming distance. It is implemented in a similar fashion as the adder tree in the acquisition AA detectors. The difference is that more resolution is provided to the correlator taps in order to obtain a better timing accuracy.

52.4.4.2.2.10.2.6.1.3.3 Combiner

This sub-block is responsible with combining the complex correlation and Hamming distance computation results when a 64-bit correlation is required. It is also responsible with the re-evaluation of the correlation peak. The figure below shows a flowchart diagram of the combiner.

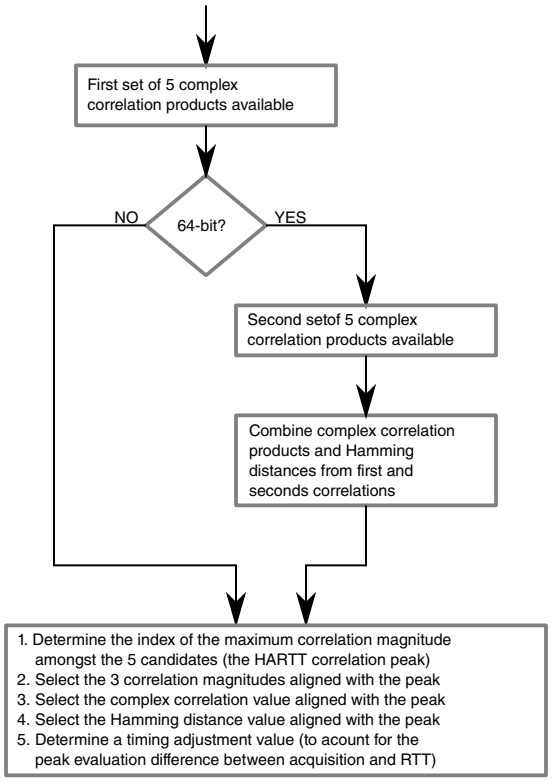

Figure 394. Combiner operation flowchart

The complex magnitude outputted by the combiner is further used by the CFO estimation algorithm.

52.4.4.2.2.10.2.6.1.3.4 Accurate CFO estimation

For a detailed description of the CFO estimation via CORDIC algorithm please consult the "Radio Frequency Fingerprinting (Fine CFO estimation)" section of the current chapter.

52.4.4.2.2.10.2.6.2 Integration considerations

As mentioned in the block description there are a few signals provided by the acquisition AA0 detector to the HARTT block. *aa_found* provides the timing reference and triggers the operation of the HARTT block. *cfo_est* is used by the Hamming distance computation for the FM symbols demodulation. Regarding the settings of the AA0 detector, when *overrd_progr_aa* is true the programmed AA is overwritten by the first half of the *rtt_bits* signal and the programmed AA length (a.k.a. SFD length) is overwritten by value 3 (which is the value corresponding to 32-bits).

Impact on other blocks in the PHY is described in the sequel.

52.4.4.2.2.10.2.6.2.1 Integration with the AA Hamming confirmation block

The purpose of the Hamming confirmation block is to provide a more reliable assessment on the Hamming distance than the one provided by the AA detectors in the acquisition module. When enabled, the operation of the AA Hamming confirmation block is triggered following the assertion of *aa_found*. After a while the AA detection is either confirmed or disconfirmed. When *overrd_progr_aa* is true, the programmed AA used by the AA Hamming confirmation block is overwritten by the first half of the *rtt_bits* signal.

When the operation of the confirmation block is enabled, the *ha_rtt_ready* indication from the HARTT is qualified by the AA confirmation event, which results in *ha_rtt_vld* signal.

52.4.4.2.2.10.2.6.2.2 Integration with the PHY state-machine

In order to support the reception of RTT packets (which have no PDU) a dedicated state is defined in the PHY state-machine, called RTT state. If *overrd_progr_aa* is true, the PHY SM transitions to the RTT state after AA is detected and confirmed.

RTT state is responsible to providing the control signals to all the blocks in the PHY, after an RTT packet is detected.

52.4.4.2.2.10.2.6.3 Computation of the fractional timing (intended for the application)

The time-stamps, used for the round-trip time computation, are locally determined by the application using the information from HARTT. It has two components:

- an integer component, computed by combining the timing of "AA detection" event (issued by the radio) with the *rtt_int_adj* value provided by HARTT
- a fractional component, computed using the 3 values contained in the *pm_pp_p0* result provided by the HARTT block

While the determination of the integer part is trivial, the computation of the fractional timing is not. The latter is addressed in the current section.

A few consideration on the main correlation lobe:

- When the data is oversampled it can be approximated by a sinc function
- A property of the sinc function is that peak of the sinc function can be estimated as $p=k*(\alpha-\gamma)$
  - where α and γ are the correlation output samples (squared correlation magnitudes) before and after the peak
  - p is the deviation from the center of the main lobe
  - α and γ are computed by the HARTT block and reported in the *pm_p0_pp* result (they represent the first and the last value of the result)
  - from now on the following notation will be used $\delta=(\alpha-\gamma)$
- k depends on the bit-sequence used for correlation
  - for RTT packets the sequence is randomly generated so it doesn't have to respect strict rules
  - there is a lot of variability of the used sequences leading to variability of k
  - flatter the main lobe larger the required k - sequences close to all-ones or all-zeros lead to very flat lobes
  - some sequences may have a periodical structure which leads to lobe smearing

52.4.4.2.2.10.2.6.3.1 Modelling of the fractional delay

Modelling of p (which is the fractional delay) as a first order polynomial was not satisfactory. Indeed a third order polynomial is used. In this case, k is replaced by a vector of 3 elements and the equation becomes:

$p=k_1*\delta+k_2*\delta^2+k_3*\delta^3$

Usually only the first and the third order terms are significant in the equation above. The coefficients k_1, k_2 and k_3 are related to the structure of the correlation sequence and they are computed for each sequence separately. Different sequences with similar properties will map on the same set of coefficients.

52.4.4.2.2.10.2.6.3.2 Dependence of the coefficients on the correlation sequence

More specifically, k_1, k_2 and k_3 depend on the context of each composing bit. To formalize this, the following notations are used for a certain sequence:

- c_{010} - count of the bits having both the adjacent neighbours logically inverted
- c_{011} - count of the bits having one of the adjacent neighbours logically inverted
- c_{111} - count of the bits having none of the adjacent neighbours logically inverted

The relation between the coefficients and the count consists in a third order polynomial. This is formalized in the equation below:

$[k_1, k_2, k_3]=[c_{010}, c_{011}, c_{111}, c_{010}^2, c_{011}^2, c_{111}^2, c_{010}^3, c_{011}^3, c_{111}^3]*\Gamma$

where Γ is the 9x3 transformation matrix.

This transformation is very useful because it greatly reduces the storage requirements. It also slightly increases the computation requirements because, first, the counts need to be determined for each sequence and second a multiplication is required to determine k_1, k_2 and k_3. **Γ** is unique for all possible sequences and it depends on the modulation scheme (modulation index - BT combination). Matrix **Γ** is pre-determined using intensive simulations and it is made available to the application from memory.

52.4.4.2.2.10.2.6.3.3 RTT block timing/frequency accuracy at hight SNR

In the figures below each blue "x" dot is the distance estimate corresponding to one RTT measurement. The red line corresponds to the averaging of all the measurements corresponding to a certain fractional delay (i.e. averaging all the dots on the vertical). To determine the red line, which is intended to show that there is no bias in the estimation, 100 distance estimates were used (i.e. 100 distance estimates per fractional delay value). The fractional delay reflects the timing uncertainty due to the sample clock which is 4 MHz for 1Mbps and 8 MHz for 2Mbps. As an example, when the frequency of the sample clock is 4 MHz, a fractional delay of 0.25 corresponds to a timing delay of 0.25/(4 MHz) = 62.5 nanoseconds.

52.4.4.2.2.10.2.6.4 Methodology for time-stamp determination

Following steps are required to determine the time-stamp for each transaction:

1. Determine the integer component of the time-stamp by capturing the "AA detection" event
2. Adjust the integer value using *rtt_int_adj* value provided in a HARTT status register (note that this value is expressed in PHY sampling rate cycles and it needs to be properly adjusted to the clock frequency)
3. Determine the [c_{010}, c_{011}, c_{111}] that correspond to the PN sequence used for the RTT transaction
4. Determine the [k_1, k_2, k_3] coefficients using the matrix transformation **Γ**
5. Compute the fractional delay using relation $p=k_1*\delta+k_2*\delta^2+k_3*\delta^3$ (δ is reported in the *PDelta* result)
6. Compute the final time-stamp combining the integer and the fractional components (note that the fractional value is expressed in PHY sampling rate cycles and it needs to be properly adjusted to the clock frequency)

52.4.4.2.2.10.2.6.5 Considerations for the choice of AA patterns

In order to get an accurate RTT estimation the AA pattern must have good autocorrelation properties and a controllable ISI at the beginning and at the end of the over-the-air transmitted waveform. In order to achieve that there are a few measures that can be taken:

- Make sure that there is a transition between the bit preceding the AA pattern and the first bit of AA
- Make sure that there is a transition between the last bit of AA and the first bit that follows after
- Use a scoring mechanism to select AA with good correlation properties
- Take into account the flatness of the main correlation lobe

The BLE protocol already imposes a transition between the last bit of the preamble and the first bit of the AA. For HADM RTT packets a rule was put in place to insure a transition at the end of the AA by defining 4 trailing bits that look like the preamble. However, for legacy packets the AA has to be chosen such that its' last bit is the complement of the first bit of the PDU transmitted over the air. It is important to keep in mind that, if FEC is used (e.g. whitening), the first OTA bit may not be the protocol bit. So, when choosing the AA pattern, the application has to have knowledge of the first protocol bit and the FEC operation that this bit may be subject to.

The BLE AA generation rules are not used in HADM because they can degrade the entropy and reduce security. This is why a scoring mechanism is required, to achieve a tradeoff between security and correlation properties. The score is computed by summing up the bit autocorrelation of the AA pattern in the vicinity of the main lobe. In HADM, at each RTT transaction, two AA patterns are computed and the one with the best score is used. An alternative would use an AA pattern that has a score less or equal than a threshold. The methodology of computing the score is given in the code below:

```
C = zeros(depth,1);
N = length(aa_pattern);
for m = 1:depth
C(m) = 2*sum(mod(aa_pattern(1:N-m)+aa_pattern((1+m):N),2)) - (N-m);
end
score = sum(abs(C));
```

The value for *depth* used by HADM is 3.

As previously shown in the current section it has been observed that the structure of the AA pattern influences the shape of the correlation (which is used to determine the ToF and thus the distance). To correlate the structure with the correlation a set of counts is being used. The flatness of the main lobe is mainly determined by c_{111}, i.e. higher this count flatter the main autocorrelation lobe. It was shown in this section how to compute the polynomial fit coefficients, depending on the counts, in order to get best accuracy. However, if the methodology presented here is not possible to implement, the AA with flat autocorrelation can be avoided by imposing a threshold for c_{111}.

As an example, for $depth$=3, the application can use only AAs for which $depth$<9 and c_{111}<8.

52.4.4.2.2.10.2.7 Operation

This section describes the 2.4GHz PHY module's operations.

52.4.4.2.2.10.2.7.1 PHY state-machine

The state-machine state diagram is depicted in Figure 395. As per the depiction in Scan mode three modes of operation are defined for the 2.4 GHz PHY:

- Non-coded FSK search: look only for non-coded packets, while keeping all the long range Bluetooth LE acquisition blocks disabled
- Long range Bluetooth LE search: search only for long range Bluetooth LE packets while keeping all the non-coded acquisition blocks disabled
- Simultaneous Non-coded and long range Bluetooth LE search: simultaneously look for long range Bluetooth LE and non-coded packets by enabling both long range and non-coded acquisition blocks

Note that the PHY block can simultaneously search for non-coded FSK packets and long range Bluetooth LE packets; however the only tested configurations are for simultaneous non-coded Bluetooth LE with long range Bluetooth LE.

The state-machine has 6 main states:

- State 0: Initialization state
  - Reset state used to recycle all the blocks in the PHY
- State 1: Acquisition state
  - Completely (for non-coded) or partially (for long range Bluetooth LE) responsible with time/frequency synchronization
    - More details about state1 are given in the sequel of this section
  - When the PHY is configured to perform simultaneous non-coded and long range Bluetooth LE search
    - Makes a decision whether to continue treating the packet as a non-coded or as a long range Bluetooth LE
- State 2: long range Bluetooth LE PD/AA

  - Only when a long range Bluetooth LE packet is detected
  - Responsible with the simultaneous LR preamble and AA search
  - It can only be entered following a long range Bluetooth LE preamble detection event
    - Keeps the preamble search to improve the CFO estimate
    - Extends the time used for the AA search process as required
- State 3: Long range Bluetooth LE AA/CI check
  - Only when a long range Bluetooth LE packet is detected
  - Tells the PHY and RBME to unpack the AA despread soft-bits
    - More details about these in the long range Bluetooth LE AA detection section
  - Turns on the Viterbi decoder
  - Looks for a match to the AA bits
  - Extracts the CI information
    - The CI is further used to configure RBME for PSDU decoding.
- State 4: Demodulation & Decoding
  - handles the PSDU demodulation and decoding for both non-coded and long range Bluetooth LE packets
- State 5: RTT state
  - This state is used for the RTT operation (for more details please consult the description of the RTT module)
  - This represents an idle state for the PHY to transition to when the reception of an RTT packets is done
  - PHY exists this state following a PHY reset issued at a higher level in the hierarchy
  - (Figures below don't show state 5 as this state is not representative for regular communication packets exchanges)

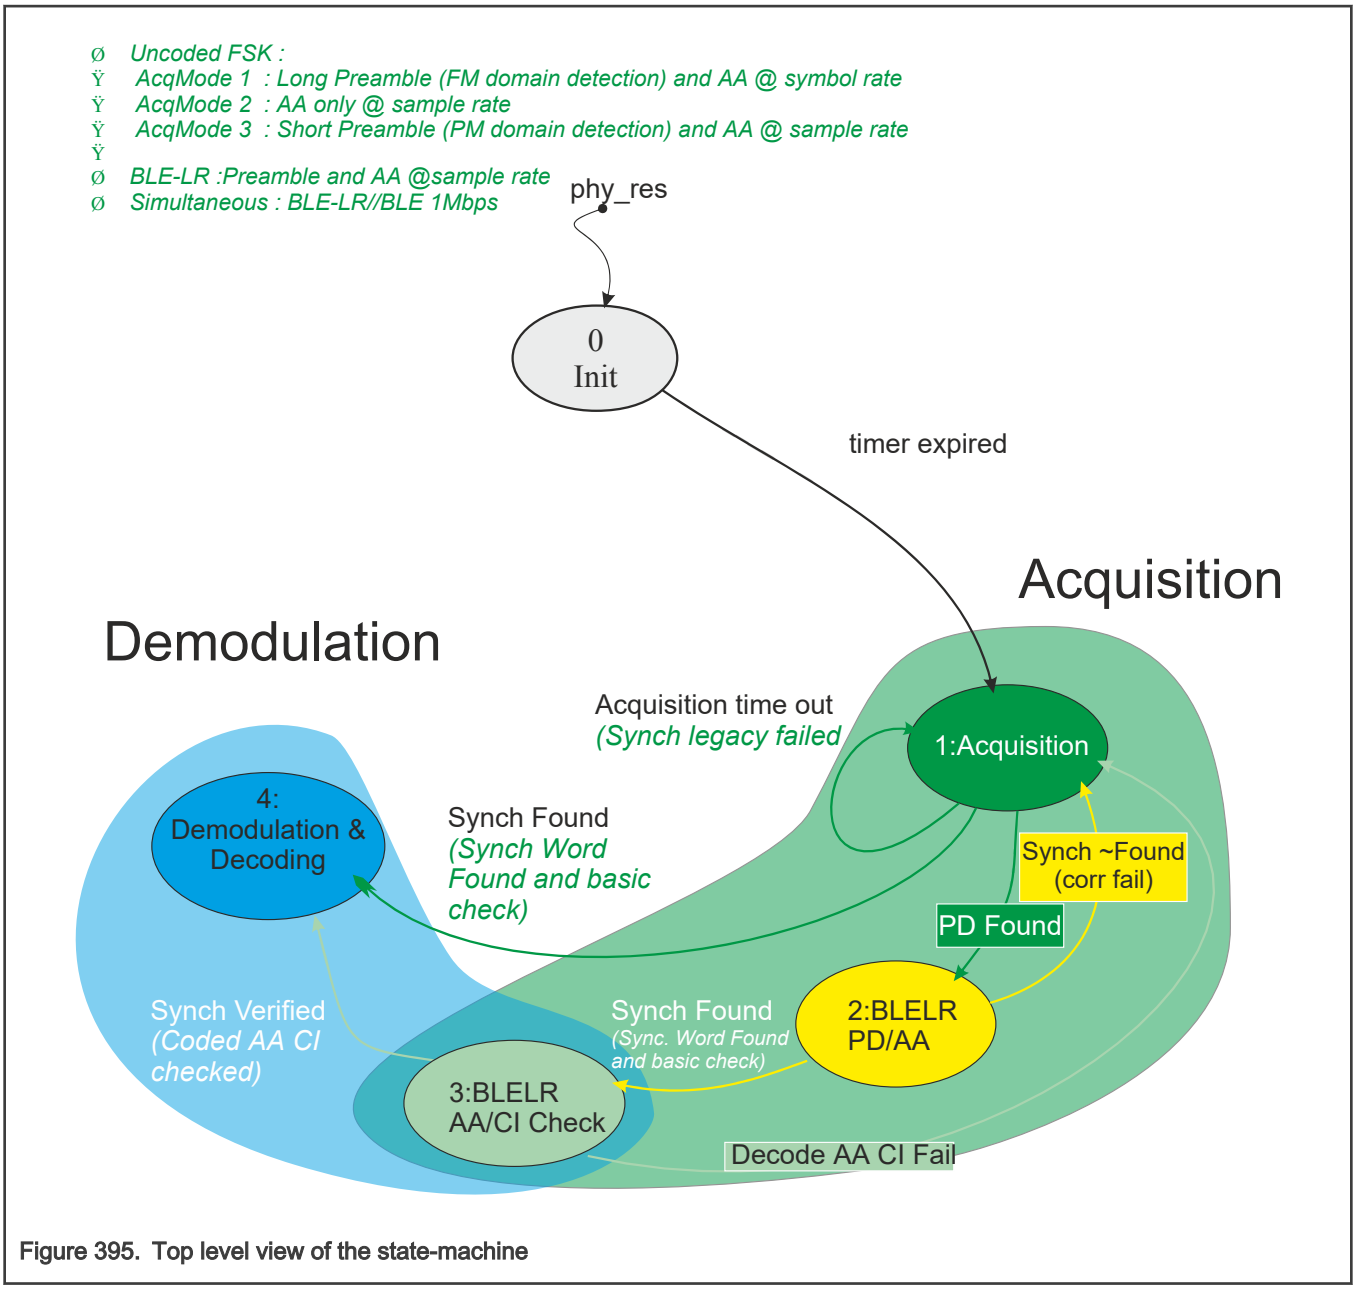

Figure 395. Top level view of the state-machine

A time out is used for the AA detection to allow for a prompt recovery. In long range and non-coded acquisition modes 1 and 3, AA detection runs in parallel with preamble detection in order to: 1) extend the AA search as needed and 2) to update the synchronization information. If neither a preamble detection nor an AA detection occur during the time-out period, the PHY state machine returns to the Acquisition state, disables AA detection and recycles all the PD block memory excepting the samples buffer.

Figure 395 illustrates two functions. The green areas are all about acquisition in a larger sense, meaning that all the processing concerning packets detection are associated to it and the blue region is about demodulation, responsible for PSDU processing and/or decoding in the RBME (Radio Bit Manipulation Engine).

For long range Bluetooth LE packets the preamble detection is responsible for packet acquisition and frequency synchronization (i.e. CFO estimation). Following a preamble found event: 1) the incoming samples are demodulated; 2) the resulting soft bits are correlated to the AA pattern; 3) finally, the correlation peak marks the location of the incoming frame and symbol timing is estimated. The soft-bits are now re-aligned to symbol timing and passed through the Viterbi decoder (State 2 of the SM) . The decoded bits are then matched to the AA pattern and the CI is extracted (State 3 of the SM) .

From a non-coded perspective as the depiction in Acquisition mode there are three acquisition modes:

- Acquisition mode 1
  - Both preamble and AA are used for packet detection and synchronization
  - The preamble detector detects the packet and synchronizes timing
  - Following a preamble detection, the AA is searched at the symbol rate
    - The AA detection outputs frequency and frame synchronization
  - This mode is suitable for packets that have long enough preambles (usually more than 6 octets)
- Acquisition mode 2
  - Only the AA is used for packet detection and time/frequency synchronization
  - This acquisition mode is suitable to be used when the packet being searched has a short preamble
- Acquisition mode 3
  - Both preamble and AA are used for packet detection and synchronization
  - The preamble detector is used merely to detect the presence of a packet
  - Following a preamble detection, the AA is searched at the sample rate
    - The AA detection outputs frequency synchronization and symbol/frame timing synchronization
  - This acquisition mode is
    - Suitable for packets which short preambles
    - Lowers power consumption and an earlier packet detection than mode 2

The figures below show detailed instantiations of the top-level state-machine, considering all the acquisition modes described earlier and all the operation modes. Figure 396 illustrates the state-machine instantiation for non-simultaneous non-coded acquisition modes or long range Bluetooth LE.

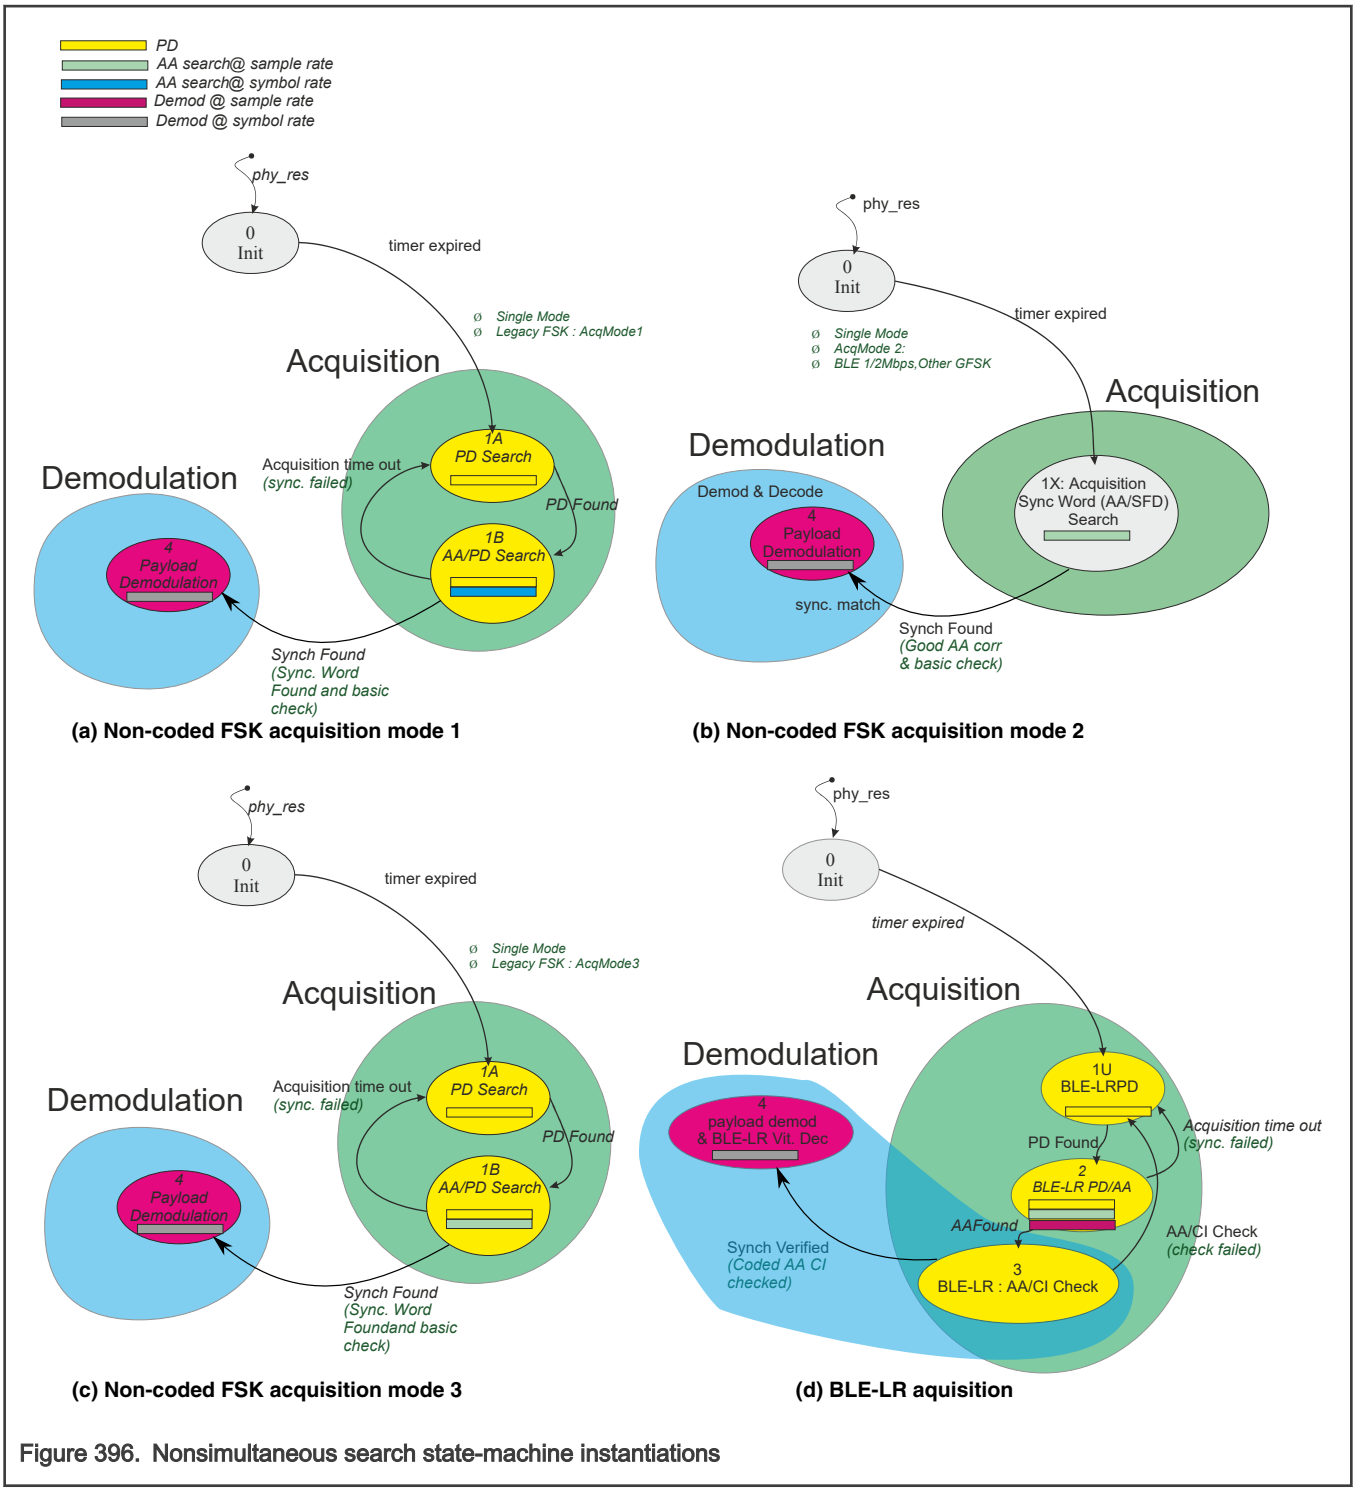

Figure 396. Nonsimultaneous search state-machine instantiations

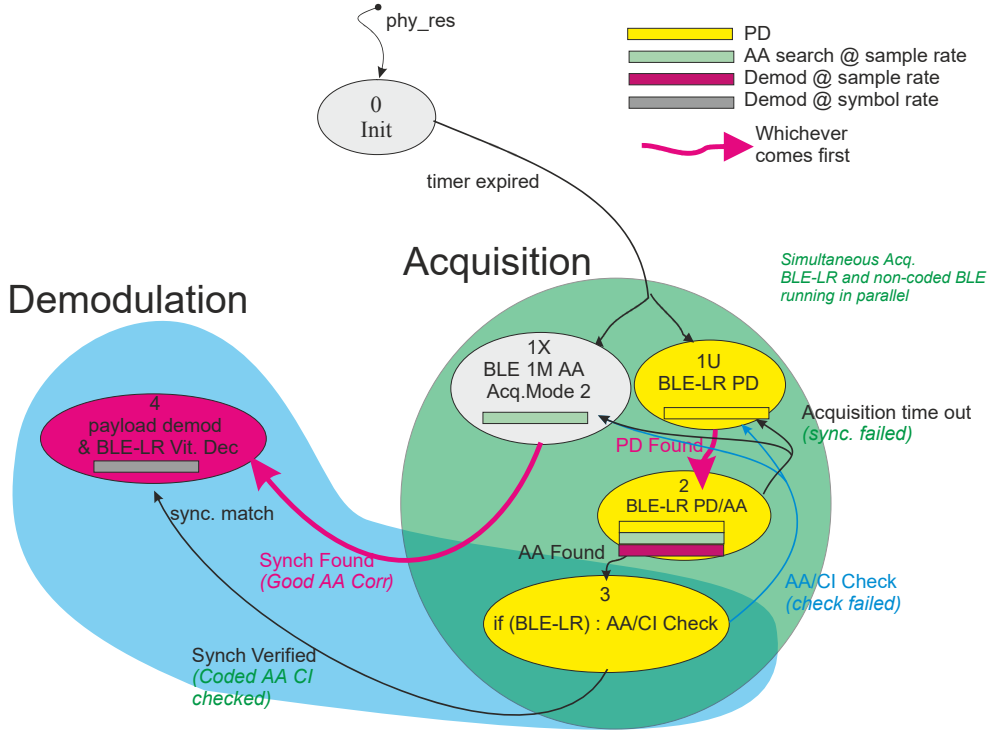
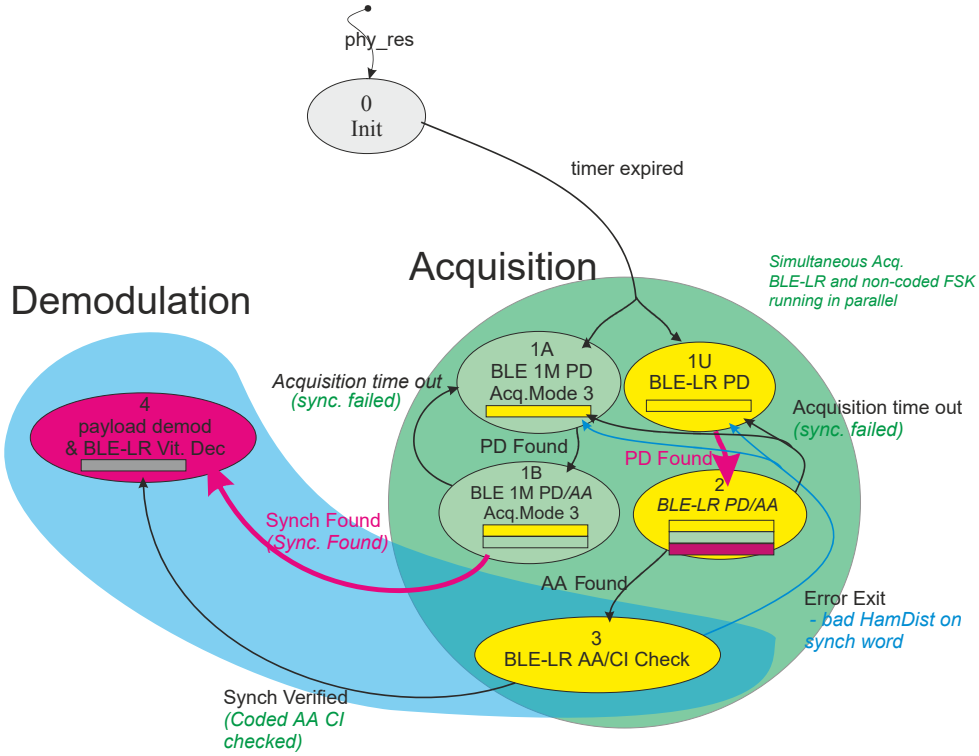
The simultaneous search mode is intended for Bluetooth LE (non-coded or long range) packets. Since the non-coded Bluetooth LE packets have a one octet long preamble, only non-coded acquisition modes 2 and 3 are suitable for the simultaneous search. Figure 397 illustrates the instantiation of the state-machine for simultaneous search of long range Bluetooth LE and non-coded Bluetooth LE 1Mbps in acquisition modes 2 and 3.



(a) Simultaneous BLE-LR and non-coded BLE 1Mbps using acquisition mode 2



(b) Simultaneous BLE-LR and non-coded BLE 1Mbps using acquisition mode 3

Figure 397. Simultaneous search state-machine instantiations

Another aspect of the PHY state machine is the fast antenna diversity (FAD) preamble search feature. FAD is a mechanism that allows antenna selection on the fly. Two antennas and a single receiver chain are used, thus, the receiving chain is used in a time-shared manner. If a detection occurs, the current antenna is immediately selected. FAD involves using the preamble detection mechanism, i.e., one of the two antennas is selected when a preamble is first found. During the FAD process the receiver has to deal with blind spots due to transient behaviour of the different blocks on the receiver chain, so, the preamble must be fairly long to be able to support FAD. The minimal preamble length needed to support FAD depends on a series of factors:

- Receiver latency (without dynamic processes)
- Time required for dynamic control processes (in the sequel AGC only is considered)
- Number of samples needed by the preamble detector to reliably provide detection, timing and CFO estimate

From simulation it has been concluded that the preamble has to be at least 4 octets long. Due to the short preamble portions available for correlation, the FAD feature can only use the preamble detection engine used by acquisition mode 3 in a non-simultaneous search. Note that, the FAD state machine is coded in state 1A, in Figure 396, subfigure (c). A more detailed illustration of the FAD state-machine is provided in Figure 398.

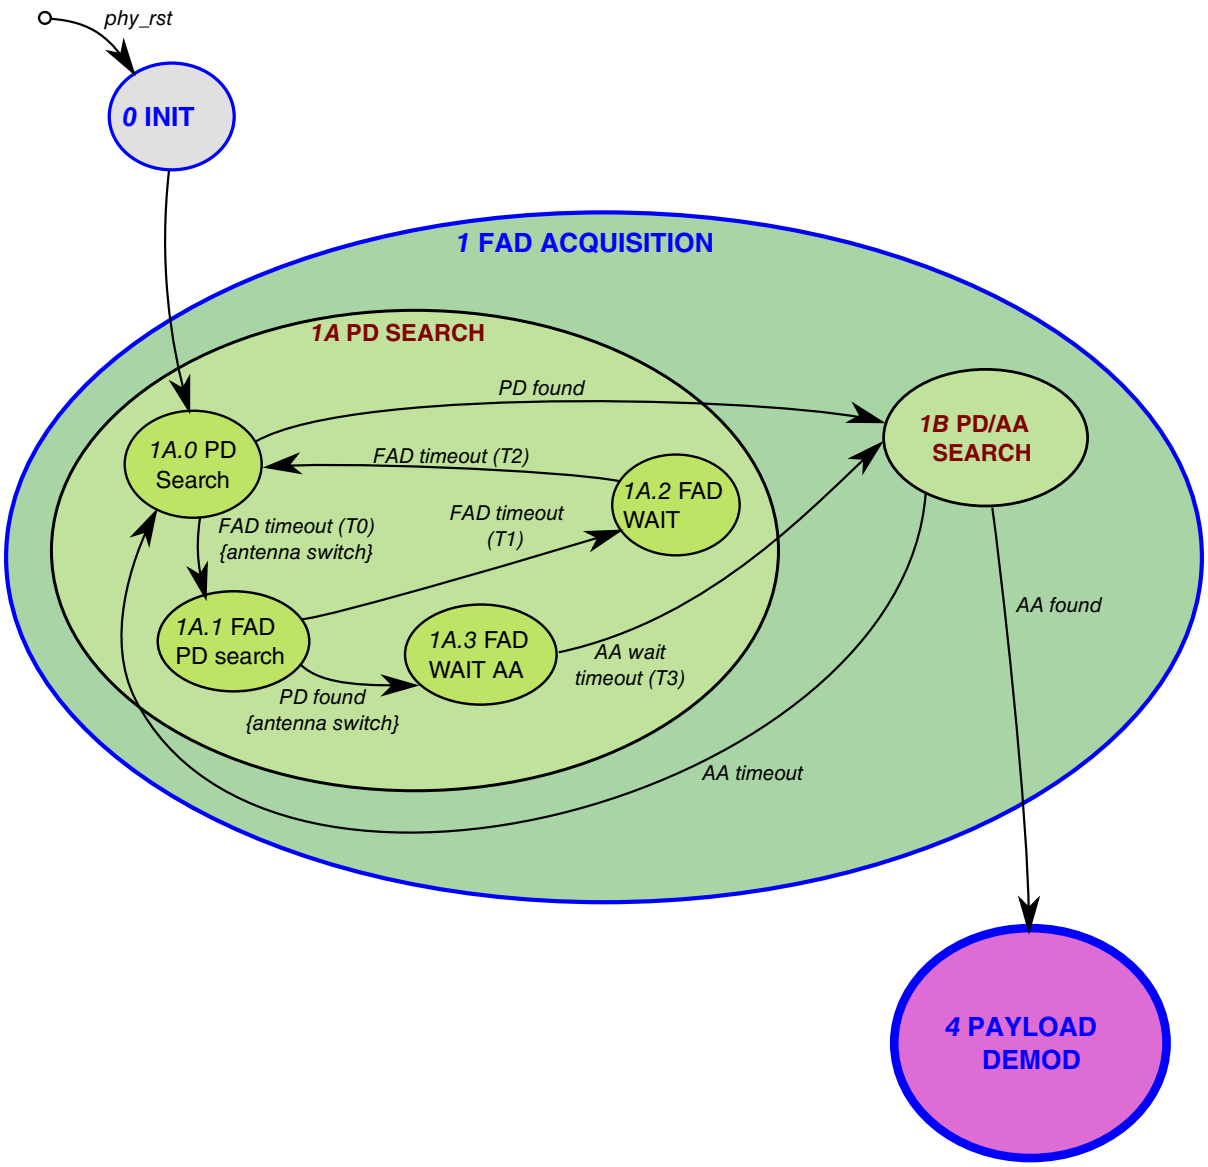


Figure 398. FAD detailed state-machine

The FAD states are:

- FAD sub-state 0 (PD Search)
  - Preamble detection over samples received from the currently selected antenna
    - Note that when the FAD is disabled in acquisition mode 3 this is the only attainable sub-state in "PD search"
- FAD sub-state 1 (FAD PD search)
  - Preamble detection over samples received from the previously selected antenna
    - Note that this is possible due to the propagation latency in the receiver
- FAD sub-state 2 (FAD wait)
  - The state machine waits for transients if a preamble pattern was not detected after antenna switch
- FAD sub-state 3 (FAD wait AA)
  - Before transitioning to AA search PHY state
  - The state machine waits for transients if a preamble pattern was detected after antenna switch

Time constants T_0, T_1 and T_2 from Figure 398 represent the dwell durations the FAD states having the same index and are illustrated in the time diagram from Figure 399. These values are configurable from registers. Figure 399 does not show T_3 because the antenna is not switched after the preamble is found so transition to the PHY state 1B occurs from FAD sub-state 0.

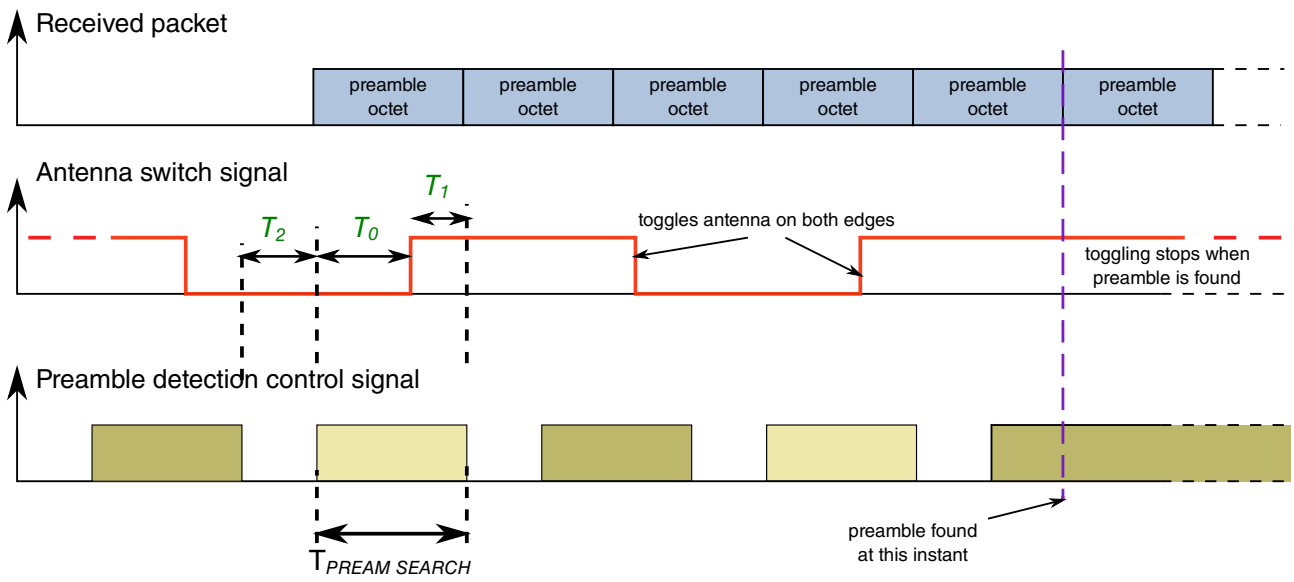

Figure 399. FAD process time diagram

Table 536 presents the recommended settings for FAD.

Table 536. Recommended parameters for FAD

Parameter name	Value
search_pd_window[6:0]	32
fad_search_pd_window[6:0]	12
fad_wait_pd_window[6:0]	12
fad_wait_synch_window[6:0]	12

52.4.4.2.2.10.2.8 Mode

This section describes all functional operation modes of the 2.4GHz PHY module.

52.4.4.2.2.10.2.8.1 Scan mode

Scan mode determines the way packets are being search for. As shown three modes of operation are defined for the 2.4 GHz PHY:

- Non-coded FSK search: look only for non-coded packets, while keeping all the Long range Bluetooth LE acquisition blocks disabled;
- Long range Bluetooth LE search: search only for long range Bluetooth LE packets while keeping all the non-coded acquisition blocks disabled;
- Simultaneous Non-coded and long range Bluetooth LE search: simultaneously look for long range and non-coded Bluetooth LE packets by enabling both long range and non-coded acquisition blocks.

Note that the PHY block is capable of performing simultaneous search of any non-code FSK use-case and long range Bluetooth LE but, from an use-cases perspective, this mode of operation is restricted to non-coded Bluetooth LE.

52.4.4.2.2.10.2.8.2 Acquisition mode

From a non-coded perspective there are three acquisition modes:

- Acquisition mode 1: both preamble and AA are used for packet detection and synchronization. The preamble detector is used to detect the packet and to realize symbol timing synchronization and, following a preamble detection, AA is being searched at symbol rate in order to get frequency and frame synchronization. This mode is suitable for packets that have long enough preambles (usually more than 6 octets) so that the symbol timing synchronization can be reliably realized;
- Acquisition mode 2: only the AA is used for packet detection and time/frequency synchronization. This acquisition mode is suitable to be used when the packet being searched has a short preamble;
- Acquisition mode 3: both preamble and AA are used for packet detection and synchronization. The preamble detector is used merely to detect the presence of a packet and, following a preamble detection, AA is being searched at sample rate in order to get frequency synchronization and symbol/frame timing synchronization. This acquisition mode is suitable for packets which short preamble, and it provides not only a lower power consumption but also an earlier packet presence indication than mode 2.

52.4.4.2.2.10.2.9 Interface

The PHY interacts with the system in a few distinct ways. The interfaces can be grouped into 5 categories: configuration, signal input, demodulation output, miscellaneous and debug.

52.4.4.2.2.10.2.9.1 PHY Configuration Interface

The PHY is configured by static signals that are observed and used throughout the receive process. It is important that these signals (typically originating from IP registers) remain static during a receive operation to avoid unpredictable behavior. Some examples of these types of configurations are PD thresholds, AA to search for, etc.

52.4.4.2.2.10.2.9.2 Signal Input Interface

The PHY processes the inputs signal from a set of signed, 6-bit phase inputs. There are three class of input data, wide band, narrow band, and raw IQ.

52.4.4.2.2.10.2.9.3 Demodulation Output

The demodulator produces soft bits in fixed-point format which are presented to the RBME block.

52.4.4.2.2.10.2.9.4 Miscellaneous

There are various other outputs from the PHY that are mostly intended for hand shake with other modules. A few significant signals are described here:

- Preamble found: indicates that Preamble was found.
- CFO estimate: Frequency offset as determined by the preamble detect engine.
- FRAC estimate: Fractional timing error estimate computed in the AA detector;
- Data rate:identified received data rate.
- AA found: indicates that an acceptable address synchronization has occurred.
- AA id: indicates which access address was found.
- corr flag: Indicates to the LQI calculator that the correlation magnitude, exceeds a specified threshold value.
- ant_out: indicates the requested antenna when FAD is enabled. May be ignored when FAD is not enabled.

52.4.4.2.2.10.2.9.5 Debug

There are various other outputs from the PHY that are mostly intended for debug. A few significant signals are described here:

- dtest_*: various outputs send to DTEST module, and then send to GPIO pin.
- phy_dma_mux: muxed one of five DMA data send to DMA module, then finally dumped to RAM

52.4.4.2.2.10.2.10 Clocking

This section describes clocks and special clocking requirements of the 2.4GHz PHY module.

Table 537. Clock signals

Signal name	Direction	Description
clk	input	32 or 26 MHz clock
vit_fast_clk_en	input	replace rx_adc_clkdiv2_vld, 8MHz for Gen4, 16MHz for Gen3.5
scan_enable	input	only used for clock gate bypass

52.4.4.2.2.10.2.11 Reset

This section describes how to reset the 2.4GHz PHY module and explains special requirements related to reset.

Table 538. Reset signals

Signal name	Direction	Description
ipg_hard_soft_reset_b	input	reset logic except regs
ipg_hard_async_reset_b	input	reset registers
phy_init	input	Soft reset to entire PHY
phy_ext_rst	input	L1_11 added, require at least one sample clock

52.4.4.2.2.10.2.12 Interrupts

This Module has no interrupts.

52.4.4.2.2.10.2.13 DMAs

This section describes all the DMAs that the 2.4GHz PHY module generates.

Table 539. DMA signal list

52.4.4.2.2.10.3 External signals

This Module has no external signals.

52.4.4.2.2.10.4 Initialization

The PHY is initialized with the configuration required by the active link layer before performing any transmit or receive operations.

52.4.4.2.2.10.5 Application information

This section describes applications supported by the 2.4GHz PHY module.

One of the possible uses of the PHY module is the frames time/frequency synchronization and PDU bits demodulation corresponding to different protocols. As an example, the PHY module supports the packet reception for Bluetooth low energy uncoded (1Mbps and 2 Mbps) and long range (125 kbps and 500 kbps).

Another use of the PHY is the high accuracy time of flight estimation which is used for localization.

52.4.4.2.2.10.6 Register descriptions

This section includes the 2.4GHz PHY module memory map and detailed descriptions of all registers.

52.4.4.2.2.10.6.1 2.4GHz PHY REGISTERS register descriptions

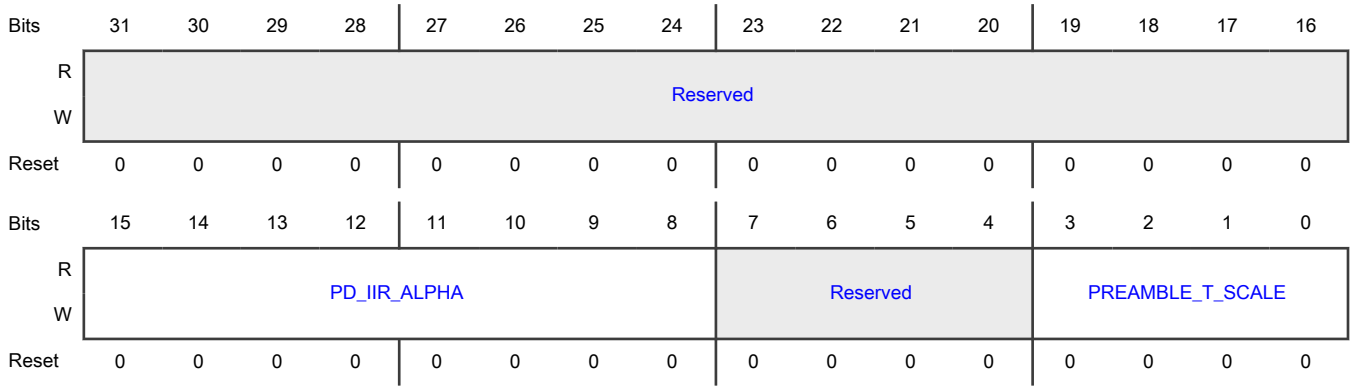
Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 PD_IIR_ALPHA	Forgetting factor used by the complex correlations smoothing leaky integrator.
7-4 —	Reserved
3-0 PREAMBLE_T_SCALE	Scaling factor used for fractional time estimation during preamble search.

52.4.4.2.2.10.6.1.3 PHY Uncoded Preamble Detect Config 1 (FSK_PD_CFG1)

Offset

Register	Offset
FSK_PD_CFG1	4h

R W	Reserved								PREAMBLE_PATTERN							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 PREAMBLE_PATTERN	8-bit preamble pattern used in FM-domain preamble detector.

52.4.4.2.2.10.6.1.4 PHY Uncoded Preamble Detect Config 2 (FSK_PD_CFG2)

Offset

Register	Offset
FSK_PD_CFG2	8h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved								PD_THRESH_ACQ_1_3_2M							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved								PD_THRESH_ACQ_1_3_1M							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

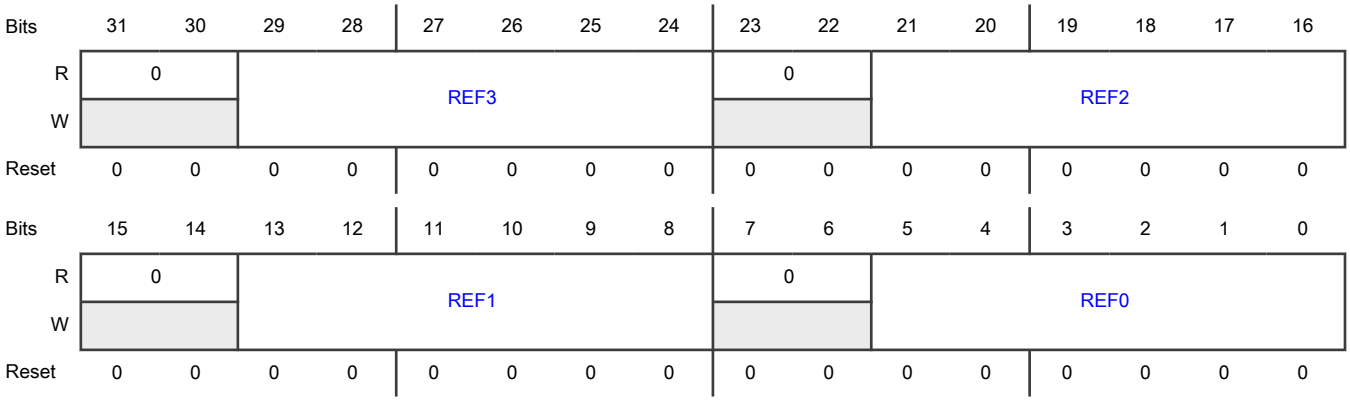
Field	Function
31-24 —	Reserved
23-16 PD_THRESH_ACQ_1_3_2M	Preamble detect threshold for acq mode 1 and 3 at data rate 2Mbps Preamble detect correlation threshold (ufix8en8). This threshold is used to define high correlation for the preamble detect logic.
15-8 —	Reserved
7-0 PD_THRESH_ACQ_1_3_1M	Preamble detect threshold for acq mode 1 and 3 at data rate 1Mbps Preamble detect correlation threshold (ufix8en8). This threshold is used to define high correlation for the preamble detect logic.

52.4.4.2.2.10.6.1.5 PHY Uncoded Preamble Detect Phase (FSK_PD_PH0)

Offset

Register	Offset
FSK_PD_PH0	Ch

Diagram



Fields

Field	Function
31-30 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-24 REF3	Uncoded preamble reference waveform sample 3 (sfix6en5)
23-22 —	Reserved
21-16 REF2	Uncoded preamble reference waveform sample 2 (sfix6en5)
15-14 —	Reserved
13-8 REF1	Uncoded preamble reference waveform sample 1 (sfix6en5)
7-6 —	Reserved
5-0 REF0	Uncoded preamble reference waveform sample 0 (sfix6en5)

52.4.4.2.2.10.6.1.6 PHY Uncoded Preamble Detect Phase (FSK_PD_PH1)

Offset

Register	Offset
FSK_PD_PH1	10h
